# Multiple-Access Channel Coding with Non-Signaling Correlations 

Omar Fawzi* Paul Fermé ${ }^{\dagger \ddagger}$

#### Abstract

We address the problem of coding for classical multiple-access channels (MACs) with the assistance of non-signaling correlations between parties. It is well-known that non-signaling assistance does not change the capacity of classical point-to-point channels. However, it was recently observed that one can construct MACs from two-player non-local games while relating the winning probability of the game to the capacity of the MAC. By considering games for which entanglement (a special kind of non-signaling correlation) increases the winning probability (e.g., the Magic Square game), this shows that for some specific kinds of channels, entanglement between the senders can increase the capacity.

In this work, we make several contributions towards understanding the capacity region for MACs with the assistance of non-signaling correlations between the parties. We develop a linear program computing the optimal success probability for coding over $n$ copies of a MAC $W$ with size growing polynomially in $n$. Solving this linear program allows us to achieve inner bounds for MACs. Applying this method to the binary adder channel, we show that using non-signaling assistance, the sum-rate $\frac{\log _{2}(72)}{4} \simeq 1.5425$ can be reached even with zero error, which beats the maximum sum-rate capacity of 1.5 in the unassisted case. For noisy channels, where the zero-error non-signaling assisted capacity region is trivial, we can use concatenated codes to obtain achievable points in the capacity region. Applied to a noisy version of the binary adder channel, we show that non-signaling assistance still improves the sum-rate capacity. Complementing these achievability results, we give an outer bound on the non-signaling assisted capacity region that has the same expression as the unassisted region except that the channel inputs are not required to be independent. Finally, we show that the capacity region with non-signaling assistance shared only between each sender and the receiver independently is the same as without assistance.

## 1 Introduction

Multiple-access channels (MACs for short) are one of the simplest models of network communication settings, where two senders aim to transmit individual messages to one receiver. The capacity of such channels has been entirely characterized by the seminal works by Liao [2] and Ahlswede [3] in terms of a simple single-letter formula. From the point of view of quantum information, it is natural to ask whether additional resources, such as quantum entanglement or more generally non-signaling correlations between the parties, change the capacity region. A non-signaling correlation is a multipartite input-output box shared between parties that, as the name suggests, cannot by itself be used to send information between parties. However, non-signaling correlations such as the ones generated by measurements of entangled quantum particles, can provide an advantage for various information processing tasks and nonlocal games. The study of such correlations has given rise to the quantum information area known as nonlocality [4]. For

[^0]example, in the context of channel coding, there exists classical point-to-point channels for which quantum entanglement between the sender and the receiver can increase the optimal success probability for sending one bit of information with a single use of the channel [5, 6. However, a well-known result [7] states that for classical point-to-point channels, entanglement and even more generally non-signaling correlations do not change the capacity of the channel; see also [8, 6].

In the network setting, behavior is different. Quek and Shor showed in [9] the existence of two-sender two-receiver interference channels with gaps between their classical, quantum-entanglement assisted and non-signaling assisted capacity regions. Following this result, Leditzky et al. [10] (see also [11]) showed that quantum entanglement shared between the two senders of a MAC can strictly enlarge the capacity region. This has been demonstrated through channels that are constructed from two-player non-local games, such as the Magic Square game [12, 13, 14, 15], by translating known gaps between classical and quantum values of games into MAC capacity gaps. Other instances of network channels for which entanglement increases the capacity region were studied in [16, 17]. This raises the following natural question: Can non-signaling correlations lead to significant gains in capacity for natural MACs? Can we find a characterization of the capacity region of the MAC when non-signaling resources between the parties are allowed?

Our Results We focus here on the MAC with two senders and we allow arbitrary tripartite non-signaling correlations between the two senders and the receiver. This is the most optimistic setting, in the sense that we only enforce the non-signaling constraints between the parties, and also the mathematically simplest setting. Even if not all non-signaling correlations are feasible within quantum theory, the setting we study here can be seen as a tractable and physically motivated outer approximation of what can be achieved with quantum theory. In fact, the quantum set is notoriously complicated and deciding membership in this set is not computable [18]. We note that very recently, Pereg et al. [19] found a multi-letter formula for the capacity of MACs with quantum entanglement shared between the two senders. Unfortunately, this characterization is very difficult to evaluate for any fixed channel.

We denote by $\mathrm{S}^{\mathrm{NS}}\left(W, k_{1}, k_{2}\right)$ the success probability of the best non-signaling assisted $\left(k_{1}, k_{2}\right)$-code for the MAC $W$. Contrary to the unassisted value that we denote $\mathrm{S}\left(W, k_{1}, k_{2}\right), \mathrm{S}^{\mathrm{NS}}\left(W, k_{1}, k_{2}\right)$ can be formulated as a linear program; see Proposition 3.1. Furthermore, using symmetries, we have developed a linear program computing $S^{\text {NS }}$ for a finite number of copies of a MAC $W$ with a size growing polynomially in the number of copies; see Theorem 3.10 and Corollary 3.11. Using this result, we describe a method to derive inner bounds on the non-signaling assisted capacity region achievable with zero error; see Proposition 4.1. Applied to the binary adder channel, which maps $\left(x_{1}, x_{2}\right) \in\{0,1\}^{2}$ to $x_{1}+x_{2} \in\{0,1,2\}$, we show that the sum-rate $\frac{\log _{2}(72)}{4} \simeq 1.5425$ can be reached with zero error, which beats the maximum classical sum-rate capacity of $\frac{3}{2}$; see Theorem 4.2. For noisy channels, where the zero-error non-signaling assisted capacity region is trivial, we can use concatenated codes to obtain achievable points in the capacity region; see Proposition 4.5. Applied to a noisy version of the binary adder channel, we show that non-signaling assistance still improves the sum-rate capacity.

In order to find outer bounds, we define a relaxed notion of non-signaling assistance and characterize its capacity region by a single-letter expression, which is the same as the well-known expression for the capacity of the MAC (see Theorem 2.2) except that the inputs $X_{1}$ and $X_{2}$ are not required to be independent; see Theorem 5.5. This gives in particular an outer bound on the non-signaling assisted capacity region; see Corollary 5.13. The main open problem that we leave is whether this outer bound on the non-signaling capacity region is tight. We give an example of a channel for which the relaxed notion of non-signaling assistance gives a strictly larger success probability than non-signaling assistance but we do not know if such a gap can persist for the capacity region.

We also study the case where non-signaling assistance is shared only between each sender and the receiver independently. Note that no assistance is shared between the senders. We show that this capacity region is the same as the capacity region without any assistance; see Theorem 6.4 and Corollary 6.5 .

We note that a similar setting with independent entangled states between each sender and the receiver was studied by Hsieh et al. [20]: a regularized characterization of the capacity region is obtained for any quantum MAC in this setting. It is simple to show using their result that for a classical MAC, this type of entanglement does not change the capacity region given in Theorem 2.2

Organization In Section 2, we define precisely the different notions of MAC capacities: the classical capacity (i.e. without any assistance) as well as the non-signaling assisted capacity. In Section 3, we address computational complexity questions concerning the probability of success of the best classical coding strategy and the best non-signaling strategy for a MAC. In Section 4, we develop numerical methods to find inner bounds on non-signaling assisted capacity regions, and apply those to the binary adder channel and a noisy variant. In Section 5, we define our relaxation of non-signaling assistance, we characterize its capacity region by a single-letter formula, and apply those to the binary adder channel. Finally, in Section 6, we show that the capacity region with non-signaling assistance shared only between each sender and the receiver independently is the same as without assistance.

## 2 Multiple Access Channels Capacities

### 2.1 Classical Capacities

Formally, a MAC $W$ is a conditional probability distribution depending on two inputs in $\mathcal{X}_{1}$ and $\mathcal{X}_{2}$, and an output in $\mathcal{Y}$, so $W:=\left(W\left(y \mid x_{1} x_{2}\right)\right)_{x_{1} \in \mathcal{X}_{1}, x_{2} \in \mathcal{X}_{2}, y \in \mathcal{Y}}$ such that $W\left(y \mid x_{1} x_{2}\right) \geq 0$ and $\sum_{y \in \mathcal{Y}} W\left(y \mid x_{1} x_{2}\right)=1$. We will denote such a MAC by $W: \mathcal{X}_{1} \times \mathcal{X}_{2} \rightarrow \mathcal{Y}$. The tensor product of two MACs $W: \mathcal{X}_{1} \times \mathcal{X}_{2} \rightarrow \mathcal{Y}$ and $W^{\prime}: \mathcal{X}_{1}^{\prime} \times \mathcal{X}_{2}^{\prime} \rightarrow \mathcal{Y}^{\prime}$ is denoted by $W \otimes W^{\prime}:\left(\mathcal{X}_{1} \times \mathcal{X}_{1}^{\prime}\right) \times\left(\mathcal{X}_{2} \times \mathcal{X}_{2}^{\prime}\right) \rightarrow \mathcal{Y} \times \mathcal{Y}^{\prime}$ and defined by $\left(W \otimes W^{\prime}\right)\left(y y^{\prime} \mid x_{1} x_{1}^{\prime} x_{2} x_{2}^{\prime}\right):=W\left(y \mid x_{1} x_{2}\right) \cdot W^{\prime}\left(y^{\prime} \mid x_{1}^{\prime} x_{2}^{\prime}\right)$. We denote by $W^{\otimes n}\left(y^{n} \mid x_{1}^{n} x_{2}^{n}\right):=\prod_{i=1}^{n} W\left(y_{i} \mid x_{1, i} x_{2, i}\right)$, for $y^{n}:=y_{1} \ldots y_{n} \in \mathcal{Y}^{n}, x_{1}^{n}:=x_{1,1} \ldots x_{1, n} \in \mathcal{X}_{1}^{n}$ and $x_{2}^{n}:=x_{2,1} \ldots x_{2, n} \in \mathcal{X}_{2}^{n}$. We will use the notation $[k]:=\{1, \ldots, k\}$.

The coding problem for a MAC $W: \mathcal{X}_{1} \times \mathcal{X}_{2} \rightarrow \mathcal{Y}$ is the following: one wants to encode messages in [ $\left.k_{1}\right]$ into $\mathcal{X}_{1}$ and messages in $\left[k_{2}\right]$ into $\mathcal{X}_{2}$ independently, which will be given as input to the channel $W$. This results in a random output in $\mathcal{Y}$, which one needs to decode back into the corresponding messages in $\left[k_{1}\right]$ and $\left[k_{2}\right]$. We will call $e_{1}:\left[k_{1}\right] \rightarrow \mathcal{X}_{1}$ the first encoder, $e_{2}:\left[k_{2}\right] \rightarrow \mathcal{X}_{2}$ the second encoder and $d: \mathcal{Y} \rightarrow\left[k_{1}\right] \times\left[k_{2}\right]$ the decoder. This is depicted in Figure 2.1.

Figure 1: Coding for a MAC $W$.
We want to maximize over all encoders $e_{1}, e_{2}$ and decoders $d$ the probability of successfully encoding and decoding the messages through $W$, i.e. the probability that $j_{1}=i_{1}$ and $j_{2}=i_{2}$, given that the input messages are taken uniformly in $\left[k_{1}\right]$ and $\left[k_{2}\right]$. We call this quantity $\mathrm{S}\left(W, k_{1}, k_{2}\right)$, which is characterized by the following optimization program:

$$
\begin{align*}
\mathrm{S}\left(W, k_{1}, k_{2}\right):= & \underset{e_{1}, e_{2}, d}{\operatorname{maximize}} \\
\text { subject to } & \frac{1}{k_{1} k_{2}} \sum_{i_{1}, i_{2}, x_{1}, x_{2}, y} W\left(y \mid x_{1} x_{2}\right) e_{1}\left(x_{1} \mid i_{1}\right) e_{2}\left(x_{2} \mid i_{2}\right) d\left(i_{1} i_{2} \mid y\right) \\
& e_{1}\left(x_{1} \mid i_{1}\right)=1, \forall i_{1} \in\left[k_{1}\right]  \tag{1}\\
& \sum_{x_{2} \in \mathcal{X}_{2}} e_{2}\left(x_{2} \mid i_{2}\right)=1, \forall i_{2} \in\left[k_{2}\right] \\
& \sum_{j_{1} \in\left[k_{1}\right], j_{2} \in\left[k_{2}\right]} d\left(j_{1} j_{2} \mid y\right)=1, \forall y \in \mathcal{Y} \\
& e_{1}\left(x_{1} \mid i_{1}\right), e_{2}\left(x_{2} \mid i_{2}\right), d\left(j_{1} j_{2} \mid y\right) \geq 0
\end{align*}
$$

Proof. One should note that we allow randomized encoders and decoders for generality reasons, although the value of the program is not changed as it is convex. Besides that remark, let us name $I_{1}, I_{2}, J_{1}, J_{2}, X_{1}, X_{2}, Y$ the random variables corresponding to $i_{1}, i_{2}, j_{1}, j_{2}, x_{1}, x_{2}, y$ in the coding and decoding process. Then, for given $e_{1}, e_{2}, d$ and $W$, the objective value of the previous program is:

$$
\begin{aligned}
& \mathbb{P}\left(J_{1}=I_{1}, J_{2}=I_{2}\right)=\frac{1}{k_{1} k_{2}} \sum_{i_{1}, i_{2}} \mathbb{P}\left(J_{1}=I_{1}, J_{2}=I_{2} \mid I_{1}=i_{1}, I_{2}=i_{2}\right) \\
& =\frac{1}{k_{1} k_{2}} \sum_{i_{1}, i_{2}, x_{1}, x_{2}} e_{1}\left(x_{1} \mid i_{1}\right) e_{2}\left(x_{2} \mid i_{2}\right) \mathbb{P}\left(J_{1}=i_{1}, J_{2}=i_{2} \mid I_{1}=i_{1}, I_{2}=i_{2}, X_{1}=x_{1}, X_{2}=x_{2}\right) \\
& =\frac{1}{k_{1} k_{2}} \sum_{i_{1}, i_{2}, x_{1}, x_{2}, y} W\left(y \mid x_{1} x_{2}\right) e_{1}\left(x_{1} \mid i_{1}\right) e_{2}\left(x_{2} \mid i_{2}\right) \mathbb{P}\left(J_{1}=i_{1}, J_{2}=i_{2} \mid I_{1}=i_{1}, I_{2}=i_{2}, X_{1}=x_{1}, X_{2}=x_{2}, Y=y\right) \\
& =\frac{1}{k_{1} k_{2}} \sum_{i_{1}, i_{2}, x_{1}, x_{2}, y} W\left(y \mid x_{1} x_{2}\right) e_{1}\left(x_{1} \mid i_{1}\right) e_{2}\left(x_{2} \mid i_{2}\right) d\left(i_{1}, i_{2} \mid y\right)
\end{aligned}
$$

Since MACs are more general than point-to-point channels (by defining $W\left(y \mid x_{1} x_{2}\right):=\hat{W}\left(y \mid x_{1}\right)$ for $\hat{W}$ a point-to-point channel and looking only at its first input), computing $\mathrm{S}\left(W, k_{1}, k_{2}\right)$ is NP-hard, and it is even NP-hard to approximate $\mathrm{S}\left(W, k_{1}, k_{2}\right)$ within a better ratio than $\left(1-e^{-1}\right)$, as a consequence of the hardness result on $\mathrm{S}(W, k)$ shown in [6].

The (classical) capacity of a MAC, as defined for example in [21], can be reformulated in the following way:

Definition 2.1 (Capacity Region $\mathcal{C}(W)$ of a MAC $W$ ). A rate pair $\left(R_{1}, R_{2}\right)$ is achievable if:

$$
\lim _{n \rightarrow+\infty} \mathrm{S}\left(W^{\otimes n},\left\lceil 2^{R_{1} n}\right\rceil,\left\lceil 2^{R_{2} n}\right\rceil\right)=1
$$

We define the (classical) capacity region $\mathcal{C}(W)$ as the closure of the set of all achievable rate pairs.
The capacity region $\mathcal{C}(W)$ is characterized by a single-letter formula:
Theorem 2.2 (Liao [2] and Ahlswede [3]). $\mathcal{C}(W)$ is the closure of the convex hull of all rate pairs $\left(R_{1}, R_{2}\right)$ satisfying:

$$
R_{1}<I\left(X_{1}: Y \mid X_{2}\right), R_{2}<I\left(X_{2}: Y \mid X_{1}\right), R_{1}+R_{2}<I\left(\left(X_{1}, X_{2}\right): Y\right),
$$

for $\left(X_{1}, X_{2}\right) \in \mathcal{X}_{1} \times \mathcal{X}_{2}$ following a product law $P_{X_{1}} \times P_{X_{2}}$, and $Y \in \mathcal{Y}$ the outcome of $W$ on inputs $X_{1}, X_{2}$.

For the zero-error (classical) capacity, this leads to the following definition:
Definition 2.3 (Zero-Error Capacity Region $\mathcal{C}_{0}(W)$ of a MAC $W$ ). A rate pair $\left(R_{1}, R_{2}\right)$ is achievable with zero-error if:

$$
\exists n_{0} \in \mathbb{N}^{*}, \forall n \geq n_{0}, \mathrm{~S}\left(W^{\otimes n},\left\lceil 2^{R_{1} n}\right\rceil,\left\lceil 2^{R_{2} n}\right\rceil\right)=1
$$

We define the zero-error (classical) capacity region $\mathcal{C}_{0}(W)$ as the closure of the set of all achievable rate pairs with zero-error.

We will also consider what we call the sum success probability $\mathrm{S}_{\text {sum }}\left(W, k_{1}, k_{2}\right)$, defined using $\frac{\mathbb{P}\left(J_{1}=I_{1}\right)+\mathbb{P}\left(J_{2}=I_{2}\right)}{2}$ rather than $\mathbb{P}\left(J_{1}=I_{1}, J_{2}=I_{2}\right)$ as an objective value, which leads to the following optimization program:

$$
\begin{align*}
\mathrm{S}_{\text {sum }}\left(W, k_{1}, k_{2}\right):= & \underset{e_{1}, e_{2}, d_{1}, d_{2}}{\operatorname{maximize}}
\end{aligned} \begin{aligned}
2 k_{1} k_{2} & \sum_{i_{1}, i_{2}, x_{1}, x_{2}, y} W\left(y \mid x_{1} x_{2}\right) e_{1}\left(x_{1} \mid i_{1}\right) e_{2}\left(x_{2} \mid i_{2}\right) d_{1}\left(i_{1} \mid y\right) \\
& +\frac{1}{2 k_{1} k_{2}} \sum_{i_{1}, i_{2}, x_{1}, x_{2}, y} W\left(y \mid x_{1} x_{2}\right) e_{1}\left(x_{1} \mid i_{1}\right) e_{2}\left(x_{2} \mid i_{2}\right) d_{2}\left(i_{2} \mid y\right) \\
\text { subject to } & \sum_{x_{1} \in \mathcal{X}_{1}} e_{1}\left(x_{1} \mid i_{1}\right)=1, \forall i_{1} \in\left[k_{1}\right] \\
& \sum_{x_{2} \in \mathcal{X}_{2}} e_{2}\left(x_{2} \mid i_{2}\right)=1, \forall i_{2} \in\left[k_{2}\right]  \tag{2}\\
& \sum_{j_{1} \in\left[k_{1}\right]} d_{1}\left(j_{1} \mid y\right)=1, \forall y \in \mathcal{Y} \\
& \sum_{j_{2} \in\left[k_{2}\right]} d_{2}\left(j_{2} \mid y\right)=1, \forall y \in \mathcal{Y} \\
& e_{1}\left(x_{1} \mid i_{1}\right), e_{2}\left(x_{2} \mid i_{2}\right), d_{1}\left(j_{1} \mid y\right), d_{2}\left(j_{2} \mid y\right) \geq 0
\end{align*}
$$

Note that we used independent decoders $d_{1}\left(j_{1} \mid y\right), d_{2}\left(j_{2} \mid y\right)$ rather than a global $d\left(j_{1} j_{2} \mid y\right)$ here. This does not change the value of the optimization program. Indeed, since the program is convex, an optimal solution can be found on the extremal points of the search space. Thus, if we had used the variable $d\left(j_{1} j_{2} \mid y\right)$, we could always take it to be a function $d$ from $\mathcal{Y}$ to $\left[k_{1}\right] \times\left[k_{2}\right]$. Taking $d_{1}, d_{2}$ as the first and second coordinates of that function satisfies the equality $d\left(j_{1} j_{2} \mid y\right)=d_{1}\left(j_{1} \mid y\right) d_{2}\left(j_{2} \mid y\right)$, and therefore, the value of the program is the same in both cases. Note that it is also true for the program computing $\mathrm{S}\left(W, k_{1}, k_{2}\right)$.

As for the usual (joint) success probability, we can define its capacity region:
Definition 2.4 (Sum-Capacity Region $\mathcal{C}_{\text {sum }}(W)$ of a MAC $W$ ). A rate pair $\left(R_{1}, R_{2}\right)$ is sum-achievable if:

$$
\lim _{n \rightarrow+\infty} \mathrm{S}_{\text {sum }}\left(W^{\otimes n},\left\lceil 2^{R_{1} n}\right\rceil,\left\lceil 2^{R_{2} n}\right\rceil\right)=1
$$

We define the sum-capacity region $\mathcal{C}_{\text {sum }}(W)$ as the closure of the set of all sum-achievable rate pairs.
However, it turns out those two notions of success define the same capacity region:
Proposition 2.5. $\mathcal{C}(W)=\mathcal{C}_{\text {sum }}(W)$
Proof. Let us focus on error probabilities rather than success ones. Call them respectively $\mathrm{E}\left(W, k_{1}, k_{2}\right):=$ $1-\mathrm{S}\left(W, k_{1}, k_{2}\right)$ and $\mathrm{E}_{\text {sum }}\left(W, k_{1}, k_{2}\right):=1-\mathrm{S}_{\text {sum }}\left(W, k_{1}, k_{2}\right)$. Let us fix a solution $e_{1}, d_{1}, e_{2}, d_{2}$ of the optimization program computing $\mathrm{S}\left(W, k_{1}, k_{2}\right)$. Let us remark first that:

$$
\sum_{i_{1}, i_{2}, x_{1}, x_{2}, y} W\left(y \mid x_{1} x_{2}\right) e_{1}\left(x_{1} \mid i_{1}\right) e_{2}\left(x_{2} \mid i_{2}\right)=k_{1} k_{2},
$$

thus, the value of the maximum error for those encoders and decoders is:

$$
\begin{align*}
& \mathrm{E}\left(W, k_{1}, k_{2}, e_{1}, d_{1}, e_{2}, d_{2}\right):=1-\frac{1}{k_{1} k_{2}}\left(\sum_{i_{1}, i_{2}, x_{1}, x_{2}, y} W\left(y \mid x_{1} x_{2}\right) e_{1}\left(x_{1} \mid i_{1}\right) e_{2}\left(x_{2} \mid i_{2}\right) d_{1}\left(i_{1} \mid y\right) d_{2}\left(i_{2} \mid y\right)\right) \\
& =\frac{1}{k_{1} k_{2}}\left(\sum_{i_{1}, i_{2}, x_{1}, x_{2}, y} W\left(y \mid x_{1} x_{2}\right) e_{1}\left(x_{1} \mid i_{1}\right) e_{2}\left(x_{2} \mid i_{2}\right)-\sum_{i_{1}, i_{2}, x_{1}, x_{2}, y} W\left(y \mid x_{1} x_{2}\right) e_{1}\left(x_{1} \mid i_{1}\right) e_{2}\left(x_{2} \mid i_{2}\right) d_{1}\left(i_{1} \mid y\right) d_{2}\left(i_{2} \mid y\right)\right) \\
& =\frac{1}{k_{1} k_{2}}\left(\sum_{i_{1}, i_{2}, x_{1}, x_{2}, y} W\left(y \mid x_{1} x_{2}\right) e_{1}\left(x_{1} \mid i_{1}\right) e_{2}\left(x_{2} \mid i_{2}\right)\left[1-d_{1}\left(i_{1} \mid y\right) d_{2}\left(i_{2} \mid y\right)\right]\right) . \tag{3}
\end{align*}
$$

Similarly, the value of the sum error for those encoder and decoders is:

$$
\begin{align*}
\mathrm{E}_{\text {sum }}\left(W, k_{1}, k_{2}, e_{1}, d_{1}, e_{2}, d_{2}\right) & :=1-\frac{1}{k_{1} k_{2}}\left(\sum_{i_{1}, i_{2}, x_{1}, x_{2}, y} W\left(y \mid x_{1} x_{2}\right) e_{1}\left(x_{1} \mid i_{1}\right) e_{2}\left(x_{2} \mid i_{2}\right) \frac{d_{1}\left(i_{1} \mid y\right)+d_{2}\left(i_{2} \mid y\right)}{2}\right) \\
& =\frac{1}{k_{1} k_{2}}\left(\sum_{i_{1}, i_{2}, x_{1}, x_{2}, y} W\left(y \mid x_{1} x_{2}\right) e_{1}\left(x_{1} \mid i_{1}\right) e_{2}\left(x_{2} \mid i_{2}\right)\left[1-\frac{d_{1}\left(i_{1} \mid y\right)+d_{2}\left(i_{2} \mid y\right)}{2}\right]\right) . \tag{4}
\end{align*}
$$

However, for $x, y \in[0,1]$, we have that:

$$
1-x y \geq \max (1-x, 1-y) \geq 1-\frac{x+y}{2}
$$

and:

$$
1-x y \leq(1-x)+(1-y)=2\left(1-\frac{x+y}{2}\right)
$$

This means that, for all $e_{1}, d_{1}, e_{2}, d_{2}$, we have:

$$
\mathrm{E}_{\text {sum }}\left(W, k_{1}, k_{2}, e_{1}, d_{1}, e_{2}, d_{2}\right) \leq \mathrm{E}\left(W, k_{1}, k_{2}, e_{1}, d_{1}, e_{2}, d_{2}\right) \leq 2 \mathrm{E}_{\text {sum }}\left(W, k_{1}, k_{2}, e_{1}, d_{1}, e_{2}, d_{2}\right)
$$

so, maximizing over all $e_{1}, d_{1}, e_{2}, d_{2}$, we get:

$$
\mathrm{E}_{\text {sum }}\left(W, k_{1}, k_{2}\right) \leq \mathrm{E}\left(W, k_{1}, k_{2}\right) \leq 2 \mathrm{E}_{\text {sum }}\left(W, k_{1}, k_{2}\right)
$$

Thus, up to a multiplicative factor 2 , the error is the same. In particular, when one of those errors tends to zero, the other one tends to zero as well. This implies that the capacity regions are the same.

### 2.2 Non-Signaling Assisted Capacities

Three-party non-signaling assistance We now consider the case where the senders and the receiver are given non-signaling assistance. This resource, which is a theoretical but easier to manipulate generalization of quantum entanglement, can be characterized as follows. A tripartite non-signaling box is
described by a joint conditional probability distribution $P\left(x_{1} x_{2}\left(j_{1} j_{2}\right) \mid i_{1} i_{2} y\right)$ such that the marginal from any two parties is independent from the removed party's input, i.e., we have:

$$
\begin{align*}
\forall x_{2}, j_{1}, j_{2}, i_{1}, i_{2}, y, i_{1}^{\prime}, & \sum_{x_{1}} P\left(x_{1} x_{2}\left(j_{1} j_{2}\right) \mid i_{1} i_{2} y\right)=\sum_{x_{1}} P\left(x_{1} x_{2}\left(j_{1} j_{2}\right) \mid i_{1}^{\prime} i_{2} y\right), \\
\forall x_{1}, j_{1}, j_{2}, i_{1}, i_{2}, y, i_{2}^{\prime}, & \sum_{x_{2}} P\left(x_{1} x_{2}\left(j_{1} j_{2}\right) \mid i_{1} i_{2} y\right)=\sum_{x_{2}} P\left(x_{1} x_{2}\left(j_{1} j_{2}\right) \mid i_{1} i_{2}^{\prime} y\right),  \tag{5}\\
\forall x_{1}, x_{2}, i_{1}, i_{2}, y, y^{\prime}, & \sum_{j_{1}, j_{2}} P\left(x_{1} x_{2}\left(j_{1} j_{2}\right) \mid i_{1} i_{2} y\right)=\sum_{j_{1}, j_{2}} P\left(x_{1} x_{2}\left(j_{1} j_{2}\right) \mid i_{1} i_{2} y^{\prime}\right) .
\end{align*}
$$

This implies that one can consider for example $P\left(x_{1} x_{2} \mid i_{1} i_{2}\right)$ since it does not depend on $y$, or even $P\left(x_{1} \mid i_{1}\right)$ since it does not depend on $i_{2}, y$. Then, in our coding scenario, when the senders and the receiver are given non-signaling assistance, it means that they share a tripartite non-signaling box, the behavior of which is described by $P$. In this case, the expression $e_{1}\left(x_{1} \mid i_{1}\right) e_{2}\left(x_{2} \mid i_{2}\right) d\left(j_{1} j_{2} \mid y\right)$ in (11) is replaced by $P\left(x_{1} x_{2}\left(j_{1} j_{2}\right) \mid i_{1} i_{2} y\right)$, as depicted in Figure 2 .

Figure 2: A non-signaling box $P$ replacing $e_{1}, e_{2}$ and $d$ in the coding problem for the MAC $W$.
The cyclicity of Figure 2 is at first sight counter-intuitive. Note first that $P$ being a non-signaling box is completely independent from $W$ : in particular, the variable $y$ does not need to follow any law in the definition of $P$ being a non-signaling box. Therefore, the remaining ambiguity is the apparent need to encode and decode at the same time. However, since $P$ is a non-signaling box, we do not need to do both at the same time. Indeed, $\forall y, P\left(x_{1} x_{2} \mid i_{1} i_{2}\right)=P\left(x_{1} x_{2} \mid i_{1} i_{2} y\right)$ by the non-signaling property of $P$. Thus, one can get the outputs $x_{1}, x_{2}$ on inputs $i_{1}, i_{2}$ without access to $y$, as that knowledge won't affect the laws of $x_{1}, x_{2}$. Then $y$ follows the law given by $W$ given those $x_{1}, x_{2}$. Finally, given access to $y$, the decoding process is described by:

$$
P\left(\left(j_{1} j_{2}\right) \mid i_{1} i_{2} y x_{1} x_{2}\right)=\frac{P\left(x_{1} x_{2}\left(j_{1} j_{2}\right) \mid i_{1} i_{2} y\right)}{P\left(x_{1} x_{2} \mid i_{1} i_{2} y\right)}=\frac{P\left(x_{1} x_{2}\left(j_{1} j_{2}\right) \mid i_{1} i_{2} y\right)}{P\left(x_{1} x_{2} \mid i_{1} i_{2}\right)}
$$

so we recover globally $P\left(\left(j_{1} j_{2}\right) \mid i_{1} i_{2} y x_{1} x_{2}\right) \times P\left(x_{1} x_{2} \mid i_{1} i_{2}\right)=P\left(x_{1} x_{2}\left(j_{1} j_{2}\right) \mid i_{1} i_{2} y\right)$ the prescribed conditional probability. The non-signaling condition ensures that it is possible to consider the conditional probabilities of each party independently. This clarifies how one can effectively encode and then decode messages through a non-signaling box.

As in the unassisted case, we want to maximize over all non-signaling box $P$ the probability of successfully encoding and decoding the messages through $W$, i.e. the probability that $j_{1}=i_{1}$ and $j_{2}=i_{2}$,
given that the input messages are taken uniformly in $\left[k_{1}\right]$ and $\left[k_{2}\right]$. We call this quantity $\mathrm{S}^{\mathrm{NS}}\left(W, k_{1}, k_{2}\right)$, which is characterized by the following optimization program:

$$
\begin{align*}
\mathrm{S}^{\mathrm{NS}}\left(W, k_{1}, k_{2}\right):=\underset{P}{\operatorname{maximize}} & \frac{1}{k_{1} k_{2}} \sum_{i_{1}, i_{2}, x_{1}, x_{2}, y} W\left(y \mid x_{1} x_{2}\right) P\left(x_{1} x_{2}\left(i_{1} i_{2}\right) \mid i_{1} i_{2} y\right) \\
\text { subject to } & \sum_{x_{1}} P\left(x_{1} x_{2}\left(j_{1} j_{2}\right) \mid i_{1} i_{2} y\right)=\sum_{x_{1}} P\left(x_{1} x_{2}\left(j_{1} j_{2}\right) \mid i_{1}^{\prime} i_{2} y\right) \\
& \sum_{x_{2}} P\left(x_{1} x_{2}\left(j_{1} j_{2}\right) \mid i_{1} i_{2} y\right)=\sum_{x_{2}} P\left(x_{1} x_{2}\left(j_{1} j_{2}\right) \mid i_{1} i_{2}^{\prime} y\right)  \tag{6}\\
& \sum_{j_{1}, j_{2}} P\left(x_{1} x_{2}\left(j_{1} j_{2}\right) \mid i_{1} i_{2} y\right)=\sum_{j_{1}, j_{2}} P\left(x_{1} x_{2}\left(j_{1} j_{2}\right) \mid i_{1} i_{2} y^{\prime}\right) \\
& \sum_{x_{1}, x_{2}, j_{1}, j_{2}} P\left(x_{1} x_{2}\left(j_{1} j_{2}\right) \mid i_{1} i_{2} y\right)=1 \\
& P\left(x_{1} x_{2}\left(j_{1} j_{2}\right) \mid i_{1} i_{2} y\right) \geq 0
\end{align*}
$$

Since it is given as a linear program, the complexity of computing $\mathrm{S}^{\mathrm{NS}}\left(W, k_{1}, k_{2}\right)$ is polynomial in the number of variables and constraints (see for instance Section 7.1 of [22]), which is a polynomial in $\left|\mathcal{X}_{1}\right|,\left|\mathcal{X}_{2}\right|,|\mathcal{Y}|, k_{1}$ and $k_{2}$. Also, as it is easy to check that a classical strategy is a particular case of a non-signaling assisted strategy, we have that $\mathrm{S}^{\mathrm{NS}}\left(W, k_{1}, k_{2}\right) \geq \mathrm{S}\left(W, k_{1}, k_{2}\right)$.

We have then the same definitions of capacity and zero-error capacity:
Definition 2.6 (Non-Signaling Assisted Capacity Region $\mathcal{C}^{\text {NS }}(W)$ of a MAC $W$ ). A rate pair $\left(R_{1}, R_{2}\right)$ is achievable with non-signaling assistance if:

$$
\lim _{n \rightarrow+\infty} S^{\mathrm{NS}}\left(W^{\otimes n},\left\lceil 2^{R_{1} n}\right\rceil,\left\lceil 2^{R_{2} n}\right\rceil\right)=1
$$

We define the non-signaling assisted capacity region $\mathcal{C}^{\mathrm{NS}}(W)$ as the closure of the set of all achievable rate pairs with non-signaling assistance.

Definition 2.7 (Zero-Error Non-Signaling Assisted Capacity Region $\mathcal{C}_{0}^{\text {NS }}(W)$ of a MAC $W$ ). A rate pair ( $R_{1}, R_{2}$ ) is achievable with zero-error and non-signaling assistance if:

$$
\exists n_{0} \in \mathbb{N}^{*}, \forall n \geq n_{0}, S^{\mathrm{NS}}\left(W^{\otimes n},\left\lceil 2^{R_{1} n}\right\rceil,\left\lceil 2^{R_{2} n}\right\rceil\right)=1
$$

We define the zero-error non-signaling assisted capacity region $\mathcal{C}_{0}^{\text {NS }}(W)$ as the closure of the set of all achievable rate pairs with zero-error and non-signaling assistance.

Independent non-signaling assistance One can also consider the case where non-signaling assistance is shared independently between the first sender and the receiver as well as between the second encoder and the receiver, which we call independent non-signaling assistance. The precise scenario is depicted in Figure 3

Figure 3: Non-signaling boxes $P^{1}, P^{2}$ replacing $e_{1}, d_{1}$ and $e_{2}, d_{2}$ in the coding problem for the MAC $W$.

This leads to the following definition of the success probability $\mathrm{S}^{\mathrm{NS}}{ }^{\mathrm{SR}}\left(W, k_{1}, k_{2}\right)$ :

$$
\begin{align*}
& \mathrm{S}^{\mathrm{NS}}\left(W, k_{1}, k_{2}\right):=\underset{P^{1}, P^{2}}{\operatorname{maximize}} \frac{1}{k_{1} k_{2}} \sum_{i_{1}, i_{2}, x_{1}, x_{2}, y} W\left(y \mid x_{1} x_{2}\right) P^{1}\left(x_{1} i_{1} \mid i_{1} y\right) P^{2}\left(x_{2} i_{2} \mid i_{2} y\right) \\
& \text { subject to } \quad \sum_{x_{1}} P^{1}\left(x_{1} j_{1} \mid i_{1} y\right)=\sum_{x_{1}} P^{1}\left(x_{1} j_{1} \mid i_{1}^{\prime} y\right) \\
& \sum_{j_{1}} P^{1}\left(x_{1} j_{1} \mid i_{1} y\right)=\sum_{j_{1}} P^{1}\left(x_{1} j_{1} \mid i_{1} y^{\prime}\right) \\
& \sum_{x_{1}, j_{1}} P^{1}\left(x_{1} j_{1} \mid i_{1} y\right)=1  \tag{7}\\
& \sum_{x_{2}} P^{2}\left(x_{2} j_{2} \mid i_{2} y\right)=\sum_{x_{2}} P^{2}\left(x_{2} j_{2} \mid i_{2}^{\prime} y\right) \\
& \sum_{j_{2}} P^{2}\left(x_{2} j_{2} \mid i_{2} y\right)=\sum_{j_{2}} P^{2}\left(x_{2} j_{2} \mid i_{2} y^{\prime}\right) \\
& \sum_{x_{2}, j_{2}} P^{2}\left(x_{2} j_{2} \mid i_{2} y\right)=1 \\
& P^{1}\left(x_{1} j_{1} \mid i_{1} y\right), P^{2}\left(x_{2} j_{2} \mid i_{2} y\right) \geq 0
\end{align*}
$$

As before, one can also consider the sum-success probability $S_{\text {sum }}^{\mathrm{NS} S R}\left(W, k_{1}, k_{2}\right)$ :

$$
\begin{align*}
\mathrm{S}_{\mathrm{sum}}^{\mathrm{NS}}\left(W, k_{1}, k_{2}\right):= & \underset{P^{1}, P^{2}}{\operatorname{maximize}} \\
\text { subject to } & \frac{1}{2 k_{1} k_{2}} \sum_{i_{1}, i_{2}, x_{1}, x_{2}, y} W\left(y \mid x_{1} x_{2}\right) P^{1}\left(x_{1} i_{1} \mid i_{1} y\right) \sum_{j_{2}} P^{2}\left(x_{2} j_{2} \mid i_{2} y\right) \\
& \frac{1}{2 k_{1} k_{2}} \sum_{i_{1}} P^{1}\left(x_{2}, x_{1} j_{1} \mid x_{2}, y\right. \\
& \sum_{j_{1} y} P^{1}\left(x_{1} j_{1} \mid i_{1} y\right)=\sum_{x_{1}} P^{1}\left(x_{1} j_{1} \mid i_{1}^{\prime} y\right) \\
& \sum_{j_{1}} P^{1}\left(x_{1} j_{1} \mid i_{1} y^{\prime}\right) P^{2}\left(x_{2} i_{2} \mid i_{2} y\right) \sum_{j_{1}} P^{1}\left(x_{1} j_{1} \mid i_{1} y\right)  \tag{8}\\
& \left.x_{1} j_{1} \mid i_{1} y\right)=1 \\
& \sum_{x_{2}, j_{1}} P^{2}\left(x_{2} j_{2} \mid i_{2} y\right)=\sum_{x_{2}} P^{2}\left(x_{2} j_{2} \mid i_{2}^{\prime} y\right) \\
& \sum_{j_{2}} P^{2}\left(x_{2} j_{2} \mid i_{2} y\right)=\sum_{j_{2}} P^{2}\left(x_{2} j_{2} \mid i_{2} y^{\prime}\right) \\
& \sum_{x_{2}, j_{2}} P^{2}\left(x_{2} j_{2} \mid i_{2} y\right)=1 \\
& P^{1}\left(x_{1} j_{1} \mid i_{1} y\right), P^{2}\left(x_{2} j_{2} \mid i_{2} y\right) \geq 0
\end{align*}
$$

Definition 2.8 (Independent Non-Signaling Assisted Capacity (resp. Sum-Capacity) Region $\mathcal{C}^{\mathrm{NS}_{\mathrm{SR}}}(W)$ (resp. $\left.\mathcal{C}_{\mathrm{sum}}^{\mathrm{NS}}(W)\right)$ of a MAC $W$ ). A rate pair $\left(R_{1}, R_{2}\right)$ is achievable (resp. sum-achievable) with independent non-signaling assistance if:

$$
\begin{gathered}
\lim _{n \rightarrow+\infty} \mathrm{S}^{\mathrm{NS}_{\mathrm{SR}}}\left(W^{\otimes n},\left\lceil 2^{R_{1} n}\right\rceil,\left\lceil 2^{R_{2} n}\right\rceil\right)=1 . \\
\text { (resp. } \left.\lim _{n \rightarrow+\infty} S_{\mathrm{sum}}^{\mathrm{NS}_{\mathrm{SR}}}\left(W^{\otimes n},\left\lceil 2^{R_{1} n}\right\rceil,\left\lceil 2^{R_{2} n}\right\rceil\right)=1 .\right)
\end{gathered}
$$

We define the independent non-signaling assisted capacity (resp. sum-capacity) region $\mathcal{C}^{\mathrm{NS}}{ }^{\mathrm{SR}}(W)$ (resp. $\mathcal{C}_{\text {sum }}^{\mathrm{NSR}_{\mathrm{SR}}}(W)$ ) as the closure of the set of all achievable (resp. sum-achievable) rate pairs with independent non-signaling assistance.

However, it turns out those two notions of success define the same capacity region:
Proposition 2.9. $\mathcal{C}^{\mathrm{NS}_{\mathrm{SR}}}(W)=\mathcal{C}_{\text {sum }}^{\mathrm{NS}_{\mathrm{SR}}}(W)$
Proof. Given non-signaling boxes $P^{1}, P^{2}$, the maximum success probability of encoding and decoding correctly with those is given by:

$$
\mathrm{S}^{\mathrm{NS}_{\mathrm{SR}}}\left(W, k_{1}, k_{2}, P^{1}, P^{2}\right):=\frac{1}{k_{1} k_{2}} \sum_{i_{1}, i_{2}, x_{1}, x_{2}, y} W\left(y \mid x_{1} x_{2}\right) P^{1}\left(x_{1} i_{1} \mid i_{1} y\right) P^{2}\left(x_{2} i_{2} \mid i_{2} y\right)
$$

This should be compared to the sum success probability of encoding and decoding correctly with those, which we call $\mathrm{S}_{\mathrm{sum}}^{\mathrm{NS}_{\mathrm{SR}}}\left(W, k_{1}, k_{2}, P^{1}, P^{2}\right)$ and is equal to:

$$
\frac{1}{k_{1} k_{2}} \sum_{i_{1}, i_{2}, x_{1}, x_{2}, y} W\left(y \mid x_{1} x_{2}\right) \frac{P^{1}\left(x_{1} i_{1} \mid i_{1} y\right) \sum_{j_{2}} P^{2}\left(x_{2} j_{2} \mid i_{2} y\right)+P^{2}\left(x_{2} i_{2} \mid i_{2} y\right) \sum_{j_{1}} P^{1}\left(x_{1} j_{1} \mid i_{1} y\right)}{2}
$$

Similarly to what was done in Proposition 2.5, we focus on error probabilities rather than success probabilities. We have that:

$$
\frac{1}{k_{1} k_{2}} \sum_{i_{1}, i_{2}, x_{1}, x_{2}, y} W\left(y \mid x_{1} x_{2}\right) \sum_{j_{1}, j_{2}} P^{1}\left(x_{1} j_{1} \mid i_{1} y\right) P^{2}\left(x_{2} j_{2} \mid i_{2} y\right)=1
$$

so we get that $\mathrm{E}^{\mathrm{NS}} \mathrm{SR}\left(W, k_{1}, k_{2}, P^{1}, P^{2}\right)$ is equal to:

$$
\frac{1}{k_{1} k_{2}} \sum_{i_{1}, i_{2}, x_{1}, x_{2}, y} W\left(y \mid x_{1} x_{2}\right)\left[\sum_{j_{1}, j_{2}} P^{1}\left(x_{1} j_{1} \mid i_{1} y\right) P^{2}\left(x_{2} j_{2} \mid i_{2} y\right)-P^{1}\left(x_{1} i_{1} \mid i_{1} y\right) P^{2}\left(x_{2} i_{2} \mid i_{2} y\right)\right]
$$

and thus:

$$
\mathrm{E}^{\mathrm{NS}_{\mathrm{SR}}}\left(W, k_{1}, k_{2}, P^{1}, P^{2}\right)=\sum_{i_{1}, i_{2}, x_{1}, x_{2}, y} W\left(y \mid x_{1} x_{2}\right) \sum_{\left(j_{1}, j_{2}\right) \neq\left(i_{1}, i_{2}\right)} P^{1}\left(x_{1} j_{1} \mid i_{1} y\right) P^{2}\left(x_{2} j_{2} \mid i_{2} y\right) .
$$

On the other hand, since:

$$
\sum_{j_{1}, j_{2}} P^{1}\left(x_{1} j_{1} \mid i_{1} y\right) P^{2}\left(x_{2} j_{2} \mid i_{2} y\right)-P^{1}\left(x_{1} i_{1} \mid i_{1} y\right) \sum_{j_{2}} P^{2}\left(x_{2} j_{2} \mid i_{2} y\right)=\sum_{j_{1} \neq i_{1}, j_{2}} P^{1}\left(x_{1} j_{1} \mid i_{1} y\right) P^{2}\left(x_{2} j_{2} \mid i_{2} y\right),
$$

and:

$$
\sum_{j_{1}, j_{2}} P^{1}\left(x_{1} j_{1} \mid i_{1} y\right) P^{2}\left(x_{2} j_{2} \mid i_{2} y\right)-P^{2}\left(x_{2} i_{2} \mid i_{2} y\right) \sum_{j_{1}} P^{1}\left(x_{1} j_{1} \mid i_{1} y\right)=\sum_{j_{1}, j_{2} \neq i_{2}} P^{1}\left(x_{1} j_{1} \mid i_{1} y\right) P^{2}\left(x_{2} j_{2} \mid i_{2} y\right),
$$

we get that $\mathrm{E}_{\mathrm{sum}}^{\mathrm{NSR}}\left(W, k_{1}, k_{2}, P^{1}, P^{2}\right)$ is equal to:

$$
\begin{align*}
& \frac{1}{k_{1} k_{2}} \sum_{i_{1}, i_{2}, x_{1}, x_{2}, y} W\left(y \mid x_{1} x_{2}\right)\left[\frac{\sum_{j_{1} \neq i_{1}, j_{2}} P^{1}\left(x_{1} j_{1} \mid i_{1} y\right) P^{2}\left(x_{2} j_{2} \mid i_{2} y\right)+\sum_{j_{1}, j_{2} \neq i_{2}} P^{1}\left(x_{1} j_{1} \mid i_{1} y\right) P^{2}\left(x_{2} j_{2} \mid i_{2} y\right)}{2}\right] \\
& =\frac{1}{k_{1} k_{2}} \sum_{i_{1}, i_{2}, x_{1}, x_{2}, y} W\left(y \mid x_{1} x_{2}\right)\left[\sum_{j_{1} \neq i_{1}, j_{2} \neq i_{2}} P^{1}\left(x_{1} j_{1} \mid i_{1} y\right) P^{2}\left(x_{2} j_{2} \mid i_{2} y\right)+\frac{\sum_{\left(j_{1}, j_{2}\right) \in S} P^{1}\left(x_{1} j_{1} \mid i_{1} y\right) P^{2}\left(x_{2} j_{2} \mid i_{2} y\right)}{2}\right], \tag{9}
\end{align*}
$$

with $S:=\left\{\left(j_{1}, i_{2}\right): j_{1} \in\left[k_{1}\right]-\left\{i_{1}\right\}\right\} \cup\left\{\left(i_{1}, j_{2}\right): j_{2} \in\left[k_{2}\right]-\left\{i_{2}\right\}\right\}$. However, we have that:

$$
\begin{align*}
& \sum_{j_{1} \neq i_{1}, j_{2} \neq i_{2}} P^{1}\left(x_{1} j_{1} \mid i_{1} y\right) P^{2}\left(x_{2} j_{2} \mid i_{2} y\right)+\frac{\sum_{\left(j_{1}, j_{2}\right) \in S} P^{1}\left(x_{1} j_{1} \mid i_{1} y\right) P^{2}\left(x_{2} j_{2} \mid i_{2} y\right)}{2} \\
\leq & \sum_{j_{1} \neq i_{1}, j_{2} \neq i_{2}} P^{1}\left(x_{1} j_{1} \mid i_{1} y\right) P^{2}\left(x_{2} j_{2} \mid i_{2} y\right)+\sum_{\left(j_{1}, j_{2}\right) \in S} P^{1}\left(x_{1} j_{1} \mid i_{1} y\right) P^{2}\left(x_{2} j_{2} \mid i_{2} y\right) \\
= & \sum_{\left(j_{1}, j_{2}\right) \neq\left(i_{1}, i_{2}\right)} P^{1}\left(x_{1} j_{1} \mid i_{1} y\right) P^{2}\left(x_{2} j_{2} \mid i_{2} y\right)  \tag{10}\\
\leq & 2\left(\sum_{j_{1} \neq i_{1}, j_{2} \neq i_{2}} P^{1}\left(x_{1} j_{1} \mid i_{1} y\right) P^{2}\left(x_{2} j_{2} \mid i_{2} y\right)+\frac{\sum_{\left(j_{1}, j_{2}\right) \in S} P^{1}\left(x_{1} j_{1} \mid i_{1} y\right) P^{2}\left(x_{2} j_{2} \mid i_{2} y\right)}{2}\right) .
\end{align*}
$$

This implies that:

$$
\mathrm{E}_{\mathrm{sum}}^{\mathrm{NS}_{\mathrm{SR}}}\left(W, k_{1}, k_{2}, P^{1}, P^{2}\right) \leq \mathrm{E}^{\mathrm{NS}_{\mathrm{SR}}}\left(W, k_{1}, k_{2}, P^{1}, P^{2}\right) \leq 2 \mathrm{E}_{\mathrm{sum}}^{\mathrm{NS}_{\mathrm{SR}}}\left(W, k_{1}, k_{2}, P^{1}, P^{2}\right),
$$

and by maximizing over all $P^{1}$ and $P^{2}$ :

$$
\mathrm{E}_{\mathrm{sum}}^{\mathrm{NS}_{\mathrm{SR}}}\left(W, k_{1}, k_{2}\right) \leq \mathrm{E}^{\mathrm{NS}}
$$

Thus, as before, the capacity regions are the same.

## 3 Properties of Non-Signaling Assisted Codes

### 3.1 Symmetrization

One can prove an equivalent formulation of the linear program computing $\mathrm{S}^{\mathrm{NS}}\left(W, k_{1}, k_{2}\right)$ with a number of variables and constraints polynomial in only $\left|\mathcal{X}_{1}\right|,\left|\mathcal{X}_{2}\right|$ and $|\mathcal{Y}|$ and independent of $k_{1}$ and $k_{2}$ :

Proposition 3.1. For a MAC $W: \mathcal{X}_{1} \times \mathcal{X}_{2} \rightarrow \mathcal{Y}$ and $k_{1}, k_{2} \in \mathbb{N}^{*}$, we have:

$$
\begin{align*}
\mathrm{S}^{\mathrm{NS}}\left(W, k_{1}, k_{2}\right)=\underset{r, r^{1}, r^{2}, p}{\operatorname{maximize}} & \frac{1}{k_{1} k_{2}} \sum_{x_{1}, x_{2}, y} W\left(y \mid x_{1} x_{2}\right) r_{x_{1}, x_{2}, y} \\
\text { subject to } & \sum_{x_{1}, x_{2}} r_{x_{1}, x_{2}, y}=1 \\
& \sum_{x_{1}} r_{x_{1}, x_{2}, y}^{1}=k_{1} \sum_{x_{1}} r_{x_{1}, x_{2}, y} \\
& \sum_{x_{2}} r_{x_{1}, x_{2}, y}^{2}=k_{2} \sum_{x_{2}} r_{x_{1}, x_{2}, y}  \tag{11}\\
& \sum_{x_{1}} p_{x_{1}, x_{2}}=k_{1} \sum_{x_{1}} r_{x_{1}, x_{2}, y}^{2} \\
& \sum_{x_{2}} p_{x_{1}, x_{2}}=k_{2} \sum_{x_{2}} r_{x_{1}, x_{2}, y}^{1} \\
& 0 \leq r_{x_{1}, x_{2}, y} \leq r_{x_{1}, x_{2}, y}^{1}, r_{x_{1}, x_{2}, y}^{2} \leq p_{x_{1}, x_{2}} \\
& p_{x_{1}, x_{2}}-r_{x_{1}, x_{2}, y}^{1}-r_{x_{1}, x_{2}, y}^{2}+r_{x_{1}, x_{2}, y} \geq 0
\end{align*}
$$

Proof. One can check that given a solution of the original program, the following choice of variables is a valid solution of the second program achieving the same objective value:

$$
\begin{align*}
& r_{x_{1}, x_{2}, y}:=\sum_{i_{1}, i_{2}} P\left(x_{1} x_{2}\left(i_{1} i_{2}\right) \mid i_{1} i_{2} y\right), \quad r_{x_{1}, x_{2}, y}^{1}:=\sum_{j_{1}, i_{1}, i_{2}} P\left(x_{1} x_{2}\left(j_{1} i_{2}\right) \mid i_{1} i_{2} y\right),  \tag{12}\\
& r_{x_{1}, x_{2}, y}^{2}:=\sum_{j_{2}, i_{1}, i_{2}} P\left(x_{1} x_{2}\left(i_{1} j_{2}\right) \mid i_{1} i_{2} y\right), \quad p_{x_{1}, x_{2}}:=\sum_{j_{1}, j_{2}, i_{1}, i_{2}} P\left(x_{1} x_{2}\left(j_{1} j_{2}\right) \mid i_{1} i_{2} y\right) .
\end{align*}
$$

Note that $p_{x_{1}, x_{2}}$ is well-defined since $\sum_{j_{1}, j_{2}, i_{1}, i_{2}} P\left(x_{1} x_{2}\left(j_{1} j_{2}\right) \mid i_{1} i_{2} y\right)$ is independent from $y$ by since $P$ is a non-signaling box.

For the other direction, given those variables, a non-signaling probability distribution $P\left(x_{1} x_{2}\left(j_{1} j_{2}\right) \mid i_{1} i_{2} y\right)$ achieving the same objective value is given by, for $j_{1} \neq i_{1}$ and $j_{2} \neq i_{2}$ :

$$
\begin{align*}
& P\left(x_{1} x_{2}\left(i_{1} i_{2}\right) \mid i_{1} i_{2} y\right):=\frac{r_{x_{1}, x_{2}, y}}{k_{1} k_{2}}, \\
& P\left(x_{1} x_{2}\left(j_{1} i_{2}\right) \mid i_{1} i_{2} y\right):=\frac{r_{x_{1}, x_{2}, y}^{1}-r_{x_{1}, x_{2}, y}}{k_{1} k_{2}\left(k_{1}-1\right)}, \\
& P\left(x_{1} x_{2}\left(i_{1} j_{2}\right) \mid i_{1} i_{2} y\right):=\frac{r_{x_{1}, x_{2}, y}^{2}-r_{x_{1}, x_{2}, y}}{k_{1} k_{2}\left(k_{2}-1\right)},  \tag{13}\\
& P\left(x_{1} x_{2}\left(j_{1} j_{2}\right) \mid i_{1} i_{2} y\right):=\frac{p_{x_{1}, x_{2}}-r_{x_{1}, x_{2}, y}^{1}-r_{x_{1}, x_{2}, y}^{2}+r_{x_{1}, x_{2}, y}}{k_{1} k_{2}\left(k_{1}-1\right)\left(k_{2}-1\right)} .
\end{align*}
$$

This symmetrization can also be done for the program computing $S_{\mathrm{sum}^{\mathrm{NS}} \mathrm{SR}}\left(W, k_{1}, k_{2}\right)$ :

## Proposition 3.2.

$$
\begin{aligned}
\mathrm{S}_{\mathrm{sum}}^{\mathrm{NS}_{\mathrm{SR}}}\left(W, k_{1}, k_{2}\right)=\underset{r^{1}, r^{2}, p^{1}, p^{2}}{\operatorname{maximize}} & \frac{1}{2 k_{1} k_{2}} \sum_{x_{1}, x_{2}, y} W\left(y \mid x_{1} x_{2}\right)\left(p_{x_{2}}^{2} r_{x_{1}, y}^{1}+p_{x_{1}}^{1} r_{x_{2}, y}^{2}\right) \\
= & \frac{1}{2}\left[\frac{1}{k_{1}} \sum_{x_{1}, y} W_{p^{2}, k_{2}}^{1}\left(y \mid x_{1}\right) r_{x_{1}, y}^{1}+\frac{1}{k_{2}} \sum_{x_{2}, y} W_{p^{1}, k_{1}}^{2}\left(y \mid x_{2}\right) r_{x_{2}, y}^{2}\right]
\end{aligned}
$$

$$
\text { with } \quad W_{p^{2}, k_{2}}^{1}\left(y \mid x_{1}\right):=\frac{1}{k_{2}} \sum_{x_{2}} W\left(y \mid x_{1} x_{2}\right) p_{x_{2}}^{2}, W_{p^{1}, k_{1}}^{2}\left(y \mid x_{2}\right):=\frac{1}{k_{1}} \sum_{x_{1}} W\left(y \mid x_{1} x_{2}\right) p_{x_{1}}^{1}
$$

$$
\text { subject to } \sum_{x_{1}} r_{x_{1}, y}^{1}=1, \sum_{x_{2}} r_{x_{2}, y}^{2}=1
$$

$$
\sum_{x_{1}} p_{x_{1}}^{1}=k_{1}, \sum_{x_{2}} p_{x_{2}}^{2}=k_{2}
$$

$$
\begin{equation*}
0 \leq r_{x_{1}, y}^{1} \leq p_{x_{1}}^{1}, 0 \leq r_{x_{2}, y}^{2} \leq p_{x_{2}}^{2} \tag{14}
\end{equation*}
$$

Proof. One can check that given a solution of the original program, the following choice of variables is a valid solution of the second program achieving the same objective value:

$$
\begin{align*}
& r_{x_{1}, y}^{1}:=\sum_{i_{1}} P^{1}\left(x_{1} i_{1} \mid i_{1} y\right), \quad p_{x_{1}}^{1}:=\sum_{j_{1}, i_{1}} P^{1}\left(x_{1} j_{1} \mid i_{1} y\right) \\
& r_{x_{2}, y}^{2}:=\sum_{i_{2}} P^{2}\left(x_{2} i_{2} \mid i_{2} y\right), \quad p_{x_{2}}^{2}:=\sum_{j_{2}, i_{2}} P^{2}\left(x_{2} j_{2} \mid i_{2} y\right) \tag{15}
\end{align*}
$$

Note that $p_{x_{1}}^{1}$ and $p_{x_{2}}^{2}$ are well-defined since $\sum_{j_{1}, i_{1}} P^{1}\left(x_{1} j_{1} \mid i_{1} y\right)$ and $\sum_{j_{2}, i_{2}} P^{2}\left(x_{2} j_{2} \mid i_{2} y\right)$ are independent from $y$ since $P^{1}$ and $P^{2}$ are non-signaling boxes.

For the other direction, given those variables, non-signaling probability distributions $P^{1}\left(x_{1} j_{1} \mid i_{1} y\right)$ and
$P^{2}\left(x_{2} j_{2} \mid i_{2} y\right)$ achieving the same objective value are given by, for $j_{1} \neq i_{1}$ and $j_{2} \neq i_{2}$ :

$$
\begin{align*}
P^{1}\left(x_{1} i_{1} \mid i_{1} y\right) & :=\frac{r_{x_{1}, y}^{1}}{k_{1}}, \\
P^{1}\left(x_{1} j_{1} \mid i_{1} y\right) & :=\frac{p_{x_{1}, y}^{1}-r_{x_{1}, y}^{1}}{k_{1}\left(k_{1}-1\right)},  \tag{16}\\
P^{2}\left(x_{2} i_{2} \mid i_{2} y\right) & :=\frac{r_{x_{2}, y}^{2}}{k_{2}}, \\
P^{2}\left(x_{2} j_{2} \mid i_{2} y\right) & :=\frac{p_{x_{2}, y}^{2}-r_{x_{2}, y}^{2}}{k_{2}\left(k_{2}-1\right)} .
\end{align*}
$$

### 3.2 Properties of $\mathrm{S}^{\mathrm{NS}}\left(W, k_{1}, k_{2}\right), \mathcal{C}^{\mathrm{NS}}(W)$ and $\mathcal{C}_{0}^{\mathrm{NS}}(W)$

Definition 3.3. We say that a conditional probability distribution $P\left(a^{n} \mid x^{n}\right)$ defined on $\times_{i=1}^{n} \mathcal{A}_{i} \times \times_{i=1}^{n} \mathcal{X}_{i}$ is non-signaling if for all $a^{n}, x^{n}, \hat{x}^{n}$, we have

$$
\forall i \in[n], \sum_{\hat{a}_{i}} P\left(a_{1} \ldots \hat{a}_{i} \ldots a_{n} \mid x_{1} \ldots x_{i} \ldots x_{n}\right)=\sum_{\hat{a}_{i}} P\left(a_{1} \ldots \hat{a}_{i} \ldots a_{n} \mid x_{1} \ldots \hat{x}_{i} \ldots x_{n}\right) .
$$

Definition 3.4. Let $P\left(a^{n} \mid x^{n}\right)$ a conditional probability distribution defined on $\times_{i=1}^{n} \mathcal{A}_{i} \times \times_{i=1}^{n} \mathcal{X}_{i}$ and $P^{\prime}\left(a^{\prime n} \mid x^{\prime n}\right)$ defined on $\times_{i=1}^{n} \mathcal{A}_{i}^{\prime} \times \times_{i=1}^{n} \mathcal{X}_{i}^{\prime}$. We define $P \otimes P^{\prime}$ the tensor product conditional probability distribution defined on $\times_{i=1}^{n}\left(\mathcal{A}_{i} \times \mathcal{A}_{i}^{\prime}\right) \times \times_{i=1}^{n}\left(\mathcal{X} i \times \mathcal{X}_{i}^{\prime}\right)$ by $\left(P \otimes P^{\prime}\right)\left(a_{1} a_{1}^{\prime} \ldots a_{n} a_{n}^{\prime} \mid x_{1} x_{1}^{\prime} \ldots x_{n} x_{n}^{\prime}\right):=$ $P\left(a^{n} \mid x^{n}\right) \cdot P^{\prime}\left(a^{\prime n} \mid x^{\prime n}\right)$.
Lemma 3.5. If both $P$ and $P^{\prime}$ are non-signaling, then $P \otimes P^{\prime}$ is non-signaling.
Proof. Let $a^{n} \in X_{j=1}^{n} \mathcal{A}_{j}, a^{\prime n} \in X_{j=1}^{n} \mathcal{A}_{j}^{\prime}, x^{n} \in X_{j=1}^{n} \mathcal{X}_{j}, x^{\prime n} \in X_{j=1}^{n} \mathcal{X}_{j}^{\prime}$ and $\hat{x}_{i} \in \mathcal{X}_{i}, \hat{x}_{i}^{\prime} \in \mathcal{X}_{i}^{\prime}$. Using the fact that $P, P^{\prime}$ are non-signaling, we have:

$$
\begin{align*}
& \sum_{\hat{a}_{i} \hat{a}_{i}^{\prime}} P\left(a_{1} a_{1}^{\prime} \ldots \hat{a}_{i} \hat{a}_{i}^{\prime} \ldots a_{n} a_{n}^{\prime} \mid x_{1} x_{1}^{\prime} \ldots x_{i} x_{i}^{\prime} \ldots x_{n} x_{n}^{\prime}\right) \\
= & \sum_{\hat{a}_{i} \hat{a}_{i}^{\prime}} P\left(a_{1} \ldots \hat{a}_{i} \ldots a_{n} \mid x_{1} \ldots x_{i} \ldots x_{n}\right) \cdot P^{\prime}\left(a_{1}^{\prime} \ldots \hat{a}_{i}^{\prime} \ldots a_{n}^{\prime} \mid x_{1}^{\prime} \ldots x_{i}^{\prime} \ldots x_{n}^{\prime}\right) \\
= & \left(\sum_{\hat{a}_{i}} P\left(a_{1} \ldots \hat{a}_{i} \ldots a_{n} \mid x_{1} \ldots x_{i} \ldots x_{n}\right)\right) \cdot\left(\sum_{\hat{a}_{i}^{\prime}} P^{\prime}\left(a_{1}^{\prime} \ldots \hat{a}_{i}^{\prime} \ldots a_{n}^{\prime} \mid x_{1}^{\prime} \ldots x_{i}^{\prime} \ldots x_{n}^{\prime}\right)\right)  \tag{17}\\
= & \left(\sum_{\hat{a}_{i}} P\left(a_{1} \ldots \hat{a}_{i} \ldots a_{n} \mid x_{1} \ldots \hat{x}_{i} \ldots x_{n}\right)\right) \cdot\left(\sum_{\hat{a}_{i}^{\prime}} P^{\prime}\left(a_{1}^{\prime} \ldots \hat{a}_{i}^{\prime} \ldots a_{n}^{\prime} \mid x_{1}^{\prime} \ldots \hat{x}_{i}^{\prime} \ldots x_{n}^{\prime}\right)\right) \\
= & \sum_{\hat{a}_{i} \hat{a}_{i}^{\prime}}\left(P \otimes P^{\prime}\right)\left(a_{1} a_{1}^{\prime} \ldots \hat{a}_{i} \hat{a}_{i}^{\prime} \ldots a_{n} a_{n}^{\prime} \mid x_{1} x_{1}^{\prime} \ldots \hat{x}_{i} \hat{x}_{i}^{\prime} \ldots x_{n} x_{n}^{\prime}\right),
\end{align*}
$$

so $P \otimes P^{\prime}$ is non-signaling.
Proposition 3.6. For a MAC $W: \mathcal{X}_{1} \times \mathcal{X}_{2} \rightarrow \mathcal{Y}$ and $k_{1}, k_{2} \in \mathbb{N}^{*}$, we have:

1. $\frac{1}{k_{1} k_{2}} \leq \mathrm{S}^{\mathrm{NS}}\left(W, k_{1}, k_{2}\right) \leq 1$.
2. $\mathrm{S}^{\mathrm{NS}}\left(W, k_{1}, k_{2}\right) \leq \min \left(\frac{\left|\mathcal{X}_{1}\right|}{k_{1}}, \frac{\left|\mathcal{X}_{2}\right|}{k_{2}}, \frac{|\mathcal{Y}|}{k_{1} k_{2}}\right)$.
3. If $k_{1}^{\prime} \leq k_{1}$ and $k_{2}^{\prime} \leq k_{2}$, then $\mathrm{S}^{\mathrm{NS}}\left(W, k_{1}^{\prime}, k_{2}^{\prime}\right) \geq \mathrm{S}^{\mathrm{NS}}\left(W, k_{1}, k_{2}\right)$.
4. For any MAC $W^{\prime}: \mathcal{X}_{1}^{\prime} \times \mathcal{X}_{2}^{\prime} \rightarrow \mathcal{Y}^{\prime}$ and $k_{1}, k_{2} \in \mathbb{N}^{*}$, we have $\mathrm{S}^{\mathrm{NS}}\left(W \otimes W^{\prime}, k_{1} k_{1}^{\prime}, k_{2} k_{2}^{\prime}\right) \geq \mathrm{S}^{\mathrm{NS}}\left(W, k_{1}, k_{2}\right)$. $\mathrm{S}^{\mathrm{NS}}\left(W^{\prime}, k_{1}^{\prime}, k_{2}^{\prime}\right)$. In particular, for any positive integer $n, \mathrm{~S}^{\mathrm{NS}}\left(W^{\otimes n}, k_{1}^{n}, k_{2}^{n}\right) \geq\left[\mathrm{S}^{\mathrm{NS}}\left(W, k_{1}, k_{2}\right)\right]^{n}$ and $\mathrm{S}^{\mathrm{NS}}\left(W \otimes W^{\prime}, k_{1}, k_{2}\right) \geq \mathrm{S}^{\mathrm{NS}}\left(W, k_{1}, k_{2}\right)$.

Proof. 1. Let us first show that $S^{\mathrm{NS}}\left(W, k_{1}, k_{2}\right) \geq \frac{1}{k_{1} k_{2}}$. Take $p_{x_{1}, x_{2}}:=\frac{k_{1} k_{2}}{\left|\mathcal{X}_{1}\right|\left|\mathcal{X}_{2}\right|}, r_{x_{1}, x_{2}, y}^{1}:=\frac{p_{x_{1}, x_{2}}}{k_{2}}$, $r_{x_{1}, x_{2}, y}^{2}:=\frac{p_{x_{1}, x_{2}}}{k_{1}}$ and $r_{x_{1}, x_{2}, y}:=\frac{p_{x_{1}, x_{2}}}{k_{1} k_{2}}=\frac{1}{\left|\mathcal{X}_{1}\right|\left|\mathcal{X}_{2}\right|}$. One can easily check that it is indeed a valid solution of the linear program computing $\mathrm{S}^{\mathrm{NS}}\left(W, k_{1}, k_{2}\right)$. Thus we have:

$$
\begin{align*}
\mathrm{S}^{\mathrm{NS}}\left(W, k_{1}, k_{2}\right) & \geq \frac{1}{k_{1} k_{2}} \sum_{x_{1}, x_{2}, y} W\left(y \mid x_{1} x_{2}\right) r_{x_{1}, x_{2}, y}=\frac{1}{k_{1} k_{2}} \sum_{x_{1}, x_{2}} \frac{1}{\left|\mathcal{X}_{1}\right|\left|\mathcal{X}_{2}\right|} \sum_{y} W\left(y \mid x_{1} x_{2}\right) \\
& =\frac{1}{k_{1} k_{2}} \sum_{x_{1}, x_{2}} \frac{1}{\left|\mathcal{X}_{1}\right|\left|\mathcal{X}_{2}\right|}=\frac{1}{k_{1} k_{2}} . \tag{18}
\end{align*}
$$

Furthermore, in order to show that it is at most 1 , let us consider an optimal solution of $\mathrm{S}^{\mathrm{NS}}\left(W, k_{1}, k_{2}\right)$. We have:

$$
\begin{align*}
\mathrm{S}^{\mathrm{NS}}\left(W, k_{1}, k_{2}\right) & =\frac{1}{k_{1} k_{2}} \sum_{x_{1}, x_{2}, y} W\left(y \mid x_{1} x_{2}\right) r_{x_{1}, x_{2}, y} \leq \frac{1}{k_{1} k_{2}} \sum_{x_{1}, x_{2}, y} W\left(y \mid x_{1} x_{2}\right) p_{x_{1}, x_{2}} \\
& =\frac{1}{k_{1} k_{2}} \sum_{x_{1}, x_{2}} p_{x_{1}, x_{2}} \sum_{y} W\left(y \mid x_{1} x_{2}\right)=\frac{1}{k_{1} k_{2}} \sum_{x_{1}, x_{2}} p_{x_{1}, x_{2}}=1, \tag{19}
\end{align*}
$$

since $\sum_{x_{1}, x_{2}} p_{x_{1}, x_{2}}=k_{1} \sum_{x_{1}, x_{2}} r_{x_{1}, x_{2}, y}^{2}=k_{1} k_{2} \sum_{x_{1}, x_{2}} r_{x_{1}, x_{2}, y}=k_{1} k_{2}$.
2. First let us show that $S^{\text {NS }}\left(W, k_{1}, k_{2}\right) \leq \frac{\left|\mathcal{X}_{1}\right|}{k_{1}}$ (the case $\mathrm{S}^{\mathrm{NS}}\left(W, k_{1}, k_{2}\right) \leq \frac{\left|\mathcal{X}_{2}\right|}{k_{2}}$ is symmetric):

$$
\begin{align*}
\mathrm{S}^{\mathrm{NS}}\left(W, k_{1}, k_{2}\right) & =\frac{1}{k_{1} k_{2}} \sum_{x_{1}, x_{2}, y} W\left(y \mid x_{1} x_{2}\right) r_{x_{1}, x_{2}, y} \leq \frac{1}{k_{1} k_{2}} \sum_{x_{1}, x_{2}, y} W\left(y \mid x_{1} x_{2}\right) r_{x_{1}, x_{2}, y}^{2} \\
& \leq \frac{1}{k_{1} k_{2}} \sum_{x_{2}, y}\left(\sum_{x_{1}^{\prime}} W\left(y \mid x_{1}^{\prime} x_{2}\right)\right) \cdot\left(\sum_{x_{1}} r_{x_{1}, x_{2}, y}^{2}\right) \quad \text { since nonnegative terms. } \\
& =\frac{1}{k_{1} k_{2}} \sum_{x_{2}, y}\left(\sum_{x_{1}^{\prime}} W\left(y \mid x_{1}^{\prime} x_{2}\right)\right) \cdot\left(\frac{1}{k_{1}} \sum_{x_{1}} p_{x_{1}, x_{2}}\right)  \tag{20}\\
& =\frac{1}{k_{1}^{2} k_{2}} \sum_{x_{1}, x_{2}} p_{x_{1}, x_{2}} \sum_{x_{1}^{\prime}}\left(\sum_{y} W\left(y \mid x_{1}^{\prime} x_{2}\right)\right)=\frac{\left|\mathcal{X}_{1}\right|}{k_{1}^{2} k_{2}} \sum_{x_{1}, x_{2}} p_{x_{1}, x_{2}}=\frac{\left|\mathcal{X}_{1}\right|}{k_{1}} .
\end{align*}
$$

Let us show now that $S^{\mathrm{NS}}\left(W, k_{1}, k_{2}\right) \leq \frac{|\mathcal{Y}|}{k_{1} k_{2}}$ :

$$
\begin{align*}
\mathrm{S}^{\mathrm{NS}}\left(W, k_{1}, k_{2}\right) & =\frac{1}{k_{1} k_{2}} \sum_{x_{1}, x_{2}, y} W\left(y \mid x_{1} x_{2}\right) r_{x_{1}, x_{2}, y} \leq \frac{1}{k_{1} k_{2}} \sum_{y}\left(\max _{x_{1}, x_{2}} W\left(y \mid x_{1} x_{2}\right)\right) \sum_{x_{1}, x_{2}} r_{x_{1}, x_{2}, y} \\
& \leq \frac{1}{k_{1} k_{2}} \sum_{y} \sum_{x_{1}, x_{2}} r_{x_{1}, x_{2}, y}=\frac{|\mathcal{Y}|}{k_{1} k_{2}} . \tag{21}
\end{align*}
$$

3. Let us assume that $k_{1}^{\prime} \leq k_{1}$ and that $k_{2}^{\prime}=k_{2}$, since this latter case will follow by symmetry. Consider an optimal solution of $\mathrm{S}^{\mathrm{NS}}\left(W, k_{1}, k_{2}\right)=\frac{1}{k_{1}} \sum_{i_{1} \in\left[k_{1}\right]} f\left(i_{1}\right)$ with:

$$
f\left(i_{1}\right):=\frac{1}{k_{2}} \sum_{x_{1}, x_{2}, y, i_{2}} W\left(y \mid x_{1} x_{2}\right) P\left(x_{1} x_{2}\left(i_{1} i_{2}\right) \mid i_{1} i_{2} y\right),
$$

and $P$ non-signaling. Let us consider $S \in \underset{S^{\prime} \subseteq\left[k_{1}\right]:\left|S^{\prime}\right|=k_{1}^{\prime}}{\operatorname{argmax}} \sum_{i_{1} \in S^{\prime}} f\left(i_{1}\right)$. Then, by construction, we have that $\frac{1}{k_{1}^{\prime}} \sum_{i_{1} \in S} f\left(i_{1}\right) \geq \frac{1}{k_{1}} \sum_{i_{1} \in\left[k_{1}\right]} f\left(i_{1}\right)=\mathrm{S}^{\mathrm{NS}}\left(W, k_{1}, k_{2}\right)$, since we have taken the average of the $k_{1}^{\prime}$ largest values of the sum.
Let us define the strategy $P^{\prime}$ on the smallest set $\mathcal{X}_{1} \times \mathcal{X}_{2} \times\left(S \times\left[k_{2}\right]\right) \times S \times\left[k_{2}\right] \times \mathcal{Y}$ :

$$
\begin{align*}
P^{\prime}\left(x_{1} x_{2}\left(j_{1} j_{2}\right) \mid i_{1} i_{2} y\right) & :=P\left(x_{1} x_{2}\left(j_{1} j_{2}\right) \mid i_{1} i_{2} y\right)+C\left(x_{1} x_{2} j_{2} \mid i_{1} i_{2} y\right), \\
\text { with } C\left(x_{1} x_{2} j_{2} \mid i_{1} i_{2} y\right) & :=\frac{1}{k_{1}^{\prime}} \sum_{j_{1}^{\prime} \in\left[k_{1}\right]-S} P\left(x_{1} x_{2}\left(j_{1}^{\prime} j_{2}\right) \mid i_{1} i_{2} y\right) . \tag{22}
\end{align*}
$$

$P^{\prime}$ is a correct conditional probability distribution. Indeed, it is nonnegative by construction, and we have that:

$$
\begin{align*}
& \quad \sum_{x_{1}, x_{2}, j_{1} \in S, j_{2}} P^{\prime}\left(x_{1} x_{2}\left(j_{1} j_{2}\right) \mid i_{1} i_{2} y\right)=\sum_{x_{1}, x_{2}, j_{1} \in S, j_{2}} P\left(x_{1} x_{2}\left(j_{1} j_{2}\right) \mid i_{1} i_{2} y\right)+\sum_{x_{1}, x_{2}, j_{1} \in S, j_{2}} C\left(x_{1} x_{2} j_{2} \mid i_{1} i_{2} y\right) \\
& =\sum_{x_{1}, x_{2} j_{2}} \sum_{j_{1} \in S} P\left(x_{1} x_{2}\left(j_{1} j_{2}\right) \mid i_{1} i_{2} y\right)+\sum_{x_{1}, x_{2}, j_{2}} \sum_{j_{1} \in S} \frac{1}{k_{1}^{\prime}} \sum_{j_{1}^{\prime} \in\left[k_{1}\right]-S} P\left(x_{1} x_{2}\left(j_{1}^{\prime} j_{2}\right) \mid i_{1} i_{2} y\right) \\
& =\sum_{x_{1}, x_{2}, j_{2}} \sum_{j_{1} \in S} P\left(x_{1} x_{2}\left(j_{1} j_{2}\right) \mid i_{1} i_{2} y\right)+\sum_{x_{1}, x_{2}, j_{2}} \sum_{j_{1}^{\prime} \in\left[k_{1}\right]-S} P\left(x_{1} x_{2}\left(j_{1}^{\prime} j_{2}\right) \mid i_{1} i_{2} y\right) \\
& =\sum_{x_{1}, x_{2}, j_{1}, j_{2}} P\left(x_{1} x_{2}\left(j_{1} j_{2}\right) \mid i_{1} i_{2} y\right)=1 . \tag{23}
\end{align*}
$$

Let us show that $P^{\prime}$ is non-signaling:
(a) First with $x_{1}$ :

$$
\begin{align*}
\sum_{x_{1}} P^{\prime}\left(x_{1} x_{2}\left(j_{1} j_{2}\right) \mid i_{1} i_{2} y\right) & =\sum_{x_{1}} P\left(x_{1} x_{2}\left(j_{1} j_{2}\right) \mid i_{1} i_{2} y\right)+\sum_{x_{1}} C\left(x_{1} x_{2} j_{2} \mid i_{1} i_{2} y\right) \\
& =\sum_{x_{1}} P\left(x_{1} x_{2}\left(j_{1} j_{2}\right) \mid i_{1} i_{2} y\right)+\frac{1}{k_{1}^{\prime}} \sum_{j_{1}^{\prime} \in\left[k_{1}\right]-S} \sum_{x_{1}} P\left(x_{1} x_{2}\left(j_{1}^{\prime} j_{2}\right) \mid i_{1} i_{2} y\right) \\
& =\sum_{x_{1}} P\left(x_{1} x_{2}\left(j_{1} j_{2}\right) \mid i_{1}^{\prime} i_{2} y\right)+\frac{1}{k_{1}^{\prime}} \sum_{j_{1}^{\prime} \in\left[k_{1}\right]-S} \sum_{x_{1}} P\left(x_{1} x_{2}\left(j_{1}^{\prime} j_{2}\right) \mid i_{1}^{\prime} i_{2} y\right) \tag{24}
\end{align*}
$$

since $P$ is non-signaling.

$$
=\sum_{x_{1}} P^{\prime}\left(x_{1} x_{2}\left(j_{1} j_{2}\right) \mid i_{1}^{\prime} i_{2} y\right) .
$$

(b) Then with $x_{2}$ :

$$
\begin{align*}
\sum_{x_{2}} P^{\prime}\left(x_{1} x_{2}\left(j_{1} j_{2}\right) \mid i_{1} i_{2} y\right) & =\sum_{x_{2}} P\left(x_{1} x_{2}\left(j_{1} j_{2}\right) \mid i_{1} i_{2} y\right)+\sum_{x_{2}} C\left(x_{1} x_{2} j_{2} \mid i_{1} i_{2} y\right) \\
& =\sum_{x_{2}} P\left(x_{1} x_{2}\left(j_{1} j_{2}\right) \mid i_{1} i_{2} y\right)+\frac{1}{k_{1}^{\prime}} \sum_{j_{1}^{\prime} \in\left[k_{1}\right]-S} \sum_{x_{2}} P\left(x_{1} x_{2}\left(j_{1}^{\prime} j_{2}\right) \mid i_{1} i_{2} y\right) \\
& =\sum_{x_{2}} P\left(x_{1} x_{2}\left(j_{1} j_{2}\right) \mid i_{1} i_{2}^{\prime} y\right)+\frac{1}{k_{1}^{\prime}} \sum_{j_{1}^{\prime} \in\left[k_{1}\right]-S} \sum_{x_{2}} P\left(x_{1} x_{2}\left(j_{1}^{\prime} j_{2}\right) \mid i_{1} i_{2}^{\prime} y\right) \tag{25}
\end{align*}
$$

since $P$ is non-signaling.

$$
=\sum_{x_{2}} P^{\prime}\left(x_{1} x_{2}\left(j_{1} j_{2}\right) \mid i_{1} i_{2}^{\prime} y\right) .
$$

(c) Finally with $\left(j_{1} j_{2}\right)$ :

$$
\begin{align*}
& \sum_{j_{1} \in S, j_{2}} P^{\prime}\left(x_{1} x_{2}\left(j_{1} j_{2}\right) \mid i_{1} i_{2} y\right)=\sum_{j_{2}} \sum_{j_{1} \in S} P\left(x_{1} x_{2}\left(j_{1} j_{2}\right) \mid i_{1} i_{2} y\right)+\sum_{j_{2}} \sum_{j_{1} \in S} C\left(x_{1} x_{2} j_{2} \mid i_{1} i_{2} y\right) \\
& =\sum_{j_{2}} \sum_{j_{1} \in S} P\left(x_{1} x_{2}\left(j_{1} j_{2}\right) \mid i_{1} i_{2} y\right)+\sum_{j_{2}} \sum_{j_{1} \in S} \frac{1}{k_{1}^{\prime}} \sum_{j_{1}^{\prime} \in\left[k_{1}\right]-S} P\left(x_{1} x_{2}\left(j_{1}^{\prime} j_{2}\right) \mid i_{1} i_{2} y\right) \\
& =\sum_{j_{2}} \sum_{j_{1} \in S} P\left(x_{1} x_{2}\left(j_{1} j_{2}\right) \mid i_{1} i_{2} y\right)+\sum_{j_{1} \in\left[k_{1}\right]-S} \sum_{1} P\left(x_{1} x_{2}\left(j_{1}^{\prime} j_{2}\right) \mid i_{1} i_{2} y\right)  \tag{26}\\
& =\sum_{j_{1}, j_{2}} P\left(x_{1} x_{2}\left(j_{1} j_{2}\right) \mid i_{1} i_{2} y\right) \\
& =\sum_{j_{1}, j_{2}} P\left(x_{1} x_{2}\left(j_{1} j_{2}\right) \mid i_{1} i_{2} y^{\prime}\right) \text { since } P \text { is non-signaling. } \\
& =\sum_{j_{1} \in S, j_{2}} P^{\prime}\left(x_{1} x_{2}\left(j_{1} j_{2}\right) \mid i_{1} i_{2} y^{\prime}\right) .
\end{align*}
$$

Thus $P^{\prime}$ is a correct solution of the program computing $S^{\mathrm{NS}}\left(W, k_{1}^{\prime}, k_{2}\right)$, and it leads to the value:

$$
\begin{align*}
\mathrm{S}^{\mathrm{NS}}\left(W, k_{1}^{\prime}, k_{2}\right) & \geq \frac{1}{k_{1}^{\prime} k_{2}} \sum_{x_{1}, x_{2}, y, i_{1} \in S, i_{2}} W\left(y \mid x_{1} x_{2}\right) P^{\prime}\left(x_{1} x_{2}\left(i_{1} i_{2}\right) \mid i_{1} i_{2} y\right) \\
& \geq \frac{1}{k_{1}^{\prime} k_{2}} \sum_{x_{1}, x_{2}, y, i_{1} \in S, i_{2}} W\left(y \mid x_{1} x_{2}\right) P\left(x_{1} x_{2}\left(i_{1} i_{2}\right) \mid i_{1} i_{2} y\right)  \tag{27}\\
& =\frac{1}{k_{1}^{\prime}} \sum_{i_{1} \in S} f\left(i_{1}\right) \geq \frac{1}{k_{1}} \sum_{i_{1} \in\left[k_{1}\right]} f\left(i_{1}\right)=\mathrm{S}^{\mathrm{NS}}\left(W, k_{1}, k_{2}\right) .
\end{align*}
$$

4. Consider optimal non-signaling probability distributions $P$ and $P^{\prime}$ reaching respectively the values $\mathrm{S}^{\mathrm{NS}}\left(W, k_{1}, k_{2}\right)$ and $\mathrm{S}^{\mathrm{NS}}\left(W^{\prime}, k_{1}^{\prime}, k_{2}^{\prime}\right)$. Then by Lemma 3.5, $P \otimes P^{\prime}$ is a non-signaling probability distribution on $\left(\mathcal{X}_{1} \times \mathcal{X}_{1}^{\prime}\right) \times\left(\mathcal{X}_{2} \times \mathcal{X}_{2}^{\prime}\right) \times\left(\left(\left[k_{1}\right] \times\left[k_{1}^{\prime}\right]\right) \times\left(\left[k_{2}\right] \times\left[k_{2}^{\prime}\right]\right)\right) \times\left(\left[k_{1}\right] \times\left[k_{1}^{\prime}\right]\right) \times\left(\left[k_{2}\right] \times\left[k_{2}^{\prime}\right]\right) \times$ $\left(\mathcal{Y} \times \mathcal{Y}^{\prime}\right)$, which is trivially in bijection with $\left(\mathcal{X}_{1} \times \mathcal{X}_{1}^{\prime}\right) \times\left(\mathcal{X}_{2} \times \mathcal{X}_{2}^{\prime}\right) \times\left(\left[k_{1} k_{1}^{\prime}\right] \times\left[k_{2} k_{2}^{\prime}\right]\right) \times\left[k_{1} k_{1}^{\prime}\right] \times$ $\left[k_{2} k_{2}^{\prime}\right] \times\left(\mathcal{Y} \times \mathcal{Y}^{\prime}\right)$. This gives a valid solution of the program computing $\mathrm{S}^{\mathrm{NS}}\left(W \otimes W^{\prime}, k_{1} k_{1}^{\prime}, k_{2} k_{2}^{\prime}\right)$.

Thus, we get that $S^{\mathrm{NS}}\left(W \otimes W^{\prime}, k_{1} k_{1}^{\prime}, k_{2} k_{2}^{\prime}\right)$ is larger than or equal to:

$$
\begin{align*}
& \sum_{x_{1} x_{1}^{\prime}, x_{2} x_{2}^{\prime}, y y^{\prime}, i_{1} i_{1}^{\prime}, i_{2} i_{2}^{\prime}}\left(W \otimes W^{\prime}\right)\left(y y^{\prime} \mid x_{1} x_{1}^{\prime} x_{2} x_{2}^{\prime}\right)\left(P \otimes P^{\prime}\right)\left(x_{1} x_{1}^{\prime} x_{2} x_{2}^{\prime}\left(i_{1} i_{1}^{\prime} i_{2} i_{2}^{\prime}\right) \mid i_{1} i_{1}^{\prime}, i_{2} i_{2}^{\prime} y y^{\prime}\right) \\
& =\sum_{x_{1} x_{1}^{\prime}, x_{2} x_{2}^{\prime}, y y^{\prime}, i_{1} i_{1}^{\prime}, i_{2} i_{2}^{\prime}}\left(W\left(y \mid x_{1} x_{2}\right) \cdot W^{\prime}\left(y^{\prime} \mid x_{1}^{\prime} x_{2}^{\prime}\right)\right)\left(P\left(x_{1} x_{2}\left(i_{1} i_{2}\right) \mid i_{1} i_{2} y\right) \cdot P^{\prime}\left(x_{1}^{\prime} x_{2}^{\prime}\left(i_{1}^{\prime} i_{2}^{\prime}\right) \mid i_{1}^{\prime} i_{2}^{\prime} y^{\prime}\right)\right) \\
& =\left(\sum_{i_{1}, i_{2}, x_{1}, x_{2}, y} W\left(y \mid x_{1} x_{2}\right) P\left(x_{1} x_{2}\left(i_{1} i_{2}\right) \mid i_{1} i_{2} y\right)\right) \cdot\left(\sum_{x_{1}^{\prime}, x_{2}^{\prime}, y^{\prime}, i_{1}^{\prime},,_{2}^{\prime}} W^{\prime}\left(y^{\prime} \mid x_{1}^{\prime} x_{2}^{\prime}\right) P^{\prime}\left(x_{1}^{\prime} x_{2}^{\prime}\left(i_{1}^{\prime} i_{2}^{\prime}\right) \mid i_{1}^{\prime} i_{2}^{\prime} y^{\prime}\right)\right) \\
& =\mathrm{S}^{\mathrm{NS}}\left(W, k_{1}, k_{2}\right) \cdot \mathrm{S}^{\mathrm{NS}}\left(W^{\prime}, k_{1}^{\prime}, k_{2}^{\prime}\right) . \tag{28}
\end{align*}
$$

In particular, applying this $n$ times on the same MAC $W$ gives the first corollary, and the second one comes from the fact that $\mathrm{S}^{\mathrm{NS}}\left(W \otimes W^{\prime}, k_{1}, k_{2}\right) \geq \mathrm{S}^{\mathrm{NS}}\left(W, k_{1}, k_{2}\right) \cdot \mathrm{S}^{\mathrm{NS}}\left(W^{\prime}, 1,1\right)=\mathrm{S}^{\mathrm{NS}}\left(W, k_{1}, k_{2}\right)$, since $\mathrm{S}^{\mathrm{NS}}\left(W^{\prime}, 1,1\right)=1$ by the first property of Proposition 3.6 .

Corollary 3.7. 1. $\mathcal{C}^{\mathrm{NS}}(W)$ is convex.
2. If $\left(R_{1}, R_{2}\right)$ is achievable with non-signaling assistance, then $R_{1} \leq \log _{2}\left|\mathcal{X}_{1}\right|, R_{2} \leq \log _{2}\left|\mathcal{X}_{2}\right|$ and $R_{1}+R_{2} \leq \log _{2}|\mathcal{Y}|$.
3. If ( $R_{1}, R_{2}$ ) is achievable with non-signaling assistance, then for all $R_{i}^{\prime} \leq R_{i},\left(R_{1}^{\prime}, R_{2}^{\prime}\right)$ is achievable with non-signaling assistance.

Proof. 1. Let $\left(R_{1}, R_{2}\right)$ and ( $\left.\tilde{R}_{1}, \tilde{R}_{2}\right)$, two pairs of rational rates achievable with non-signaling assistance for $W$, ie:

$$
\mathrm{S}^{\mathrm{NS}}\left(W^{\otimes n},\left\lceil 2^{R_{1} n}\right\rceil,\left\lceil 2^{R_{2} n}\right\rceil\right) \underset{n \rightarrow+\infty}{\rightarrow} 1 \text { and } \mathrm{S}^{\mathrm{NS}}\left(W^{\otimes n},\left\lceil 2^{\tilde{R}_{1} n}\right\rceil,\left\lceil 2^{\tilde{R}_{2} n}\right\rceil\right) \underset{n \rightarrow+\infty}{\rightarrow} 1
$$

Let $\lambda \in(0,1)$ rational and define $R_{\lambda, i}:=\lambda \cdot R_{i}+(1-\lambda) \cdot \tilde{R}_{i}$, let us show that $\left(R_{\lambda, 1}, R_{\lambda, 2}\right)$ is achievable with non-signaling assistance. Let us call respectively $k_{i}:=2^{R_{i}}, \tilde{k}_{i}:=2^{\tilde{R}_{i}}, k_{\lambda, i}:=2^{R_{\lambda, i}}=k_{i}^{\lambda} \cdot k_{i}^{(1-\lambda)}$. We have $R_{\lambda, i} n=\lambda \cdot R_{i} n+(1-\lambda) \cdot \tilde{R}_{i} n=(\lambda n) \cdot R_{i}+(1-\lambda) n \cdot \tilde{R}_{i}$. This is the idea of time-sharing: for $\lambda n$ copies of the MAC, we use the strategy with rate $\left(R_{1}, R_{2}\right)$ and for the $(1-\lambda) n$ other copies of the MAC, we use the strategy with rate $\left(\tilde{R}_{1}, \tilde{R}_{2}\right)$. There exists some $n$ such that $\lambda n,(1-\lambda) n, \lambda n R_{i},(1-$ $\lambda) n \tilde{R}_{i}$ are integers, since everything is rational. This implies that $k_{i}^{\lambda n}, \tilde{k}_{i}^{(1-\lambda) n}, k_{\lambda, i}^{n}$ are integers. Thus, thanks to the fourth property of Proposition 3.6, we have:

$$
\begin{align*}
& \mathrm{S}^{\mathrm{NS}}\left(W^{\otimes n}, k_{\lambda, 1}^{n}, k_{\lambda, 2}^{n}\right) \geq \mathrm{S}^{\mathrm{NS}}\left(W^{\otimes(\lambda n)}, k_{1}^{\lambda n}, k_{2}^{\lambda n}\right) \cdot \mathrm{S}^{\mathrm{NS}}\left(W^{\otimes((1-\lambda) n)}, \tilde{k}_{1}^{(1-\lambda) n}, \tilde{k}_{2}^{(1-\lambda) n}\right) \\
& n \rightarrow+\infty \tag{29}
\end{align*} 1 \cdot 1=1 .
$$

Thus in particular, since we have $\mathrm{S}^{\mathrm{NS}}\left(W^{\otimes n}, k_{\lambda, 1}^{n}, k_{\lambda, 2}^{n}\right) \leq 1$, we get that $\mathrm{S}^{\mathrm{NS}}\left(W^{\otimes n}, k_{\lambda, 1}^{n}, k_{\lambda, 2}^{n}\right) \underset{n \rightarrow+\infty}{\rightarrow} 1$, so ( $R_{\lambda, 1}, R_{\lambda, 2}$ ) is achievable with non-signaling assistance. Finally, since $\mathcal{C}^{\mathrm{NS}}(W)$ is defined as the closure of achievable rates with non-signaling assistance, we get that $\mathcal{C}^{\mathrm{NS}}(W)$ is convex.
2. By the second property of Proposition 3.6. we have that $\mathrm{S}^{\mathrm{NS}}\left(W^{\otimes n}, k_{1}^{n}, k_{2}^{n}\right) \leq \frac{\left|\mathcal{X}_{1}^{n}\right|}{k_{1}^{n}}$. In particular, if one takes $R_{1}>\log _{2}\left|\mathcal{X}_{1}\right|$, then $k_{1}>\left|\mathcal{X}_{1}\right|$ and we get that $S^{\mathrm{NS}}\left(W^{\otimes n}, k_{1}^{n}, k_{2}^{n}\right) \leq\left(\frac{\left|\mathcal{X}_{1}\right|}{k_{1}}\right)^{n} \underset{n \rightarrow+\infty}{\rightarrow} 0$, so
$R_{1}>\log _{2}\left|\mathcal{X}_{1}\right|$ is not achievable with non-signaling assistance. Symmetrically, $R_{2}>\log _{2}\left|\mathcal{X}_{2}\right|$ is not achievable with non-signaling assistance.
Furthermore, if one takes $R_{1}+R_{2}>\log _{2}|\mathcal{Y}|$, then in particular $k_{1} k_{2}>|\mathcal{Y}|$, so by the second property of Proposition 3.6, $\mathrm{S}^{\mathrm{NS}}\left(W^{\otimes n}, k_{1}^{n}, k_{2}^{n}\right) \leq \frac{\left|\mathcal{Y}^{n}\right|}{k_{1}^{n} k_{2}^{n}}=\left(\frac{|\mathcal{Y}|}{k_{1} k_{2}}\right)^{n} \underset{n \rightarrow+\infty}{\rightarrow} 0$. Thus, $R_{1}+R_{2}>\log _{2}|\mathcal{Y}|$ is not achievable with non-signaling assistance.
3. Since $\left(R_{1}, R_{2}\right)$ is achievable with non-signaling assistance, we have $S^{\mathrm{NS}}\left(W^{\otimes n},\left\lceil 2^{n R_{1}}\right\rceil,\left\lceil 2^{n R_{2}}\right\rceil\right) \underset{n \rightarrow+\infty}{\rightarrow}$ 1. But, for all positive integer $n$, we have that $\left\lceil 2^{n R_{1}^{\prime}}\right\rceil \leq\left\lceil 2^{n R_{1}}\right\rceil$ and $\left\lceil 2^{n R_{2}^{\prime}}\right\rceil \leq\left\lceil 2^{n R_{2}}\right\rceil$, so by the third property of Proposition 3.6 , we have that $S^{\operatorname{NS}}\left(W^{\otimes n},\left\lceil 2^{n R_{1}^{\prime}}\right\rceil,\left\lceil 2^{n R_{2}^{\prime}}\right\rceil\right) \geq \mathrm{S}^{\mathrm{NS}}\left(W^{\otimes n},\left\lceil 2^{n R_{1}}\right\rceil,\left\lceil 2^{n R_{2}}\right\rceil\right)$. Thus $S^{\mathrm{NS}}\left(W^{\otimes n},\left\lceil 2^{n R_{1}^{\prime}}\right\rceil,\left\lceil 2^{n R_{2}^{\prime}}\right\rceil \underset{n \rightarrow+\infty}{\rightarrow} 1\right.$ since it is upper bounded by 1 , and so $\left(R_{1}^{\prime}, R_{2}^{\prime}\right)$ is achievable with non-signaling assistance.

Proposition 3.8. $\mathcal{C}_{0}^{\mathrm{NS}}(W)$ is the closure of the set of rate pairs $\left(R_{1}, R_{2}\right)$ such that:

$$
\exists n \in \mathbb{N}^{*}, S^{N S}\left(W^{\otimes n},\left\lceil 2^{R_{1} n}\right\rceil,\left\lceil 2^{R_{2} n}\right\rceil\right)=1
$$

Proof. It is clear that if $\left(R_{1}, R_{2}\right)$ is such that $\exists n_{0} \in \mathbb{N}^{*}, \forall n \geq n_{0}, \mathrm{~S}^{\mathrm{NS}}\left(W^{\otimes n},\left\lceil 2^{R_{1} n}\right\rceil,\left\lceil 2^{R_{2} n}\right\rceil\right)=1$, then in particular $\exists n \in \mathbb{N}^{*}, S^{\mathrm{NS}}\left(W^{\otimes n},\left\lceil 2^{R_{1} n}\right\rceil,\left\lceil 2^{R_{2} n}\right\rceil\right)=1$. So, $\mathcal{C}_{0}^{\mathrm{NS}}(W)$, which is the closure of the former rate pairs, is in particular included in the closure of the latter rate pairs.

For the other inclusion, consider a rate pair ( $R_{1}, R_{2}$ ) and let us assume that there exists some positive integer $n$ such that $S^{\mathrm{NS}}\left(W^{\otimes n},\left\lceil 2^{R_{1} n}\right\rceil,\left\lceil 2^{R_{2} n}\right\rceil\right)=1$. Let us show that for any ( $R_{1}^{\prime}, R_{2}^{\prime}$ ) such that $R_{1}^{\prime}<R_{1}$ and $R_{2}^{\prime}<R_{2}$ :

$$
\exists n_{0} \in \mathbb{N}^{*}, \forall n \geq n_{0}, S^{\mathrm{NS}}\left(W^{\otimes n},\left\lceil 2^{R_{1}^{\prime} n}\right\rceil,\left\lceil 2^{R_{2}^{\prime} n}\right\rceil\right)=1
$$

which is enough to conclude, since we consider only closure of such sets.
First, for all positive integer $m$, we have that $S^{\mathrm{NS}}\left(W^{\otimes n m},\left\lceil 2^{R_{1} n m}\right\rceil,\left\lceil 2^{R_{2} n m}\right\rceil\right)=1$. By the fourth property of Proposition 3.6, we have that $S^{\mathrm{NS}}\left(\left(W^{\otimes n}\right)^{\otimes m},\left\lceil 2^{R_{1} n}\right\rceil^{m},\left\lceil 2^{R_{2} n}\right\rceil^{m}\right) \geq\left[\mathrm{S}^{\mathrm{NS}}\left(W^{\otimes n},\left\lceil 2^{R_{1} n}\right\rceil,\left\lceil 2^{R_{2} n}\right\rceil\right)\right]^{m}=$ 1 , so $S^{\mathrm{NS}}\left(\left(W^{\otimes n}\right)^{\otimes m},\left\lceil 2^{R_{1} n}\right\rceil^{m},\left\lceil 2^{R_{2} n}\right\rceil^{m}\right)=1$ since $\mathrm{S}^{\mathrm{NS}}\left(W, k_{1}, k_{2}\right) \leq 1$ by the first property of Proposition 3.6. But $\left(W^{\otimes n}\right)^{\otimes m}=W^{\otimes n m}$, and $\left\lceil 2^{R_{1} n}\right\rceil^{m} \geq\left\lceil 2^{R_{1} n m}\right\rceil,\left\lceil 2^{R_{2} n}\right\rceil^{m} \geq\left\lceil 2^{R_{2} n m}\right\rceil$, so by the third property of Proposition 3.6, we have $\mathrm{S}^{\mathrm{NS}}\left(W^{\otimes n m},\left\lceil 2^{R_{1} n m}\right\rceil,\left\lceil 2^{R_{2} n m}\right\rceil\right) \geq 1$, so $\mathrm{S}^{\mathrm{NS}}\left(W^{\otimes n m},\left\lceil 2^{R_{1} n m}\right\rceil,\left\lceil 2^{R_{2} n m}\right\rceil\right)=1$.

Then, consider some $r \in\{0, \ldots, n-1\}$. By the fourth property of Proposition 3.6, we have that:

$$
\begin{align*}
\mathrm{S}^{\mathrm{NS}}\left(W^{\otimes(n m+r)},\left\lceil 2^{R_{1} n m}\right\rceil,\left\lceil 2^{R_{2} n m}\right\rceil\right) & =\mathrm{S}^{\mathrm{NS}}\left(W^{\otimes n m} \otimes W^{\otimes r},\left\lceil 2^{R_{1} n m}\right\rceil,\left\lceil 2^{R_{2} n m}\right\rceil\right) \\
& \geq \mathrm{S}^{\mathrm{NS}}\left(W^{\otimes n m},\left\lceil 2^{R_{1} n m}\right\rceil,\left\lceil 2^{R_{2} n m}\right\rceil\right)=1, \tag{30}
\end{align*}
$$

so $S^{\mathrm{NS}}\left(W^{\otimes(n m+r)},\left\lceil 2^{R_{1} n m}\right\rceil,\left\lceil 2^{R_{2} n m}\right\rceil\right)=1$. But $\left\lceil 2^{R_{1} n m}\right\rceil=\left\lceil 2^{\frac{R_{1} n m}{n m+r}(n m+r)}\right\rceil=\left\lceil 2^{\frac{R_{1}}{1+\delta}(n m+r)}\right\rceil$ with $\delta=\frac{r}{n m} \leq$ $\frac{1}{m}$, and symmetrically $\left\lceil 2^{R_{1} n m}\right\rceil=\left\lceil 2^{\frac{R_{1}}{1+\delta}(n m+r)}\right\rceil$. Thus in particular, for all $R_{1}^{\prime} \leq \frac{R_{1}}{1+\frac{1}{m}}$ and $R_{2}^{\prime} \leq \frac{R_{2}}{1+\frac{1}{m}}$, we have that for all $n^{\prime} \geq n m, \mathrm{~S}^{\mathrm{NS}}\left(W^{\otimes n^{\prime}},\left\lceil 2^{R_{1}^{\prime} n^{\prime}}\right\rceil,\left\lceil 2^{R_{2}^{\prime} n^{\prime}}\right\rceil\right)=1$. So for any $\left(R_{1}^{\prime}, R_{2}^{\prime}\right)$ such that $R_{1}^{\prime}<R_{1}$ and $R_{2}^{\prime}<R_{2}$, there is large enough $m$ such that $R_{1}^{\prime} \leq \frac{R_{1}}{1+\frac{1}{m}}$ and $R_{2}^{\prime} \leq \frac{R_{2}}{1+\frac{1}{m}}$, and thus we get the expected property on $\left(R_{1}^{\prime}, R_{2}^{\prime}\right)$ for $n_{0}:=n m$.

### 3.3 Linear Program with Reduced Size for Structured Channels

Although $\mathrm{S}^{\mathrm{NS}}\left(W, k_{1}, k_{2}\right)$ can be computed in polynomial time in $W, k_{1}$ and $k_{2}$, a channel of the form $W^{\otimes n}$ has exponential size in $n$. Thus, the linear program for $S^{\mathrm{NS}}\left(W^{\otimes n}, k_{1}, k_{2}\right)$ grows exponentially with $n$. However, using the invariance of $W^{\otimes n}$ under permutations, one can find a much smaller linear program computing $\mathrm{S}^{\mathrm{NS}}\left(W^{\otimes n}, k_{1}, k_{2}\right)$.

Definition 3.9. Let $G$ a group acting on $\mathcal{X}_{1}, \mathcal{X}_{2}, \mathcal{Y}$. We say that a MAC $W: \mathcal{X}_{1} \times \mathcal{X}_{2} \rightarrow \mathcal{Y}$ is invariant under the action of $G$ if:

$$
\forall g \in G, W\left(g \cdot y \mid g \cdot x_{1} g \cdot x_{2}\right)=W\left(y \mid x_{1} x_{2}\right) .
$$

In particular, for $W^{\otimes n}: \mathcal{X}_{1}^{n} \times \mathcal{X}_{2}^{n} \rightarrow \mathcal{Y}^{n}$, the symmetric group $G:=S_{n}$ acts in a natural way in any set $\mathcal{A}$ raised to power $n$. So for $\sigma \in S_{n}$, we have that:

$$
W^{\otimes n}\left(\sigma \cdot y^{n} \mid \sigma \cdot x_{1}^{n} \sigma \cdot x_{2}^{n}\right)=\prod_{i=1}^{n} W\left(y_{\sigma(i)} \mid x_{1, \sigma(i)} x_{2, \sigma(i)}\right)=\prod_{i=1}^{n} W\left(y_{i} \mid x_{1, i} x_{2, i}\right)=W^{\otimes n}\left(y^{n} \mid x_{1}^{n} x_{2}^{n}\right)
$$

and so $W^{\otimes n}$ is invariant under the action of $S_{n}$.
Let $\mathcal{Z}:=\left\{\mathcal{X}_{1}, \mathcal{X}_{2}, \mathcal{Y}, \mathcal{X}_{1} \times \mathcal{Y}, \mathcal{X}_{2} \times \mathcal{Y}, \mathcal{X}_{1} \times \mathcal{X}_{2}, \mathcal{X}_{1} \times \mathcal{X}_{2} \times \mathcal{Y}\right\}$. Let us call $\mathcal{O}_{G}(\mathcal{A})$ the set of orbits of $\mathcal{A}$ under the action of $G$. Then, one can find an equivalent smaller linear program for $\mathrm{S}^{\mathrm{NS}}\left(W, k_{1}, k_{2}\right)$ :

Theorem 3.10. Let $W: \mathcal{X}_{1} \times \mathcal{X}_{2} \rightarrow \mathcal{Y}$ a MAC invariant under the action of $G$. Let us name systematically $w \in \mathcal{O}_{G}\left(\mathcal{X}_{1} \times \mathcal{X}_{2} \times \mathcal{Y}\right), u \in \mathcal{O}_{G}\left(\mathcal{X}_{1} \times \mathcal{X}_{2}\right), u^{1} \in \mathcal{O}_{G}\left(\mathcal{X}_{1}\right), u^{2} \in \mathcal{O}_{G}\left(\mathcal{X}_{2}\right), v^{1} \in \mathcal{O}_{G}\left(\mathcal{X}_{1} \times \mathcal{Y}\right), v^{2} \in \mathcal{O}_{G}\left(\mathcal{X}_{2} \times \mathcal{Y}\right), v \in$ $\mathcal{O}_{G}(\mathcal{Y})$. We will also call $z_{\mathcal{A}}$ the projection of $z \in \mathcal{O}_{G}(\mathcal{B})$ on $\mathcal{A}$, for $\mathcal{A}, \mathcal{B} \in \mathcal{Z}$ and $\mathcal{A}$ projection of $\mathcal{B}$; note that $z_{\mathcal{A}} \in \mathcal{O}_{G}(\mathcal{A})$, since by definition of the action, the projection of an orbit is an orbit. Let us finally call $W(w):=W\left(y \mid x_{1} x_{2}\right)$ for any $\left(x_{1}, x_{2}, y\right) \in w$, which is well-defined since $W$ is invariant under $G$. We have that $\mathrm{S}^{\mathrm{NS}}\left(W, k_{1}, k_{2}\right)$ is the solution of the following linear program:

$$
\begin{align*}
& \mathrm{S}^{\mathrm{NS}}\left(W, k_{1}, k_{2}\right)=\underset{r, r^{1}, r^{2}, p}{\operatorname{maximize}} \frac{1}{k_{1} k_{2}} \sum_{w \in \mathcal{O}_{G}\left(\mathcal{X}_{1} \times \mathcal{X}_{2} \times \mathcal{Y}\right)} W(w) r_{w} \\
& \text { subject to } \sum_{w: w_{\mathcal{Y}}=v} r_{w}=|v|, \forall v \in \mathcal{O}_{G}(\mathcal{Y}) \\
& \sum_{w: w_{\mathcal{X}_{2} \mathcal{Y}}=v^{2}} r_{w}^{1}=k_{1} \sum_{w: w_{\mathcal{X}_{2} \mathcal{Y}}=v^{2}} r_{w}, \forall v^{2} \in \mathcal{O}_{G}\left(\mathcal{X}_{2} \times \mathcal{Y}\right) \\
& \sum_{w: w_{\mathcal{X}_{1} \mathcal{y}}=v^{1}} r_{w}^{2}=k_{2} \sum_{w: w_{\mathcal{X}_{1}} \mathcal{y}=v^{1}} r_{w}, \forall v^{1} \in \mathcal{O}_{G}\left(\mathcal{X}_{1} \times \mathcal{Y}\right) \\
& \sum_{u: u \mathcal{X}_{2}=v_{\mathcal{X}_{2}}^{2}} p_{u}=\frac{\left|v_{\mathcal{X}_{2}}^{2}\right|}{\left|v^{2}\right|} k_{1} \sum_{w: w_{\mathcal{X}_{2} \mathcal{y}}=v^{2}} r_{w}^{2}, \forall v^{2} \in \mathcal{O}_{G}\left(\mathcal{X}_{2} \times \mathcal{Y}\right)  \tag{31}\\
& \sum_{u: u_{\mathcal{X}_{1}}=v_{\mathcal{X}_{1}}^{1}} p_{u}=\frac{\left|v_{\mathcal{X}_{1}}^{1}\right|}{\left|v^{1}\right|} k_{2} \sum_{w: w_{\mathcal{X}_{1} \mathcal{Y}}=v^{1}} r_{w}^{1}, \forall v^{1} \in \mathcal{O}_{G}\left(\mathcal{X}_{1} \times \mathcal{Y}\right) \\
& 0 \leq r_{w} \leq r_{w}^{1}, r_{w}^{2} \leq \frac{|w|}{\left|w_{\mathcal{X}_{1} \mathcal{X}_{2}}\right|} p_{w_{\mathcal{X}_{1} \mathcal{X}_{2}}}, \forall w \in \mathcal{O}_{G}\left(\mathcal{X}_{1} \times \mathcal{X}_{2} \times \mathcal{Y}\right) \\
& \frac{|w|}{\left|w_{\mathcal{X}_{1} \mathcal{X}_{2}}\right|} p_{w_{\mathcal{X}_{1} \mathcal{X}_{2}}}-r_{w}^{1}-r_{w}^{2}+r_{w} \geq 0, \forall w \in \mathcal{O}_{G}\left(\mathcal{X}_{1} \times \mathcal{X}_{2} \times \mathcal{Y}\right) .
\end{align*}
$$

Corollary 3.11. For a channel $W: \mathcal{X}_{1} \times \mathcal{X}_{2} \rightarrow \mathcal{Y}, \mathrm{~S}^{\mathrm{NS}}\left(W^{\otimes n}, k_{1}, k_{2}\right)$ is the solution of a linear program of size bounded by $O\left(n^{\left|\mathcal{X}_{1}\right| \cdot\left|\mathcal{X}_{2}\right| \cdot|\mathcal{Y}|-1}\right)$, thus it can be computed in polynomial time in $n$.

Proof. We use the linear program obtained in Theorem 3.10 with $G:=S_{n}$ acting on $W^{\otimes n}$ as described before. The number of variables and constraints is linear in the number of orbits of the action of $S^{n}$ on the different sets $\mathcal{A} \in \mathcal{Z}$, where here $\mathcal{Z}=\left\{\mathcal{X}_{1}^{n}, \mathcal{X}_{2}^{n}, \mathcal{Y}^{n}, \mathcal{X}_{1}^{n} \times \mathcal{Y}^{n}, \mathcal{X}_{2}^{n} \times \mathcal{Y}^{n}, \mathcal{X}_{1}^{n} \times \mathcal{X}_{2}^{n}, \mathcal{X}_{1}^{n} \times \mathcal{X}_{2}^{n} \times \mathcal{Y}^{n}\right\}$. For example, for $\mathcal{A} \in \mathcal{X}_{1}^{n} \times \mathcal{X}_{2}^{n} \times \mathcal{Y}^{n}$, we have that:

$$
\left|\mathcal{O}_{S_{n}}\left(\mathcal{X}_{1}^{n} \times \mathcal{X}_{2}^{n} \times \mathcal{Y}^{n}\right)\right|=\binom{n+\left|\mathcal{X}_{1}\right|\left|\mathcal{X}_{2}\right||\mathcal{Y}|-1}{\left|\mathcal{X}_{1}\right|\left|\mathcal{X}_{2}\right||\mathcal{Y}|-1} \leq\left(n+\left|\mathcal{X}_{1}\right|\left|\mathcal{X}_{2}\right||\mathcal{Y}|-1\right)^{\left|\mathcal{X}_{1}\right|\left|\mathcal{X}_{2}\right||\mathcal{Y}|-1}
$$

So the number of variables and constraints is $O\left(n^{\left|\mathcal{X}_{1}\right| \cdot\left|\mathcal{X}_{2}\right| \cdot|\mathcal{Y}|-1}\right)$. Note also that all the numbers occurring this linear program are integers or fractions of integers, with those integers ranging in $\left[\left(\left|\mathcal{X}_{1}\right|\left|\mathcal{X}_{2}\right||\mathcal{Y}|\right)^{n}\right]$, thus of size $O\left(n \log \left(\left|\mathcal{X}_{1}\right|\left|\mathcal{X}_{2}\right||\mathcal{Y}|\right)\right)$. So the size of this linear program is bounded by $O\left(n^{\left|\mathcal{X}_{1}\right| \cdot\left|\mathcal{X}_{2}\right| \cdot|\mathcal{Y}|-1}\right)$, and thus $\mathrm{S}^{\mathrm{NS}}\left(W^{\otimes n}, k_{1}, k_{2}\right)$ can be computed in polynomial time in $n$; see for instance Section 7.1 of [22].

In order to prove Theorem [3.10, we will need several lemmas. For all of them, $\mathcal{A}$ and $\mathcal{B}$ will denote finite sets on which a group $G$ is acting, and $x^{G}$ will denote the orbit of $x$ under $G$ :
Lemma 3.12. Let $\tau \in \mathcal{O}_{G}(\mathcal{A} \times \mathcal{B})$, and call $\nu:=\tau_{\mathcal{A}}$ and $\mu:=\tau_{\mathcal{B}}$. For $x \in \nu$, let us call $B_{\tau}^{x}:=$ $\{y:(x, y) \in \tau\}$. Then, $\left|B_{\tau}^{x}\right|=\left|B_{\tau}^{x^{\prime}}\right|=: c_{\tau}^{\nu}$ for any $x, x^{\prime} \in \nu$, and furthermore, we have that $c_{\tau}^{\nu}=\frac{|\tau|}{|\nu|}$. Symmetrically, the same occurs for $A_{\tau}^{y}:=\{x:(x, y) \in \tau\}$ with $y \in \mu$, where one gets that $\left|A_{\tau}^{y}\right|=\left|A_{\tau}^{y^{\prime}}\right|=$ : $c_{\tau}^{\mu}=\frac{|\tau|}{|\mu|}$ for $y, y^{\prime} \in \mu$.
Proof. Let $x, x^{\prime} \in \nu$. Thus there exists $g \in G$ such that $x^{\prime}=g \cdot x$. Let:

$$
\begin{aligned}
f: B_{\tau}^{x} & \rightarrow B_{\tau}^{x^{\prime}} \\
y & \mapsto g \cdot y .
\end{aligned}
$$

First, $f$ is well defined. Indeed, if $y \in B_{\tau}^{x}=\{y:(x, y) \in \tau\}$, then $g \cdot y \in\{y:(g \cdot x, y) \in \tau\}=B_{\tau}^{x^{\prime}}$, since $\tau \in \mathcal{O}_{G}(\mathcal{A} \times \mathcal{B})$. Let us show that $f$ is injective. If $g \cdot y=g \cdot y^{\prime}$, then $g^{-1} \cdot(g \cdot y)=\left(g^{-1} g\right) \cdot y=y$, $g^{-1} \cdot\left(g \cdot y^{\prime}\right)=y^{\prime}$, so $y=y^{\prime}$. Thus we get that $\left|B_{\tau}^{x}\right| \leq\left|B_{\tau}^{x^{\prime}}\right|$. By a symmetric argument with $x^{\prime}$ replacing $x$ and $g^{-1}$ replacing $g$, we get that $\left|B_{\tau}^{x^{\prime}}\right| \leq\left|B_{\tau}^{x}\right|$, and so $\left|B_{\tau}^{x}\right|=\left|B_{\tau}^{x^{\prime}}\right|=: c_{\tau}^{\nu}$.

Furthermore, $\left\{B_{\tau}^{x}\right\}_{x \in \nu}$ is a partition of $\tau$, so $\sum_{x \in \nu}\left|B_{\tau}^{x}\right|=|\nu| c_{\tau}^{\nu}=|\tau|$, and thus $c_{\tau}^{\nu}=\frac{|\tau|}{|\nu|}$.
Lemma 3.13. For any $(x, y) \in \mathcal{A} \times \mathcal{B}$ and $v_{(x, y)^{G}}$ variable indexed by orbits of $\mathcal{A} \times \mathcal{B}$, let us define the variable $v_{x, y}:=\frac{v_{(x, y) G}}{\left|(x, y)^{G}\right|}$. We have:

$$
\sum_{x \in \mathcal{A}} v_{x, y}=\frac{1}{\left|y^{G}\right|} \sum_{\tau \in \mathcal{O}_{G}(\mathcal{A} \times \mathcal{B}): \tau_{\mathcal{B}}=y^{G}} v_{\tau}, \forall y \in \mathcal{B} .
$$

Proof.

$$
\begin{align*}
\sum_{x \in \mathcal{A}} v_{x, y} & =\sum_{\tau \in \mathcal{O}_{G}(\mathcal{A} \times \mathcal{B}): \tau_{\mathcal{B}}=y^{G}} \sum_{x \in \mathcal{A}:(x, y) \in \tau} v_{x, y} \\
& =\sum_{\tau \in \mathcal{O}_{G}(\mathcal{A} \times \mathcal{B}): \tau_{\mathcal{B}}=y^{G}} \sum_{x \in \mathcal{A}:(x, y) \in \tau} \frac{v_{\tau}}{|\tau|} \text { since }(x, y)^{G}=\tau \\
& =\sum_{\tau \in \mathcal{O}_{G}(\mathcal{A} \times \mathcal{B}): \tau_{\mathcal{B}}=y^{G}}^{c_{\tau}^{y^{G}} \frac{v_{\tau}}{|\tau|} \text { by Lemma 3.12, since } y \in \tau_{\mathcal{B}}}  \tag{32}\\
& =\sum_{\tau \in \mathcal{O}_{G}(\mathcal{A} \times \mathcal{B}): \tau_{\mathcal{B}}=y^{G}} \frac{|\tau|}{\left|y^{G}\right|} \frac{v_{\tau}}{|\tau|}=\frac{1}{\left|y^{G}\right|} \sum_{\tau \in \mathcal{O}_{G}(\mathcal{A} \times \mathcal{B}): \tau_{\mathcal{B}}=y^{G}} v_{\tau} .
\end{align*}
$$

Lemma 3.14. For any $\tau \in \mathcal{O}_{G}(\mathcal{A} \times \mathcal{B}), \mu \in \mathcal{O}_{G}(\mathcal{B})$ and $v_{x, y}$ variable indexed by elements of $\mathcal{A} \times \mathcal{B}$, let us define $v_{\tau}:=\sum_{(x, y) \in \tau} v_{x, y}$. We have:

$$
\sum_{\tau \in \mathcal{O}_{G}(\mathcal{A} \times \mathcal{B}): \tau_{\mathcal{B}}=\mu} v_{\tau}=\sum_{y \in \mu} \sum_{x \in \mathcal{A}} v_{x, y} .
$$

Proof.

$$
\sum_{\tau \in \mathcal{O}_{G}(\mathcal{A} \times \mathcal{B}): \tau_{\mathcal{B}}=\mu} v_{\tau}=\sum_{\tau \in \mathcal{O}_{G}(\mathcal{A} \times \mathcal{B}): \tau_{\mathcal{B}}=\mu} \sum_{(x, y) \in \tau} v_{x, y}=\sum_{y \in \mu} \sum_{x \in \mathcal{A}} v_{x, y}
$$

Proof of Theorem 3.10. Let $r_{x_{1}, x_{2}, y}, r_{x_{1}, x_{2}, y}^{1}, r_{x_{1}, x_{2}, y}^{2}, p_{x_{1}, x_{2}}$ a feasible solution of the program defined in Proposition 3.1, and call $S:=\frac{1}{k_{1} k_{2}} \sum_{x_{1}, x_{2}, y} W\left(y \mid x_{1} x_{2}\right) r_{x_{1}, x_{2}, y}$ its value. Define:

$$
\begin{align*}
& r_{w}:=\sum_{\left(x_{1}, x_{2}, y\right) \in w} r_{x_{1}, x_{2}, y}, \quad r_{w}^{1}:=\sum_{\left(x_{1}, x_{2}, y\right) \in w} r_{x_{1}, x_{2}, y}^{1} \\
& r_{w}^{2}:=\sum_{\left(x_{1}, x_{2}, y\right) \in w} r_{x_{1}, x_{2}, y}^{2}, \quad p_{u}:=\sum_{\left(x_{1}, x_{2}\right) \in u} p_{x_{1}, x_{2}} . \tag{33}
\end{align*}
$$

Let us show that $r_{w}, r_{w}^{1}, r_{w}^{2}, p_{u}$ is a feasible solution of the program defined in Theorem 3.10, and that its value $S^{*}:=\frac{1}{k_{1} k_{2}} \sum_{w} W(w) r_{w}=S$.

First, we have $S^{*}=S$. Indeed:

$$
\begin{align*}
S^{*} & =\frac{1}{k_{1} k_{2}} \sum_{w} W(w) r_{w}=\frac{1}{k_{1} k_{2}} \sum_{w} W(w) \sum_{\left(x_{1}, x_{2}, y\right) \in w} r_{x_{1}, x_{2}, y} \\
& =\frac{1}{k_{1} k_{2}} \sum_{w} \sum_{\left(x_{1}, x_{2}, y\right) \in w} W\left(y \mid x_{1} x_{2}\right) r_{x_{1}, x_{2}, y} \quad \text { since } W(w)=W\left(y \mid x_{1} x_{2}\right) \text { for all }\left(x_{1}, x_{2}, y\right) \in w  \tag{34}\\
& =\frac{1}{k_{1} k_{2}} \sum_{x_{1}, x_{2}, y} W\left(y \mid x_{1} x_{2}\right) r_{x_{1}, x_{2}, y}=S
\end{align*}
$$

Then, all the constraints are satisfied. Indeed, thanks to Lemma 3.14, we have for the first constraint:

$$
\sum_{w: w_{\mathcal{Y}}=v} r_{w}=\sum_{y \in v} \sum_{x_{1}, x_{2}} r_{x_{1}, x_{2}, y}=\sum_{y \in v} 1=|v| .
$$

For the second constraint (and symmetrically for the third constraint), we have:

$$
\sum_{w: w_{\mathcal{X}_{2} \mathcal{Y}}=v^{2}} r_{w}^{1}=\sum_{\left(x_{2}, y\right) \in v^{2}} \sum_{x_{1}} r_{x_{1}, x_{2}, y}^{1}=\sum_{\left(x_{2}, y\right) \in v^{2}} k_{1} \sum_{x_{1}} r_{x_{1}, x_{2}, y}=k_{1} \sum_{w: w_{\mathcal{X}_{2} \mathcal{Y}}=v^{2}} r_{w}
$$

For the fourth (and symmetrically for the fifth), we have:

$$
\begin{align*}
\sum_{w: w \mathcal{X}_{2} \mathcal{Y}=v^{2}} r_{w}^{2} & =\sum_{\left(x_{2}, y\right) \in v^{2}} \sum_{x_{1}} r_{x_{1}, x_{2}, y}^{2}=\sum_{\left(x_{2}, y\right) \in v^{2}} \frac{1}{k_{1}} \sum_{x_{1}} p_{x_{1}, x_{2}}=\frac{1}{k_{1}} \sum_{x_{2} \in v_{\mathcal{X}_{2}}^{2}} \sum_{y:\left(x_{2}, y\right) \in v^{2}} \sum_{x_{1}} p_{x_{1}, x_{2}} \\
& =\frac{1}{k_{1}} \sum_{x_{2} \in v_{\mathcal{X}_{2}}^{2}} \frac{\left|v^{2}\right|}{\left|v_{\mathcal{X}_{2}}^{2}\right|} \sum_{x_{1}} p_{x_{1}, x_{2}} \text { thanks to Lemma 3.12 }  \tag{35}\\
& =\frac{1}{k_{1}} \frac{\left|v^{2}\right|}{\left|v_{\mathcal{X}_{2}}^{2}\right|} \sum_{u: u \mathcal{X}_{2}=v_{\mathcal{X}_{2}}^{2}} p_{u} .
\end{align*}
$$

Finally for the last constraints, we only need to compute:

$$
\sum_{\left(x_{1}, x_{2}, y\right) \in w} p_{x_{1}, x_{2}}=\sum_{\left(x_{1}, x_{2}\right) \in w_{\mathcal{X}_{1} \mathcal{x}_{2}}} \sum_{y:\left(x_{1}, x_{2}, y\right) \in w} p_{x_{1}, x_{2}}=\sum_{\left(x_{1}, x_{2}\right) \in w_{\mathcal{X}_{1} \mathcal{X}_{2}}} \frac{|w|}{\left|w_{\mathcal{X}_{1} \mathcal{X}_{2}}\right|} p_{x_{1}, x_{2}}=\frac{|w|}{\mid w_{\mathcal{X}_{1} \mathcal{X}_{2} \mid}} p_{w_{\mathcal{X}_{1} \mathcal{X}_{2}}},
$$

which implies that the linear inequalities on $p_{x_{1}, x_{2}}, r_{x_{1}, x_{2}, y}, r_{x_{1}, x_{2}, y}^{1}, r_{x_{1}, x_{2}, y}^{2}$ get transposed respectively to the values $\frac{|w|}{\left|w_{\mathcal{X}_{1} \chi_{2}}\right|} p_{w_{\mathcal{X}_{1} \mathcal{X}_{2}}}, r_{w}, r_{w}^{1}, r_{w}^{2}$. Indeed, for instance, one has for any $x_{1}, x_{2}, y$ that $p_{x_{1}, x_{2}}-r_{x_{1}, x_{2}, y}^{1}-$ $r_{x_{1}, x_{2}, y}^{2}+r_{x_{1}, x_{2}, y} \geq 0$. Thus for some orbit $w$ :

$$
\sum_{\left(x_{1}, x_{2}, y\right) \in w}\left(p_{x_{1}, x_{2}}-r_{x_{1}, x_{2}, y}^{1}-r_{x_{1}, x_{2}, y}^{2}+r_{x_{1}, x_{2}, y}\right) \geq 0
$$

and then $\frac{|w|}{\left|w_{\mathcal{X}_{1} \mathcal{X}_{2}}\right|} p_{w_{\mathcal{X}_{1} \mathcal{X}_{2}}}-r_{w}^{1}-r_{w}^{2}+r_{w} \geq 0$, which was what we wanted to show.
Now let us consider a feasible solution $r_{w}, r_{w}^{1}, r_{w}^{2}, p_{u}$ of the program defined in Theorem 3.10, with a value $S^{*}:=\frac{1}{k_{1} k_{2}} \sum_{w} W(w) r_{w}$. Define:

$$
\begin{align*}
& r_{x_{1}, x_{2}, y}:=\frac{r_{\left(x_{1}, x_{2}, y\right)^{G}}}{\left|\left(x_{1}, x_{2}, y\right)^{G}\right|}, \quad r_{x_{1}, x_{2}, y}^{1}:=\frac{r_{\left(x_{1}, x_{2}, y\right)^{G}}^{1}}{\left|\left(x_{1}, x_{2}, y\right)^{G}\right|},  \tag{36}\\
& r_{x_{1}, x_{2}, y}^{2}:=\frac{r_{\left(x_{1}, x_{2}, y\right)^{G}}^{2}}{\left|\left(x_{1}, x_{2}, y\right)^{G}\right|}, \quad p_{x_{1}, x_{2}}:=\frac{p_{\left(x_{1}, x_{2}\right)^{G}}}{\left|\left(x_{1}, x_{2}\right)^{G}\right|} .
\end{align*}
$$

Let us show that $r_{x_{1}, x_{2}, y}, r_{x_{1}, x_{2}, y}^{1}, r_{x_{1}, x_{2}, y}^{2}, p_{x_{1}, x_{2}}$ is a feasible solution of the program defined in Proposition 3.1, and that its value $S:=\frac{1}{k_{1} k_{2}} \sum_{x_{1}, x_{2}, y} W\left(y \mid x_{1} x_{2}\right) r_{x_{1}, x_{2}, y}=S^{*}$.

First we have $S=S^{*}$. Indeed:

$$
\begin{align*}
S & =\frac{1}{k_{1} k_{2}} \sum_{x_{1}, x_{2}, y} W\left(y \mid x_{1} x_{2}\right) r_{x_{1}, x_{2}, y}=\frac{1}{k_{1} k_{2}} \sum_{x_{1}, x_{2}, y} W\left(y \mid x_{1} x_{2}\right) \frac{r_{\left(x_{1}, x_{2}, y\right)^{G}}}{\mid r_{\left(x_{1}, x_{2}, y\right)^{G} \mid}} \\
& =\frac{1}{k_{1} k_{2}} \sum_{w} \sum_{\left(x_{1}, x_{2}, y\right) \in w} W\left(y \mid x_{1} x_{2}\right) \frac{r_{w}}{|w|}=\frac{1}{k_{1} k_{2}} \sum_{w} \sum_{\left(x_{1}, x_{2}, y\right) \in w} W(w) \frac{r_{w}}{|w|}  \tag{37}\\
& =\frac{1}{k_{1} k_{2}} \sum_{w}|w| W(w) \frac{r_{w}}{|w|}=\frac{1}{k_{1} k_{2}} \sum_{w} W(w) r_{w}=S^{*} .
\end{align*}
$$

Then, all the constraints are satisfied. Indeed, thanks to Lemma 3.13, we have for the first constraint:

$$
\sum_{x_{1}, x_{2}} r_{x_{1}, x_{2}, y}=\frac{1}{\left|y^{G}\right|} \sum_{w: w y=y^{G}} r_{w}=\frac{\left|y^{G}\right|}{\left|y^{G}\right|}=1
$$

For the second constraint (and symmetrically for the third constraint), we have:

$$
\sum_{x_{1}} r_{x_{1}, x_{2}, y}^{1}=\frac{1}{\mid\left(x_{2}, y\right)^{G \mid}} \sum_{w: w_{\mathcal{X}_{2}} y=\left(x_{2}, y\right)^{G}} r_{w}^{1}=\frac{k_{1}}{\mid\left(x_{2}, y\right)^{G \mid}} \sum_{w: w \mathcal{X}_{2} y=\left(x_{2}, y\right)^{G}} r_{w}=k_{1} \sum_{x_{1}} r_{x_{1}, x_{2}, y}
$$

For the fourth (and symmetrically for the fifth), we have:

$$
\begin{align*}
\sum_{x_{1}} r_{x_{1}, x_{2}, y}^{2} & =\frac{1}{\mid\left(x_{2}, y\right)^{G \mid}} \sum_{w: w_{\mathcal{X}_{2}} y=\left(x_{2}, y\right)^{G}} r_{w}^{2}=\frac{1}{\left|\left(x_{2}, y\right)^{G}\right|} \frac{1}{k_{1}} \frac{\left|\left(x_{2}, y\right)^{G}\right|}{\left|\left(x_{2}, y\right)_{\mathcal{X}_{2}}^{G}\right|} \sum_{u: u_{\mathcal{X}_{2}}=\left(x_{2}, y\right)_{\mathcal{X}_{2}}^{G}} p_{u} \\
& =\frac{1}{k_{1}} \frac{1}{\left|\left(x_{2}, y\right)_{\mathcal{X}_{2}}^{G}\right|} \sum_{u: u_{\mathcal{X}_{2}}=\left(x_{2}, y\right)_{\mathcal{X}_{2}}^{G}} p_{u}=\frac{1}{k_{1}} \frac{1}{\left|x_{2}^{G}\right|} \sum_{u: u_{\mathcal{X}_{2}}=x_{2}^{G}} p_{u} \text { since }\left(x_{2}, y\right)_{\mathcal{X}_{2}}^{G}=x_{2}^{G}  \tag{38}\\
& =\frac{1}{k_{1}} \sum_{x_{1}} p_{x_{1}, x_{2}} .
\end{align*}
$$

Finally, to conclude with the last constraints, one has only to see that for any $x_{1}, x_{2}, y$ :

$$
\frac{\left|\left(x_{1}, x_{2}, y\right)^{G}\right|}{\left|\left(x_{1}, x_{2}, y\right)_{\mathcal{X}_{1} \mathcal{X}_{2}}^{G}\right|} p_{\left(x_{1}, x_{2}, y\right)_{\mathcal{X}_{1} \mathcal{X}_{2}}^{G}}=\frac{\left|\left(x_{1}, x_{2}, y\right)^{G}\right|}{\left|\left(x_{1}, x_{2}\right)^{G}\right|} p_{\left(x_{1}, x_{2}\right)^{G}}=\left|\left(x_{1}, x_{2}, y\right)^{G}\right| p_{x_{1}, x_{2}},
$$

which implies that the linear inequalities on $\frac{|w|}{\left|w_{\mathcal{X}_{1} \mathcal{X}_{2}}\right|} p_{w_{\mathcal{X}_{1} \mathcal{X}_{2}}}, r_{w}, r_{w}^{1}, r_{w}^{2}$ get transposed respectively to the values $p_{x_{1}, x_{2}}, r_{x_{1}, x_{2}, y}, r_{x_{1}, x_{2}, y}^{1}, r_{x_{1}, x_{2}, y}^{2}$. Indeed, for instance, one has for any $w$ that $\frac{|w|}{\left|w_{\mathcal{X}_{1} \mathcal{X}_{2}}\right|} p_{w_{\mathcal{X}_{1} \mathcal{X}_{2}}}-r_{w}^{1}-$ $r_{w}^{2}+r_{w} \geq 0$. But for any $\left(x_{1}, x_{2}, y\right) \in w$, one has that $r_{x_{1}, x_{2}, y}=\frac{r_{w}}{|w|}, r_{x_{1}, x_{2}, y}^{1}=\frac{r_{w}^{1}}{|w|}, r_{x_{1}, x_{2}, y}^{2}=\frac{r_{w}^{2}}{|w|}$. Thanks to the previous inequality, we have that $p_{x_{1}, x_{2}}=\frac{p_{w_{1} \mathcal{X}_{2}}}{\left|w_{\mathcal{X}_{1} \mathcal{X}_{2}}\right|}$, and thus:

$$
p_{x_{1}, x_{2}}-r_{x_{1}, x_{2}, y}^{1}-r_{x_{1}, x_{2}, y}^{2}+r_{x_{1}, x_{2}, y}=\frac{p_{w_{\mathcal{X}_{1} \mathcal{X}_{2}}}}{\left|w_{\mathcal{X}_{1} \mathcal{X}_{2}}\right|}-\frac{r_{w}^{1}}{|w|}-\frac{r_{w}^{2}}{|w|}+\frac{r_{w}}{|w|} \geq 0
$$

which was what we wanted to show.

## 4 Non-Signaling Achievability Bounds

### 4.1 Zero-Error Non-Signaling Assisted Achievable Rate Pairs

We will now present a numerical method to find efficiently inner bounds on $\mathcal{C}_{0}^{\text {NS }}(W)$. Thanks to Corollary 3.11, we know how to decide in polynomial time in $n, k_{1}, k_{2}$ whether $S^{\mathrm{NS}}\left(W^{\otimes n}, k_{1}, k_{2}\right)=1$. However, by Proposition 3.8, if $\mathrm{S}^{\mathrm{NS}}\left(W^{\otimes n}, k_{1}, k_{2}\right)=1$, then we have that $\left(\frac{\log \left(k_{1}\right)}{n}, \frac{\log \left(k_{2}\right)}{n}\right) \in \mathcal{C}_{0}^{\mathrm{NS}}(W)$, which describes a way of computing achievable points for that capacity region. More precisely, this leads to the following result:

Proposition 4.1 (Inner Bounds on $\mathcal{C}_{0}^{\mathrm{NS}}(W)$ ). Let us define the zero-error non-signaling assisted $n$-shots capacity region $\mathcal{C}_{0, \leq n}^{\mathrm{NS}}(W)$ in the following way:

$$
\mathcal{C}_{0, \leq n}^{\mathrm{NS}}(W):=\left\{\left(\frac{\log \left(k_{1}\right)}{n}, \frac{\log \left(k_{2}\right)}{n}\right): \mathrm{S}^{\mathrm{NS}}\left(W^{\otimes n}, k_{1}, k_{2}\right)=1\right\} .
$$

Then, we have that $\forall n \in \mathbb{N}, \mathcal{C}_{0, \leq n}^{\mathrm{NS}}(W) \subseteq \mathcal{C}_{0}^{\mathrm{NS}}(W)$, and that one can decide in polynomial time in $n, k_{1}, k_{2}$ if $\left(\frac{\log \left(k_{1}\right)}{n}, \frac{\log \left(k_{2}\right)}{n}\right) \in \mathcal{C}_{0, \leq n}^{\mathrm{NS}}(W)$.

This implies that we can find efficiently achievable rate pairs for MACs.

Application to the binary adder channel The binary adder channel $W_{\text {BAC }}$ is the following MAC:

$$
\forall x_{1}, x_{2} \in\{0,1\}, \forall y \in\{0,1,2\}, W_{\mathrm{BAC}}\left(y \mid x_{1} x_{2}\right):=\delta_{y, x_{1}+x_{2}} .
$$

Its classical capacity region $\mathcal{C}\left(W_{\mathrm{BAC}}\right)$ is well known and consists of all $\left(R_{1}, R_{2}\right)$ such that $R_{1} \leq 1, R_{2} \leq$ $1, R_{1}+R_{2} \leq \frac{3}{2}$, as a consequence of Theorem 2.2 . Its zero-error classical capacity $\mathcal{C}_{0}\left(W_{\mathrm{BAC}}\right)$ is not yet characterized. A lot of work has been done in finding outer and inner bounds on this region [23, 24, 25, [26, 27, 28, 29, 30, 31, 32, 33]. To date, the best lower bound on the sum-rate capacity is $\log _{2}(240 / 6) \simeq$ 1.3178 [32].

Thanks to Proposition 4.1, we were able to compute the regions $\mathcal{C}_{0, \leq n}^{\mathrm{NS}}(W)$ for $n$ going up to 7 , which led to Figure 4. The code can be found on GitHub, It uses Mosek linear programming solver [34].

Note that the linear program from Theorem 3.10 has still a large number of variables and constraints although polynomial in $n$. Specifically, for $n=2$, it has 244 variables and 480 constraints; for $n=3$, it has 1112 variables and 2054 constraints; for $n=7$, it has 95592 variables and 162324 constraints; finally, for $n=8$, it has 226911 variables and 383103 constraints.

Figure 4: Capacity regions of the binary adder channel $W_{\text {BAC }}$. The black dashed curve depicts the classical capacity region $\mathcal{C}\left(W_{\mathrm{BAC}}\right)$, whereas the grey dashed curve shows the best known inner bound border on the zero-error classical capacity region $\mathcal{C}_{0}\left(W_{\mathrm{BAC}}\right)$, made from results by [32, 28, 27]; see [32] for a description of this border. On the other hand, the continuous curves depict the best zero-error non-signaling assisted achievable rate pairs for respectively 2,3 and 7 copies of the binary adder channel.

The first noticeable result coming from these curves is that the zero-error non-signaling assisted sumrate capacity beats with only 7 copies the classical sum-rate capacity of $\frac{3}{2}$, even without a zero-error constraint, with a value of $\frac{2 \log _{2}(42)}{7} \simeq 1.5406$, coming from the fact that $S^{\mathrm{NS}}\left(W_{\mathrm{BAC}}^{\otimes 7}, 42,42\right)=1$ and Proposition 3.8. This implies that $\mathcal{C}_{0}^{\mathrm{NS}}\left(W_{\mathrm{BAC}}\right)$ has larger sum-rate pairs than $\mathcal{C}\left(W_{\mathrm{BAC}}\right)$, and that $\mathcal{C}^{\mathrm{NS}}\left(W_{\mathrm{BAC}}\right)$ is strictly larger than $\mathcal{C}\left(W_{\mathrm{BAC}}\right)$. This sum-rate can even be increased up to $\frac{\log _{2}(72)}{4} \simeq 1.5425$, since we
have computed $\mathrm{S}^{\mathrm{NS}}\left(W_{\mathrm{BAC}}^{\otimes 8}, 72,72\right)=1$, which is the largest number of copies we have been able to manage with our efficient version of the linear program from Theorem 3.10. This should be compared with the upper bound on the non-signaling assisted sum-rate capacity coming from Proposition 5.6, which is $\log _{2}(3) \simeq 1.5850$ for $R_{1}=R_{2}$.

Another surprising property is the speed at which one obtains efficient zero-error non-signaling assisted codes compared to classical zero-error codes. Indeed, with only three copies of the binary adder channel, one gets that $\mathrm{S}^{\mathrm{NS}}\left(W_{\mathrm{BAC}}^{\otimes 3}, 4,5\right)=1$, which corresponds to a sum-rate of $\frac{2+\log _{2}(5)}{3} \simeq 1.4406$, which already largely beats the best known zero-error achieved sum-rate of $\log _{2}(240 / 6) \simeq 1.3178$ [32]. These results are summarized in the following theorem:

Theorem 4.2. We have that $\left(\frac{\log _{2}(72)}{8}, \frac{\log _{2}(72)}{8}\right) \in \mathcal{C}_{0}^{\mathrm{NS}^{2}}\left(W_{\mathrm{BAC}}\right)$ but $\left(\frac{\log _{2}(72)}{8}, \frac{\log _{2}(72)}{8}\right) \notin \mathcal{C}\left(W_{\mathrm{BAC}}\right)$, and as a consequence, we have that $\mathcal{C}\left(W_{\mathrm{BAC}}\right) \subsetneq \mathcal{C}^{\mathrm{NS}}\left(W_{\mathrm{BAC}}\right)$.

Proof. Since $2^{8 \frac{\log _{2}(72)}{8}}=72$ and numerically $S^{\mathrm{NS}}\left(W_{\mathrm{BAC}}^{\otimes 8}, 72,72\right)=1$ thanks to Corollary 3.11, we get that $\left(\frac{\log _{2}(72)}{8}, \frac{\log _{2}(72)}{8}\right) \in \mathcal{C}_{0}^{\mathrm{NS}}\left(W_{\mathrm{BAC}}\right)$ by Proposition 3.8 . However, $\frac{\log _{2}(72)}{8}+\frac{\log _{2}(72)}{8}>\frac{3}{2}$ so $\left(\frac{\log _{2}(72)}{8}, \frac{\log _{2}(72)}{8}\right) \notin$ $\mathcal{C}\left(W_{\mathrm{BAC}}\right)$ by Theorem 2.2 applied to $W_{\mathrm{BAC}}$. Since $\mathcal{C}\left(W_{\mathrm{BAC}}\right) \subseteq \mathcal{C}^{\mathrm{NS}}\left(W_{\mathrm{BAC}}\right)$ and $\mathcal{C}_{0}^{\mathrm{NS}}\left(W_{\mathrm{BAC}}\right) \subseteq \mathcal{C}^{\mathrm{NS}}\left(W_{\mathrm{BAC}}\right)$, we thus get that $\mathcal{C}\left(W_{\mathrm{BAC}}\right) \subsetneq \mathcal{C}^{\mathrm{NS}}\left(W_{\mathrm{BAC}}\right)$.

### 4.2 Non-Signaling Assisted Achievable Rate Pairs with Non-Zero Error

We have analyzed the non-signaling assisted capacity region through zero-error strategies and applied it to the BAC. However, if some noise is added to that channel, its zero-error non-signaling assisted capacity region becomes trivial (see Proposition 4.6). Thus, the previous method fails to find significant inner bounds on the non-signaling assisted capacity region of noisy MACs.

In this section, we use concatenated codes to obtain achievable rate pairs, and apply it to a noisy version of the BAC:

Definition 4.3 (Concatenated Codes). Given a MAC $W$ and a non-signaling assisted code $P$, define $W[P]:\left[k_{1}\right] \times\left[k_{2}\right] \rightarrow[\ell]$ with $W[P]\left(j \mid i_{1} i_{2}\right):=\sum_{x_{1}, x_{2}, y} W\left(y \mid x_{1} x_{2}\right) P\left(x_{1} x_{2} j \mid i_{1} i_{2} y\right):$

Note that $W[P]$ is a MAC since $W[P]\left(j \mid i_{1} i_{2}\right) \geq 0$ and:

$$
\begin{align*}
\sum_{j} W[P]\left(j \mid i_{1} i_{2}\right) & =\sum_{x_{1}, x_{2}, y} W\left(y \mid x_{1} x_{2}\right) \sum_{j} P\left(x_{1} x_{2} j \mid i_{1} i_{2} y\right) \\
& =\sum_{x_{1}, x_{2}}\left(\sum_{y} W\left(y \mid x_{1} x_{2}\right)\right) P\left(x_{1} x_{2} \mid i_{1} i_{2}\right) \text { since } P \text { is non-signaling }  \tag{39}\\
& =\sum_{x_{1}, x_{2}} P\left(x_{1} x_{2} \mid i_{1} i_{2}\right)=1
\end{align*}
$$

The following proposition states that combining a classical code to a non-signaling strategy leads to inner bounds on the non-signaling assisted capacity region of a MAC:
Proposition 4.4. If $P$ is a non-signaling assisted code for the MAC $W$, we have that $\mathcal{C}(W[P]) \subseteq \mathcal{C}^{\mathrm{NS}}(W)$. Proof. Let $\left(R_{1}, R_{2}\right) \in \mathcal{C}(W[P])$. Then, by definition, we have that:

$$
\lim _{n \rightarrow+\infty} \mathrm{S}\left(W[P]^{\otimes n},\left\lceil 2^{R_{1} n}\right\rceil,\left\lceil 2^{R_{2} n}\right\rceil\right)=1
$$

Let us fix $\varepsilon>0$. For a large enough $N$, we have $\mathrm{S}\left(W[P]^{\otimes N},\left\lceil 2^{R_{1} N}\right\rceil,\left\lceil 2^{R_{2} N}\right\rceil\right) \geq 1-\varepsilon$. Let us call $\ell_{1}:=\left\lceil 2^{R_{1} N}\right\rceil$ and $\ell_{2}:=\left\lceil 2^{R_{2} N}\right\rceil$. Thus, there exists encoders $e_{1}:\left[\ell_{1}\right] \rightarrow\left[k_{1}\right], e_{2}:\left[\ell_{2}\right] \rightarrow\left[k_{2}\right]$ and a decoder $d:[\ell] \rightarrow\left[\ell_{1}\right] \times\left[\ell_{2}\right]$ such that:

$$
\frac{1}{\ell_{1} \ell_{2}} \sum_{i_{1}, i_{2}, j} W[P]\left(j \mid i_{1} i_{2}\right) \sum_{a_{1} \in\left[\ell_{1}\right], a_{2} \in\left[\ell_{2}\right]} e_{1}\left(i_{1} \mid a_{1}\right) e_{2}\left(i_{2} \mid a_{2}\right) d\left(a_{1} a_{2} \mid j\right) \geq 1-\varepsilon .
$$

In particular, we have:

$$
\frac{1}{\ell_{1} \ell_{2}} \sum_{x_{1}, x_{2}, y} W\left(y \mid x_{1} x_{2}\right)\left[\sum_{i_{1}, i_{2}, j, a_{1}, a_{2}} P\left(x_{1} x_{2} j \mid i_{1} i_{2} y\right) e_{1}\left(i_{1} \mid a_{1}\right) e_{2}\left(i_{2} \mid a_{2}\right) d\left(a_{1} a_{2} \mid j\right)\right] \geq 1-\varepsilon
$$

Let us define $\hat{P}\left(x_{1} x_{2}\left(b_{1} b_{2}\right) \mid a_{1} a_{2} y\right):=\sum_{i_{1}, i_{2}, j} P\left(x_{1} x_{2} j \mid i_{1} i_{2} y\right) e_{1}\left(i_{1} \mid a_{1}\right) e_{2}\left(i_{2} \mid a_{2}\right) d\left(b_{1} b_{2} \mid j\right)$. Then, one can easily check that $\hat{P}$ is non-signaling, and thus:

$$
\mathrm{S}^{\mathrm{NS}}\left(W^{\otimes N}, \ell_{1}, \ell_{2}\right) \geq \frac{1}{\ell_{1} \ell_{2}} \sum_{x_{1}, x_{2}, y} W\left(y \mid x_{1} x_{2}\right) \sum_{a_{1}, a_{2}} \hat{P}\left(x_{1} x_{2}\left(a_{1}, a_{2}\right) \mid a_{1} a_{2} y\right) \geq 1-\varepsilon
$$

This implies that $\lim _{n \rightarrow+\infty} \mathrm{S}^{\mathrm{NS}}\left(W^{\otimes n},\left\lceil 2^{R_{1} n}\right\rceil,\left\lceil 2^{R_{2} n}\right\rceil\right)=1$, i.e. $\left(R_{1}, R_{2}\right) \in \mathcal{C}^{\mathrm{NS}}(W)$.
Thanks to Proposition 4.4, we have for any non-signaling assisted code $P, \mathcal{C}\left(W^{\otimes n}[P]\right) \subseteq \mathcal{C}^{\mathrm{NS}}\left(W^{\otimes n}\right)$. But if $\left(R_{1}, R_{2}\right) \in \mathcal{C}^{\mathrm{NS}}\left(W^{\otimes n}\right)$, we have that $\left(\frac{R_{1}}{n}, \frac{R_{2}}{n}\right) \in \mathcal{C}^{\mathrm{NS}}(W)$. Thus, applying Theorem 2.2 on $W^{\otimes n}[P]$ leads to inner bounds on $\mathcal{C}^{\mathrm{NS}}(W)$ :
Proposition 4.5 (Inner Bounds on $\mathcal{C}^{\mathrm{NS}}(W)$ ). For any number of copies $n$, number of inputs $k_{1} \in\left[\left|\mathcal{X}_{1}\right|^{n}\right]$ and $k_{2} \in\left[\left|\mathcal{X}_{2}\right|^{n}\right]$, non-signaling assisted codes $P$ on inputs in $\left[k_{1}\right]$, $\left[k_{2}\right]$ for $W^{\otimes n}$, and distributions $q_{1}, q_{2}$ on $\left[k_{1}\right],\left[k_{2}\right]$, we have that the following $\left(R_{1}, R_{2}\right)$ are in $\mathcal{C}^{\mathrm{NS}}(W)$ :

$$
R_{1} \leq \frac{I\left(I_{1}: J \mid I_{2}\right)}{n}, R_{2} \leq \frac{I\left(I_{2}: J \mid I_{1}\right)}{n}, R_{1}+R_{2} \leq \frac{I\left(\left(I_{1}, I_{2}\right): J\right)}{n}
$$

for $\left(I_{1}, I_{2}\right) \in\left[k_{1}\right] \times\left[k_{2}\right]$ following the product law $q_{1} \times q_{2}$, and $J \in[\ell]$ the outcome of $W^{\otimes n}[P]$ on inputs $I_{1}, I_{2}$. In particular, the corner points of this capacity region are given by:

$$
\left(\frac{I\left(I_{1}: J \mid I_{2}\right)}{n}, \frac{I\left(I_{2}: J\right)}{n}\right) \text { and }\left(\frac{I\left(I_{1}: J\right)}{n}, \frac{I\left(I_{2}: J \mid I_{1}\right)}{n}\right) .
$$

Proof. The achievable region comes from the previous discussion. We just need to prove that the corner points are of the given form. If $R_{1}=\frac{I\left(I_{1}: J \mid I_{2}\right)}{n}$, constraints on $R_{2}$ and $R_{1}+R_{2}$ leads to a maximum $R_{2}=\min \left(\frac{I\left(I_{2}: J \mid I_{1}\right)}{n}, \frac{I\left(\left(I_{1}, I_{2}\right): J\right)}{n}-\frac{I\left(I_{1}: J \mid I_{2}\right)}{n}\right)$. However, $I\left(\left(I_{1}, I_{2}\right): J\right)-I\left(I_{1}: J \mid I_{2}\right)=I\left(I_{2}: J\right)$ by the chain rule. We only need to show that $I\left(I_{2}: J\right) \leq I\left(I_{2}: J \mid I_{1}\right)$ and the proof will be complete, since the other corner point is symmetric. We have:

$$
I\left(I_{2}: J\right)=H\left(I_{2}\right)-H\left(I_{2} \mid J\right)=H\left(I_{2} \mid I_{1}\right)-H\left(I_{2} \mid J\right) \leq H\left(I_{2} \mid I_{1}\right)-H\left(I_{2} \mid J I_{1}\right)=I\left(I_{2}: J \mid I_{1}\right),
$$

the second equality coming from the fact that $I_{1}$ and $I_{2}$ are independent, and the inequality coming from the fact that $H(A \mid B C) \leq H(A \mid B)$ for any $A, B, C$.

Application to the Noisy Binary Adder Channel We will now apply this strategy to a noisy version of the BAC. We will consider flip errors $\varepsilon_{1}, \varepsilon_{2}$ of inputs $x_{1}, x_{2}$ on $W_{\mathrm{BAC}}$, which leads to the following definition of $W_{\mathrm{BAC}, \varepsilon_{1}, \varepsilon_{2}}$ :

$$
\begin{align*}
\forall y, x_{1}, x_{2}, W_{\mathrm{BAC}, \varepsilon_{1}, \varepsilon_{2}}\left(y \mid x_{1} x_{2}\right) & :=\left(1-\varepsilon_{1}\right)\left(1-\varepsilon_{2}\right) W_{\mathrm{BAC}}\left(y \mid x_{1} x_{2}\right) \\
& +\varepsilon_{1}\left(1-\varepsilon_{2}\right) W_{\mathrm{BAC}}\left(y \mid \overline{x_{1}} x_{2}\right) \\
& +\left(1-\varepsilon_{1}\right) \varepsilon_{2} W_{\mathrm{BAC}}\left(y \mid x_{1} \overline{x_{2}}\right)  \tag{40}\\
& +\varepsilon_{1} \varepsilon_{2} W_{\mathrm{BAC}}\left(y \mid \overline{x_{1} x_{2}}\right) .
\end{align*}
$$

First, let us note that the zero-error non-signaling assisted capacity region of $W_{\mathrm{BAC}, \varepsilon_{1}, \varepsilon_{2}}$ is trivial for $\varepsilon \in(0,1)$ :
Proposition 4.6. If $\varepsilon_{1}, \varepsilon_{2} \in(0,1)$, then $\mathcal{C}_{0}^{\mathrm{NS}}\left(W_{\mathrm{BAC}, \varepsilon_{1}, \varepsilon_{2}}\right)=\{(0,0)\}$.
Proof. If $S^{\text {NS }}\left(W^{\otimes n}, k_{1}, k_{2}\right)=1$, then $\forall y^{n}, x_{1}^{n}, x_{2}^{n}: W^{\otimes n}\left(y^{n} \mid x_{1}^{n} x_{2}^{n}\right)>0 \Longrightarrow r_{x_{1}^{n}, x_{2}^{n}, y^{n}}=p_{x_{1}^{n}, x_{2}^{n}}$. Indeed, we have for an optimal $p, r$ that:

$$
\mathrm{S}^{\mathrm{NS}}\left(W^{\otimes n}, k_{1}, k_{2}\right)=\frac{1}{k_{1} k_{2}} \sum_{x_{1}^{n}, x_{2}^{n}, y^{n}} W^{\otimes n}\left(y^{n} \mid x_{1}^{n} x_{2}^{n}\right) r_{x_{1}^{n}, x_{2}^{n}, y^{n}} \leq \frac{1}{k_{1} k_{2}} \sum_{x_{1}^{n}, x_{2}^{n}, y^{n}} W^{\otimes n}\left(y^{n} \mid x_{1}^{n} x_{2}^{n}\right) p_{x_{1}^{n}, x_{2}^{n}}=1,
$$

which implies the previous statement. But, for $W_{\mathrm{BAC}, \varepsilon_{1}, \varepsilon_{2}}^{\otimes n}$, one can easily check that for all $y^{n}, x_{1}^{n}, x_{2}^{n}$, $W^{\otimes n}\left(y^{n} \mid x_{1}^{n} x_{2}^{n}\right)>0$ since $\varepsilon_{1}, \varepsilon_{2} \in(0,1)$. Indeed, you just have to flip the inputs to a valid preimage of the output. Thus if $\mathrm{S}^{N S}\left(W_{\mathrm{BAC}, \varepsilon_{1}, \varepsilon_{2}}^{\otimes n}, k_{1}, k_{2}\right)=1$, we have that $\forall y^{n}, x_{1}^{n}, x_{2}^{n}, r_{x_{1}^{n}, x_{2}^{n}, y^{n}}=p_{x_{1}^{n}, x_{2}^{n}}$. In particular, this implies that $\sum_{x_{1}^{n}, x_{2}^{n}} r_{x_{1}^{n}, x_{2}^{n}, y^{n}}=\sum_{x_{1}^{n}, x_{2}^{n}} p_{x_{1}^{n}, x_{2}^{n}}$, therefore $1=k_{1} k_{2}$, so $k_{1}=1$ and $k_{2}=1$. Thus $\mathrm{S}^{N S}\left(W^{\otimes n}, 2^{n R_{1}}, 2^{n R_{2}}\right)=1$ implies that $\left(R_{1}, R_{2}\right)=(0,0)$.

We have then applied the numerical method described in Proposition 4.5 to $W_{\mathrm{BAC}, \varepsilon_{1}, \varepsilon_{2}}$ for the symmetric case $\varepsilon_{1}=\varepsilon_{2}=\varepsilon:=10^{-3}$. Since it is hard to go through all non-signaling assisted codes $P$ and product distributions $q_{1}, q_{2}$, we have applied the heuristic of using non-signaling assisted codes obtained while optimizing $\mathrm{S}^{\mathrm{NS}}\left(W^{\otimes n}, k_{1}, k_{2}\right)$ in the symmetrized linear program. We have combined them with uniform $q_{1}, q_{2}$, as the form of those non-signaling assisted codes coming from our optimization program is symmetric. We have evaluated the achievable corner points for all $k_{1}, k_{2} \leq 2^{n}$ for $n \leq 5$ copies which led to Figure 5

Compared to the noiseless binary adder channel, we can first notice that the classical capacity region is slightly smaller, with a classical sum-rate capacity of 1.478 at most. On the other hand, although the zero-error non-signaling assisted capacity of $W_{\mathrm{BAC}, \varepsilon, \varepsilon}$ is completely trivial, we have with our concatenated codes strategy found significant rate pairs achievable with non-signaling assistance. In particular, we have reached a non-signaling assisted sum-rate capacity of 1.493 which beats the best classical sum-rate capacity. Thus, it shows that non-signaling assistance can improve the capacity of the noisy binary adder channel as well.

Figure 5: Capacity regions of the noisy binary adder channel $W_{\mathrm{BAC}, \varepsilon, \varepsilon}$ for $\varepsilon=10^{-3}$. The black dashed curve depicts the classical capacity region $\mathcal{C}\left(W_{\mathrm{BAC}, \varepsilon, \varepsilon}\right)$ which was found numerically using Theorem 2.2. The red point depicts the zero-error non-signaling assisted capacity region (Proposition 4.6). The blue curve depicts achievable non-signaling assisted rates pairs obtained from $\mathcal{C}\left(W_{\mathrm{BAC}, \varepsilon, \varepsilon}^{\otimes 5}[P]\right)$ through the numerical method described in Proposition 4.5.

## 5 Relaxed Non-Signaling Assisted Capacity Region and Outer Bounds

A natural question that arises when studying the strength of non-signaling assistance is whether a result similar to Theorem 2.2 can be found to describe by a single-letter formula the non-signaling assisted capacity region of MACs. In particular, dropping the constraint that ( $X_{1}, X_{2}$ ) is in product form in Theorem 2.2 seems to be a particularly good candidate to characterize the non-signaling assisted capacity region of MACs, as this looks quite similar to allowing correlations between parties.

We have not been able to show the equivalence between this region and the non-signaling assisted capacity region; however, it turns out to be equivalent to the capacity region defined by a slight relaxation of non-signaling assistance, which we call $\mathrm{S}^{\overline{N S}}\left(W, k_{1}, k_{2}\right)$. In particular, this will give us the best known outer bound on the non-signaling capacity.

Definition 5.1.

$$
\begin{align*}
\mathrm{S}^{\overline{\mathrm{NS}}}\left(W, k_{1}, k_{2}\right):=\underset{r, p}{\operatorname{maximize}} & \frac{1}{k_{1} k_{2}} \sum_{x_{1}, x_{2}, y} W\left(y \mid x_{1} x_{2}\right) r_{x_{1}, x_{2}, y} \\
\text { subject to } & \sum_{x_{1}, x_{2}} r_{x_{1}, x_{2}, y} \leq 1 \\
& \sum_{x_{1}, x_{2}} p_{x_{1}, x_{2}}=k_{1} k_{2}  \tag{41}\\
& \sum_{x_{1}} p_{x_{1}, x_{2}} \geq k_{1} \sum_{x_{1}} r_{x_{1}, x_{2}, y} \\
& \sum_{x_{2}} p_{x_{1}, x_{2}} \geq k_{2} \sum_{x_{2}} r_{x_{1}, x_{2}, y} \\
& 0 \leq r_{x_{1}, x_{2}, y} \leq p_{x_{1}, x_{2}}
\end{align*}
$$

The following proposition shows that this is indeed a relaxation of the non-signaling constraint.
Proposition 5.2. $\mathrm{S}^{\mathrm{NS}}\left(W, k_{1}, k_{2}\right) \leq \mathrm{S}^{\overline{\mathrm{NS}}}\left(W, k_{1}, k_{2}\right)$.
Proof. Let us take a solution $\left(p_{x_{1}, x_{2}}, r_{x_{1}, x_{2}, y}, r_{x_{1}, x_{2}, y}^{1}, r_{x_{1}, x_{2}, y}^{2}\right)_{x_{1} \in \mathcal{X}_{1}, x_{2} \in \mathcal{X}_{2}, y \in \mathcal{Y}}$ of the linear program computing $\mathrm{S}^{\mathrm{NS}}\left(W, k_{1}, k_{2}\right)$. Let us show that $\left(p_{x_{1}, x_{2}}, r_{x_{1}, x_{2}, y}\right)_{x_{1} \in \mathcal{X}_{1}, x_{2} \in \mathcal{X}_{2}, y \in \mathcal{Y}}$ is a solution of the linear program computing $\mathrm{S}^{\overline{\mathrm{NS}}}\left(W, k_{1}, k_{2}\right)$ with a same objective value, from which the proposition follows.

They have indeed the same value, since the definition which is the same for both programs depends only on $r_{x_{1}, x_{2}, y}$. Let us show that all constraints are satisfied for $\left(p_{x_{1}, x_{2}}, r_{x_{1}, x_{2}, y}\right)_{x_{1} \in \mathcal{X}_{1}, x_{2} \in \mathcal{X}_{2}, y \in \mathcal{Y}}$.

We have $\sum_{x_{1}, x_{2}} r_{x_{1}, x_{2}, y}=1 \leq 1$ so the first constraint is satisfied. We have then that:

$$
\sum_{x_{1}, x_{2}} p_{x_{1}, x_{2}}=k_{1} \sum_{x_{1}, x_{2}} r_{x_{1}, x_{2}, y}^{2}=k_{1} k_{2} \sum_{x_{1}, x_{2}} r_{x_{1}, x_{2}, y}=k_{1} k_{2},
$$

so the second constraint is satisfied.
For the third constraint (and symmetrically the fourth constraint), we have:

$$
\sum_{x_{1}} p_{x_{1}, x_{2}}=k_{1} \sum_{x_{1}} r_{x_{1}, x_{2}, y}^{2} \geq k_{1} \sum_{x_{1}} r_{x_{1}, x_{2}, y} .
$$

Finally, we have directly $0 \leq r_{x_{1}, x_{2}, y} \leq p_{x_{1}, x_{2}}$, so the last constraint is satisfied.
We can now introduce the relaxed non-signaling assisted capacity region $\mathcal{C}^{\overline{\mathrm{NS}}}(W)$ :
Definition $5.3\left(\mathcal{C}^{\overline{\mathrm{NS}}}(W)\right)$. A rate pair $\left(R_{1}, R_{2}\right)$ is achievable with relaxed non-signaling assistance if:

$$
\lim _{n \rightarrow+\infty} S^{\overline{\mathrm{NS}}}\left(W^{\otimes n},\left\lceil 2^{R_{1} n}\right\rceil,\left\lceil 2^{R_{2} n}\right\rceil\right)=1 .
$$

We define $\mathcal{C}^{\overline{\mathrm{NS}}}(W)$ as the closure of the convex hull of the set of all achievable rate pairs with relaxed non-signaling assistance.

Remark. One could show as in the non-relaxed case that $\mathcal{C}^{\overline{\mathrm{NS}}}(W)$ is convex without taking the convex hull in its definition.

A direct property that follows from this definition and Proposition 5.2 is the fact that the non-signaling assisted capacity region is included in the relaxed non-signaling assisted capacity region.

Corollary 5.4. $\mathcal{C}^{\mathrm{NS}}(W) \subseteq \mathcal{C}^{\overline{\mathrm{NS}}}(W)$.

We present now the main result of this section, the characterization of $\mathcal{C}^{\overline{\mathrm{NS}}}(W)$ by a single-letter formula.

Theorem 5.5 (Characterization of $\left.\mathcal{C}^{\overline{\mathrm{NS}}}(W)\right) \cdot \mathcal{C}^{\overline{\mathrm{NS}}}(W)$ is the closure of the convex hull of all rate pairs ( $R_{1}, R_{2}$ ) satisfying:

$$
R_{1}<I\left(X_{1}: Y \mid X_{2}\right), R_{2}<I\left(X_{2}: Y \mid X_{1}\right), R_{1}+R_{2}<I\left(\left(X_{1}, X_{2}\right): Y\right),
$$

for ( $X_{1}, X_{2}$ ) following some law $P_{X_{1} X_{2}}$ on $\mathcal{X}_{1} \times \mathcal{X}_{2}$, and $Y \in \mathcal{Y}$ the outcome of $W$ on inputs $X_{1}, X_{2}$.
Remark. Note that the only difference with the classical capacity region of MACs in Theorem 2.2 is that the joint distribution of $X_{1}$ and $X_{2}$ does not have any product form constraints here.

The proof of Theorem 5.5 will be divided in Proposition 5.12 (outer bound part) and Proposition 5.17 (achievability part). But first, let us apply these results to the binary adder channel.

Application to the Binary Adder Channel Let us determine the relaxed non-signaling assisted capacity of the binary adder channel which will be plotted in Figure 6 .
Proposition 5.6. $\mathcal{C}^{\overline{\mathrm{NS}}}\left(W_{\mathrm{BAC}}\right)$ has the following description:

$$
\mathcal{C}^{\overline{\mathrm{NS}}}\left(W_{\mathrm{BAC}}\right)=\bigcup_{q \in\left[\frac{1}{2}, \frac{2}{3}\right]}\left\{\left(R_{1}, R_{2}\right): R_{1} \leq h(q), R_{2} \leq h(q), R_{1}+R_{2} \leq q+h(q)\right\}
$$

Remark. Note that for $q=\frac{1}{2}$, the bound becomes $R_{1} \leq 1, R_{2} \leq 1, R_{1}+R_{2} \leq \frac{3}{2}$ and when $q=\frac{2}{3}$ the bound becomes $R_{1} \leq \log _{2}(3)-\frac{2}{3}, R_{2} \leq \log _{2}(3)-\frac{2}{3}, R_{1}+R_{2} \leq \log _{2}(3)$.

Proof. We use the characterization of $\mathcal{C}^{\overline{\mathrm{NS}}}$ provided by Theorem 5.5
Let us consider an arbitrary $P_{X_{1} X_{2}}=\left(p_{00}, p_{01}, p_{10}, p_{11}\right)$. First, we have that $I\left(\left(X_{1}, X_{2}\right): Y\right)=H(Y)-$ $H\left(Y \mid X_{1} X_{2}\right)=H(Y)$ since $Y$ is a deterministic function of $\left(X_{1}, X_{2}\right)$. Then, we have that $I\left(X_{1}: Y \mid X_{2}\right)=$ $H\left(Y \mid X_{2}\right)-H\left(Y \mid X_{1} X_{2}\right)=H\left(Y \mid X_{2}\right)$ for the same reason. Furthermore, given $X_{2}, Y$ is a deterministic function of $X_{1}$, so we have $I\left(X_{1}: Y \mid X_{2}\right)=H\left(Y \mid X_{2}\right)-H\left(Y \mid X_{1} X_{2}\right)=H\left(X_{1} \mid X_{2}\right)$. Symmetrically we have as well $I\left(X_{2}: Y \mid X_{1}\right)=H\left(X_{2} \mid X_{1}\right)$. In all:

$$
\mathcal{C}^{\overline{\mathrm{NS}}}\left(W_{\mathrm{BAC}}\right)=\bigcup_{P_{X_{1} X_{2}}}\left\{\left(R_{1}, R_{2}\right): R_{1} \leq H\left(X_{1} \mid X_{2}\right), R_{2} \leq H\left(X_{2} \mid X_{1}\right), R_{1}+R_{2} \leq H\left(X_{1}+X_{2}\right)\right\}
$$

Let us call $B_{1}\left(P_{X_{1} X_{2}}\right):=H\left(X_{1} \mid X_{2}\right), B_{2}\left(P_{X_{1} X_{2}}\right):=H\left(X_{2} \mid X_{1}\right), B_{12}\left(P_{X_{1} X_{2}}\right):=H\left(X_{1}+X_{2}\right)$ the three bounds. Let us call $P_{\bar{X}_{1} \bar{X}_{2}}=\left(p_{11}, p_{10}, p_{01}, p_{00}\right)$. One can notice that:

$$
\begin{align*}
B_{1}\left(P_{\bar{X}_{1} \bar{X}_{2}}\right) & =H\left(\bar{X}_{1} \mid \bar{X}_{2}\right)=H\left(1-X_{1} \mid 1-X_{2}\right)=H\left(X_{1} \mid X_{2}\right)=B_{1}\left(P_{X_{1} X_{2}}\right), \\
B_{2}\left(P_{\bar{X}_{1} \bar{X}_{2}}\right) & =H\left(1-X_{2} \mid 1-X_{1}\right)=H\left(X_{2} \mid X_{1}\right)=B_{2}\left(P_{X_{1} X_{2}}\right), \\
B_{12}\left(P_{\bar{X}_{1} \bar{X}_{2}}\right) & =H\left(\bar{X}_{1}+\bar{X}_{2}\right)=H\left(1-X_{1}+1-X_{2}\right)  \tag{42}\\
& =H\left(2-\left(X_{1}+X_{2}\right)\right)=H\left(X_{1}+X_{2}\right)=B_{12}\left(P_{X_{1} X_{2}}\right) .
\end{align*}
$$

Since $B_{12}\left(P_{X_{1} X_{2}}\right)=H\left(X_{1}+X_{2}\right)=H\left(p_{00}, p_{11}, p_{01}+p_{10}\right)$, it is concave in $P_{X_{1} X_{2}}$ as $H$ is concave and $\left(p_{00}, p_{11}, p_{01}+p_{10}\right)$ is linear in $P_{X_{1} X_{2}}$. Also, $B_{1}\left(P_{X_{1} X_{2}}\right)=H\left(X_{1} \mid X_{2}\right)=-D\left(P_{X_{1} X_{2}}| | I \otimes P_{X_{2}}\right)$ is concave in $P_{X_{1} X_{2}}$ as the divergence $D$ is jointly convex and $I \otimes P_{X_{2}}$ is linear in $P_{X_{1} X_{2}}$. By symmetry, $B_{2}\left(P_{X_{1} X_{2}}\right)$
is as well concave in $P_{X_{1} X_{2}}$. Let us consider any of those three bounds, which we call $B$. We have by concavity of $B$ and the fact that $B\left(P_{X_{1} X_{2}}\right)=B\left(P_{\bar{X}_{1} \bar{X}_{2}}\right)$ :

$$
B\left(P_{X_{1} X_{2}}\right)=\frac{B\left(P_{X_{1} X_{2}}\right)+B\left(P_{\bar{X}_{1} \bar{X}_{2}}\right)}{2} \leq B\left(\frac{P_{X_{1} X_{2}}+P_{\hat{X}_{1} \hat{X}_{2}}}{2}\right)=B\left(\frac{q}{2}, \frac{1-q}{2}, \frac{1-q}{2}, \frac{q}{2}\right)
$$

with $q=p_{00}+p_{11}$. This holds for the three bounds at the same time, so we can restrict ourselves to the distributions of the form $\left(\frac{q}{2}, \frac{1-q}{2}, \frac{1-q}{2}, \frac{q}{2}\right)$ for some $q \in[0,1]$, i.e., $P_{X_{1} X_{2}}(0,0)=P_{X_{1} X_{2}}(1,1)=\frac{q}{2}$ and $P_{X_{1} X_{2}}(0,1)=P_{X_{1} X_{2}}(1,0)=\frac{1-q}{2}$.

We have $P_{Y}(0)=P_{Y}(2)=\frac{q}{2}$ and $P_{Y}(1)=1-q$, so:

$$
\begin{align*}
B_{12}\left(P_{X_{1} X_{2}}\right) & =H(Y)=-q \log \left(\frac{q}{2}\right)-(1-q) \log (1-q) \\
& =-q(\log (q)-1)-(1-q) \log (1-q)  \tag{43}\\
& =q+h(q) .
\end{align*}
$$

We have $P_{X_{2}}(0)=P_{X_{1} X_{2}}(0,0)+P_{X_{1} X_{2}}(1,0)=\frac{q}{2}+\frac{1-q}{2}=\frac{1}{2}$ so $P_{X_{2}}(1)=\frac{1}{2}$. Thus:

$$
B_{1}\left(P_{X_{1} X_{2}}\right)=H\left(X_{1} \mid X_{2}\right)=\frac{1}{2} H\left(X_{1} \mid X_{2}=0\right)+\frac{1}{2} H\left(X_{1} \mid X_{2}=1\right) .
$$

We have $P_{X_{1} \mid X_{2}=0}(0)=\frac{P_{X_{1} X_{2}}(0,0)}{P_{X_{2}}(0)}=q$ so $H\left(X_{1} \mid X_{2}=0\right)=h(q)$. On the other hand, we have $P_{X_{1} \mid X_{2}=1}(1)=\frac{P_{X_{1} X_{2}}(1,1)}{P_{X_{2}}(1)}=q$ so we get as well $H\left(Y \mid X_{2}=1\right)=h(q)$, and $B_{1}\left(P_{X_{1} X_{2}}\right)=H\left(X_{1} \mid X_{2}\right)=h(q)$. Symmetrically, we also get $B_{2}\left(P_{X_{1} X_{2}}\right)=h(q)$. Therefore, we get that $\mathcal{C}^{\overline{\mathrm{NS}}}\left(W_{\mathrm{BAC}}\right)$ is the closure of the convex hull of:

$$
\bigcup_{q \in[0,1]}\left\{\left(R_{1}, R_{2}\right): R_{1}<h(q), R_{2}<h(q), R_{1}+R_{2}<q+h(q)\right\} .
$$

However this set is already convex, so we have:

$$
\mathcal{C}^{\overline{\mathrm{NS}}}\left(W_{\mathrm{BAC}}\right)=\bigcup_{q \in[0,1]}\left\{\left(R_{1}, R_{2}\right): R_{1} \leq h(q), R_{2} \leq h(q), R_{1}+R_{2} \leq q+h(q)\right\}
$$

Finally, we can restrict ourselves to $q \in\left[\frac{1}{2}, \frac{2}{3}\right]$, since $h$ is increasing from 0 to $\frac{1}{2}$ (thus $q \mapsto q+h(q)$ as well), and the fact that $q \mapsto q+h(q)$ achieves its maximum for $q=\frac{2}{3}$ with $\frac{2}{3}+h\left(\frac{2}{3}\right)=\log _{2}(3)$ and then decreases (whereas $h$ is decreasing from $\frac{1}{2}$ to 1 ), which completes the proof.

As before, one can also define a symmetrized version of the relaxed linear program computing the value $\mathrm{S}^{\overline{\mathrm{NS}}}\left(W^{\otimes n}, k_{1}, k_{2}\right)$ in polynomial time in $n$ and compute the zero-error $n$-shots capacity region by looking at the rates where $\mathrm{S}^{\overline{\mathrm{NS}}}\left(W^{\otimes n}, k_{1}, k_{2}\right)=1$. We have computed this up to 7 copies of the binary adder channel, which led to Figure 6.

The first noticeable result coming from these curves is that the values $S^{\overline{N S}}$ and $S^{N S}$ differ. While the highest sum-rate of $\frac{2 \log _{2}(42)}{7} \simeq 1.5406$ is achieved on 7 copies of the binary adder channel with zero-error and non-signaling assistance, coming from the fact that $\mathrm{S}^{\mathrm{NS}}\left(W_{\mathrm{BAC}}^{\otimes 7}, 42,42\right)=1$, we have that $S^{\overline{N S}}\left(W_{\mathrm{BAC}}^{\otimes 7}, 44,44\right)=1>\mathrm{S}^{\mathrm{NS}}\left(W_{\mathrm{BAC}}^{\otimes 7}, 44,44\right) \simeq 0.9581$ which implies that a sum-rate of $\frac{2 \log _{2}(44)}{7} \simeq 1.5598$ is achieved on 7 copies of the binary adder channel with zero-error and relaxed non-signaling assistance. It also largely beats the best found sum-rate of $\frac{\log _{2}(72)}{4} \simeq 1.5425$ achieved on 8 copies with the regular version. However the fact that the non-signaling assisted capacity region is strictly contained in the relaxed one is still open, as the same rates could potentially be achieved by the cost of using more copies of the channel.

Figure 6: Comparison of relaxed and regular non-signaling assisted capacity regions of the binary adder channel. The black dashed curve depicts the classical capacity region $\mathcal{C}\left(W_{\mathrm{BAC}}\right)$, whereas the grey dotted curve depicts the relaxed non-signaling assisted capacity region $\mathcal{C}^{\overline{\mathrm{NS}}}\left(W_{\mathrm{BAC}}\right)$ as described in Proposition 5.6 . In particular, the curved corners are obtained by taking $R_{1}=h\left(R_{2}\right)$ for $R_{2} \in\left[\frac{1}{2}, \frac{2}{3}\right]$ and symmetrically by switching the roles played by $R_{1}$ and $R_{2}$. The continuous blue (respectively red) curve depicts the zeroerror (respectively relaxed) non-signaling assisted achievable rate pairs for 7 copies of the binary adder channel.

### 5.1 Outer Bound Part of Theorem 5.5

In order to prove Proposition 5.12, we use a connection between hypothesis testing and relaxed nonsignaling assisted codes as established in [8] for point-to-point channels.

Definition 5.7 (Hypothesis Testing). Given distributions $P^{(0)}$ and $P^{(1)}$ on the same space $C$, we define $\beta_{1-\varepsilon}\left(P^{(0)}, P^{(1)}\right)$ to be the minimum type II error $\sum_{r \in C} T_{r} P^{(1)}(r)$ that can be achieved by statistical tests $T$ which give a type I error no greater than $\varepsilon$, i.e. $\sum_{r \in C} T_{r} P^{(0)}(r) \geq 1-\varepsilon$.

In other words, we have that:

$$
\begin{align*}
\beta_{1-\varepsilon}\left(P^{(0)}, P^{(1)}\right)=\underset{T_{r}}{\operatorname{minimize}} & \sum_{r \in C} T_{r} P^{(1)}(r) \\
\text { subject to } & \sum_{r \in C} T_{r} P^{(0)}(r) \geq 1-\varepsilon  \tag{44}\\
& 0 \leq T_{r} \leq 1 .
\end{align*}
$$

Lemma 5.8. For any relaxed non-signaling assisted code $\left(p_{x_{1}, x_{2}}, r_{x_{1}, x_{2}, y}\right)_{x_{1} \in \mathcal{X}_{1}, x_{2} \in \mathcal{X}_{2}, y \in \mathcal{Y}}$ with $\left(k_{1}, k_{2}\right)$ messages and a probability of success $1-\varepsilon$, if $P_{X_{1} X_{2}}\left(x_{1}, x_{2}\right)=\frac{p_{x_{1}, x_{2}}}{k_{1} k_{2}}$ and $Y \in \mathcal{Y}$ is the outcome of $W$ on
inputs $X_{1}, X_{2}$, we have:

$$
\begin{align*}
& \beta_{1-\varepsilon}\left(P_{X_{1} X_{2} Y}, P_{X_{1} X_{2}} \times P_{Y \mid X_{2}}\right) \leq \frac{1}{k_{1}} \\
& \beta_{1-\varepsilon}\left(P_{X_{1} X_{2} Y}, P_{X_{1} X_{2}} \times P_{Y \mid X_{1}}\right) \leq \frac{1}{k_{2}}  \tag{45}\\
& \beta_{1-\varepsilon}\left(P_{X_{1} X_{2} Y}, P_{X_{1} X_{2}} \times P_{Y}\right) \leq \frac{1}{k_{1} k_{2}} .
\end{align*}
$$

Remark. These three bounds are actually achieved with the same statistical test.
Proof. This result is a direct generalization of Theorem 9 in [8] for point-to-point channels, itself a generalization of Theorem 27 in [35] without non-signaling assistance.

Let us name $W_{0}:=W$ and $W_{1}$ a MAC yet to be defined. The coding strategy described by $r_{x_{1}, x_{2}, y}$ and $p_{x_{1}, x_{2}}$ leads to a probability of success on channel $i \in\{0,1\}$ is given by:

$$
\begin{align*}
1-\varepsilon_{i} & =\frac{1}{k_{1} k_{2}} \sum_{x_{1}, x_{2}, y} r_{x_{1}, x_{2}, y} W_{i}\left(y \mid x_{1} x_{2}\right) \\
& =\sum_{x_{1}, x_{2}, y: p_{x_{1}, x_{2}>0}>} \frac{r_{x_{1}, x_{2}, y}}{p_{x_{1}, x_{2}}} W_{i}\left(y \mid x_{1} x_{2}\right) \frac{p_{x_{1}, x_{2}}}{k_{1} k_{2}} \quad \text { since } 0 \leq r_{x_{1}, x_{2}, y} \leq p_{x_{1}, x_{2}}  \tag{46}\\
& =\sum_{x_{1}, x_{2}, y} T_{x_{1}, x_{2}, y} W_{i}\left(y \mid x_{1} x_{2}\right) \frac{p_{x_{1}, x_{2}}}{k_{1} k_{2}},
\end{align*}
$$

with $T_{x_{1}, x_{2}, y}:=\frac{r_{x_{1}, x_{2}, y}}{p_{x_{1}, x_{2}}}$ if $p_{x_{1}, x_{2}}>0$, and $T_{x_{1}, x_{2}, y}:=0$ otherwise.
If now $Y$ is the output of the channel $W_{i}$, the joint distribution of $X_{1}, X_{2}, Y$ is given by $P_{X_{1} X_{2} Y}^{(i)}\left(x_{1}, x_{2}, y\right)=$ $W_{i}\left(y \mid x_{1} x_{2}\right) P_{X_{1} X_{2}}\left(x_{1}, x_{2}\right)=W_{i}\left(y \mid x_{1} x_{2}\right) \frac{p_{x_{1}, x_{2}}}{k_{1} k_{2}}$.

On the other hand, we have that for all $x_{1}, x_{2}, y, 0 \leq T_{x_{1}, x_{2}, y} \leq 1$ since $0 \leq r_{x_{1}, x_{2}, y} \leq p_{x_{1}, x_{2}}$. So we get that:

$$
1-\varepsilon_{i}=\sum_{x_{1}, x_{2}, y} T_{x_{1}, x_{2}, y} P_{X_{1} X_{2} Y}^{(i)}\left(x_{1}, x_{2}, y\right)
$$

Since $\sum_{x_{1}, x_{2}, y} T_{x_{1}, x_{2}, y} P_{X_{1} X_{2} Y}^{(0)}\left(x_{1}, x_{2}, y\right) \geq 1-\varepsilon_{0}$ and $0 \leq T_{x_{1}, x_{2}, y} \leq 1$, we have:

$$
\beta_{1-\varepsilon_{0}}\left(P^{(0)}, P^{(1)}\right) \leq \sum_{x_{1}, x_{2}, y} T_{x_{1}, x_{2}, y} P_{X_{1} X_{2} Y}^{(1)}\left(x_{1}, x_{2}, y\right)=1-\varepsilon_{1} .
$$

Let us now consider three general cases, depending on the fact that $W_{1}$ does not depend on $x_{1}, x_{2}$ or both: $W_{1}\left(y \mid x_{1} x_{2}\right):=Q^{(1)}\left(y \mid x_{2}\right) ; W_{1}\left(y \mid x_{1} x_{2}\right):=Q^{(2)}\left(y \mid x_{1}\right) ; W_{1}\left(y \mid x_{1} x_{2}\right):=Q^{(0)}(y)$. These will give respectively the three bounds we want.

First, let us consider the case where $W_{1}\left(y \mid x_{1} x_{2}\right):=Q^{(1)}\left(y \mid x_{2}\right)$ (the second case where $W_{1}\left(y \mid x_{1} x_{2}\right):=$ $Q^{(2)}\left(y \mid x_{1}\right)$ being symmetric), we have that:

$$
\begin{align*}
1-\varepsilon_{1} & =\sum_{x_{1}, x_{2}, y} T_{x_{1}, x_{2}, y} Q^{(1)}\left(y \mid x_{2}\right) \frac{p_{x_{1}, x_{2}}}{k_{1} k_{2}}=\frac{1}{k_{1} k_{2}} \sum_{x_{2}, y} Q^{(1)}\left(y \mid x_{2}\right) \sum_{x_{1}} T_{x_{1}, x_{2}, y} p_{x_{1}, x_{2}} \\
& =\frac{1}{k_{1} k_{2}} \sum_{x_{2}, y} Q^{(1)}\left(y \mid x_{2}\right) \sum_{x_{1}} r_{x_{1}, x_{2}, y} \leq \frac{1}{k_{1} k_{2}} \sum_{x_{2}, y} Q^{(1)}\left(y \mid x_{2}\right) \frac{1}{k_{1}} \sum_{x_{1}} p_{x_{1}, x_{2}}  \tag{47}\\
& =\frac{1}{k_{1}} \sum_{x_{1}, x_{2}} \frac{p_{x_{1}, x_{2}}}{k_{1} k_{2}} \sum_{y} Q^{(1)}\left(y \mid x_{2}\right)=\frac{1}{k_{1}} \sum_{x_{1}, x_{2}} \frac{p_{x_{1}, x_{2}}}{k_{1} k_{2}}=\frac{1}{k_{1}} .
\end{align*}
$$

For the third case, when $W_{1}\left(y \mid x_{1} x_{2}\right):=Q^{(0)}(y)$, we have:

$$
\begin{align*}
1-\varepsilon_{1} & =\sum_{x_{1}, x_{2}, y} T_{x_{1}, x_{2}, y} Q^{(0)}(y) \frac{p_{x_{1}, x_{2}}}{k_{1} k_{2}}=\frac{1}{k_{1} k_{2}} \sum_{y} Q^{(0)}(y) \sum_{x_{1}, x_{2}} T_{x_{1}, x_{2}, y} p_{x_{1}, x_{2}}  \tag{48}\\
& =\frac{1}{k_{1} k_{2}} \sum_{y} Q^{(0)}(y) \sum_{x_{1}, x_{2}} r_{x_{1}, x_{2}, y} \leq \frac{1}{k_{1} k_{2}} \sum_{y} Q^{(0)}(y)=\frac{1}{k_{1} k_{2}} .
\end{align*}
$$

In those three cases, we have respectively $P_{X_{1} X_{2} Y}^{(1)}=P_{X_{1} X_{2}} \times Q_{Y \mid X_{2}}^{(1)} ; P_{X_{1} X_{2}} \times Q_{Y \mid X_{1}}^{(2)} ; P_{X_{1} X_{2}} \times Q_{Y}^{(0)}$. Specializing those cases with $Q_{Y \mid X_{2}}^{(1)}:=P_{Y \mid X_{2}} ; Q_{Y \mid X_{1}}^{(2)}:=P_{Y \mid X_{1}} ; Q_{Y}^{(0)}:=P_{Y}$ and using the fact that $\beta_{1-\varepsilon_{0}}\left(P^{(0)}, P^{(1)}\right) \leq 1-\varepsilon_{1}$ concludes the proof.

Lemma 5.9. For any relaxed non-signaling assisted code $\left(p_{x_{1}, x_{2}}, r_{x_{1}, x_{2}, y}\right)_{x_{1} \in \mathcal{X}_{1}, x_{2} \in \mathcal{X}_{2}, y \in \mathcal{Y}}$ with $\left(k_{1}, k_{2}\right)$ messages and a probability of success $1-\varepsilon$, if $P_{X_{1} X_{2}}\left(x_{1}, x_{2}\right)=\frac{p_{x_{1}, x_{2}}}{k_{1} k_{2}}$ and $Y \in \mathcal{Y}$ is the outcome of $W$ on inputs $X_{1}, X_{2}$, we have:

$$
\begin{align*}
\log \left(k_{1}\right) & \leq \frac{I\left(X_{1}: Y \mid X_{2}\right)+h(\varepsilon)}{1-\varepsilon}, \\
\log \left(k_{2}\right) & \leq \frac{I\left(X_{2}: Y \mid X_{1}\right)+h(\varepsilon)}{1-\varepsilon},  \tag{49}\\
\log \left(k_{1}\right)+\log \left(k_{2}\right) & \leq \frac{I\left(\left(X_{1}, X_{2}\right): Y\right)+h(\varepsilon)}{1-\varepsilon} .
\end{align*}
$$

Proof. Thanks to Lemma 5.8, with the fact that $P_{X_{1} X_{2}}=P_{X_{1} \mid X_{2}} \times P_{X_{2}}=P_{X_{2} \mid X_{1}} \times P_{X_{1}}$, we have already:

$$
\begin{align*}
& \beta_{1-\varepsilon}\left(P_{X_{1} X_{2} Y},\left(P_{X_{1} \mid X_{2}} \times P_{Y \mid X_{2}}\right) \times P_{X_{2}}\right) \leq \frac{1}{k_{1}} \\
& \beta_{1-\varepsilon}\left(P_{X_{1} X_{2} Y},\left(P_{X_{2} \mid X_{1}} \times P_{Y \mid X_{1}}\right) \times P_{X_{1}}\right) \leq \frac{1}{k_{2}}  \tag{50}\\
& \beta_{1-\varepsilon}\left(P_{X_{1} X_{2} Y}, P_{X_{1} X_{2}} \times P_{Y}\right) \leq \frac{1}{k_{1} k_{2}}
\end{align*}
$$

Following the steps of section G in [35], since any hypothesis test is a binary-output transformation, by data-processing inequality for divergence, we have that:

$$
\begin{align*}
& d\left(1-\varepsilon \| \beta_{1-\varepsilon}\left(P_{X_{1} X_{2} Y},\left(P_{X_{1} \mid X_{2}} \times P_{Y \mid X_{2}}\right) \times P_{X_{2}}\right)\right) \\
& =d\left(\beta_{1-\varepsilon}\left(P_{X_{1} X_{2} Y}, P_{X_{1} X_{2} Y}\right) \| \beta_{1-\varepsilon}\left(P_{X_{1} X_{2} Y},\left(P_{X_{1} \mid X_{2}} \times P_{Y \mid X_{2}}\right) \times P_{X_{2}}\right)\right)  \tag{51}\\
& \leq D\left(P_{X_{1} X_{2} Y} \|\left(P_{X_{1} \mid X_{2}} \times P_{Y \mid X_{2}}\right) \times P_{X_{2}}\right)=I\left(X_{1}: Y \mid X_{2}\right)
\end{align*}
$$

where the binary divergence $d(a \| b):=a \log \left(\frac{a}{b}\right)+(1-a) \log \left(\frac{1-a}{1-b}\right)$ and satisfies, $d(a \| b) \geq-h(a)-$ $a \log (b)$ and thus:

$$
\log \left(\frac{1}{b}\right) \leq \frac{d(a \| b)+h(a)}{a}=\frac{d(a \| b)+h(1-a)}{a}
$$

This leads to:

$$
\log \left(k_{1}\right) \leq \frac{1}{\log \left(\left(\beta_{1-\varepsilon}\left(P_{X_{1} X_{2} Y},\left(P_{X_{1} \mid X_{2}} \times P_{Y \mid X_{2}}\right) \times P_{X_{2}}\right)\right)\right)} \leq \frac{I\left(X_{1}: Y \mid X_{2}\right)+h(\varepsilon)}{1-\varepsilon} .
$$

Similarly for the two other inequalities, since $D\left(P_{X_{1} X_{2} Y} \|\left(P_{X_{2} \mid X_{1}} \times P_{Y \mid X_{1}}\right) \times P_{X_{1}}\right)=I\left(X_{2}: Y \mid X_{1}\right)$ and $D\left(P_{X_{1} X_{2} Y} \| P_{X_{1} X_{2}} \times P_{Y}\right)=I\left(\left(X_{1}, X_{2}\right): Y\right)$, we get:

$$
\begin{align*}
\log \left(k_{1}\right) & \leq \frac{I\left(X_{1}: Y \mid X_{2}\right)+h(\varepsilon)}{1-\varepsilon}, \\
\log \left(k_{2}\right) & \leq \frac{I\left(X_{2}: Y \mid X_{1}\right)+h(\varepsilon)}{1-\varepsilon},  \tag{52}\\
\log \left(k_{1}\right)+\log \left(k_{2}\right) & \leq \frac{I\left(\left(X_{1}, X_{2}\right): Y\right)+h(\varepsilon)}{1-\varepsilon} .
\end{align*}
$$

In order to show additivity of the outer bound, we use the following lemma.
Lemma 5.10. For any distribution $P_{X_{1}^{n} X_{2}^{n}}$ of $\left(X_{1}^{n}, X_{2}^{n}\right)$, if $Y^{n} \in \mathcal{Y}^{n}$ is the outcome of $W^{n}$ on inputs $X_{1}^{n}, X_{2}^{n}$, we have:

$$
\begin{gather*}
I\left(X_{1}^{n}: Y^{n} \mid X_{2}^{n}\right) \leq \sum_{i=1}^{n} I\left(X_{1, i}: Y_{i} \mid X_{2, i}\right) \\
I\left(X_{2}^{n}: Y^{n} \mid X_{1}^{n}\right) \leq \sum_{i=1}^{n} I\left(X_{2, i}: Y_{i} \mid X_{1, i}\right)  \tag{53}\\
I\left(\left(X_{1}^{n}, X_{2}^{n}\right): Y^{n}\right) \leq \sum_{i=1}^{n} I\left(\left(X_{1, i}, X_{2, i}\right): Y_{i}\right) .
\end{gather*}
$$

Proof. Consider $n$ copies of the MAC $W$. Let us write $X_{1,-i}:=X_{1,1} \ldots X_{1, i-1} X_{1, i+1} \ldots X_{1, n}$ and $Z^{n}:=$ $Z_{1} \ldots Z_{n}$. We have:

$$
\begin{align*}
I\left(X_{1}^{n}: Y^{n} \mid X_{2}^{n}\right) & =I\left(X_{1}^{n}: Y^{n} \mid X_{2}^{n}\right) \\
& =\sum_{i=1}^{n} I\left(X_{1}^{n}: Y_{i} \mid X_{2}^{n} Y^{i-1}\right) \text { by the chain rule } \\
& =\sum_{i=1}^{n} I\left(X_{1, i}: Y_{i} \mid X_{2}^{n} Y^{i-1}\right)+\sum_{i=1}^{n} I\left(X_{1,-i}: Y_{i} \mid X_{2}^{n} Y^{i-1} X_{1, i}\right)  \tag{54}\\
& =\sum_{i=1}^{n} I\left(X_{1, i}: Y_{i} \mid X_{2}^{n} Y^{i-1}\right),
\end{align*}
$$

where the last equality comes from Lemma 5.11. As a result,

$$
\begin{align*}
I\left(X_{1}^{n}: Y^{n} \mid X_{2}^{n}\right) & =\sum_{i=1}^{n} H\left(Y_{i} \mid X_{2}^{n} Y^{i-1}\right)-H\left(Y_{i} \mid X_{2}^{n} Y^{i-1} X_{1, i}\right) \\
& =\sum_{i=1}^{n} H\left(Y_{i} \mid X_{2}^{n} Y^{i-1}\right)-H\left(Y_{i} \mid X_{2, i} X_{1, i}\right) \text { since } X_{2,-i} Y^{i-1} \rightarrow\left(X_{1, i}, X_{2, i}\right) \rightarrow Y_{i} \text { Markov chain. } \\
& \leq \sum_{i=1}^{n} H\left(Y_{i} \mid X_{2, i}\right)-H\left(Y_{i} \mid X_{2, i} X_{1, i}\right)=\sum_{i=1}^{n} I\left(X_{1, i}: Y_{i} \mid X_{2, i}\right) . \tag{55}
\end{align*}
$$

Symmetrically by switching the roles of $X_{1}$ and $X_{2}$, we get the second part of Lemma 5.10.

For the sum-rate case:

$$
\begin{aligned}
I\left(\left(X_{1}^{n}, X_{2}^{n}\right): Y^{n}\right) & =\sum_{i=1}^{n} I\left(\left(X_{1}^{n}, X_{2}^{n}\right): Y_{i} \mid Y^{i-1}\right) \text { by the chain rule } \\
& =\sum_{i=1}^{n} I\left(\left(X_{1, i}, X_{2, i}\right): Y_{i} \mid Y^{i-1}\right)+\sum_{i=1}^{n} I\left(\left(X_{1,-i}, X_{2,-i}\right): Y_{i} \mid Y^{i-1} X_{1, i} X_{2, i}\right) \\
& =\sum_{i=1}^{n} I\left(\left(X_{1, i}, X_{2, i}\right): Y_{i} \mid Y^{i-1}\right) \text { since }\left(X_{1,-i}, X_{2,-i}\right) \rightarrow Y^{i-1} X_{1, i} X_{2, i} \rightarrow Y_{i} \text { Markov chain. } \\
& =\sum_{i=1}^{n} H\left(Y_{i} \mid Y^{i-1}\right)-H\left(Y_{i} \mid Y^{i-1} X_{1, i} X_{2, i}\right) \\
& =\sum_{i=1}^{n} H\left(Y_{i} \mid Y^{i-1}\right)-H\left(Y_{i} \mid X_{1, i} X_{2, i}\right) \text { since } Y^{i-1} \rightarrow\left(X_{1, i}, X_{2, i}\right) \rightarrow Y_{i} \text { Markov chain. } \\
& \leq \sum_{i=1}^{n} H\left(Y_{i}\right)-H\left(Y_{i} \mid X_{2, i} X_{1, i}\right)=\sum_{i=1}^{n} I\left(\left(X_{1, i}, X_{2, i}\right): Y_{i}\right) .
\end{aligned}
$$

We next prove a technical lemma that was used in the previous proof.
Lemma 5.11. For any distribution $P_{X_{1}^{n} X_{2}^{n}}$ of $\left(X_{1}^{n}, X_{2}^{n}\right)$, if $Y^{n} \in \mathcal{Y}^{n}$ is the outcome of $W^{n}$ on inputs $X_{1}^{n}, X_{2}^{n}$, we have:

$$
I\left(X_{1,-i}: Y_{i} \mid X_{1, i} X_{2}^{n} Y^{i-1}\right)=0
$$

Proof. Let us show that, conditioned on any particular instance of $X_{1, i}=x_{i, 1}, X_{2}^{n}=x_{2}^{n}, Y_{1}^{i-1}=y^{i-1}$, $X_{1,-i}$ and $Y_{i}$ are independent.

We have:

$$
\mathbb{P}\left(Y_{i}=y_{i} \mid X_{1, i}=x_{i, 1}, X_{2}^{n}=x_{2}^{n}, Y_{1}^{i-1}=y^{i-1}\right)=\mathbb{P}\left(Y_{i}=y_{i} \mid X_{1, i}=x_{i, 1}, X_{2, i}=x_{2, i}\right)=W\left(y_{i} \mid x_{1, i} x_{2, i}\right),
$$

by definition of the law of $Y_{i}$. On the other hand, we have that:

$$
\mathbb{P}\left(X_{1}^{n}=x_{1}^{n}, X_{2}^{n}=x_{2}^{n}, Y^{n}=y_{n}\right)=\mathbb{P}\left(X_{1}^{n}=x_{1}^{n}, X_{2}^{n}=x_{2}^{n}\right) \prod_{j=1}^{n} W\left(y_{j} \mid x_{1, j} x_{2, j}\right)
$$

Thus, we have:

$$
\begin{align*}
& \mathbb{P}\left(X_{1, i}=x_{i, 1}, X_{2}^{n}=x_{2}^{n}, Y_{1}^{i-1}=y^{i-1}\right)=\sum_{x_{1,-i}, x_{2}^{n}, y_{i}, \ldots, y_{n}} \mathbb{P}\left(X_{1}^{n}=x_{1}^{n}, X_{2}^{n}=x_{2}^{n}\right) \prod_{j=1}^{n} W\left(y_{j} \mid x_{1, j} x_{2, j}\right) \\
& =\sum_{x_{1,-i}, x_{2}^{n}} \mathbb{P}\left(X_{1}^{n}=x_{1}^{n}, X_{2}^{n}=x_{2}^{n}\right) \prod_{j=1}^{i-1} W\left(y_{j} \mid x_{1, j} x_{2, j}\right) \prod_{j=i}^{n}\left(\sum_{y_{j}} W\left(y_{j} \mid x_{1, j} x_{2, j}\right)\right)  \tag{56}\\
& =\sum_{x_{1,-i}, x_{2}^{n}} \mathbb{P}\left(X_{1}^{n}=x_{1}^{n}, X_{2}^{n}=x_{2}^{n}\right) \prod_{j=1}^{i-1} W\left(y_{j} \mid x_{1, j} x_{2, j}\right) .
\end{align*}
$$

And then:
$\mathbb{P}\left(X_{1,-i}=x_{1,-i} \mid X_{1, i}=x_{i, 1}, X_{2}^{n}=x_{2}^{n}, Y_{1}^{i-1}=y^{i-1}\right)=\frac{\sum_{x_{2}^{n}} \mathbb{P}\left(X_{1}^{n}=x_{1}^{n}, X_{2}^{n}=x_{2}^{n}\right) \prod_{j=1}^{i-1} W\left(y_{j} \mid x_{1, j} x_{2, j}\right)}{\sum_{x_{1,-i, x_{2}^{n}}} \mathbb{P}\left(X_{1}^{n}=x_{1}^{n}, X_{2}^{n}=x_{2}^{n}\right) \prod_{j=1}^{i-1} W\left(y_{j} \mid x_{1, j} x_{2, j}\right)}$.

But:

$$
\begin{align*}
& \mathbb{P}\left(X_{1,-i}=x_{1,-i}, Y_{i}=y_{i} \mid X_{1, i}=x_{i, 1}, X_{2}^{n}=x_{2}^{n}, Y_{1}^{i-1}=y^{i-1}\right) \\
& =\frac{\sum_{x_{2}^{n}} \mathbb{P}\left(X_{1}^{n}=x_{1}^{n}, X_{2}^{n}=x_{2}^{n}\right) \prod_{j=1}^{i} W\left(y_{j} \mid x_{1, j} x_{2, j}\right)}{\sum_{x_{1,-i}, x_{2}^{n}} \mathbb{P}\left(X_{1}^{n}=x_{1}^{n}, X_{2}^{n}=x_{2}^{n}\right) \prod_{j=1}^{i-1} W\left(y_{j} \mid x_{1, j} x_{2, j}\right)} \\
& =\mathbb{P}\left(X_{1,-i}=x_{1,-i} \mid X_{1, i}=x_{i, 1}, X_{2}^{n}=x_{2}^{n}, Y_{1}^{i-1}=y^{i-1}\right) W\left(y_{i} \mid x_{1, i} x_{2, i}\right) \\
& =\mathbb{P}\left(X_{1,-i}=x_{1,-i} \mid X_{1, i}=x_{i, 1}, X_{2}^{n}=x_{2}^{n}, Y_{1}^{i-1}=y^{i-1}\right) \mathbb{P}\left(Y_{i}=y_{i} \mid X_{1, i}=x_{i, 1}, X_{2}^{n}=x_{2}^{n}, Y_{1}^{i-1}=y^{i-1}\right) . \tag{57}
\end{align*}
$$

Thus, conditioned on any particular instance of $X_{1, i}=x_{i, 1}, X_{2}^{n}=x_{2}^{n}, Y_{1}^{i-1}=y^{i-1}, X_{1,-i}$ and $Y_{i}$ are independent, and so $I\left(X_{1,-i}: Y_{i} \mid X_{1, i} X_{2}^{n} Y^{i-1}\right)=0$.

Combining the previous results gives the desired outer bound.
Proposition 5.12 (Outer bound part of Theorem 5.5). If a rate pair is achievable with relaxed nonsignaling assistance then it is in the closure of the convex hull of all ( $R_{1}, R_{2}$ ) satisfying:

$$
R_{1}<I\left(X_{1}: Y \mid X_{2}\right), R_{2}<I\left(X_{2}: Y \mid X_{1}\right), R_{1}+R_{2}<I\left(\left(X_{1}, X_{2}\right): Y\right)
$$

for ( $X_{1}, X_{2}$ ) following some law $P_{X_{1} X_{2}}$ on $\mathcal{X}_{1} \times \mathcal{X}_{2}$, and $Y \in \mathcal{Y}$ the outcome of $W$ on inputs $X_{1}, X_{2}$.
Proof. Consider ( $R_{1}, R_{2}$ ) achievable with relaxed non-signaling assistance: we have a sequence of relaxed non-signaling assisted codes for $n$ copies of the MAC $W$ with $k_{1}=2^{n R_{1}}, k_{2}=2^{n R_{2}}$ messages and an error probability $\varepsilon_{n} \underset{n \rightarrow+\infty}{ } 0$, along with associated distributions of $X_{1}^{n} X_{2}^{n} Y^{n}$.

Thus combining Lemma 5.9 and Lemma 5.10, we have that:

$$
\begin{align*}
R_{1} & \leq \frac{1}{n} \frac{I\left(X_{1}^{n}: Y^{n} \mid X_{2}^{n}\right)+h\left(\varepsilon_{n}\right)}{1-\varepsilon_{n}} \leq \frac{1}{n} \frac{\sum_{i=1}^{n} I\left(X_{1, i}: Y_{i} \mid X_{2, i}\right)+h\left(\varepsilon_{n}\right)}{1-\varepsilon_{n}}, \\
R_{2} & \leq \frac{1}{n} \frac{I\left(X_{2}^{n}: Y^{n} \mid X_{1}^{n}\right)+h\left(\varepsilon_{n}\right)}{1-\varepsilon_{n}} \leq \frac{1}{n} \frac{\sum_{i=1}^{n} I\left(X_{2, i}: Y_{i} \mid X_{1, i}\right)+h\left(\varepsilon_{n}\right)}{1-\varepsilon_{n}},  \tag{58}\\
R_{1}+R_{2} & \leq \frac{1}{n} \frac{I\left(\left(X_{1}^{n}, X_{2}^{n}\right): Y^{n}\right)+h\left(\varepsilon_{n}\right)}{1-\varepsilon_{n}} \leq \frac{1}{n} \frac{\sum_{i=1}^{n} I\left(\left(X_{1, i}, X_{2, i}\right): Y_{i}\right)+h\left(\varepsilon_{n}\right)}{1-\varepsilon_{n}} .
\end{align*}
$$

Then let us consider some random variable $Q$ uniform on $[n]$ and independent from ( $X_{1}^{n}, X_{2}^{n}, Y^{n}$ ). Then we can write:

$$
\sum_{i=1}^{n} I\left(X_{1, i}: Y_{i} \mid X_{2, i}\right)=\sum_{i=1}^{n} I\left(X_{1, i}: Y_{i} \mid X_{2, i}, Q=i\right)=n I\left(X_{1, Q}: Y_{Q} \mid X_{2, Q}, Q\right)
$$

Since $Y_{Q}$ conditioned on $X_{1, Q}$ and $X_{2, Q}$ still follows the law of the MAC $W\left(y \mid x_{1} x_{2}\right)$, we can take $X_{1}=X_{1, Q}, X_{2}=X_{2, Q}$, and then the output of the channel $Y$ satisfies $Y=Y_{Q}$, and thus we obtain:

$$
R_{1} \leq \frac{I\left(X_{1}: Y \mid X_{2}, Q\right)+\frac{h\left(\varepsilon_{n}\right)}{n}}{1-\varepsilon_{n}}
$$

Doing this similarly on the other conditional mutual informations, we get:

$$
\begin{align*}
R_{1} & \leq \frac{I\left(X_{1}: Y \mid X_{2}, Q\right)+\frac{h\left(\varepsilon_{n}\right)}{n}}{1-\varepsilon_{n}}, \\
R_{2} & \leq \frac{I\left(X_{2}: Y \mid X_{1}, Q\right)+\frac{h\left(\varepsilon_{n}\right)}{n}}{1-\varepsilon_{n}},  \tag{59}\\
R_{1}+R_{2} & \leq \frac{I\left(\left(X_{1}, X_{2}\right): Y \mid Q\right)+\frac{h\left(\varepsilon_{n}\right)}{n}}{1-\varepsilon_{n}} .
\end{align*}
$$

By taking the limit as $n$ goes to infinity, since the limit of $\varepsilon_{n}$ is 0 , then the limit of $\frac{h\left(\varepsilon_{n}\right)}{n}$ is 0 as well and we get that ( $R_{1}, R_{2}$ ) must be in the set of rate pairs such that:

$$
\begin{align*}
R_{1} & \leq I\left(X_{1}: Y \mid X_{2}, Q\right), \\
R_{2} & \leq I\left(X_{2}: Y \mid X_{1}, Q\right),  \tag{60}\\
R_{1}+R_{2} & \leq I\left(\left(X_{1}, X_{2}\right): Y \mid Q\right),
\end{align*}
$$

for some uniform $Q$ in a finite set, $\left(X_{1}, X_{2}\right)$ any joint law depending on $Q$, and $Y$ the output of $W$ on inputs ( $X_{1}, X_{2}$ ).

Finally, in order to show that this is the right region, one has only to see that the corner points of this region, such as for instance $\left(I\left(X_{1}: Y \mid Q\right), I\left(X_{2}: Y \mid X_{1}, Q\right)\right.$ ), are finite convex combination of the points $\left(I\left(X_{1}: Y \mid Q=q\right), I\left(X_{2}: Y \mid X_{1}, Q=q\right)\right)$ which are all in the capacity region of the theorem by taking $\left(X_{1} X_{2}\right) \sim P_{X_{1} X_{2} \mid Q=q}$. This implies that $\left(R_{1}, R_{2}\right)$ is in the convex hull of that region, so we can drop the random variable $Q$ and the proof is completed.

The main consequence of that outer bound on the relaxed non-signaling assisted capacity region is that it holds also for the non-signaling assisted capacity region thanks to Corollary 5.4.

Corollary 5.13 (Outer Bound on the Non-Signaling Assisted Capacity Region). If a rate pair is achievable with non-signaling assistance, then it is in the closure of the convex hull of all $\left(R_{1}, R_{2}\right)$ satisfying:

$$
R_{1}<I\left(X_{1}: Y \mid X_{2}\right), R_{2}<I\left(X_{2}: Y \mid X_{1}\right), R_{1}+R_{2}<I\left(\left(X_{1}, X_{2}\right): Y\right),
$$

for $\left(X_{1}, X_{2}\right)$ following any law $P_{X_{1} X_{2}}$ on $\mathcal{X}_{1} \times \mathcal{X}_{2}$, and $Y \in \mathcal{Y}$ the outcome of $W$ on inputs $X_{1}, X_{2}$.

### 5.2 Achievability Part of Theorem 5.5

In order to construct the relaxed non-signaling assisted code for achievability, we will need the notions of jointly and conditional typical sets. We will consider the following typical sets defined in Chapter 2.5 of [36]: $\mathcal{T}_{\varepsilon}^{n}\left(X_{1}, X_{2}, Y\right), \mathcal{T}_{\varepsilon}^{n}\left(X_{1}, X_{2}\right), \mathcal{T}_{\varepsilon}^{n}(Y), \mathcal{T}_{\varepsilon}^{n}\left(X_{1} \mid x_{2}^{n}\right), \mathcal{T}_{\varepsilon}^{n}\left(X_{2} \mid x_{1}^{n}\right), \mathcal{T}_{\varepsilon}^{n}\left(X_{1} \mid x_{2}^{n}, y^{n}\right), \mathcal{T}_{\varepsilon}^{n}\left(X_{2} \mid x_{1}^{n}, y^{n}\right)$, $\mathcal{T}_{\varepsilon}^{n}\left(X_{1}, X_{2} \mid y^{n}\right)$. Recall that:

Definition 5.14 (Typical set and conditional typical set). We have the following definitions:

1. $\mathcal{T}_{\varepsilon}^{n}\left(X_{1}, X_{2}\right):=\left\{\left(x_{1}^{n}, x_{2}^{n}\right):\left|\pi\left(x_{1}, x_{2} \mid x_{1}^{n}, x_{2}^{n}\right)-P_{X_{1} X_{2}}\left(x_{1}, x_{2}\right)\right| \leq \varepsilon P_{X_{1} X_{2}}\left(x_{1}, x_{2}\right)\right.$ for all $\left.\left(x_{1}, x_{2}\right) \in \mathcal{X}_{1} \times \mathcal{X}_{2}\right\}$ where $\pi\left(x_{1}, x_{2} \mid x_{1}^{n}, x_{2}^{n}\right):=\frac{\left|\left\{i:\left(x_{1, i}, x_{2, i}\right)=\left(x_{1}, x_{2}\right)\right\}\right|}{n}$. This definition generalizes for any $t$-uple of variables.
2. $\forall y^{n} \in \mathcal{T}_{\varepsilon}^{n}(Y), \mathcal{T}_{\varepsilon}^{n}\left(X_{1}, X_{2} \mid y^{n}\right):=\left\{\left(x_{1}^{n}, x_{2}^{n}\right):\left(x_{1}^{n}, x_{2}^{n}, y^{n}\right) \in \mathcal{T}_{\varepsilon}^{n}\left(X_{1}, X_{2}, Y\right)\right\}$

A crucial property of such typical sets is the typical average lemma:

Lemma 5.15 (Typical Average Lemma [36]). Let $\left(x_{1}^{n}, x_{2}^{n}\right) \in \mathcal{T}_{\varepsilon}^{n}\left(X_{1}, X_{2}\right)$. Then for any nonnegative function $g$ on $\mathcal{X}_{1} \times \mathcal{X}_{2}$ :

$$
(1-\varepsilon) \mathbb{E}\left[g\left(X_{1}, X_{2}\right)\right] \leq \frac{1}{n} \sum_{i=1}^{n} g\left(x_{1, i}, x_{2, i}\right) \leq(1+\varepsilon) \mathbb{E}\left[g\left(X_{1}, X_{2}\right)\right] .
$$

In particular, with this tool, we can derive the following properties:
Lemma 5.16 (Properties of typical sets [36]). We have, among others, the following statements about typical sets:

1. $\forall\left(x_{1}^{n}, x_{2}^{n}\right) \in \mathcal{T}_{\varepsilon}^{n}\left(X_{1}, X_{2}\right), 2^{-n(1+\varepsilon) H\left(X_{1}, X_{2}\right)} \leq P_{X_{1}^{n} X_{2}^{n}}\left(x_{1}^{n}, x_{2}^{n}\right) \leq 2^{-n(1-\varepsilon) H\left(X_{1}, X_{2}\right)}$.
2. $\lim _{n \rightarrow+\infty} \mathbb{P}\left(\left(X_{1}^{n}, X_{2}^{n}\right) \in \mathcal{T}_{\varepsilon}^{n}\left(X_{1}, X_{2}\right)\right)=1$.
3. $\left|\mathcal{T}_{\varepsilon}^{n}\left(X_{1}, X_{2}\right)\right| \leq 2^{n(1+\varepsilon) H\left(X_{1}, X_{2}\right)}$.
4. For $n$ sufficiently large, $\left|\mathcal{T}_{\varepsilon}^{n}\left(X_{1}, X_{2}\right)\right| \geq(1-\varepsilon) 2^{n(1-\varepsilon) H\left(X_{1}, X_{2}\right)}$.
5. If $\left(x_{1}^{n}, x_{2}^{n}\right) \in \mathcal{T}_{\varepsilon}^{n}\left(X_{1}, X_{2}\right)$ then $x_{1}^{n} \in \mathcal{T}_{\varepsilon}^{n}\left(X_{1}\right)$ and $x_{2}^{n} \in \mathcal{T}_{\varepsilon}^{n}\left(X_{2}\right)$.
6. $\forall y^{n} \in \mathcal{T}_{\varepsilon}^{n}(Y), \mathcal{T}_{\varepsilon}^{n}\left(X_{1}, X_{2} \mid y^{n}\right) \subseteq \mathcal{T}_{\varepsilon}^{n}\left(X_{1}, X_{2}\right)$.
7. $\forall\left(x_{1}^{n}, x_{2}^{n}, y^{n}\right) \in \mathcal{T}_{\varepsilon}^{n}\left(X_{1}, X_{2}, Y\right), 2^{-n(1+\varepsilon) H\left(X_{1}, X_{2} \mid Y\right)} \leq P_{X_{1}^{n} X_{2}^{n} Y^{n}}\left(x_{1}^{n}, x_{2}^{n} \mid y^{n}\right) \leq 2^{-n(1-\varepsilon) H\left(X_{1}, X_{2} \mid Y\right)}$.
8. $\forall y^{n} \in \mathcal{T}_{\varepsilon}^{n}(Y),\left|\mathcal{T}_{\varepsilon}^{n}\left(X_{1}, X_{2} \mid y^{n}\right)\right| \leq 2^{n(1+\varepsilon) H\left(X_{1}, X_{2} \mid Y\right)}$.
9. For $\varepsilon^{\prime}<\varepsilon$ and $n$ sufficiently large, we get $\forall y^{n} \in \mathcal{T}_{\varepsilon^{\prime}}^{n}(Y),\left|\mathcal{T}_{\varepsilon}^{n}\left(X_{1}, X_{2} \mid y^{n}\right)\right| \geq(1-\varepsilon) 2^{n(1-\varepsilon) H\left(X_{1}, X_{2} \mid Y\right)}$.

Proof. We reproduce the proof of the last statement here to emphasize on the fact that there is an $n_{0}$ such that for all $n \geq n_{0}$ and for all $y^{n} \in \mathcal{T}_{\varepsilon^{\prime}}^{n}(Y)$, the property holds.

For any $\varepsilon>\varepsilon^{\prime}>0$, let us show that there exists $n$ such that we have:

$$
\forall y^{n} \in \mathcal{T}_{\varepsilon^{\prime}}^{n}(Y), \mathbb{P}\left(\left(X_{1}^{n}, X_{2}^{n}, y^{n}\right) \in \mathcal{T}_{\varepsilon}^{n}\left(X_{1}, X_{2}, Y\right)\right) \geq 1-\varepsilon,
$$

where $X_{1}^{n}, X_{2}^{n}$ are drawn from the distribution $P_{X_{1}^{n} X_{2}^{n} \mid Y^{n}=y^{n}}$. This will imply the statement. Indeed, we have that:

$$
\begin{align*}
\mathbb{P}\left(\left(X_{1}^{n}, X_{2}^{n}, y^{n}\right) \in \mathcal{T}_{\varepsilon}^{n}\left(X_{1}, X_{2}, Y\right)\right) & =\sum_{\left(x_{1}^{n}, x_{2}^{n}\right) \in \mathcal{T}_{\varepsilon}^{n}\left(X_{1}, X_{2} \mid y^{n}\right)} P_{X_{1}^{n} X_{2}^{n} \mid Y^{n}}\left(x_{1}^{n}, x_{2}^{n} \mid y^{n}\right)  \tag{61}\\
& \leq\left|\mathcal{T}_{\varepsilon}^{n}\left(X_{1}, X_{2} \mid y^{n}\right)\right| 2^{-n(1-\varepsilon) H\left(X_{1}, X_{2} \mid Y\right)},
\end{align*}
$$

since $P_{X_{1}^{n} X_{2}^{n} \mid Y^{n}}\left(x_{1}^{n}, x_{2}^{n} \mid y^{n}\right) \leq 2^{-n(1-\varepsilon) H\left(X_{1}, X_{2} \mid Y\right)}$ as $\left(x_{1}^{n}, x_{2}^{n}, y^{n}\right) \in \mathcal{T}_{\varepsilon}^{n}\left(X_{1}, X_{2}, Y\right)$. Thus, we have that $\left|\mathcal{T}_{\varepsilon}^{n}\left(X_{1}, X_{2} \mid y^{n}\right)\right| \geq(1-\varepsilon) 2^{n(1-\varepsilon) H\left(X_{1}, X_{2} \mid Y\right)}$. In order to prove our result, we take the proof in Appendix 2A of [36]. We take $y^{n} \in \mathcal{T}_{\varepsilon^{\prime}}^{n}(\mathcal{Y})$ and $\left(X_{1}^{n}, X_{2}^{n}\right) \sim P_{X_{1}^{n} X_{2}^{n} \mid Y^{n}}\left(x_{1}^{n}, x_{2}^{n} \mid y^{n}\right)=\prod_{i=1}^{n} P_{X_{1} X_{2} \mid Y}\left(x_{1, i}, x_{2, i} \mid y_{i}\right)$. Applied to our choice of variables, we have the following result :

$$
\begin{align*}
& \mathbb{P}\left(\left(X_{1}^{n}, X_{2}^{n}, y^{n}\right) \notin \mathcal{T}_{\varepsilon}^{n}\left(X_{1}, X_{2}, Y\right)\right) \\
& =\mathbb{P}\left(\exists\left(x_{1}, x_{2}, y\right):\left|\pi\left(x_{1}, x_{2}, y \mid X_{1}^{n}, X_{2}^{n}, y^{n}\right)-P_{X_{1} X_{2} Y}\left(x_{1}, x_{2}, y\right)\right|>\varepsilon P_{X_{1} X_{2} Y}\left(x_{1}, x_{2}, y\right)\right) \\
& \leq \sum_{x_{1}, x_{2}, y} \mathbb{P}\left(\left|\pi\left(x_{1}, x_{2}, y \mid X_{1}^{n}, X_{2}^{n}, y^{n}\right)-P_{X_{1} X_{2} Y}\left(x_{1}, x_{2}, y\right)\right|>\varepsilon P_{X_{1} X_{2} Y}\left(x_{1}, x_{2}, y\right)\right) \text { by union bound, } \\
& =\sum_{x_{1}, x_{2}, y} \mathbb{P}\left(\left|\frac{\pi\left(x_{1}, x_{2}, y \mid X_{1}^{n}, X_{2}^{n}, y^{n}\right)}{P_{X_{1} X_{2} Y}\left(x_{1}, x_{2}, y\right)}-1\right|>\varepsilon\right) \\
& =\sum_{x_{1}, x_{2}, y} \mathbb{P}\left(\left|\frac{\pi\left(x_{1}, x_{2}, y \mid X_{1}^{n}, X_{2}^{n}, y^{n}\right)}{P_{X_{1} X_{2} \mid Y}\left(x_{1}, x_{2} \mid y\right) \pi\left(y \mid y^{n}\right)} \frac{\pi\left(y \mid y^{n}\right)}{P_{Y}(y)}-1\right|>\varepsilon\right)  \tag{62}\\
& \leq \sum_{x_{1}, x_{2}, y} \mathbb{P}\left(\frac{\pi\left(x_{1}, x_{2}, y \mid X_{1}^{n}, X_{2}^{n}, y^{n}\right)}{\pi\left(y \mid y^{n}\right)}>\frac{1+\varepsilon}{1+\varepsilon^{\prime}} P_{X_{1} X_{2} \mid Y}\left(x_{1}, x_{2} \mid y\right)\right) \\
& +\sum_{x_{1}, x_{2}, y} \mathbb{P}\left(\frac{\pi\left(x_{1}, x_{2}, y \mid X_{1}^{n}, X_{2}^{n}, y^{n}\right)}{\pi\left(y \mid y^{n}\right)}<\frac{1-\varepsilon}{1-\varepsilon^{\prime}} P_{X_{1} X_{2} \mid Y}\left(x_{1}, x_{2} \mid y\right)\right)
\end{align*}
$$

since $y^{n} \in \mathcal{T}_{\varepsilon^{\prime}}^{n}(\mathcal{Y})$ and thus $1-\varepsilon^{\prime} \leq \frac{\pi\left(y \mid y^{n}\right)}{P_{Y}(y)} \leq 1+\varepsilon^{\prime}$. However, since $\varepsilon^{\prime}<\varepsilon$, we have $\frac{1+\varepsilon}{1+\varepsilon^{\prime}}>1$ and $\frac{1-\varepsilon}{1-\varepsilon^{\prime}}<1$. We will show that for all $x_{1}, x_{2}, y$ with $P_{Y}(y)>0$, we have $\frac{\pi\left(x_{1}, x_{2}, y \mid X_{1}^{n}, X_{2}^{n}, y^{n}\right)}{\pi\left(y \mid y^{n}\right)} \underset{n \rightarrow+\infty}{\rightarrow} P_{X_{1} X_{2} \mid Y}\left(x_{1}, x_{2} \mid y\right)$ in probability, with a convergence rate independent from $y^{n} \in \mathcal{T}_{\varepsilon^{\prime}}^{n}(Y)$, which will be enough to conclude the proof.

Let us fix some $x_{1}, x_{2}$, $y$ with $P_{Y}(y)>0$. Since $y^{n} \in \mathcal{T}_{\varepsilon^{\prime}}^{n}(Y)$, we have in particular $\left(1-\varepsilon^{\prime}\right) P_{Y}(y) \leq$ $\pi\left(y \mid y^{n}\right) \leq\left(1+\varepsilon^{\prime}\right) P_{Y}(y)$. Thus $N:=\left|\left\{i: y_{i}=y\right\}\right|=n \pi\left(y \mid y^{n}\right) \geq\left(1-\varepsilon^{\prime}\right) P_{Y}(y) n$. Then we have:

$$
\frac{\pi\left(x_{1}, x_{2}, y \mid X_{1}^{n}, X_{2}^{n}, y^{n}\right)}{\pi\left(y \mid y^{n}\right)}=\frac{1}{N} \sum_{i \in S} Z_{i} \text { with } Z_{i}:=\mathbb{1}_{\left(X_{1, i}, X_{2, i}\right)=\left(x_{1}, x_{2}\right)} \text { and } S:=\left\{i: y_{i}=y\right\}
$$

Thus, all $Z_{i}$ with $i \in S$ are independent and follow the same law:

$$
Z_{i}:= \begin{cases}1 & \text { with probability } P_{X_{1} X_{2} \mid Y}\left(x_{1}, x_{2} \mid y\right) \\ 0 & \text { otherwise }\end{cases}
$$

Furthermore, we have $\mathbb{E}\left[Z_{i}\right]=P_{X_{1} X_{2} \mid Y}\left(x_{1}, x_{2} \mid y\right)$, and all $Z_{i}$ have the same variance $\sigma_{x_{1}, x_{2} \mid y}^{2}<+\infty$ (depending only on $X_{1}, X_{2}, Y, x_{1}, x_{2}, y$ ). Thus we can apply Chebyshev inequality:

$$
\mathbb{P}\left(\left|\frac{1}{N} \sum_{i \in S} Z_{i}-P_{X_{1} X_{2} \mid Y}\left(x_{1}, x_{2} \mid y\right)\right| \geq \eta\right) \leq \frac{\sigma_{x_{1}, x_{2} \mid y}^{2}}{N \eta^{2}} .
$$

However, since $N \geq\left(1-\varepsilon^{\prime}\right) P_{Y}(y) n$, we get:

$$
\mathbb{P}\left(\left|\frac{\pi\left(x_{1}, x_{2}, y \mid X_{1}^{n}, X_{2}^{n}, y^{n}\right)}{\pi\left(y \mid y^{n}\right)}-P_{X_{1} X_{2} \mid Y}\left(x_{1}, x_{2} \mid y\right)\right| \geq \eta\right) \leq \frac{\sigma_{x_{1}, x_{2} \mid y}^{2}}{\eta^{2}\left(1-\varepsilon^{\prime}\right) P_{Y}(y) n} \underset{n \rightarrow+\infty}{\rightarrow} 0 .
$$

Thus, we have $\frac{\pi\left(x_{1}, x_{2}, y \mid X_{1}^{n}, X_{2}^{n}, y^{n}\right)}{\pi\left(y \mid y^{n}\right)} \underset{n \rightarrow+\infty}{\rightarrow} P_{X_{1} X_{2} \mid Y}\left(x_{1}, x_{2} \mid y\right)$ in probability with a convergence rate independent from $y^{n} \in \mathcal{T}_{\varepsilon^{\prime}}^{n}(Y)$.

Proposition 5.17 (Achievability part of Theorem 5.5). If a rate pair is in the closure of the convex hull of ( $R_{1}, R_{2}$ ) satisfying:

$$
R_{1}<I\left(X_{1}: Y \mid X_{2}\right), R_{2}<I\left(X_{2}: Y \mid X_{1}\right), R_{1}+R_{2}<I\left(\left(X_{1}, X_{2}\right): Y\right),
$$

for ( $X_{1}, X_{2}$ ) following some law $P_{X_{1} X_{2}}$ on $\mathcal{X}_{1} \times \mathcal{X}_{2}$, and $Y \in \mathcal{Y}$ the outcome of $W$ on inputs $X_{1}, X_{2}$, then it is in $\mathcal{C}^{\overline{\mathrm{NS}}}(W)$.
Proof. Let us fix $\varepsilon, \varepsilon^{\prime} \in(0,1)$ such that $\varepsilon^{\prime}<\varepsilon \leq \frac{1}{2}$. Let $n \in \mathbb{N}$ which will be chosen large enough during the proof.

We consider $n$ independent random variables $\left(X_{1, i} X_{2, i} Y_{i}\right) \sim P_{X_{1} X_{2} Y}$, with $P_{X_{1} X_{2} Y}\left(x_{1, i}, x_{2, i}, y_{i}\right)=$ $W\left(y_{i} \mid x_{1, i} x_{2, i}\right) P_{X_{1} X_{2}}\left(x_{1, i}, x_{2, i}\right)$. We call $P_{X_{1}^{n} X_{2}^{n} Y^{n}}$ the law of their product. We have then $P_{X_{1}^{n} X_{2}^{n}}\left(x_{1}^{n}, x_{2}^{n}\right):=$ $\prod_{i=1}^{n} P_{X_{1} X_{2}}\left(x_{1, i}, x_{2, i}\right)$. If $\hat{Y}$ is the output of $W^{\otimes n}$ on $X_{1}^{n} X_{2}^{n}$, we have that:

$$
\begin{align*}
P_{X_{1}^{n} X_{2}^{n} \hat{Y}}\left(x_{1}^{n}, x_{2}^{n}, y^{n}\right) & =W^{\otimes n}\left(y^{n} \mid x_{1}^{n} x_{2}^{n}\right) P_{X_{1}^{n} X_{2}^{n}}\left(x_{1}^{n}, x_{2}^{n}\right)=W^{\otimes n}\left(y^{n} \mid x_{1}^{n} x_{2}^{n}\right) \prod_{i=1}^{n} P_{X_{1} X_{2}}\left(x_{1, i}, x_{2, i}\right) \\
& =\prod_{i=1}^{n} W\left(y_{i} \mid x_{1, i} x_{2, i}\right) P_{X_{1} X_{2}}\left(x_{1, i}, x_{2, i}\right)=\prod_{i=1}^{n} P_{X_{1} X_{2} Y}\left(x_{1, i}, x_{2, i}, y_{i}\right) \tag{63}
\end{align*}
$$

Thus, $\hat{Y}$ follows the product law of $Y_{i}$, i.e. $\hat{Y}=Y^{n}$.
Let us consider $C_{1}, C_{2}, C_{3}$ some positive numbers independent from $n$ and $\varepsilon$ which we will define later, $k_{1}=2^{n R_{1}}, k_{2}=2^{n R_{2}}$ integers with ( $R_{1}, R_{2}$ ) positive rates such that:

$$
\begin{align*}
R_{1} & \leq I\left(X_{1}: Y \mid X_{2}\right)-\frac{1}{n}-C_{1} \varepsilon, \\
R_{2} & \leq I\left(X_{2}: Y \mid X_{1}\right)-\frac{1}{n}-C_{2} \varepsilon,  \tag{64}\\
R_{1}+R_{2} & \leq I\left(\left(X_{1}, X_{2}\right): Y\right)-\frac{1}{n}-C_{3} \varepsilon .
\end{align*}
$$

We define a solution of $S^{\overline{N S}}\left(W^{\otimes n}, 2^{n R_{1}}, 2^{n R_{2}}\right)$ in the following way:

$$
p_{x_{1}^{n}, x_{2}^{n}}:= \begin{cases}\frac{2^{n\left(R_{1}+R_{2}\right)} P_{X_{1}^{n}} X_{2}^{n}\left(x_{1}^{n}, x_{2}^{n}\right)}{\sum_{\left(x_{1}^{n}, x_{2}^{n}\right) \in \mathcal{T}_{\varepsilon}^{n}\left(X_{1}, X_{2}\right)} P_{X_{1}^{n} X_{2}^{n}\left(x_{1}^{n}, x_{2}^{n}\right)}} & \text { if }\left(x_{1}^{n}, x_{2}^{n}\right) \in \mathcal{T}_{\varepsilon}^{n}\left(X_{1}, X_{2}\right) \\ 0 \text { otherwise }\end{cases}
$$

and

$$
r_{x_{1}^{n}, x_{2}^{n}, y^{n}}:= \begin{cases}p_{x_{1}^{n}, x_{2}^{n}} & \text { if }\left(x_{1}^{n}, x_{2}^{n}, y^{n}\right) \in \mathcal{T}_{\varepsilon^{\prime}}^{n}\left(X_{1}, X_{2}, Y\right) \\ 0 & \text { otherwise }\end{cases}
$$

By construction, the constraint $0 \leq r_{x_{1}^{n}, x_{2}^{n}, y^{n}} \leq p_{x_{1}^{n}, x_{2}^{n}}$ is satisfied. We have also that:

$$
\sum_{x_{1}^{n}, x_{2}^{n}} p_{x_{1}^{n}, x_{2}^{n}}=\sum_{\left(x_{1}^{n}, x_{2}^{n}\right) \in \mathcal{T}_{\varepsilon}^{n}\left(X_{1}, X_{2}\right)} \frac{2^{n\left(R_{1}+R_{2}\right)} P_{X_{1}^{n} X_{2}^{n}}\left(x_{1}^{n}, x_{2}^{n}\right)}{\sum_{\left(x_{1}^{n}, x_{2}^{n}\right) \in \mathcal{T}_{\varepsilon}^{n}\left(X_{1}, X_{2}\right)} P_{X_{1}^{n} X_{2}^{n}}\left(x_{1}^{n}, x_{2}^{n}\right)}=2^{n\left(R_{1}+R_{2}\right)}=k_{1} k_{2}
$$

If $\left(x_{1}^{n}, x_{2}^{n}, y^{n}\right) \in \mathcal{T}_{\varepsilon^{\prime}}^{n}\left(X_{1}, X_{2}, Y\right)$, we have that $\left(x_{1}^{n}, x_{2}^{n}\right) \in \mathcal{T}_{\varepsilon^{\prime}}^{n}\left(X_{1}, X_{2}\right) \subseteq \mathcal{T}_{\varepsilon}^{n}\left(X_{1}, X_{2}\right)$, so in that case:

$$
r_{x_{1}^{n}, x_{2}^{n}, y^{n}}=\frac{2^{n\left(R_{1}+R_{2}\right)} P_{X_{1}^{n} X_{2}^{n}}\left(x_{1}^{n}, x_{2}^{n}\right)}{\sum_{\left(x_{1}^{n}, x_{2}^{n}\right) \in \mathcal{T}_{\varepsilon}^{n}\left(X_{1}, X_{2}\right)} P_{X_{1}^{n} X_{2}^{n}}\left(x_{1}^{n}, x_{2}^{n}\right)} .
$$

If $y^{n} \notin \mathcal{T}_{\varepsilon^{\prime}}^{n}(Y)$, then for all $\left(x_{1}^{n}, x_{2}^{n}\right),\left(x_{1}^{n}, x_{2}^{n}, y^{n}\right) \notin \mathcal{T}_{\varepsilon^{\prime}}^{n}\left(X_{1}, X_{2}, Y\right)$, so $\sum_{x_{1}^{n}, x_{2}^{n}} r_{x_{1}^{n}, x_{2}^{n}, y^{n}}=0 \leq 1$ in that case.

Otherwise, if $y^{n} \in \mathcal{T}_{\mathcal{E}^{\prime}}^{n}(Y)$, then:

$$
\begin{align*}
& \sum_{x_{1}^{n}, x_{2}^{n}} r_{x_{1}^{n}, x_{2}^{n}, y^{n}}=2^{n\left(R_{1}+R_{2}\right)} \frac{\sum_{\left(x_{1}^{n}, x_{2}^{n}\right) \in \mathcal{T}_{\varepsilon^{\prime}}^{n}\left(X_{1}, X_{2} \mid y^{n}\right)} P_{X_{1}^{n} X_{2}^{n}}\left(x_{1}^{n}, x_{2}^{n}\right)}{\sum_{\left(x_{1}^{n}, x_{2}^{n}\right) \in \mathcal{T}_{\varepsilon}^{n}\left(X_{1}, X_{2}\right)} P_{X_{1}^{n} X_{2}^{n}}\left(x_{1}^{n}, x_{2}^{n}\right)} \\
& \leq 2^{n\left(R_{1}+R_{2}\right)} \frac{\sum_{\left(x_{1}^{n}, x_{2}^{n}\right) \in \mathcal{T}_{\varepsilon}^{n}\left(X_{1}, X_{2} \mid y^{n}\right)} P_{X_{1}^{n} X_{2}^{n}}\left(x_{1}^{n}, x_{2}^{n}\right)}{\sum_{\left(x_{1}^{n}, x_{2}^{n}\right) \in \mathcal{T}_{\varepsilon}^{n}\left(X_{1}, X_{2}\right)} P_{X_{1}^{n} X_{2}^{n}}\left(x_{1}^{n}, x_{2}^{n}\right)}  \tag{65}\\
& \leq 2^{n\left(R_{1}+R_{2}\right)} \frac{2^{-n(1-\varepsilon) H\left(X_{1}, X_{2}\right)}}{2^{-n(1+\varepsilon) H\left(X_{1}, X_{2}\right)}} \frac{\left|\mathcal{T}_{\varepsilon}^{n}\left(X_{1}, X_{2} \mid y^{n}\right)\right|}{\left|\mathcal{T}_{\varepsilon}^{n}\left(X_{1}, X_{2}\right)\right|} \text { since }\left(x_{1}^{n}, x_{2}^{n}\right) \in \mathcal{T}_{\varepsilon}^{n}\left(X_{1}, X_{2}\right) \\
& =2^{n\left(R_{1}+R_{2}+2 \varepsilon H\left(X_{1}, X_{2}\right)\right)} \frac{\left|\mathcal{T}_{\varepsilon}^{n}\left(X_{1}, X_{2} \mid y^{n}\right)\right|}{\left|\mathcal{T}_{\varepsilon}^{n}\left(X_{1}, X_{2}\right)\right|} \text {. }
\end{align*}
$$

But $\left|\mathcal{T}_{\varepsilon}^{n}\left(X_{1}, X_{2} \mid y^{n}\right)\right| \leq 2^{n(1+\varepsilon) H\left(X_{1}, X_{2} \mid Y\right)}$ and for a large enough $n$ we have that $\left|\mathcal{T}_{\varepsilon}^{n}\left(X_{1}, X_{2}\right)\right| \geq$ $(1-\varepsilon) 2^{n(1-\varepsilon) H\left(X_{1}, X_{2}\right)} \geq 2^{n\left((1-\varepsilon) H\left(X_{1}, X_{2}\right)-\frac{1}{n}\right)}$, so in that case:

$$
\sum_{x_{1}^{n}, x_{2}^{n}} r_{x_{1}^{n}, x_{2}^{n}, y^{n}} \leq 2^{n\left(R_{1}+R_{2}+2 \varepsilon H\left(X_{1}, X_{2}\right)\right)} \frac{2^{n(1+\varepsilon) H\left(X_{1}, X_{2} \mid Y\right)}}{2^{n\left((1-\varepsilon) H\left(X_{1}, X_{2}\right)-\frac{1}{n}\right)}}=2^{n\left(R_{1}+R_{2}-I\left(X_{1}, X_{2}: Y\right)+\frac{1}{n}+C_{3} \varepsilon\right)} \leq 1,
$$

since $I\left(X_{1}, X_{2}: Y\right)=H\left(X_{1}, X_{2}\right)-H\left(X_{1}, X_{2} \mid Y\right)$ and $R_{1}+R_{2} \leq I\left(X_{1}, X_{2}: Y\right)-\frac{1}{n}-C_{3} \varepsilon$, with $C_{3}:=H\left(X_{1}, X_{2} \mid Y\right)+3 H\left(X_{1}, X_{2}\right)$.

Let us focus on the constraint $\sum_{x_{1}^{n}} p_{x_{1}^{n}, x_{2}^{n}} \geq k_{1} \sum_{x_{1}^{n}} r_{x_{1}^{n}, x_{2}^{n}, y^{n}}$ (the symmetric constraint $\sum_{x_{2}^{n}} p_{x_{1}^{n}, x_{2}^{n}} \geq$ $k_{2} \sum_{x_{2}^{n}} r_{x_{1}^{n}, x_{2}^{n}, y^{n}}$ will be achieved for symmetric reasons).

Let us fix $\left(x_{2}^{n}, y^{n}\right)$. If $\left(x_{2}^{n}, y^{n}\right) \notin \mathcal{T}_{\varepsilon^{\prime}}^{n}\left(X_{2}, Y\right)$, then for all $x_{1}^{n},\left(x_{1}^{n}, x_{2}^{n}, y^{n}\right) \notin \mathcal{T}_{\varepsilon^{\prime}}^{n}\left(X_{1}, X_{2}, Y\right)$, thus $r_{x_{1}^{n}, x_{2}^{n}, y^{n}}=0$ and the constraint is fulfilled. Let us assume that $\left(x_{2}^{n}, y^{n}\right) \in \mathcal{T}_{\varepsilon^{\prime}}^{n}\left(X_{2}, Y\right)$. Since $r_{x_{1}^{n}, x_{2}^{n}, y^{n}}>0$ implies that $\left(x_{1}^{n}, x_{2}^{n}, y^{n}\right) \in \mathcal{T}_{\varepsilon^{\prime}}^{n}\left(X_{1}, X_{2}, Y\right)$, we have that:

$$
\sum_{x_{1}^{n}} r_{x_{1}^{n}, x_{2}^{n}, y^{n}}=\sum_{x_{1}^{n} \in \mathcal{T}_{\varepsilon^{\prime}}^{n}\left(X_{1} \mid x_{2}^{n}, y^{n}\right)} r_{x_{1}^{n}, x_{2}^{n}, y^{n}}=\sum_{x_{1}^{n} \in \mathcal{T}_{\varepsilon^{\prime}}^{n}\left(X_{1} \mid x_{2}^{n}, y^{n}\right)} p_{x_{1}^{n}, x_{2}^{n}} .
$$

Thus:

$$
\begin{align*}
& \frac{\sum_{x_{1}^{n}} p_{x_{1}^{n}, x_{2}^{n}}^{k_{1} \sum_{x_{1}^{n}} r_{x_{1}^{n}, x_{2}^{n}, y^{n}}}}{} \geq \frac{1}{k_{1}} \frac{\sum_{x_{1} \in \mathcal{T}_{\varepsilon}^{n}\left(X_{1} \mid x_{2}^{n}\right)} P_{X_{1}^{n} X_{2}^{n}}\left(x_{1}^{n}, x_{2}^{n}\right)}{\sum_{x_{1} \in \mathcal{T}_{\varepsilon}^{\prime}\left(X_{1} \mid x_{2}^{n}, y^{n}\right)} P_{X_{1}^{n} X_{2}^{n}}\left(x_{1}^{n}, x_{2}^{n}\right)} \geq \frac{1}{k_{1}} \frac{\sum_{x_{1} \in \mathcal{T}_{\varepsilon}^{n}\left(X_{1} \mid x_{2}^{n}\right)} P_{X_{1}^{n} X_{2}^{n}}\left(x_{1}^{n}, x_{2}^{n}\right)}{\sum_{x_{1} \in \mathcal{T}_{\varepsilon}^{n}\left(X_{1} \mid x_{2}^{n}, y^{n}\right)} P_{X_{1}^{n} X_{2}^{n}}\left(x_{1}^{n}, x_{2}^{n}\right)}  \tag{66}\\
& \geq \frac{1}{k_{1}} \frac{2^{-n(1+\varepsilon) H\left(X_{1}, X_{2}\right)}}{2^{-n(1-\varepsilon) H\left(X_{1}, X_{2}\right)}} \frac{\left|\mathcal{T}_{\varepsilon}^{n}\left(X_{1} \mid x_{2}^{n}\right)\right|}{\left|\mathcal{T}_{\varepsilon}^{n}\left(X_{1} \mid x_{2}^{n}, y^{n}\right)\right|} \geq 2^{n\left(-R_{1}-2 \varepsilon H\left(X_{1}, X_{2}\right)\right)} \frac{\left|\mathcal{T}_{\varepsilon}^{n}\left(X_{1} \mid x_{2}^{n}\right)\right|}{\left|\mathcal{T}_{\varepsilon}^{n}\left(X_{1} \mid x_{2}^{n}, y^{n}\right)\right|} .
\end{align*}
$$

$\operatorname{But}\left|\mathcal{T}_{\varepsilon}^{n}\left(X_{1} \mid x_{2}^{n}, y^{n}\right)\right| \leq 2^{n(1+\varepsilon) H\left(X_{1} \mid X_{2} Y\right)}$ and for a large enough $n$ we have $\forall x_{2}^{n} \in \mathcal{T}_{\varepsilon^{\prime}}^{n}\left(X_{2}\right),\left|\mathcal{T}_{\varepsilon}^{n}\left(X_{1} \mid x_{2}^{n}\right)\right| \geq$ $(1-\varepsilon) 2^{n(1-\varepsilon) H\left(X_{1} \mid X_{2}\right)} \geq 2^{n\left((1-\varepsilon) H\left(X_{1} \mid X_{2}\right)-\frac{1}{n}\right)}$, so we get with $C_{1}:=2 H\left(X_{1}, X_{2}\right)+H\left(X_{1} \mid X_{2} Y\right)+H\left(X_{1} \mid X_{2}\right)$ (symmetrically $\left.C_{2}:=2 H\left(X_{1}, X_{2}\right)+H\left(X_{2} \mid X_{1} Y\right)+H\left(X_{2} \mid X_{1}\right)\right)$ :

$$
\frac{\sum_{x_{1}^{n}} p_{x_{1}^{n}, x_{2}^{n}}}{k_{1} \sum_{x_{1}^{n}} r_{x_{1}^{n}, x_{2}^{n}, y^{n}}} \geq 2^{n\left(H\left(X_{1} \mid X_{2}\right)-\frac{1}{n}-H\left(X_{1} \mid X_{2} Y\right)-R_{1}-C_{1} \varepsilon\right)}=2^{n\left(I\left(X_{1}: Y \mid X_{2}\right)-\frac{1}{n}-C_{1} \varepsilon-R_{1}\right)} \geq 1 .
$$

For a large enough $n$, all constraints are satisfied, thus $\left(p_{x_{1}^{n}, x_{2}^{n}}, r_{x_{1}^{n}, x_{2}^{n}, y^{n}}\right)$ is a valid solution. Then:

$$
\begin{align*}
& \mathrm{S}^{\overline{\mathrm{NS}}}\left(W^{\otimes n}, 2^{n R_{1}}, 2^{n R_{2}}\right) \geq \frac{1}{2^{n\left(R_{1}+R_{2}\right)}} \sum_{\left(x_{1}^{n}, x_{2}^{n}, y^{n}\right) \in \mathcal{T}_{\varepsilon^{\prime}}^{n}\left(X_{1}, X_{2}, Y\right)} W^{\otimes n}\left(y^{n} \mid x_{1}^{n} x_{2}^{n}\right) r_{x_{1}^{n}, x_{2}^{n}, y^{n}} \\
& =\frac{1}{2^{n\left(R_{1}+R_{2}\right)}} \sum_{\left(x_{1}^{n}, x_{2}^{n}, y^{n}\right) \in \mathcal{T}_{\varepsilon^{\prime}}^{n}\left(X_{1}, X_{2}, Y\right)} \frac{P_{X_{1}^{n} X_{2}^{n} Y^{n}\left(x_{1}^{n}, x_{2}^{n}, y^{n}\right)}^{P_{X_{1}^{n} X_{2}^{n}}\left(x_{1}^{n}, x_{2}^{n}\right)}}{\sum_{\left(x_{1}^{n}, x_{2}^{n}\right) \in \mathcal{T}_{\varepsilon}^{n}\left(X_{1}, X_{2}\right)} P_{X_{1}^{n} X_{2}^{n}\left(x_{1}^{n}, x_{2}^{n}\right)}^{2^{n\left(R_{1}+R_{2}\right)} P_{X^{n}} X_{n}^{n}\left(x_{1}^{n}, x_{2}^{n}\right.}}  \tag{67}\\
& =\frac{\sum_{\left(x_{1}^{n}, x_{2}^{n}, y^{n}\right) \in \mathcal{T}_{\varepsilon^{\prime}}^{n}\left(X_{1}, X_{2}, Y\right)} P_{X_{1}^{n} X_{2}^{n} Y^{n}}\left(x_{1}^{n}, x_{2}^{n}, y^{n}\right)}{\sum_{\left(x_{1}^{n}, x_{2}^{n}\right) \in \mathcal{T}_{\varepsilon}^{n}\left(X_{1}, X_{2}\right)} P_{X_{1}^{n} X_{2}^{n}}\left(x_{1}^{n}, x_{2}^{n}\right)} \underset{n \rightarrow+\infty}{\rightarrow} 1,
\end{align*}
$$

since typical sets cover asymptotically the whole probability mass. Thus, since $\mathrm{S}^{\overline{\mathrm{NS}}}\left(W^{\otimes n}, 2^{n R_{1}}, 2^{n R_{2}}\right) \leq$ 1 , we get that $S^{\overline{N S}}\left(W^{\otimes n}, 2^{n R_{1}}, 2^{n R_{2}}\right) \underset{n \rightarrow+\infty}{\rightarrow} 1$. Thus for sufficiently large $n$ we can achieve a rate pair arbitrarily close to the outer bound. Finally, since $\mathcal{C}^{\overline{\mathrm{NS}}}(W)$ is closed and convex, a rate pair that is in the closure of the convex hull of the initial region is also in $\mathcal{C}^{\overline{\mathrm{NS}}}(W)$, and thus the proof is completed.

## 6 Independent Non-Signaling Assisted Capacity Region

The goal of this section is to show that independent non-signaling assistance does not change the capacity region of a MAC $W$, i.e. that $\mathcal{C}^{\operatorname{NS}}{ }^{\operatorname{SR}}(W)=\mathcal{C}(W)$. In order to prove this result, we will need some properties in the one-sender one-receiver case from [6]. Specifically, let us first recall the definition of the maximum success probability $\mathrm{S}(W, k)$ of transmitting $k$ messages using the channel $W$ :

$$
\begin{align*}
\mathrm{S}(W, k):= & \underset{e, d}{\operatorname{maximize}}
\end{align*} \frac{1}{k} \sum_{i, x, y} W(y \mid x) e(x \mid i) d(i \mid y),
$$

Then, the following characterization of $\mathrm{S}(W, k)$ can be derived:
Proposition 6.1 (Proposition 2.1 of [6]). $\mathrm{S}(W, k)=\frac{1}{k_{S \subseteq}} \max _{S \subseteq X:|S| \leq k} f_{W}(S)$ with $f_{W}(S):=\sum_{y \in Y} \max _{x \in S} W(y \mid x)$.
As in the MAC scenario, one can consider non-signaling assistance shared between the sender and the receiver, which leads to the following maximum success probability $\mathrm{S}^{\mathrm{NS}}(W, k)$ :

$$
\begin{align*}
\mathrm{S}^{\mathrm{NS}}(W, k):=\underset{P}{\operatorname{maximize}} & \frac{1}{k} \sum_{i, x, y} W(y \mid x) P(x i \mid i y) \\
\text { subject to } & \sum_{x} P(x j \mid i y)=\sum_{x} P\left(x j \mid i^{\prime} y\right) \\
& \sum_{j} P(x j \mid i y)=\sum_{j} P\left(x j \mid i y^{\prime}\right)  \tag{69}\\
& \sum_{x, j} P(x j \mid i y)=1 \\
& P(x j \mid i y) \geq 0
\end{align*}
$$

A symmetrization can also be done to simplify the expression of the linear program defining $\mathrm{S}^{\mathrm{NS}}(W, k)$ :
Proposition 6.2 (Appendix A of [6]).

$$
\begin{align*}
\mathrm{S}^{\mathrm{NS}}(W, k)=\underset{r, p}{\operatorname{maximize}} & \frac{1}{k} \sum_{x, y} W(y \mid x) r_{x, y} \\
\text { subject to } & \sum_{x} r_{x, y}=1  \tag{70}\\
& \sum_{x} p_{x}=k \\
& 0 \leq r_{x, y} \leq p_{x}
\end{align*}
$$

Finally, the main tool we will use from [6] is the following random coding technique, which describes how to find a classical code with a success probability close to the non-signaling assisted one:

Theorem 6.3 (Theorem 3.1 of [6]). Given a solution $r, p$ of the program computing $S^{\mathrm{NS}}(W, k)$, we have that:

$$
\mathbb{E}_{S}\left[\frac{f_{W}(S)}{\ell}\right] \geq \frac{k}{\ell}\left(1-\left(1-\frac{1}{k}\right)^{\ell}\right) \cdot \frac{1}{k} \sum_{x, y} W(y \mid x) r_{x, y}
$$

for the multiset $S$ obtained by choosing $\ell$ elements of $\mathcal{X}$ independently according to the distribution $\left(\frac{p_{x}}{k}\right)_{x \in \mathcal{X}}$.

We can now state our result on independent non-signaling assistance, which says that even in one-shot scenarios, the success probability with and without that assistance are close:

Theorem 6.4. For any $\ell_{1}, k_{1}, \ell_{2}, k_{2}$ :

$$
\min \left(\frac{k_{1}}{\ell_{1}}\left(1-\left(1-\frac{1}{k_{1}}\right)^{\ell_{1}}\right), \frac{k_{2}}{\ell_{2}}\left(1-\left(1-\frac{1}{k_{2}}\right)^{\ell_{2}}\right)\right) \mathrm{S}_{\mathrm{sum}}^{\mathrm{NS}_{\mathrm{SR}}}\left(W, k_{1}, k_{2}\right) \leq \mathrm{S}_{\mathrm{sum}}\left(W, \ell_{1}, \ell_{2}\right) .
$$

In particular, this will imply that the capacity regions are the same:
Corollary 6.5. $\mathcal{C}^{\mathrm{NS}_{\mathrm{SR}}}(W)=\mathcal{C}(W)$.
Proof. We will show that $\mathcal{C}_{\mathrm{sum}}^{\mathrm{Ns}} \mathrm{SS}_{\mathrm{sR}}(W)=\mathcal{C}_{\text {sum }}(W)$, which is enough to conclude thanks to Proposition 2.5 and Proposition 2.9. We apply Theorem 6.4 on the MAC $W^{\otimes n}$.

Let us fix $k_{1}=2^{n R_{1}}, k_{2}=2^{n R_{2}}$ and $\ell_{1}=\frac{2^{n R_{1}}}{n}, \ell_{2}=\frac{2^{n R_{2}}}{n}$. Since:

$$
\frac{k}{\ell}\left(1-\left(1-\frac{1}{k}\right)^{\ell}\right) \geq \frac{k}{\ell}\left(1-e^{-\frac{\ell}{k}}\right) \geq 1-\frac{\ell}{2 k}
$$

and $1-\frac{\ell_{1}}{2 k_{1}}=1-\frac{\ell_{2}}{2 k_{2}}=1-\frac{1}{2 n}$, we get:

$$
\left(1-\frac{1}{2 n}\right) \mathrm{S}_{\mathrm{sum}}^{\mathrm{NS}_{\mathrm{SR}}}\left(W^{\otimes n}, 2^{n R_{1}}, 2^{n R_{1}}\right) \leq \mathrm{S}_{\mathrm{sum}}\left(W^{\otimes n}, \frac{2^{n R_{1}}}{n}, \frac{2^{n R_{2}}}{n}\right) .
$$

As $1-\frac{1}{2 n}$ tends to 1 when $n$ tends to infinity, we get that $\forall \varepsilon>0, \exists N \in \mathbb{N}, \forall n \geq N$ :

$$
(1-\varepsilon) S_{\mathrm{sum}}^{\mathrm{NS}_{\mathrm{SR}}}\left(W^{\otimes n}, 2^{n R_{1}}, 2^{n R_{1}}\right) \leq \mathrm{S}_{\mathrm{sum}}\left(W^{\otimes n}, 2^{n\left(R_{1}-\frac{\log (n)}{n}\right)}, 2^{n\left(R_{2}-\frac{\log (n)}{n}\right)}\right)
$$

Thus, if $\lim _{n \rightarrow+\infty} S_{\mathrm{sum}}^{\mathrm{NS}}\left(W^{\otimes n}, 2^{n R_{1}}, 2^{n R_{1}}\right)=1$, we have that for all $R_{1}^{\prime}<R_{1}$ and $R_{2}^{\prime}<R_{2}$ :

$$
\lim _{n \rightarrow+\infty} \mathrm{S}_{\mathrm{sum}}\left(W^{\otimes n}, 2^{n R_{1}^{\prime}}, 2^{n R_{1}^{\prime}}\right) \geq 1-\varepsilon
$$

Since this is true for all $\varepsilon>0$, we get in fact that $\lim _{n \rightarrow+\infty} \mathrm{S}_{\text {sum }}\left(W^{\otimes n}, 2^{n R_{1}^{\prime}}, 2^{n R_{1}^{\prime}}\right)=1$. This implies that $\mathcal{C}_{\text {sum }}^{\mathrm{NS}_{\mathrm{SR}}}(W) \subseteq \mathcal{C}_{\text {sum }}(W)$, and thus that the capacity regions are equal as the other inclusion is always satisfied.

In order to prove Theorem 6.4, we will need the following lemma:
Lemma 6.6. If $S_{1}, S_{2}$ are classical codes (i.e. multisets with elements in $\mathcal{X}_{1}, \mathcal{X}_{2}$ ) of size $\ell_{1}, \ell_{2}$ :

$$
\mathrm{S}_{\mathrm{sum}}\left(W, \ell_{1}, \ell_{2}\right) \geq \frac{1}{2}\left(\frac{f_{W_{S_{2}, \ell_{2}}^{1}}\left(S_{1}\right)}{\ell_{1}}+\frac{f_{W_{S_{1}, \ell_{1}}^{2}}\left(S_{2}\right)}{\ell_{2}}\right)
$$

where $W_{S_{2}, \ell_{2}}^{1}$ is the channel defined by $W_{S_{2}, \ell_{2}}^{1}\left(y \mid x_{1}\right)=\frac{1}{\ell_{2}} \sum_{i_{2}=1}^{\ell_{2}} W\left(y \mid x_{1} S_{2}^{i_{2}}\right)$ and similarly for $W_{S_{1}, \ell_{1}}^{2}$.
Proof. Let us define $e_{1}\left(x_{1} \mid i_{1}\right):=\mathbb{1}_{S_{1}^{i_{1}}=x_{1}}$ and $e_{2}\left(x_{2} \mid i_{2}\right):=\mathbb{1}_{S_{2}^{i_{2}}=x_{2}}$. Then for fixed $y$, let us take $j_{1}^{y} \in$ $\operatorname{argmax}_{i_{1}}\left\{\sum_{i_{2}=1}^{\ell_{2}} W\left(y \mid S_{1}^{i_{1}} S_{2}^{i_{2}}\right)\right\}, j_{2}^{y} \in \operatorname{argmax}_{i_{2}}\left\{\sum_{i_{1}=1}^{\ell_{1}} W\left(y \mid S_{1}^{i_{1}} S_{2}^{i_{2}}\right)\right\}$ and then define $d\left(j_{1} \mid y\right):=\mathbb{1}_{j_{1}=j_{1}^{y}}$, $d\left(j_{2} \mid y\right):=\mathbb{1}_{j_{2}=j_{2}}$. We have then:

$$
\begin{align*}
& \mathrm{S}_{\text {sum }}\left(W, \ell_{1}, \ell_{2}\right) \geq \frac{1}{\ell_{1} \ell_{2}} \sum_{i_{1}, i_{2}, x_{1}, x_{2}, y} W\left(y \mid x_{1} x_{2}\right) \mathbb{1}_{S_{1}^{i_{1}}=x_{1}} \mathbb{1}_{S_{2}^{i_{2}}=x_{2}} \frac{\mathbb{1}_{i_{1}=i_{1}^{y}}^{y}+\mathbb{1}_{i_{2}=i_{2}^{y}}^{2}}{2} \\
& =\frac{1}{\ell_{1} \ell_{2}} \sum_{i_{1}, i_{2}, y} W\left(y \mid S_{1}^{i_{1}} S_{2}^{i_{2}}\right) \frac{\mathbb{i}_{i_{1}=i_{1}^{y}}+\mathbb{1}_{i_{2}=i_{2}^{y}}^{y}}{2}=\frac{1}{\ell_{1} \ell_{2}} \sum_{y} \frac{1}{2}\left(\sum_{i_{2}} W\left(y \mid S_{1}^{i_{1}^{y}} S_{2}^{i_{2}}\right)+\sum_{i_{1}} W\left(y \mid S_{1}^{i_{1}} S_{2}^{i_{2}^{y}}\right)\right) \\
& =\frac{1}{\ell_{1} \ell_{2}} \sum_{y} \frac{1}{2}\left(\max _{i_{1}} \sum_{i_{2}} W\left(y \mid S_{1}^{i_{1}} S_{2}^{i_{2}}\right)+\max _{i_{2}} \sum_{i_{1}} W\left(y \mid S_{1}^{i_{1}} S_{2}^{i_{2}}\right)\right)  \tag{71}\\
& =\frac{1}{2}\left(\frac{\sum_{y} \max _{i_{1}}\left[\frac{1}{\ell_{2}} \sum_{i_{2}} W\left(y \mid S_{1}^{i_{1}} S_{2}^{i_{2}}\right)\right]}{\ell_{1}}+\frac{\sum_{y} \max _{i_{2}}\left[\frac{1}{\ell_{1}} \sum_{i_{1}} W\left(y \mid S_{1}^{i_{1}} S_{2}^{i_{2}}\right)\right]}{\ell_{2}}\right) \\
& =\frac{1}{2}\left(\frac{\sum_{y} \max _{i_{1}} W_{S_{2}, \ell_{2}}^{1}\left(y \mid S_{1}^{i_{1}}\right)}{\ell_{1}}+\frac{\sum_{y} \max _{i_{2}} W_{S_{1}, \ell_{1}}^{2}\left(y \mid S_{2}^{i_{2}}\right)}{\ell_{2}}\right)=\frac{1}{2}\left(\frac{f_{W_{S_{2}, \ell_{2}}^{1}}^{\ell_{1}}\left(S_{1}\right)}{f_{W_{S_{1}, \ell_{1}}^{2}}\left(S_{2}\right)}\right) .
\end{align*}
$$

We have now all the tools to prove Theorem 6.4
Proof of Theorem 6.4. Let us consider an optimal solution $r^{1}, r^{2}, p^{1}, p^{2}$ of the program of Proposition 3.2 computing $S_{\text {sum }}^{\mathrm{NS}}\left(W, k_{1}, k_{2}\right)$.

Let us fix some multiset $S_{2}$ with elements in $\mathcal{X}_{2}$ of size $\ell_{2}$. Note that $r^{1}$ and $p^{1}$ are a feasible solution of the program of Proposition 6.2 computing $\mathrm{S}^{\mathrm{NS}}\left(W_{S_{2}, \ell_{2}}^{1}, k_{1}\right)$. As a result, we can apply Theorem 6.3 and get the following statement. For the multiset $S_{1}$ obtained by choosing $\ell_{1}$ elements of $\mathcal{X}_{1}$ independently according to the distribution $\left(\frac{p_{x_{1}}^{1}}{k_{1}}\right)_{x_{1} \in \mathcal{X}_{1}}$, we have:

$$
\mathbb{E}_{S_{1}}\left[\frac{f_{W_{S_{2}, \ell_{2}}^{1}}\left(S_{1}\right)}{\ell_{1}}\right] \geq \frac{k_{1}}{\ell_{1}}\left(1-\left(1-\frac{1}{k_{1}}\right)^{\ell_{1}}\right) \cdot \frac{1}{k_{1}} \sum_{x_{1}, y} W_{S_{2}, \ell_{2}}^{1}\left(y \mid x_{1}\right) r_{x_{1}, y}^{1} .
$$

Now, let $S_{2}$ be the multiset obtained by choosing $\ell_{2}$ elements of $\mathcal{X}_{2}$ independently according to the distribution $\left(\frac{p_{x_{2}}^{2}}{k_{2}}\right)_{x_{2} \in \mathcal{X}_{2}}$. We have:

$$
\begin{align*}
& \mathbb{E}_{S_{2}}\left[\frac{1}{k_{1}} \sum_{x_{1}, y} W_{S_{2}, \ell_{2}}^{1}\left(y \mid x_{1}\right) r_{x_{1}, y}^{1}\right]=\mathbb{E}_{S_{2}}\left[\frac{1}{k_{1}} \sum_{x_{1}, y} \frac{1}{\ell_{2}} \sum_{i_{2}=1}^{\ell_{2}} W\left(y \mid x_{1} S_{2}^{i_{2}}\right) r_{x_{1}, y}^{1}\right] \\
& =\frac{1}{\ell_{2}} \sum_{i_{2}=1}^{\ell_{2}} \mathbb{E}_{X_{2}^{i_{2}} \sim \frac{p_{x_{2}}^{2}}{k_{2}}}\left[\frac{1}{k_{1}} \sum_{x_{1}, y} W\left(y \mid x_{1} X_{2}^{i_{2}}\right) r_{x_{1}, y}^{1}\right]=\mathbb{E}_{X_{2} \sim \frac{p_{p_{2}}^{2}}{k_{2}}}\left[\frac{1}{k_{1}} \sum_{x_{1}, y} W\left(y \mid x_{1} X_{2}\right) r_{x_{1}, y}^{1}\right]  \tag{72}\\
& =\frac{1}{k_{1}} \sum_{x_{1}, x_{2}, y} \frac{p_{x_{2}}^{2}}{k_{2}} W\left(y \mid x_{1} x_{2}\right) r_{x_{1}, y}^{1}=\frac{1}{k_{1}} \sum_{x_{1}, y} W_{p^{2}, k_{2}}^{1}\left(y \mid x_{1}\right) r_{x_{1}, y}^{1} .
\end{align*}
$$

Thus in all, we have:

$$
\begin{align*}
\mathbb{E}_{S_{2}}\left[\mathbb{E}_{S_{1}}\left[\frac{f_{W_{S_{2}, \ell_{2}}^{1}}\left(S_{1}\right)}{\ell_{1}}\right]\right] & \geq \mathbb{E}_{S_{2}}\left[\frac{k_{1}}{\ell_{1}}\left(1-\left(1-\frac{1}{k_{1}}\right)^{\ell_{1}}\right) \cdot \frac{1}{k_{1}} \sum_{x_{1}, y} W_{S_{2}, \ell_{2}}^{1}\left(y \mid x_{1}\right) r_{x_{1}, y}^{1}\right] \\
& =\frac{k_{1}}{\ell_{1}}\left(1-\left(1-\frac{1}{k_{1}}\right)^{\ell_{1}}\right) \cdot \mathbb{E}_{S_{2}}\left[\frac{1}{k_{1}} \sum_{x_{1}, y} W_{S_{2}, \ell_{2}}^{1}\left(y \mid x_{1}\right) r_{x_{1}, y}^{1}\right]  \tag{73}\\
& \geq \frac{k_{1}}{\ell_{1}}\left(1-\left(1-\frac{1}{k_{1}}\right)^{\ell_{1}}\right) \cdot \frac{1}{k_{1}} \sum_{x_{1}, y} W_{p^{2}, k_{2}}^{1}\left(y \mid x_{1}\right) r_{x_{1}, y}^{1},
\end{align*}
$$

and symmetrically for $\mathbb{E}_{S_{1}}\left[\mathbb{E}_{S_{2}}\left[\frac{f_{W_{S_{1}, \ell_{1}}}\left(S_{2}\right)}{\ell_{2}}\right]\right]$. Since there exists classical codes $S_{1}^{*}, S_{2}^{*}$ such that:

$$
\frac{1}{2}\left(\frac{f_{W_{S_{2}^{*}, \ell_{2}}^{1}}\left(S_{1}^{*}\right)}{\ell_{1}}+\frac{f_{W_{S_{1}^{*}, \ell_{1}}^{2}}\left(S_{2}^{*}\right)}{\ell_{2}}\right) \geq \mathbb{E}_{S_{1}, S_{2}}\left[\frac{1}{2}\left(\frac{f_{W_{S_{2}, \ell_{2}}^{1}}\left(S_{1}\right)}{\ell_{1}}+\frac{f_{W_{S_{1}, \ell_{1}}^{2}}\left(S_{2}\right)}{\ell_{2}}\right)\right]
$$

by applying Lemma 6.6, we get:

$$
\begin{align*}
& \mathrm{S}_{\mathrm{sum}}\left(W, \ell_{1}, \ell_{2}\right) \geq \frac{1}{2}\left(\frac{f_{W_{S_{2}^{*}, \ell_{2}}^{1}}\left(S_{1}^{*}\right)}{\ell_{1}}+\frac{f_{W_{S_{1}^{*}, \ell_{1}}^{2}}\left(S_{2}^{*}\right)}{\ell_{2}}\right) \geq \mathbb{E}_{S_{1}, S_{2}}\left[\frac{1}{2}\left(\frac{f_{W_{S_{2}, \ell_{2}}^{1}}\left(S_{1}\right)}{\ell_{1}}+\frac{f_{W_{S_{1}, \ell_{1}}^{2}}\left(S_{2}\right)}{\ell_{2}}\right)\right] \\
& =\frac{1}{2}\left(\mathbb{E}_{S_{2}}\left[\mathbb{E}_{S_{1}}\left[\frac{f_{W_{S_{2}, \ell_{2}}^{1}}\left(S_{1}\right)}{\ell_{1}}\right]\right]+\mathbb{E}_{S_{1}}\left[\mathbb{E}_{S_{2}}\left[\frac{f_{W_{S_{1}, \ell_{1}}^{2}}\left(S_{2}\right)}{\ell_{2}}\right]\right]\right) \\
& \geq \frac{1}{2}\left(\frac{k_{1}}{\ell_{1}}\left(1-\left(1-\frac{1}{k_{1}}\right)^{\ell_{1}}\right) \cdot \frac{1}{k_{1}} \sum_{x_{1}, y} W_{p^{2}}^{1}\left(y \mid x_{1}\right) r_{x_{1}, y}^{1}+\frac{k_{2}}{\ell_{2}}\left(1-\left(1-\frac{1}{k_{2}}\right)^{\ell_{2}}\right) \cdot \frac{1}{k_{2}} \sum_{x_{2}, y} W_{p^{1}}^{2}\left(y \mid x_{2}\right) r_{x_{2}, y}^{2}\right) \\
& \geq \min \left(\frac{k_{1}}{\ell_{1}}\left(1-\left(1-\frac{1}{k_{1}}\right)^{\ell_{1}}\right), \frac{k_{2}}{\ell_{2}}\left(1-\left(1-\frac{1}{k_{2}}\right)^{\ell_{2}}\right)\right) \mathrm{S}_{\mathrm{sum}}^{\mathrm{NSSR}}\left(W, k_{1}, k_{2}\right) . \tag{74}
\end{align*}
$$

Remark. In the whole proof of Theorem 6.4, as well as the properties it depends on, we have never used the fact that the output of the channel $y$ was the same for both decoders $d_{1}$ and $d_{2}$. This implies that the result also holds for interference channels, i.e. two-sender two-receiver channels $W$ ( $y_{1} y_{2} \mid x_{2} x_{2}$ ). Specifically, non-signaling assistance shared between the first sender and the first receiver and independently shared between the second sender and the second receiver does not change the capacity region of interference channels.

## 7 Conclusion

In this work, we have studied the impact of non-signaling assistance on the capacity of multiple-access channels. We have developed an efficient linear program computing the success probability of the best non-signaling assisted code for a finite number of copies of a multiple-access channel. In particular, this gives lower bounds on the zero-error non-signaling assisted capacity of multiple-access channels. Applied to the binary adder channel, these results were used to prove that a sum-rate of $\frac{\log _{2}(72)}{4} \simeq 1.5425$ can be reached with zero error, which beats the maximum classical sum-rate capacity of $\frac{3}{2}$. For noisy channels, we have developed a technique giving lower bounds through the use of concatenated codes. Applied to the noisy binary adder channel, this technique was used to show that non-signaling assistance still improves the sum-rate capacity. We have also found an outer bound on the non-signaling assisted capacity region through a relaxed notion of non-signaling assistance, whose capacity region was characterized by a singleletter formula. Finally, we have shown that independent non-signaling assistance does not change the capacity region.

Our results suggest that quantum entanglement may also increase the capacity of such channels. However, even for the binary adder channel, this question remains open. One could also ask if such efficient methods to compute the best non-signaling assisted codes can be extended to Gaussian multiple-access channels. Finally, establishing a single-letter formula for the non-signaling assisted capacity of multipleaccess channels is the main open question left by this work. It remains open even for the binary adder channel. Proving that non-signaling assistance and relaxed non-signaling assistance coincide asymptotically would directly answer this question and show that the capacity region is described in Theorem 5.5.

## Acknowledgements

We would like to thank Mario Berta and Andreas Winter for discussions about the use of non-signaling correlations for multiple access channels as well as the anonymous referees for their suggestions that improved the paper. This work is funded by the European Research Council (ERC Grant AlgoQIP, Agreement No. 851716). We also acknowledge funding from the European Union's Horizon 2020 research and innovation programme under Grant Agreement No 101017733 within the QuantERA II Programme.
