### Abstract

Groundwater from various shallow and deep reservoirs converges in interaction with marine waters into the limestone aquifer of the Balaruc peninsula (Thau lagoon, southern France). This aquifer faces temporary phenomena of marine water intrusion through the Vise submarine spring located at -29.5 meters below the lagoon level. Since the 1960s, seven flow reversal phenomena have occurred, the last one occurring between 11/28/2020 and 03/14/2022. During these phenomena, which can last from a few weeks to several months, the salty water is absorbed from the lagoon to the conduit of the submarine spring, which leads to the salinization of the underlying karst aquifer. The monitoring of flow, water specific conductivity and water temperature data from the karst submarine spring is a key element of the research project to understand the hydrogeological functioning of the karst aquifer under normal conditions or during flow reversal periods. This monitoring allows the characterization of the (in- or out-) flows

at the submarine spring, the evaluation of the volume or mass balances, the identification of the hydrogeological and physico-chemical responses (water temperature, specific conductivity) observed within the karstic aquifer. Here, we present the means implemented offshore to acquire data at the submarine spring over the 06/25/2019 - 12/31/2022 time period together with lagoon water's physico-chemical parameters and levels and onshore groundwater's physico-chemical parameters and levels acquired at springs and boreholes from the karst aquifer

## Value of the data

- This dataset provides new information on a Mediterranean coastal karst aquifer which is characterized by a submarine spring which presents periods of flow reversals.
- This dataset compiles information on the submarine spring flow and its specific conductivity and temperature (for a period of 3.5 years), lagoon water level, as well as groundwater level, specific conductivity and temperature measurements within the karst aquifer.
- The data can be useful to hydrogeologists in their research on understanding the functioning of coastal karst aquifers and more broadly on understanding marine intrusion phenomena in heterogeneous environments through karst conduits.
- To our knowledge, this data is an unique example where total flow reversal was monitored.
- Submarine spring flow, groundwater data (level, temperature and specific conductivity), as well as water levels and water density of the lagoon may be used in density dependent numerical models.

### 1. Objective

This dataset was generated to study the behavior of a Mediterranean coastal (lagoon) karst aquifer for which the flow reversal phenomenon has occurred several times in the past through a submarine karst spring. The equipment and the monitoring of the submarine spring constitute a key element of the research project to understand of the hydrogeological functioning of the karst system during regular conditions, when fresh groundwater flows out of the submarine spring, as well as during disruptive events, when flow reversal and salty water intrusion through the spring occur [5, 6, 7].

### 2. Data description

The location of the Vise submarine spring, observation boreholes and stations for measuring the level and the salinity of the lagoon are reported in Figure 1 (all sites are projected in Lambert 93 in the RGF 93 geographic reference system – EPSG:2154). Sites' coordinates (WGS 84 and EPSG:2154) with hypertext links to the French geological survey's BRGM groundwater database (BSS) and straight distances to the Vise spring are reported in Table 1.

Table 2 presents for each site, the date intervals for each parameter and indicates the type of device used to collect the data.

Figures 2 to 5 present and illustrate the experimental measurement device of the Vise submarine spring as well as the main phases of the installation works.

Figure 6 presents (a) hourly flow of the Vise submarine spring, (b) hourly water level of the Thau lagoon, (c) piezometric levels measured in the boreholes of the karst aquifer. The gray frame indicates the period of flow reversal.

Figure 7 presents specific conductivity (daily mean) of groundwater from boreholes located in the karst aquifer and at of flowing water at the submarine spring (Vise, BSS002JDMR). The gray frame indicates the period of flow reversal.

Figure 8 presents the specifically designed device used to perform punctual velocity controls at the outlet of the stilling tube. This figure show also results of estimation of the flows of the submarine spring from measurements.

### 2.1. Submarine spring data

The submarine spring flow dataset is contained in the Vise\_Submarine\_Spring.xlsx file, which contains three excel sheets. The first sheet named "Flow" contains the data of the hourly averages of the flow rates measured at a time step of 5 minutes between 06/26/2019 and 12/31/2022. The number of data used (N) for the calculation of the arithmetic mean and the associated standard deviation are reported. During regular flowing conditions (i.e. groundwater flows out of the spring), the flow rate is positive. During flow reversal periods, the flow rate becomes negative. The "Comments" column is used to qualify this flow context. The second sheet named "SpC" and the third sheet named "Temp" contain, data of the hourly averages of water specific conductivity and temperature data, respectively, measured at a 5 minutes time step between 06/26/2019 and 10/13/2022. In the "SpC" and "Temp" excel sheets, the data from the 2 measurement probes of the experimental device are presented. The number of data used (N) for the calculation of the arithmetic mean and the associated standard deviation are reported. During flow reversal periods, the specific conductivity and temperature measured are those of the lagoon water, these measurements make it possible to qualify the physico-chemical properties of the salty water infiltrated by the karst spring during disruptive events.

### 2.2. Lagoon data

The lagoon water level dataset is contained in the Thau\_Lagoon.xlsx file, which contains two excel sheets. The first excel sheet named "WaterLevel" contains the hourly data of the lagoon water levels measured at the H-lagoon site (Figure 1, table 1). The data is expressed in meters above sea level. Measured lagoon water level fluctuations were repeatedly checked at the reference point using a manual water level gauge. The second excel sheet contains the raw salinity and temperature data measured at station 104-P-0001 [1] acquired on a weekly time step which can be used to estimate the variations of the water density in the lagoon. Interpolated data to daily time steps are also reported (period from 01/01/2017 to 12/26/2022).

### 2.3 Groundwater

The groundwater dataset is contained in the Thau\_karst\_groundwater.xlsx file, which has 9 sheets, one for each of the following stations referenced in Table 1 (BSS002JCUL; BSS002JEKD; BSS002JDNJ; BSS002JDVA; BSS002JDXA; BSS002JDNH; BSS002JEHM; BSS002JEKE; BSS004AXZH). Each sheet contains piezometric data (expressed in m.a.s.l) between 01/01/2017 and 12/31/2022 for the longest time series (figure 6, table 2). With the exception of point BSS002JEKD, the sheets also provides the groundwater temperature and

specific conductivity data. Information on the depth of the measurement probe is indicated into the metadata section of each excel sheet.

(d) view of a diver installing the water collector on the underwater spring. (e, f) view of the electromagnetic flowmeter(2). (g) view of the stilling tube (3) installed above the flowmeter (2).

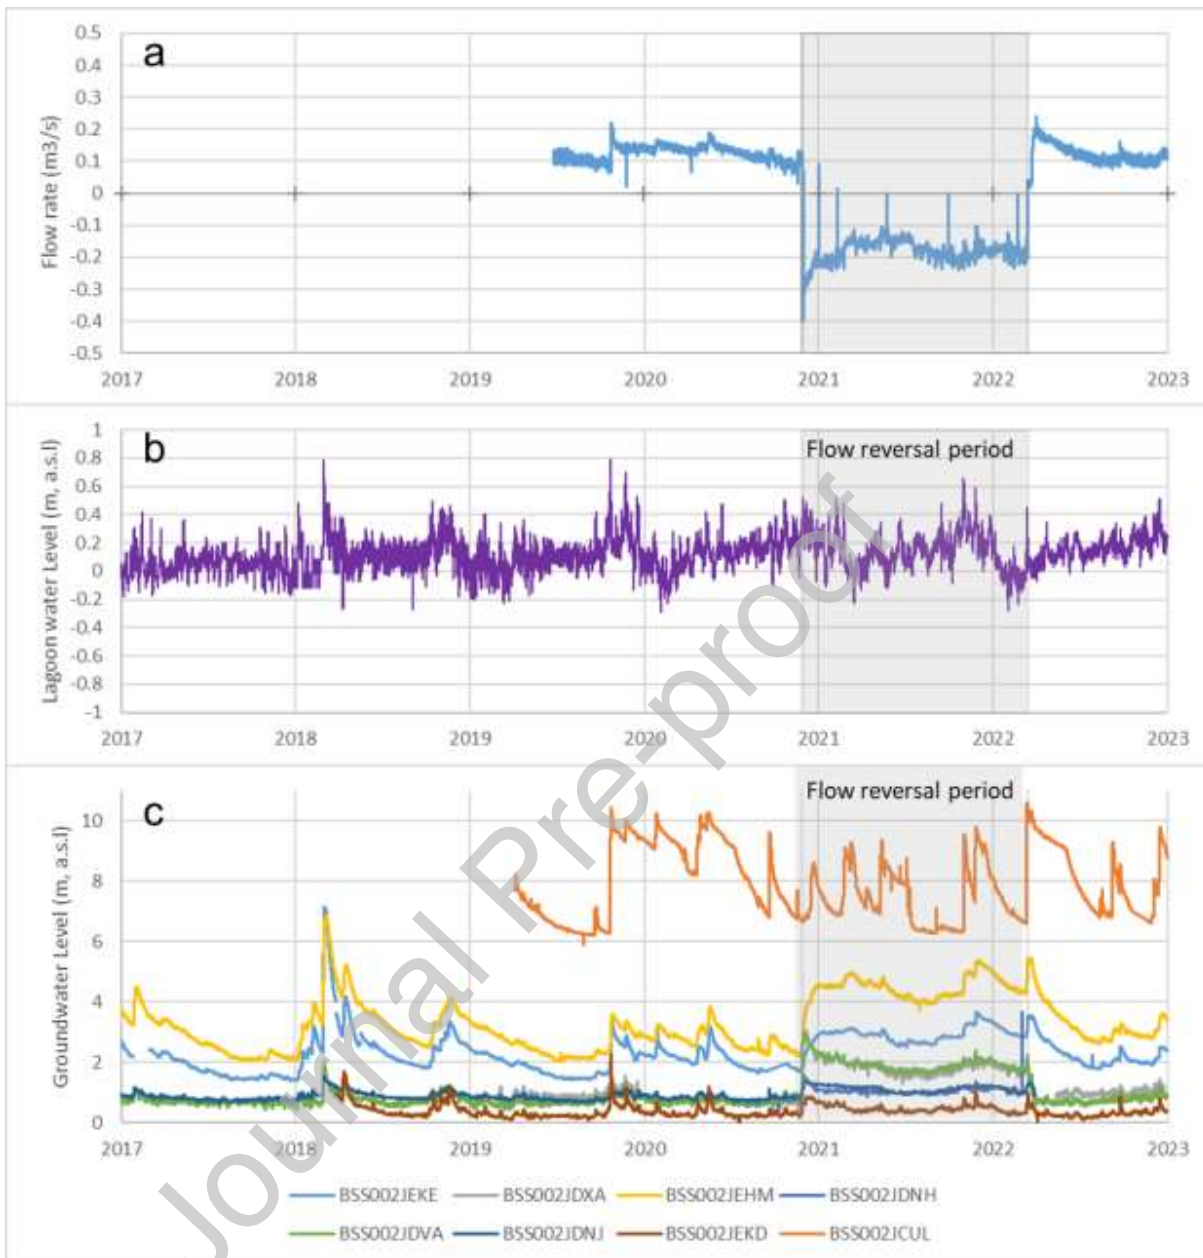

Figure 6. (a) hourly average flowrate of the Vise submarine spring , (b) hourly water level of the Thau lagoon, (c) piezometric levels measured in the boreholes of the karst aquifer. The gray frame indicates the period of flow reversal.

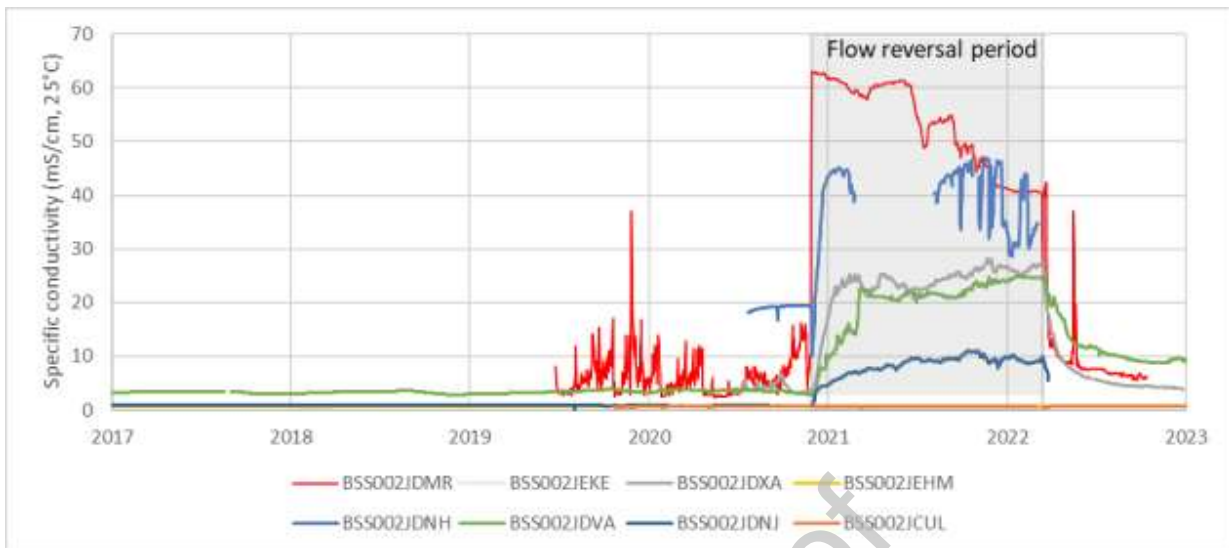

Figure 7. Specific conductivity (daily mean) of the water measured in the boreholes of the karst aquifer, on shore springs and at the Vise submarine spring (BSS002JDMR). The gray frame indicates the period of flow reversal.

### 3. Experimental design, materials and methods

#### 3.1 Description of the submarine spring flow context

The Vise submarine spring (BSS002JDMR) located in the Thau lagoon (southern France) is one of the most important natural outlets of the Jurassic karstified limestone aquifer [2], the other overflow outlets of the karst aquifer being the springs of Cauvy (BSS002JDNJ), Ambressac (BSS002JECEB) and Issanka (BSS002JCUL) located onshore on the peninsula of Balaruc [3].

The submarine spring flows into the Thau lagoon at a depth of 29.5 m [4], at the level of a bench of shell limestone attributed to the Miocene [2] (Figure 3). The main spring emerges from a shell limestone slab and has a rectangular orifice of reduced size (1.2 m x 0.18 m to 0.25 m, Figure 4b). The opening seems to extend in depth following a circular conduit 0.5 m - diameter, explored over a few meters depth (4-5 m) only.

#### 3.2 Description of the experimental device

##### 3.2.1 Preparatory work around the sub-marine spring

All the underwater operations were carried out from two work barges by a team of three professional divers assisted by a pilot (Figure 5 a). A silt-removal operation using a sucker tool and the installation of a metal formwork (2m x 2m) around the submarine spring was done to facilitate the removal of the old metal nozzle and the installation of the experimental device on the submarine spring (Figure 3, Figure 4 , Figure 5 g).

### 3.2.2 Description of the experimental device

Following the diving surveys carried out in May 2018, a fiberglass water collection device was designed to replace the old, totally corroded metal nozzle (figure 5b) which had been installed in the 1980s for spring capture [3].

The new water collector (Figure 5c) installed in May 2019 has the following characteristics:

- One-piece tube in vinyl ester with molding appearance gel coat, smooth inner face and raw outer face of gelcoat;
- White color ;
- Diameter: 1016 mm, height 2700 mm (with three arches of 700 x 700 mm at the base), thickness 12 mm, with flange DN 1000 mm PN 6 bars in the upper part;
- PVC side tube with DN 100 flange, shrunk and secured to the central tube; this tube is intended to receive the measurement probes;
- Lateral tube in PE DN 32 mm, shrunk and made integral with the central tube, this tube serves as a suction tapping at the right of the griffin for a pump installed on the ground for water sampling.

To meet the constraints of immersion, the absence of moving parts, and the absence of constriction to allow the passage of a diver, only flow measurements by ultrasound or electromagnetism could reasonably be considered. We opted for an electromagnetic flowmeter which is more compact, measures in both directions (i.e. inflow or outflow) and allows an accuracy of around 5%. The model installed was supplied by the Krohne company (Figure 5e, f).

The model delivered by Krohne has the following characteristics:

- Optiflux 4300W model waterproof flowmeter with waterproof connectors,
- diameter DN 1000 mm,
- remote electronics on land and connected to the flowmeter by two cables of 180 m with waterproof connectors,
- measurement range that can reach a flow in both directions from 0 to 20,000 m<sup>3</sup>/h adjusted on site from 0 to 5,000 m<sup>3</sup>/h,
- A DN 1000 mm fiberglass upper stilling 1.5 m high tube was then placed above the flow meter -(Figure 5e, f),.

### 3.2.2 Installation of the experimental measuring device

To ensure the stability and water tightness of the system, one m<sup>3</sup> of concrete was poured around the collector. The filling of the void around the water collector was then carried out with gravel and the materials previously extracted during the desilting. These various works represented a cumulative diving time of 51 hours.

After installing the flowmeter, two level-conductivity-temperature probes were placed in the DN 100 mm tube in order to measure these variables in line with the griffin, at a depth of 29.55 m. These probes have been duplicated to ensure redundancy intended to reinforce validation and secure measurements. The characteristics of the probes are as follows (type

OTT PLS C): Pressure range: 0-40 m of water; Temperature range -5/+45°C; SpC range 0-100 mS/cm.

Cables and hoses between the spring and the shore were fixed on concrete pads to ensure their ballast then buried under 0.3 to 0.5 m of sediments. These four cables and hoses approximately 180 m long are distributed as follows : 32 mm diameter HDPE tube for water sampling, 50 mm diameter corrugated PELD sheath for the power supply cable and the flowmeter measurement cable, PELD corrugated sheath diameter 50 mm for the two OTT-PLC probes. A 2 m<sup>3</sup>/h vacuum pump was installed to ensure on-demand sampling of water from the Vise in order to be able to carry out water sampling and manual control measurements.

All cables from the experimental device were connected in an electrical cabinet which includes the following parts : the necessary electrical protections; the electronic box of the flowmeter; an OTT NetDL measurement unit equipped with a GPRS modem and the following inputs: 6 inputs 4-20mA ; 1 RS485 SDI12 input.

The measuring station was programmed to communicate the rawdata to a BRGM data server. Flow, level, SpC and temperature recording and remote transmission began on June 25, 2019.

### **3.2 Verification of the submarine flow measured by the experimental measuring device**

The Krohne electromagnetic flowmeter has been factory calibrated by the manufacturer, the absolute uncertainty is less than 5%. After the installation in the marine environment, we imagined an experiment to check the proper functioning of the experimental device.

The control of the velocity field at the outlet of the experimental device's stilling tube was carried out using a device specially developed within the framework of this project (Figure 8a). The device is made up of a Seacraft ENC underwater navigation unit (1) equipped with a speed sensor (2) initially developed to record the movement of a diver underwater (azimuth, depth, distance). The flow velocity sensor is set at the end of a bar with marks in order to more easily position the measurement points at the outlet of the stilling tube. The measurements from the central (1) are noted by the diver on an underwater slate (3) and also filmed by a small waterproof camera (4).

The velocity field control measurements allow to estimate the order of magnitude of the flows from the submarine source (0.16 m<sup>3</sup>/s on November 14, 2019). These measurements are used to validate the data produced by the electromagnetic flowmeter, the average daily flow being 0.139 m<sup>3</sup>/s (+/- 0.007) on November 14, 2019.

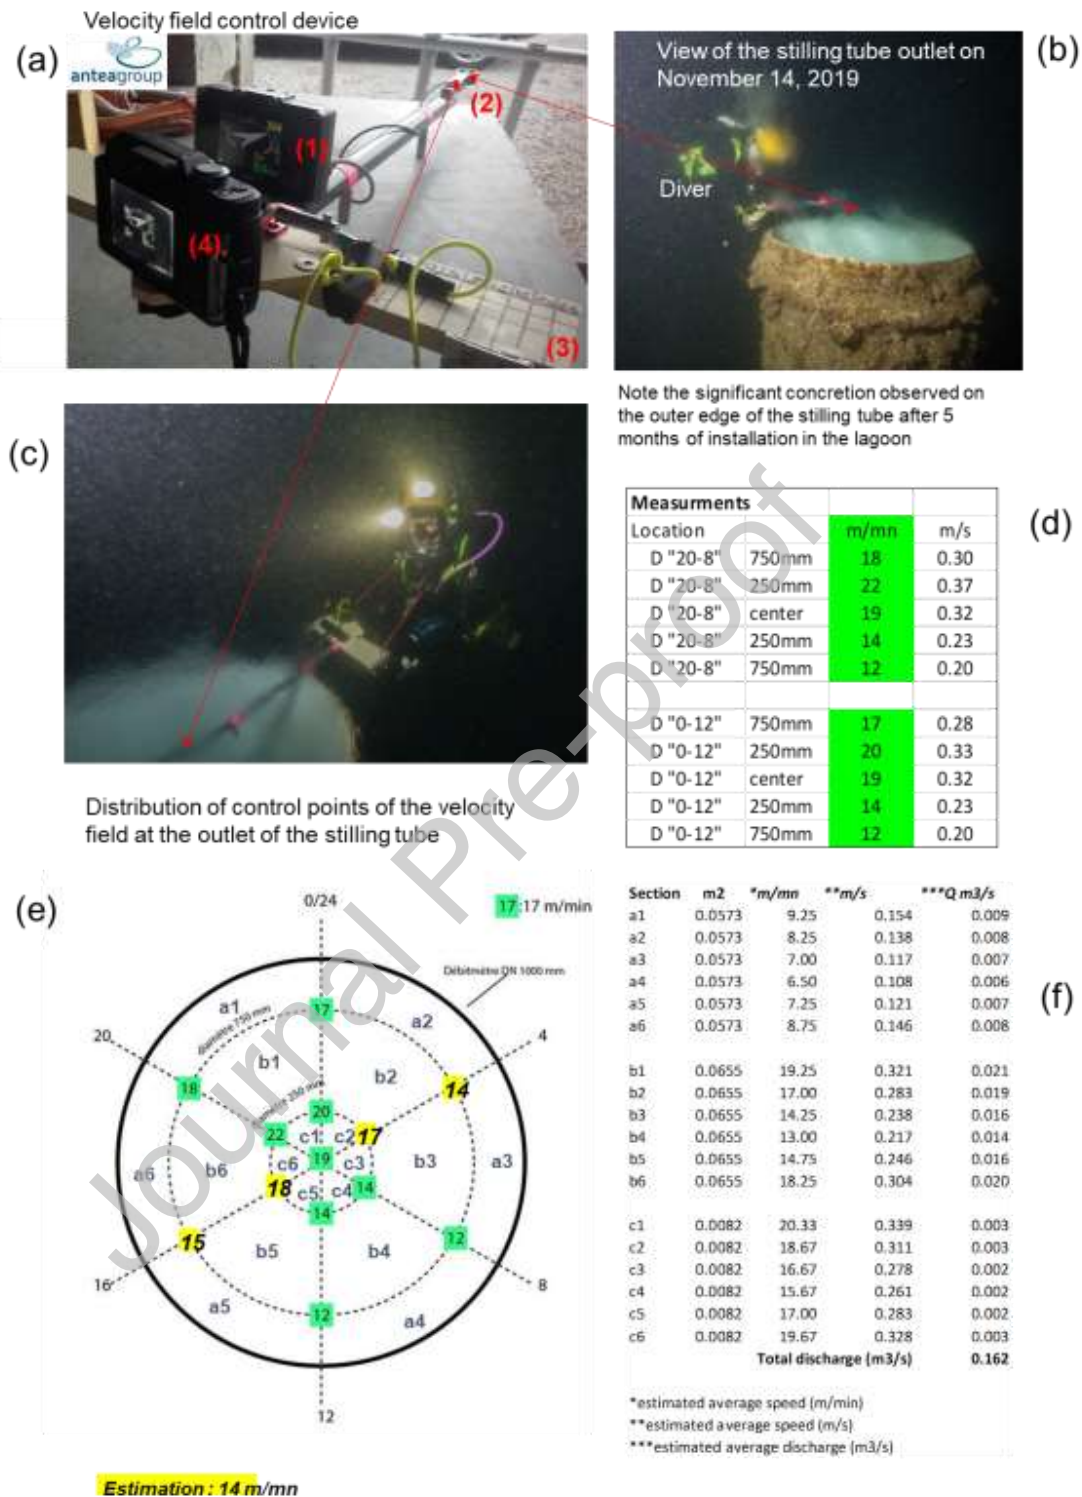

Figure 8. (a) View of the device specially developed to performed punctual velocity controls at the outlet of the stilling tube [1: Seacraft ENC underwater navigation unit, 2: flow velocity sensor, 3: underwater slate, 4: waterproof camera]. (b, c) Diver performing a velocity control

measurement at the outlet of the stilling tube. d) Results of velocity measurements. (e) Location of velocity measurement and estimation points. (f) Estimation of the flows of the different sections from estimated velocity, estimation of total discharge of submarine spring.

### 3.3 Data collection and result synthesis

The raw data collected at the submarine spring of the Vise and within the groundwater observatory are stored in the Hydras 3 software (OTT company). The exports in excel were carried out in order to present the results (Vise\_Submarine\_Spring.xlsx, Thau\_karst\_groundwater.xlsx) in the Mendeley repository directory. The calculations of the hourly average values and the associated standard deviations were carried out with used of dynamic pivot tables of Excel.

### Ethics statements

Authors have read and follow the ethical requirements for publication in Data in Brief. This work meets these requirements and authors confirm that the current work does not involve human subjects, animal experiments, or any data collected from social media platforms

### CRedit author statement

**Ladouche Bernard** : Conceptualization, Methodology, Funding acquisition, Data curation, Writing –original draft; **Maréchal Jean-christophe** : Writing- Reviewing and Editing; **Lamotte Claudine**: Conceptualization, Methodology, Writing- Reviewing and Editing, Project administration; **Durand Vincent**: Conceptualization, Methodology; **Bailly-Comte Vincent**: Conceptualization, Methodology, Writing- Reviewing and Editing; **Hakoun Vivien**: Writing- Reviewing and Editing

### Acknowledgments

This work is part of the Dem'Eaux Thau Project, funded by: European Community, French State, Région Occitanie, Agence de l'Eau RMC, SMBT, City of Balaruc-Les-Bains, Montpellier Méditerranée Métropole and BRGM.

### Declaration of interests

The authors declare that they have no known competing financial interests or personal relationships that could have appeared to influence the work reported in this paper.
