HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

HOW RARE EARTH ELEMENTS HELP US TO BETTER UNDERSTAND FLUID CIRCULATIONS AND IRON OXIDES ASSOCIATED ON CATACLASTIC DEFORMATION BANDS IN POROUS SANDSTONES: CASE STUDY IN THE BASSIN DU SUD-EST, PROVENCE, FRANCE

The Critical Zone, the heterogeneous, near surface environment (hydrosphere, ecosystems, atmosphere,...) in which complex interactions involving rock, soil, water, air, and living organisms regulate the natural habitat and determine the availability of life-sustaining resources is a zone of circulation and concentration of matter and energy (Brantley et al., 2007). This is where strong interactions between the hydrosphere and rocks occur and act on biogeochemical cycles and may influence concentration of elements, such as some critical metals like rare earth elements (REE). Moreover, present day exploration readdresses the old problem about the control of cataclastic deformation bands (CDBs) on fluid flow, which is still debated in petroleum research. CDBs are common structures in porous sandstones (Saillet and Wibberley, 2010). These structures are tabular zones of finite width that have experienced grain rotation, crushing, cataclasis or cementation and they correspond to the localization of strain in porous rocks.

Field and laboratory measurements exhibit evidence of porosity reduction in the CDBs (ratio of 0.5 to 0.25 of the host rock porosity) and that the CDBs permeability is significantly reduced by one to six orders of magnitude relative to the host rock (Fossen and Bale, 2007).

In fluid saturated rocks, CDBs seem to behave like transient barriers, whereas in unsaturated rocks, their effect on fluid flow is not clear. In the critical zone, a barrier effect was observed for paleo-fluids (Eichhubl et al., 2004) whereas laboratory tests suggest that CDBs could be capillarity conduits (Sigda and Wilson, 2003). In this work, we try to further understand and find field, mineralogical and geochemical evidences for CDBs behaviour. For that, we examine the spatial distribution of oxidation fronts and CDBs in the porous sandstones of Bedoin (SE France) to discuss interaction between fluid flow and CDBs in the critical zone. It appears that the oxidation fronts underline preferential pathways for the ground water, and CDBs seems to constitute a trap where the oxides contained in the fluid accumulate. The rare earth element (REE) patterns show a decreasing slope from light REE to heavy REE, and europium or cerium anomalies, which provides information about the oxidizing fluids.
