HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

Between Denisovans and Neanderthals: Strashnaya Cave in the Altai Mountains

New data from Strashnaya Cave have revealed previously unknown complexity in hominin occupation of the Altai Mountains, including the first regional evidence for the presence of anatomically modern humans.

Keywords: Altai, Strashnaya Cave, Middle Palaeolithic, human origins

The Altai Mountains have come to be regarded as a crucial region in the discussion of human origins. Palaeogenetic and palaeoanthropological discoveries have provided evidence for the long-term cohabitation of this area by the Denisovans and Neanderthals, and for genetic flow between these two groups (Slon et al. 2017). The techno-typological features of Altai region Middle Palaeolithic assemblages have facilitated the identification of three main traditions: the Denisovan, Kara-Bom and Sibiryachikha. The Denisovan and Kara-Bom types reflect an autochthonous development of the local Upper Palaeolithic, Levallois-based industries, and correlate with the evolution of Denisovans into anatomically modern humans (Derevianko et al. 2014).

From 2013–2017, archaeological investigations at the Strashnaya Cave (51°10'26.0"– 83°01'42.6") in north-western Altai, Russia (Figure 1) have revealed Middle and Upper Palaeolithic lithic assemblages, human remains and unique bone tools and ornaments. These finds are helping to address the question of the peopling of Northern Asia. A total of 13 lithological layers were identified, with an overall thickness of approximately 10m (Figure 2). Layers 1 and 2 are dated to the Holocene, and the underlying layers to the Pleistocene. The Pleistocene layers comprised seven Middle Palaeolithic layers (10–4) and one Upper Palaeolithic layer (3).

Radiocarbon dates allow us to attribute the top part of layer 3 (horizon 31a) to oxygen isotope stage (OIS) 2, while the bottom of layer 3 (horizons 31b and 33) dates to OIS 3. Absolute dates from layers 4 and 5 correspond to OIS 3, although this does not match the Middle Palaeolithic industry found within these layers. This reflects complex site stratigraphy and disturbance by rodents (Figure 2). New OSL dates are being prepared in order to address this inconsistency. The Middle Palaeolithic assemblages, comprising 3862 items from layers 10–4, are dominated by thick flakes with large striking platforms, created by radial and orthogonal techniques. Levallois convergent and preferential technologies were used to produce points and flakes (Figure 3.6–8). Some artefacts from the Middle Palaeolithic assemblages indicate features of blade production (Figure 3.10). The tool kit comprises various side scrapers, truncated-faceted tools, retouched points, and notched and denticulate tools (Figure 3.5 & 3.9).

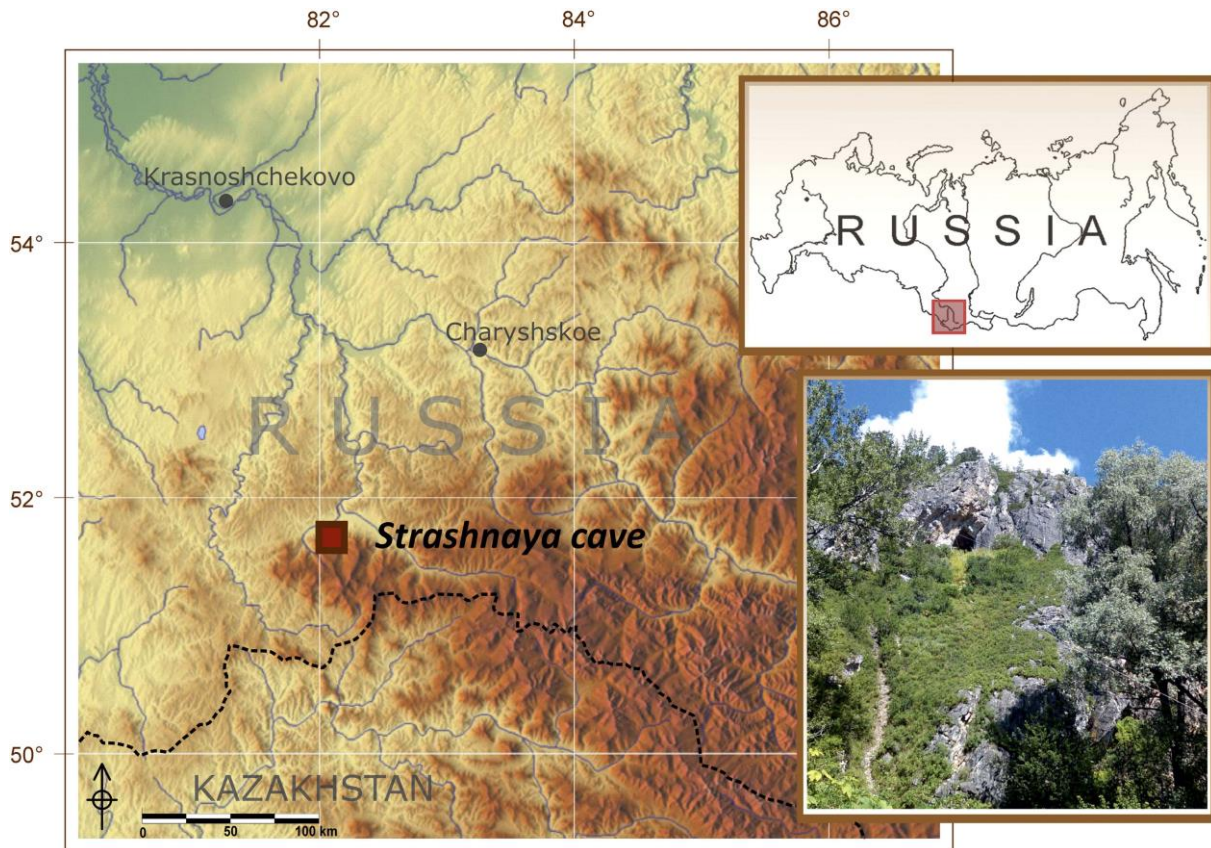

Figure 1. Map of the Altai region showing the Strashnaya Cave.

The Upper Palaeolithic assemblages (1788 items from horizons 31a, 31b and 33) include blade and bladelet prismatic cores, and several radial and Levallois cores. The tool kits comprise end-scrapers, retouched blades and flakes, splintered pieces, borers and sidescrapers (Figure 3.1–4). The bone industry from horizons 31a, 31b and 33 includes: ornaments, bone tools (needles (Figures 4.9–10)), an intermediate tool (Figure 4.16), an awl (Figure 4.15), a burnisher (Figure 4.13), a tool made from red deer antler (Figure 4.14) and three fragments of hunting weaponry (Figure 4.6–8). The ornaments are intentionally manufactured pendants and buttons (Figure 4.1, 4–5, 11–12), along with several fossil mollusc shells (Figure 4.2–3).

The AMH remains recovered from horizon 31a comprise eight teeth, probably belonging to a 7–9-year-old individual (Figure 5). The metric and morphological features demonstrate similarities with Siberian Upper Palaeolithic remains from the Malta, Listvenka and Afontova Gora sites, while also sharing morphological features with modern Native Americans (Viola 2009; Zubova et al. 2017) (Figure 5).

The Strashnaya Cave provides new information concerning Middle and Upper Palaeolithic variability in the Altai Mountains. Even without supportive absolute dates, similarities between Strashnaya Cave and Denisovan Middle Palaeolithic techno-complexes suggest that they could be associated. Layer 3 (horizons 31a, 31b and 33) characterises three different cultural-chronological phases in the human habitation of the cave.

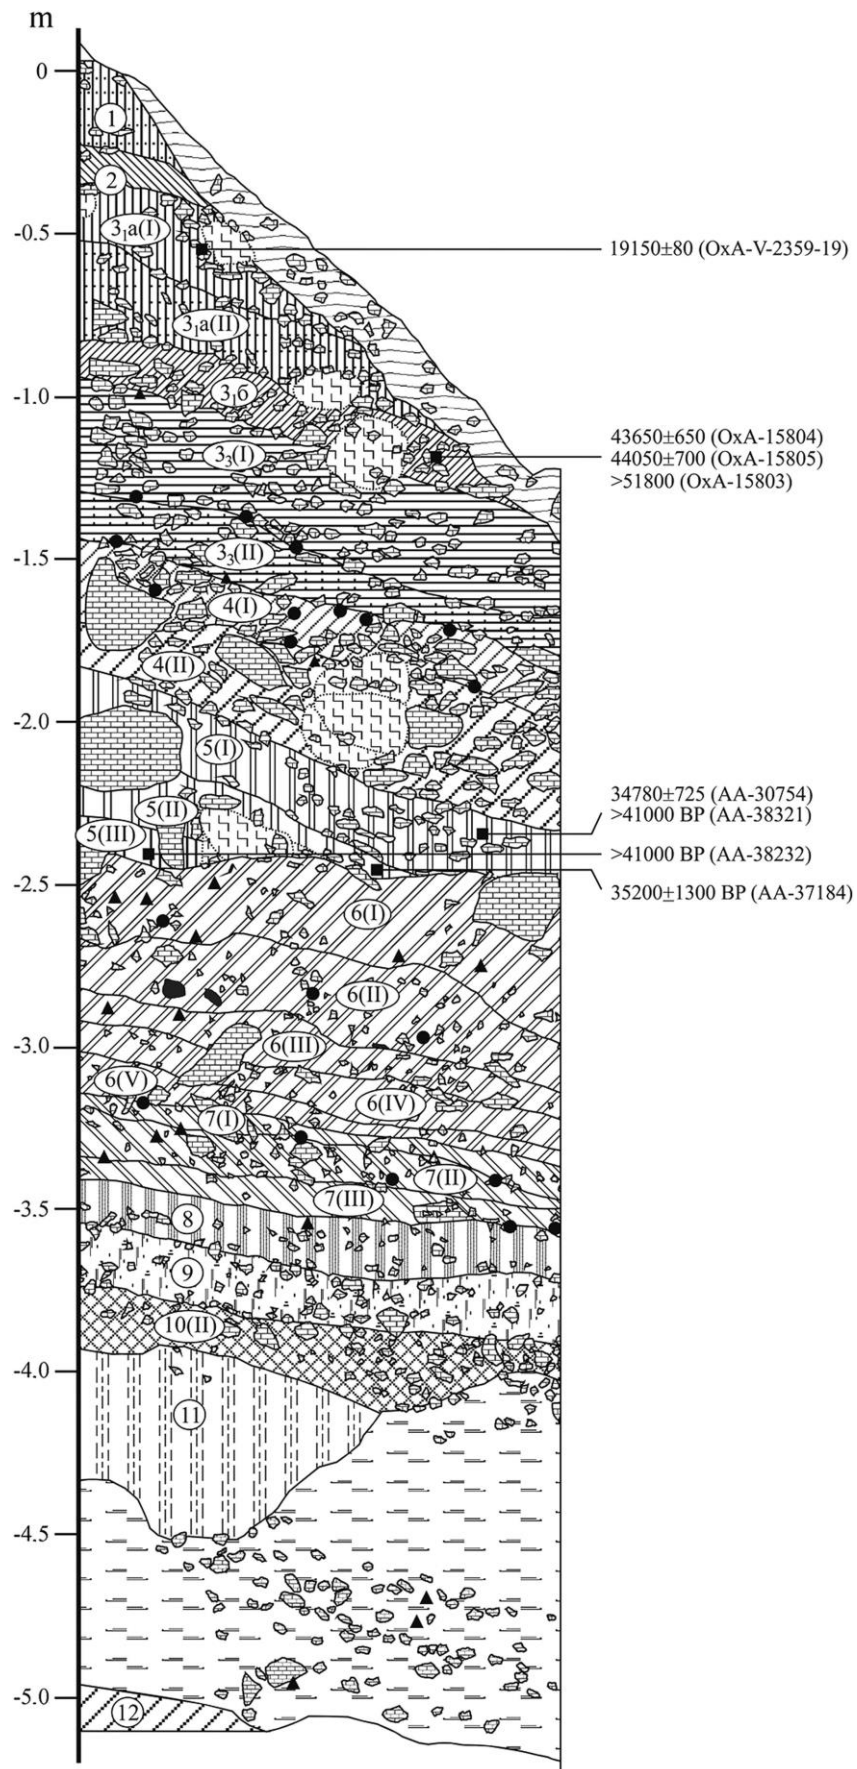

Figure 2. Stratigraphy of Strashnaya Cave (after the 2016 excavation).

Figure 3. Lithic artefacts from the Middle and Upper Palaeolithic layers of Strashnaya Cave.

Horizon 33 represents the Denisovan phase, as illustrated by radial and Levallois flaking techniques, accompanied by several blade cores, Upper Palaeolithic tool types, ornaments and bone tools (Figure 4.4–5, 9, 16). The second phase, from horizon 31b, dates to 45 kyr BC, and represents the Kara-Bom Early Upper Palaeolithic blade-based tradition with bone points (Figure 4.7). The third tradition, from horizon 31a and dating to 20 kyr BC, represents the advanced Upper Palaeolithic with bladelet technology, personal ornaments and bone tools. To date, bone ornaments (red deer incisor pendants) and bone tools (needles) have only been known in the early chronological context in Denisova Cave (Derevianko et al. 2014). Thus, these finds from Strashnaya Cave significantly complement the evidence for modern behaviour in the region.
