<b>Abstract:</b>	The paper investigates the microstructure evolution and phase analysis of the Sm 60 Ni 40 alloy. The arc melted sample retained the high temperature stable (> 600 °C) Sm 7 Ni 3 and Sm 3 Ni 2 phases along with the congruently melting SmNi phase. Annealing the as-cast sample at 630 o C for 100 hours stabilized the high temperature stable (600 °C - 630 °C) Sm 3 Ni 2 phase. Rietveld refinement was performed to resolve the crystal structure of Sm 3 Ni 2 phase and it was observed that Sm 3 Ni 2 phase stabilizes in monoclinic crystal structure (space group: C2/m) with a lattice parameter of a=13.49 Å, b=3.75 Å, c=9.68 Å and β=106.6°. The Curie temperature of the Sm 3 Ni 2 phase was determined to be ~110 K. The high squareness ratio of 82% along with high coercivity of 3 T indicates that the Sm 3 Ni 2 phase possess spontaneous uniaxial magnetic anisotropy.

Intermetallics

Dear Professor

I am submitting herewith a manuscript titled “**Microstructure evolution and phase analysis of Sm<sub>60</sub>Ni<sub>40</sub> alloy**” by G.Vijayaragavan, D. Prabhu, M. B. Ponnuchamy, K. R. S. Preethi Meher, Ravi Gautam, Mainak Saha, R. Gopalan, K. G. Pradeep, to be considered for publication in Intermetallics.

Sm based binary alloy systems with low melting eutectics are studied with interest as they are considered potential bonding materials for consolidation of Sm-Fe-N magnets at low temperatures. Sm-Ni is one such system with one of the eutectic reactions at 630 °C. In this report, we present the experimental results on the microstructure and phase evolution of the Sm<sub>60</sub>Ni<sub>40</sub> alloy both in as cast and annealed (630 °C for 100 hr) states in comparison with the thermodynamically predicted phase formation sequence at various temperatures. Interestingly, we were able to stabilize significant (80% area fraction) proportion of the high temperature stable Sm<sub>3</sub>Ni<sub>2</sub> phase at room temperature. Though the crystal structure of this phase is reported in Open quantum material database OQMD to be rhombohedral based on DFT calculations with certain assumptions, in the present work our experimental observation is providing a **new information i.e. the structure of Sm<sub>3</sub>Ni<sub>2</sub> being Monoclinic** in contrast from the one reported in OQMD. We have also resolved the crystal structural of Sm<sub>3</sub>Ni<sub>2</sub> phase using XRD Rietveld analysis an information which was not available in literature prior to this work. Further, we have also reported the magnetic properties of this phase in this paper.

We believe the information provided in this paper is novel and would be most suitable to the journal exclusively dedicated to “intermetallics”, and we hope you will find it worthy of publication in your valued journal.

Thank you  
Yours sincerely  
On behalf of the team of authors,

(D PRABHU)

### **Highlights of the paper**

- The paper reports the structural and magnetic properties of a high temperature stable  $\text{Sm}_3\text{Ni}_2$  phase, not reported experimentally earlier in literature to the best of our knowledge.
- The structure is determined to be monoclinic (space group  $C2/m$ ) with a Curie temperature of 110 K.

## Abstract:

The paper investigates the microstructure evolution and phase analysis of the  $\text{Sm}_{60}\text{Ni}_{40}$  alloy. The arc melted sample retained the high temperature stable ( $> 600\text{ }^\circ\text{C}$ )  $\text{Sm}_7\text{Ni}_3$  and  $\text{Sm}_3\text{Ni}_2$  phases along with the congruently melting  $\text{SmNi}$  phase. Annealing the as-cast sample at  $630\text{ }^\circ\text{C}$  for 100 hours stabilized the high temperature stable ( $600\text{ }^\circ\text{C} - 630\text{ }^\circ\text{C}$ )  $\text{Sm}_3\text{Ni}_2$  phase. Rietveld refinement was performed to resolve the crystal structure of  $\text{Sm}_3\text{Ni}_2$  phase and it was observed that  $\text{Sm}_3\text{Ni}_2$  phase stabilizes in monoclinic crystal structure (space group:  $C2/m$ ) with a lattice parameter of  $a=13.49\text{ \AA}$ ,  $b=3.75\text{ \AA}$ ,  $c=9.68\text{ \AA}$  and  $\beta=106.6^\circ$ . The Curie temperature of the  $\text{Sm}_3\text{Ni}_2$  phase was determined to be  $\sim 110\text{ K}$ . The high squareness ratio of 82% along with high coercivity of 3 T indicates that the  $\text{Sm}_3\text{Ni}_2$  phase possess spontaneous uniaxial magnetic anisotropy.

## 1. Introduction

Recently, Sm-based low melting eutectics are being explored in literature as a potential metal binder for consolidation of Sm-Fe-N due to its good wettability and strong reducing ability [1]. In particular, Sm-Cu and Sm-Ni based alloy systems with eutectic melting points below the decomposition temperature of  $\text{Sm}_2\text{Fe}_{17}\text{N}_3$  are considered prospective materials.

Sm-Ni binary system consisting of multiple eutectic compositions could be explored for its suitability as an ideal binder alloy. Recently, a few reports emerged investigating the phase formation in Sm-Ni system. Pan et al. [2] studied the Sm-Ni system across the entire composition range and developed the phase diagram using differential thermal analysis and X-ray diffraction techniques.  $\text{SmNi}$  and  $\text{SmNi}_5$ ,  $\text{Sm}_3\text{Ni}$  were identified to be congruently melting phases while,  $\text{SmNi}_2$ ,  $\text{SmNi}_3$ ,  $\text{Sm}_2\text{Ni}_7$ ,  $\text{Sm}_5\text{Ni}_{19}$  and  $\text{Sm}_2\text{Ni}_{17}$  phases form by peritectic reaction.

1 The binary Sm-Ni phase diagram has further been evaluated by Xuping et al. [3] and the  
2 observations were consistent with the reported literature. Independently, G. Borzone et al. [4]  
3 reported the formation of two new metastable phases  $\text{Sm}_3\text{Ni}_2$  and  $\text{Sm}_7\text{Ni}_3$  by peritectic reaction  
4 which decompose at temperature below 600 and 619 °C respectively. The crystal structure of  
5 the  $\text{Sm}_7\text{Ni}_3$  phase was reported based on the indexing of diffraction pattern to hp20- $\text{Fe}_3\text{Th}_7$   
6 structure type. To the best of our knowledge, no experimental data has been reported for the  
7 crystal structure of  $\text{Sm}_3\text{Ni}_2$  apart from the one available in the open quantum data base which  
8 is theoretically predicted structure using density function theory calculations [5][6]. However,  
9 intermetallic phases with composition  $\text{R}_3\text{Ni}_2$  form via peritectic reaction as reported in the  
10 literature for  $\text{R} = \text{Tb}, \text{Dy}, \text{Ho}, \text{Er}, \text{Y}$  and  $\text{Gd}$ . The crystallographic information is also available  
11 for  $\text{Tb}_3\text{Ni}_2$ ,  $\text{Dy}_3\text{Ni}_2$ ,  $\text{Ho}_3\text{Ni}_2$ ,  $\text{Er}_3\text{Ni}_2$  and  $\text{Gd}_3\text{Ni}_2$  compounds. Monoclinic structure for  $\text{Tb}_3\text{Ni}_2$   
12 and  $\text{Dy}_3\text{Ni}_2$  [ $\text{Dy}_3\text{Ni}_2$  type, mS20, C2/m] [7], hexagonal for  $\text{Er}_3\text{Ni}_2$  [ $\text{Er}_3\text{Ni}_2$  type, hR45, R-3] [8]  
13 and tetragonal structure for  $\text{Y}_3\text{Ni}_2$  [ $\text{Y}_3\text{Ni}_2$  type, tP80,  $P4_12_12$ ] [9] exist. The  $\text{Ho}_3\text{Ni}_2$  exist at  
14 low temperature [ $\text{Dy}_3\text{Ni}_2$  type, mS20, C2/m] [7] as well as at high temperatures [ $\text{Er}_3\text{Ni}_2$  type,  
15 hR45, R-3] [8]. Recently, monoclinic structure was reported for  $\text{Gd}_3\text{Ni}_2$  [ $\text{Dy}_3\text{Ni}_2$  type, mS20,  
16 C2/m] with lattice parameters [ $a = 1.3418$ ,  $b = 0.372$ ,  $c = 0.9640$  nm and  $\beta = 106.2^\circ$ ] [10]. In  
17 this study, we have investigated the Sm-Ni system close to the eutectic reaction (E3) having  
18 substantially lower reaction temperature (623 °C) as indicated in Fig. 1a. i.e. a fixed Ni content  
19 of 40 at. % towards understanding the microstructure evolution, phase stability and their  
20 magnetic properties.

## 2. Experimental details

21 The  $\text{Sm}_{60}\text{Ni}_{40}$  (at. %) composition was melted using vacuum arc melting technique under inert  
22 Argon atmosphere. Elemental Samarium (Sm) and Nickel (Ni) with purity higher than 99.9%  
23 was used for preparing the alloy ingots. To compensate for the losses during melting, 1 wt.%  
24 excess Sm was added. In order to understand the phase formation as a function of temperature,

1 Sm-Ni phase diagram was generated using CALPHAD (Calculation of Phase Diagram)  
2 approach with the thermodynamic data available elsewhere [NIMS CPDDB  
3 (<https://mits.nims.go.jp>)] [11], [12]. The annealing temperature of 630 °C for 100 hours just  
4 above the corresponding eutectic reaction temperature (i.e. 623 °C for the composition under  
5 study) was determined from the phase diagram in order to obtain a homogeneous  
6 microstructure. The arc melted bulk alloy ingot was wrapped in a tantalum foil and sealed in a  
7 quartz tube filled partially with argon for heat treatment.

18 Phase analysis and crystal structure investigation were carried out by X-Ray diffraction (XRD)  
19 using Cu- $k_{\alpha}$  radiation (Panalytical, X'pert pro, Netherlands). The XRD patterns were obtained  
20 from fine powder samples by crushing the as-cast and annealed ingots. Phase identification of  
21 the as-cast sample was performed utilizing crystallographic data from the Inorganic Materials  
22 Database (Atom Work) of NIMS, Japan (<https://mits.nims.go.jp>) [13]. The XRD pattern of  
23 annealed samples were subjected to Rietveld refinement using Fullprof software for discerning  
24 the different phases. Crystal structure information of  $R_3Ni_2$  stoichiometry phases with other  
25 rare earths such as Tb, Dy, Ho, Er, Y, Gd is available in literature [10]. The XRD patterns  
26 were fit using pseudo-Voigt profile with axial divergence asymmetry. Microstructure imaging  
27 and composition analysis was performed using FEG-Scanning electron microscope (SEM)  
28 (Zeiss, Merlin Compact, Germany) attached with an energy dispersive X-ray spectrometer  
29 (EDS) (EDAX, Octane plus, USA). Three-dimensional elemental distribution analysis at near  
30 atomic-scale was performed using a local electrode atom probe tomography (LEAP) (Cameca,  
31 5000XR, USA). Site-specific atom probe tomography (APT) tips was prepared using a dual-  
32 beam Focused ion beam (FIB) (Thermofisher scientific, Helios G4 UX) following the lift out  
33 procedure described elsewhere [14],[15]. APT measurement was carried out in the laser pulsing  
34 mode with laser pulse frequency of 250 kHz and 30 pJ pulse energy while the tips were  
35 maintained at 60 K. Data reconstruction and analysis was performed using IVAS 3.8.10

### 15 **3. Results and Discussion**

16  
17  
18 Fig. 1a shows the generated equilibrium phase diagram of Sm-Ni. It can be noticed that 3  
19 different eutectic reactions namely, E1 (1275 °C), E2 (821 °C) and E3 (623 °C) are possible,  
20 and it can be observed that the reaction temperature decreases with increasing Sm content.  
21 Table 1 summarizes all the possible reactions and the associated phases that are products of the  
22 various reactions [12]. The enlarged portion (in fig. 1b) shows the phase field around E3 where  
23 the composition under study lies. The schematic of microstructure evolution as a function of  
24 temperature is shown for the desired composition of Sm<sub>60</sub>Ni<sub>40</sub> in fig. 1b. Accordingly, the ideal  
25 microstructure at room temperate should consist of SmNi and Sm<sub>3</sub>Ni with phase fraction of 60  
26 and 40 vol.% respectively. Fig. 2(a) shows the backscattered electron (BSE) image of the as  
27 cast sample. Three different phases corresponding to varying contrast (dark, white, and grey  
28 phase) are identified. To estimate the composition of the individual phases, EDS line scan was  
29 performed along the red dotted line shown in fig. 2(a) cutting across the three phases. The  
30 concentration profile obtained from EDS is shown in fig 2(b) and the three phases could be  
31 identified as SmNi (dark), Sm<sub>7</sub>Ni<sub>3</sub> (white) and Sm<sub>3</sub>Ni<sub>2</sub> (grey). The intensity distribution of Sm  
32 and Ni in the elemental map (fig. 2 (c & d)) is in agreement with the concentration profile. The  
33 as-cast microstructure consisting of high temperature stable Sm<sub>7</sub>Ni<sub>3</sub> and Sm<sub>3</sub>Ni<sub>2</sub> phases  
34 retained along with SmNi suggests non-equilibrium solidification of the molten liquid due to  
35 the water-cooling of the copper mold used in the arc melting furnace. According to fig. 1b,

1 SmNi should be the first solid phase emerging out of the Sm<sub>60</sub>Ni<sub>40</sub> liquid phase at 850 °C as  
2 indicated in the schematic. Upon further solidification, a peritectic reaction between the  
3 remaining liquid and SmNi solid phase is expected at 630 °C. The observation of Sm<sub>3</sub>Ni<sub>2</sub> being  
4 spatially separated from the SmNi phase suggests the suppression of peritectic reaction [P1 in  
5 table.1]. The remaining liquid therefore should have undergone eutectic solidification at 623  
6 °C resulting in the formation of 17 Vol.% Sm<sub>3</sub>Ni<sub>2</sub> and 43 Vol.% Sm<sub>7</sub>Ni<sub>3</sub> phases. However, the  
7 thermodynamically predicted phase fraction of Sm<sub>3</sub>Ni<sub>2</sub> and Sm<sub>7</sub>Ni<sub>3</sub> phases at 623 °C are 12  
8 Vol.% and 46 Vol. % respectively, indicating no further phase change.

20 Fig 3. shows the XRD powder diffraction pattern of the as-cast sample. Most of the peaks  
21 correspond to the SmNi and Sm<sub>7</sub>Ni<sub>3</sub> phases. Few unknown peaks were observed which did not  
22 correspond to either of the phases. it is plausible that Sm<sub>3</sub>Ni<sub>2</sub> phase (detected in SEM analysis)  
23 could contribute to diffraction resulting in the observation of additional peaks. However, it  
24 should be noted that, peak position was not in agreement with crystal structure predicted in  
25 OQMD for Sm<sub>3</sub>Ni<sub>2</sub> [5][6].

35 Therefore, to obtain equilibrium microstructure, the sample was annealed at 630 °C for 100 h  
36 based on fig. 1b followed by furnace cooling. Fig. 4 shows the Rietveld refined XRD pattern  
37 for the annealed sample which indicates the presence of Sm<sub>3</sub>Ni<sub>2</sub> and SmNi phases. The  
38 microstructure of the annealed sample is shown in fig. 5a which contains three different regions  
39 of varying contrast. The grey contrast region appears to be the major phase while the dark and  
40 white regions are present as minor fractions. SEM-EDS line scan was carried out along the red  
41 dotted line shown in fig. 5a cutting across all three contrasting regions to obtain their local  
42 chemical composition. Fig. 5b shows the concentration profile and based on the contents of  
43 Sm and Ni present, the three phases were identified to be Sm<sub>3</sub>Ni<sub>2</sub> (~80 % area fraction, grey  
44 phase), SmNi (~10 % area fraction, dark phase) and Sm<sub>3</sub>Ni (~10% area fraction, white phase).

64  
65

1 presence of three phases. The sporadic distribution of equilibrium SmNi and Sm<sub>3</sub>Ni phases  
2 along with their spatially separated nature suggest that the precipitation of these two phases are  
3 due to the partial decomposition of the Sm<sub>3</sub>Ni<sub>2</sub> phase below 600 °C. Further, close observation  
4 of the Sm<sub>3</sub>Ni precipitate (in fig. 5c) revealed an intragranular phase contrast which are distinct,  
5 indicative of the coexistence of multiple phases within, possibly in their metastable states.  
6 SEM-EDS line scan performed along the dotted line in fig. 5c does not show any significant  
7 variation in chemical composition across the metastable region which was also confirmed by  
8 the elemental mapping in fig. 5d. To further ascertain their phase constituents, site-specific  
9 APT measurement was performed along the multiphase contrast (metastable) region. Fig. 6a  
10 shows the elemental distribution map of Ni which appears to be inhomogeneous. 1D  
11 concentration profile along a 10 nm diameter cylindrical region of interest indicates local  
12 composition variations corresponding to Sm, SmNi, Sm<sub>3</sub>Ni and Sm-Ni-O. To further visualize  
13 the distribution of Oxygen rich regions, and to determine their local chemical composition, an  
14 8 at.% isoconcentration surface was used to delineate the atom map of O as shown in inset of  
15 Fig. 6b. The proximity histogram corresponding to one of the O rich regions (marked in  
16 rectangle) is constituted with  $24.9 \pm 0.89$  at.% O,  $15.8 \pm 0.75$  at.% Ni and  $59.1 \pm 1.01$  at.% Sm.  
17 Significant amount of O seems to have been incorporated in the sample post-annealing even  
18 though annealing was performed under controlled Ar atmosphere. Based on the APT  
19 determined local chemical composition, it can be inferred that the Oxygen rich regions could  
20 be metastable and may not be related to any stable oxide phases. However, the Sm<sub>3</sub>Ni<sub>2</sub> is  
21 resolved to be monoclinic with space group C2/m. The refined lattice parameter values are  $a =$   
22  $13.487 \text{ \AA}$ ,  $b = 3.754 \text{ \AA}$ , and  $c = 9.682 \text{ \AA}$  &  $\beta = 106.6^\circ$  different from the crystal structure and  
23 parameters reported in the OQMD for this structure [5][6]. However, it could be noted that the  
24 reported data is similar to isostructural Gd<sub>3</sub>Ni<sub>2</sub> reported by et al [10].

1 Having stabilized significant fraction (80% area fraction) of high-temperature stable  $\text{Sm}_3\text{Ni}_2$   
2 phase in the annealed condition, detailed magnetic property evaluation has been performed.  
3  
4 The temperature dependent magnetization measured with an applied field of 500 Oe for the as-  
5 cast alloy is shown in fig. 7a which shows two magnetic transitions. The first transition  
6  
7 identified as  $T_{C1}$  at 45 K correspond to the curie temperature of SmNi compound which was  
8  
9 identified as  $T_{C1}$  at 45 K correspond to the curie temperature of SmNi compound which was  
10  
11 found to be in good agreement with the value reported in literature [16],[17]. The second Curie  
12  
13 transition identified as  $T_{C2}$  at 110 K should be that of either  $\text{Sm}_7\text{Ni}_3$  or  $\text{Sm}_3\text{Ni}_2$ , but it could not  
14  
15 be ascertained as the magnetic properties of these high temperature phases are not yet reported.  
16  
17 Fig.7b shows the hysteresis loop measured for the as-cast alloy at 20 K (below  $T_{C1}$ ), 100 K  
18  
19 (below  $T_{C2}$ ) and 120 K (above  $T_{C2}$ ). The hysteresis loop at 20 K exhibited a two-phase  
20  
21 behaviour suggesting that two ferromagnetic phases are magnetically decoupled. At 100 K  
22  
23 (above the  $T_C$  of SmNi phase), a well-defined hysteresis loop can be observed with a coercivity  
24  
25 of 1 kOe corresponding to either of  $\text{Sm}_7\text{Ni}_3$  or  $\text{Sm}_3\text{Ni}_2$  phases. At 120 K, the hysteresis vanishes  
26  
27 and a linear change in magnetization typical of a paramagnetic behaviour observed since it is  
28  
29 well above the curie temperature of all the ferromagnetic phases present in the as-cast alloy.

34  
35  
36  
37  
38  
39 Figure 8a. shows the temperature dependent magnetization curve measured for the annealed  
40  
41 sample which contains ~80% (area fraction) of  $\text{Sm}_3\text{Ni}_2$  phase. The Curie transition at 45 K  
42  
43 ( $T_{C1}$  i.e. of SmNi) was observed but only as a small slope change due to the low volume fraction  
44  
45 of the SmNi phase present in the annealed sample. Whereas the  $T_{C2}$  remained similar to the as-  
46  
47 cast sample at 110 K. The inset shows the derivative of the M vs T to clearly identify the two  
48  
49 Curie transition temperatures. Based on the SEM microstructure obtained area fraction of  
50  
51 phases and taking into account the thermomagnetic behaviour of the as-cast and annealed  
52  
53 samples, the transition at 110 K should correspond to the Curie temperature of  $\text{Sm}_3\text{Ni}_2$  phase.  
54  
55 The  $\text{Sm}_7\text{Ni}_3$  and  $\text{Sm}_3\text{Ni}$  phases present in the as-cast and annealed samples respectively may

be diamagnetic or have a Curie temperature below 5 K. The hysteresis loop of the annealed sample shown in fig. 8b is similar to the as-cast sample for the 120 K and 100 K. The dominant  $\text{Sm}_3\text{Ni}_2$  phase present in the annealed sample exhibits a very high coercivity  $\sim 3$  T at 20 K. The high coercivity and squareness (82%) of the hysteresis loop clearly suggests that the  $\text{Sm}_3\text{Ni}_2$  is a hard magnetic phase with high uniaxial anisotropy. The high magnetocrystalline anisotropy of the  $\text{Sm}_3\text{Ni}_2$  phase could be due to the Sm ion having a positive Stevens coefficient ( $\alpha_J = 4 \times 10^{-2}$ ) [18] with a prolate shell [19]. The large separation distance between the zero-field cooled and field cooled thermomagnetic measurements carried out at an applied field of 5 T for the annealed sample shown in fig. 8b as inset further confirms the strong anisotropy of the  $\text{Sm}_3\text{Ni}_2$  phase [20]. Recently, it was reported that Sm based alloys could act as binders for the consolidation of Sm-Fe-N powders. The magnetic properties of the binder alloy which will be present in the intergranular/interparticle regions is crucial and is considered favourable if they are paramagnetic as they can decouple the ferromagnetic interactions. The paramagnetic nature of  $\text{Sm}_3\text{Ni}_2$  phase at room temperature highlights the possibility of further exploration as a potential binder material towards consolidation of Sm-Fe-N based bulk magnets.

#### 4. Summary

The microstructure evolution, phase formation and magnetic properties of  $\text{Sm}_{60}\text{Ni}_{40}$  alloy both in as cast and annealed (630 °C for 100h) conditions were investigated. The major observations are summarized below,

1. Significant fractions (~80% area fraction) of high temperature stable  $\text{Sm}_3\text{Ni}_2$  can be stabilized at room temperature by annealing the as-cast material slightly above the E3 temperature.
2. The crystal structure of  $\text{Sm}_3\text{Ni}_2$  phase has been determined using XRD Rietveld analysis to be monoclinic.
3. At room temperature  $\text{Sm}_3\text{Ni}_2$  phase is paramagnetic which can exhibit high uniaxial magnetocrystalline anisotropy below 110K.
4. The very high coercivity of ~ 3 T observed at 20 K combined with 82% squareness ratio confirms the hard magnetic nature of  $\text{Sm}_3\text{Ni}_2$  phase.

Based on the above observations, it can be concluded that appropriate heat treatment protocols could be devised to synthesize phase pure  $\text{Sm}_3\text{Ni}_2$  alloy which offers the potential of utilizing them as binder material for the synthesis of high-performance Sm-Fe-N based bulk magnets.

**Table.1.** shows reaction in enlarged portion of the Sm-Ni phase diagram [12]

Reaction	Type	Temperature (°C)	ID
$L \rightarrow \alpha - \text{Sm} + \text{Sm}_2\text{Ni}_{17}$	Eutectic	1275	E1
$L \rightarrow \text{SmNi} + \text{SmNi}_2$	Eutectic	821	E2
$L \rightarrow \text{Sm}_3\text{Ni}_2 + \text{Sm}_7\text{Ni}_3$	Eutectic	623	E3
$L + \text{SmNi} \rightarrow \text{Sm}_3\text{Ni}_2$	Peritectic	630	P1
$L + \text{Sm}_3\text{Ni} \rightarrow \text{Sm}_7\text{Ni}_3$	Peritectic	652	P2
