## Microgrid optimal design: definition & challenges

### Microgrids

Definition: **standalone energy systems**, e.g. needed for rural electrification

#### Sizing

#### Microgrid design objectives:

- (min) Lifecycle cost = Investment + Operation + Replace
- (max) Quality of Service ( $\rightarrow$  min load shedding)
- and also: environmental impact...

#### Two intertwined optimization problems

- o Microgrid **sizing**: find the optimal components' size
- o **Energy management (EM)**: choose, at each instant, the optimal power flows

Fact: model type **restricts** choice of optimization method

Q: Which **microgrid model & optim methods** yield:  
 o fast convergence? (~ in seconds)  
 o reliable convergence? (close to global optimum)  
 o robustness against data uncertainty?

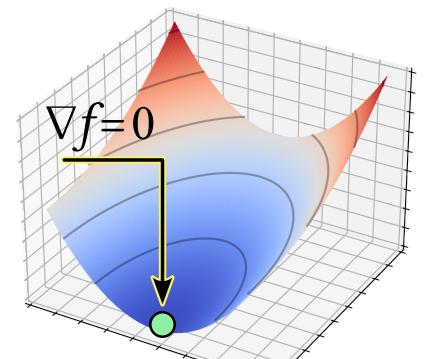

### Microgrid sizing tool

Since each project is a specific design  
 $\rightarrow$  need for reliable microgrid sizing tool

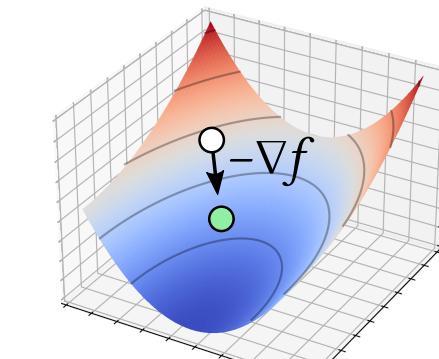

- weather & load time series
- prices of components
- technical bounds

$\Delta$  Uncertainty of project data:  
**anticipative** Energy Management may not be applicable on field (w/o forecast).

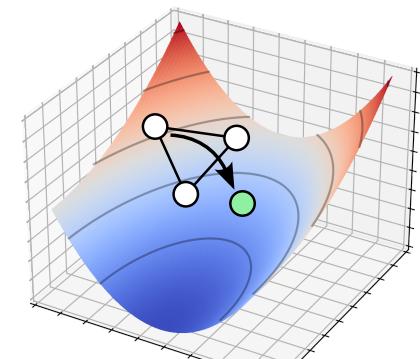

### 1. Blackbox (BB)

### 1b. Gradient-based

## Two ½ flavors of optimization

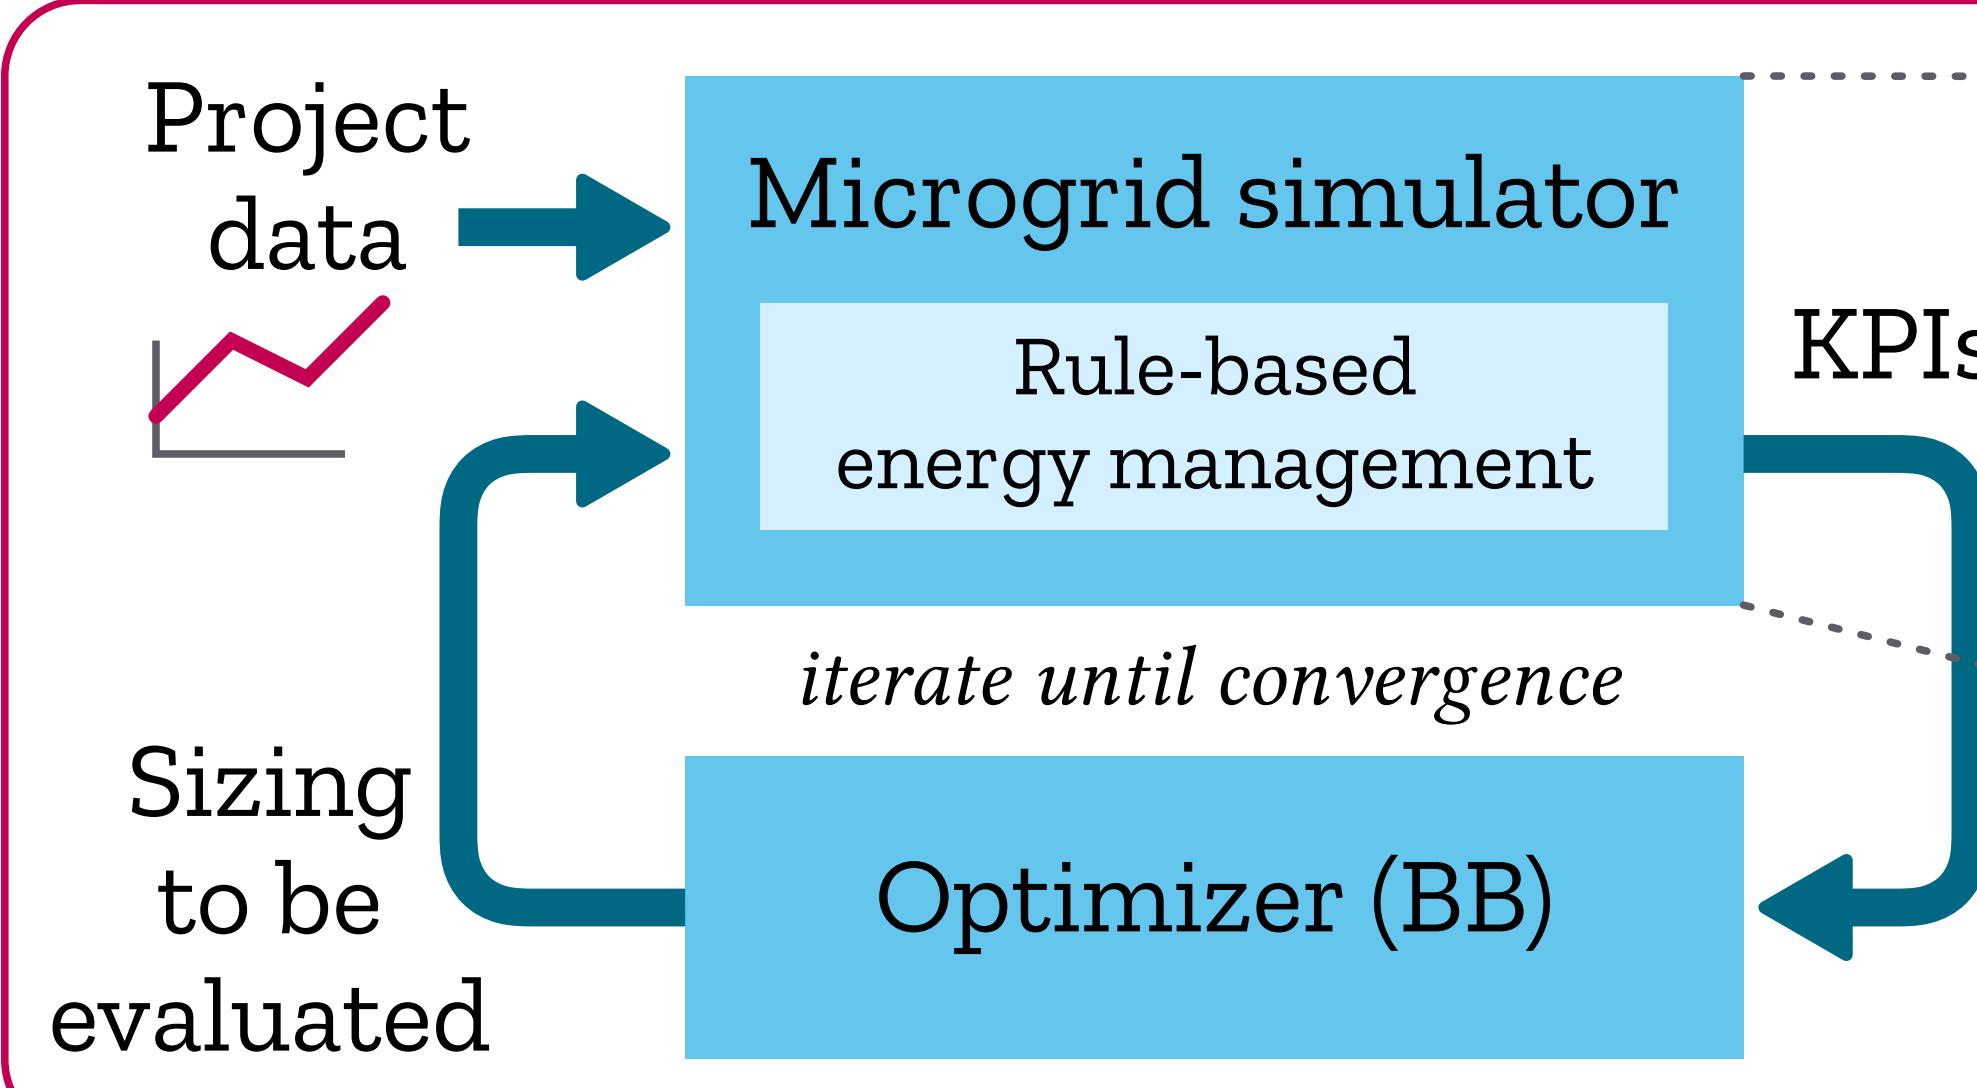

### 1a. Derivative-free

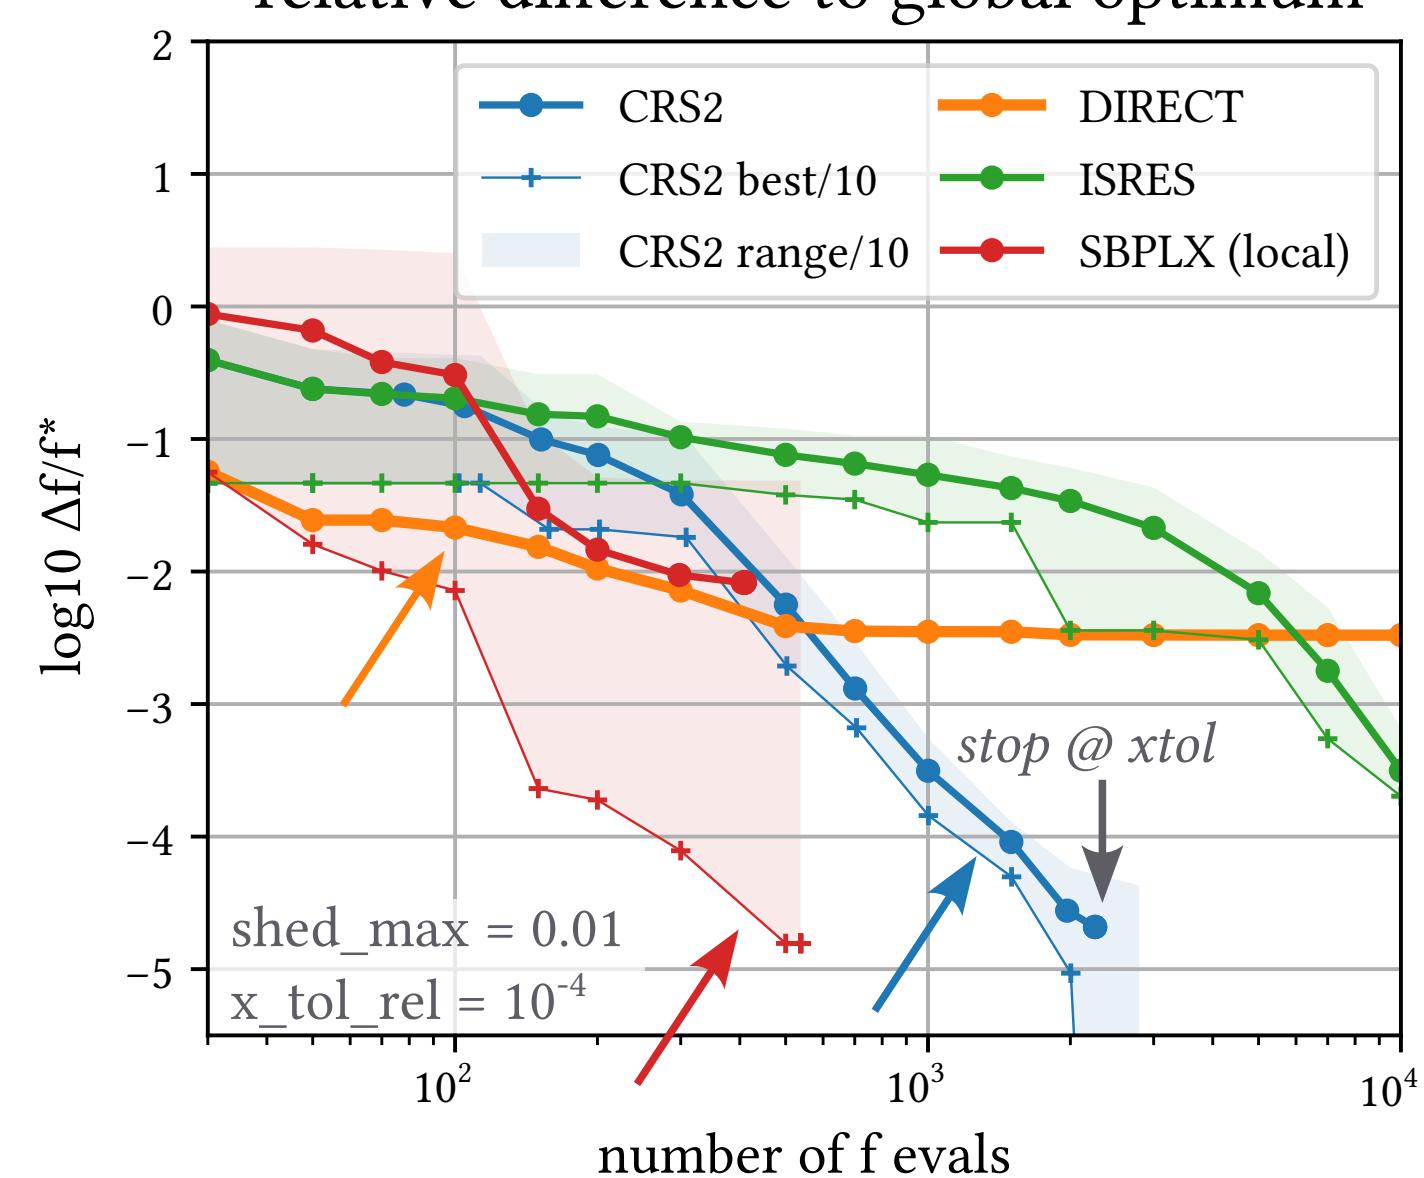

Microgrid model: **imperative** code (“simulator”)  
 Simulator: sizing  $x \mapsto \text{KPIs}(x)$

Fact:  $T_{\text{optim}} \approx T_{\text{sim}} \times \text{neval} \rightarrow$  Needs:

- o **fast** simulation code:  $T_{\text{sim}} \downarrow$  (i.e. Julia's JIT)
- o frugal optimizer:  $\text{neval} \downarrow$  (but also reliable)

Optimality vs Computational budget: relative difference to global optimum

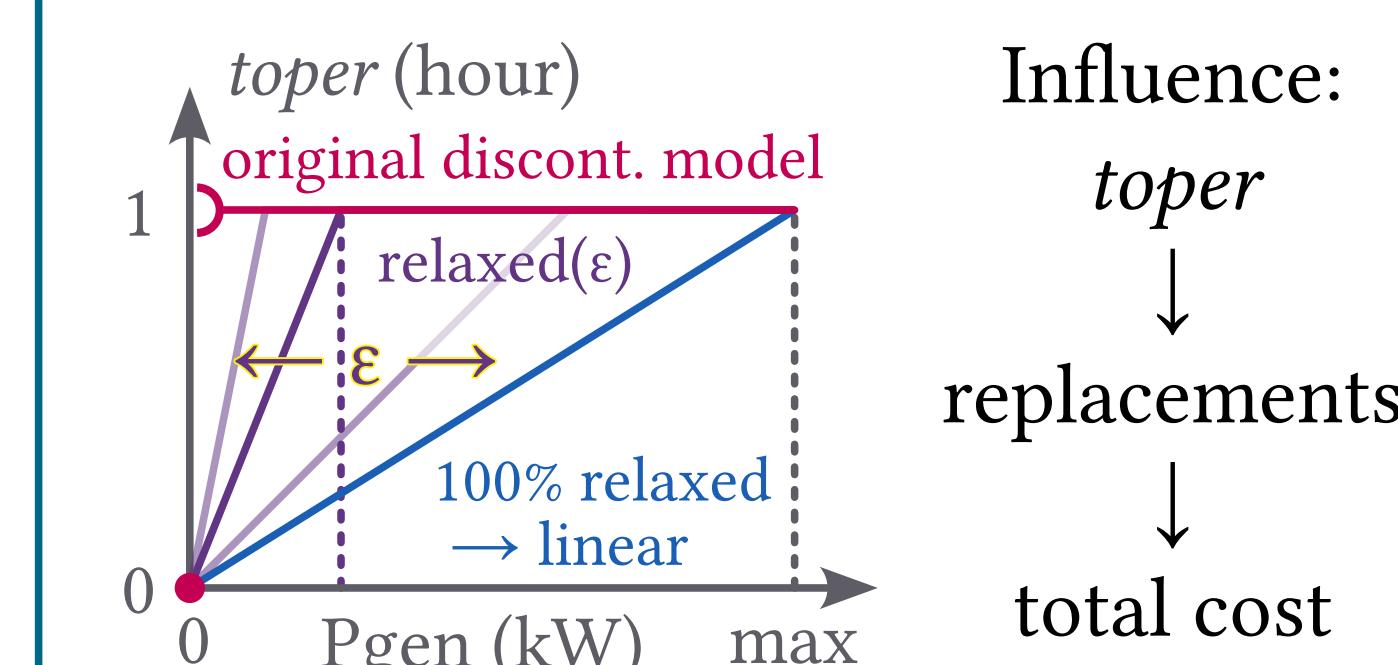

#### Q: choice of optimizer?

- o Tools: NLOpt.jl library of optimization algorithms
- Benchmark lessons:
  1. if small budget (~100 iter): DIRECT best & fully reliable
  2. if medium budget (~1k iter): CRS2 best & pretty reliable
  3. if local method (SBPLX): multistart is required

#### Issue: discontinuities of some model expressions

Example: counting of the operation time of generator

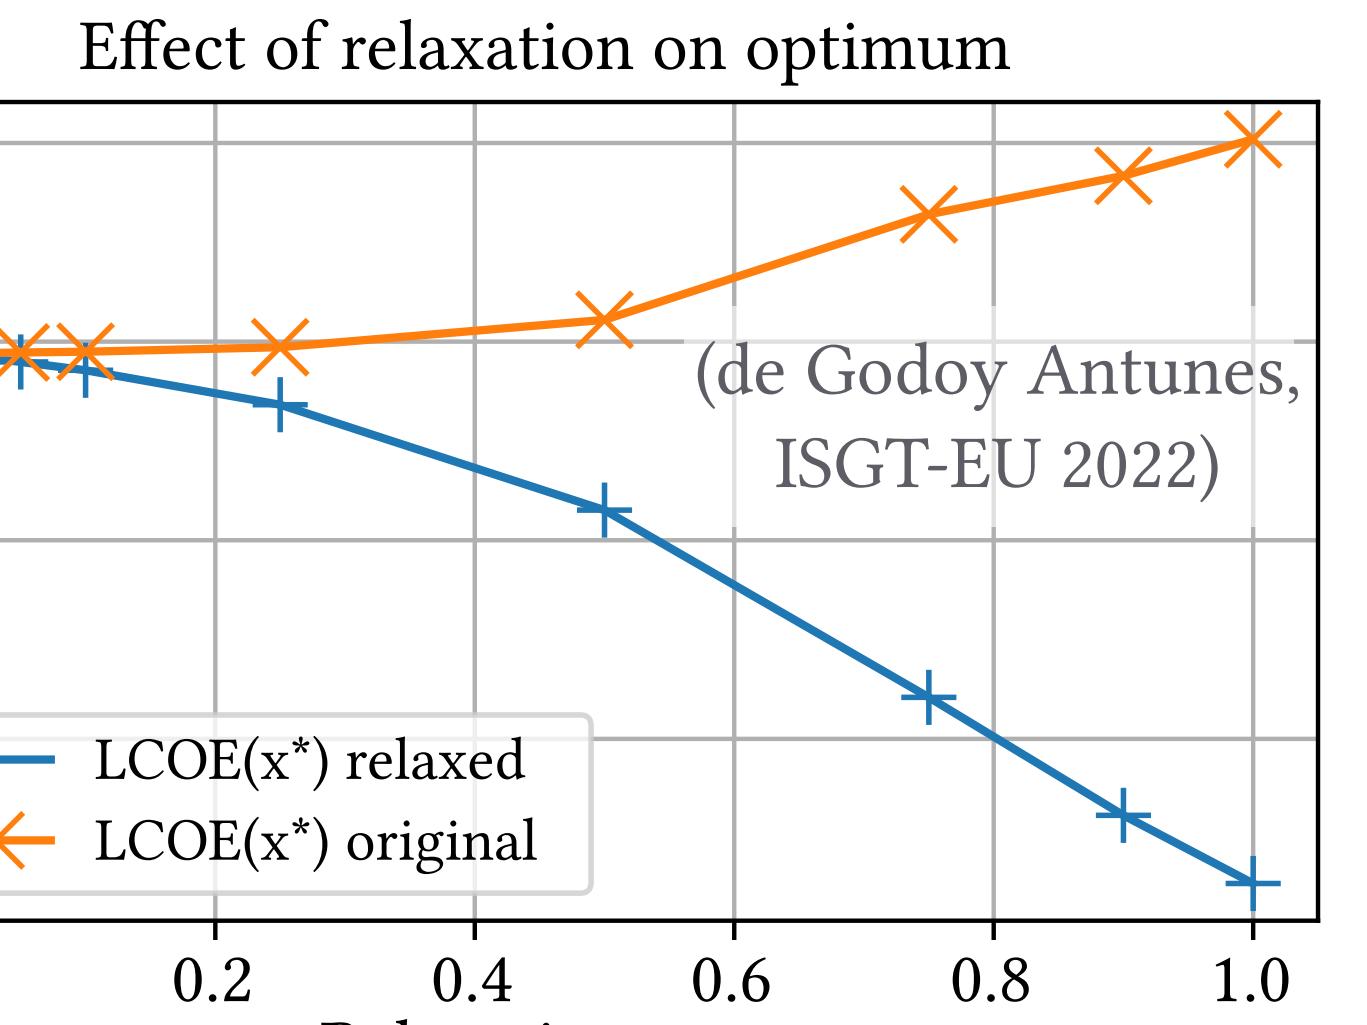

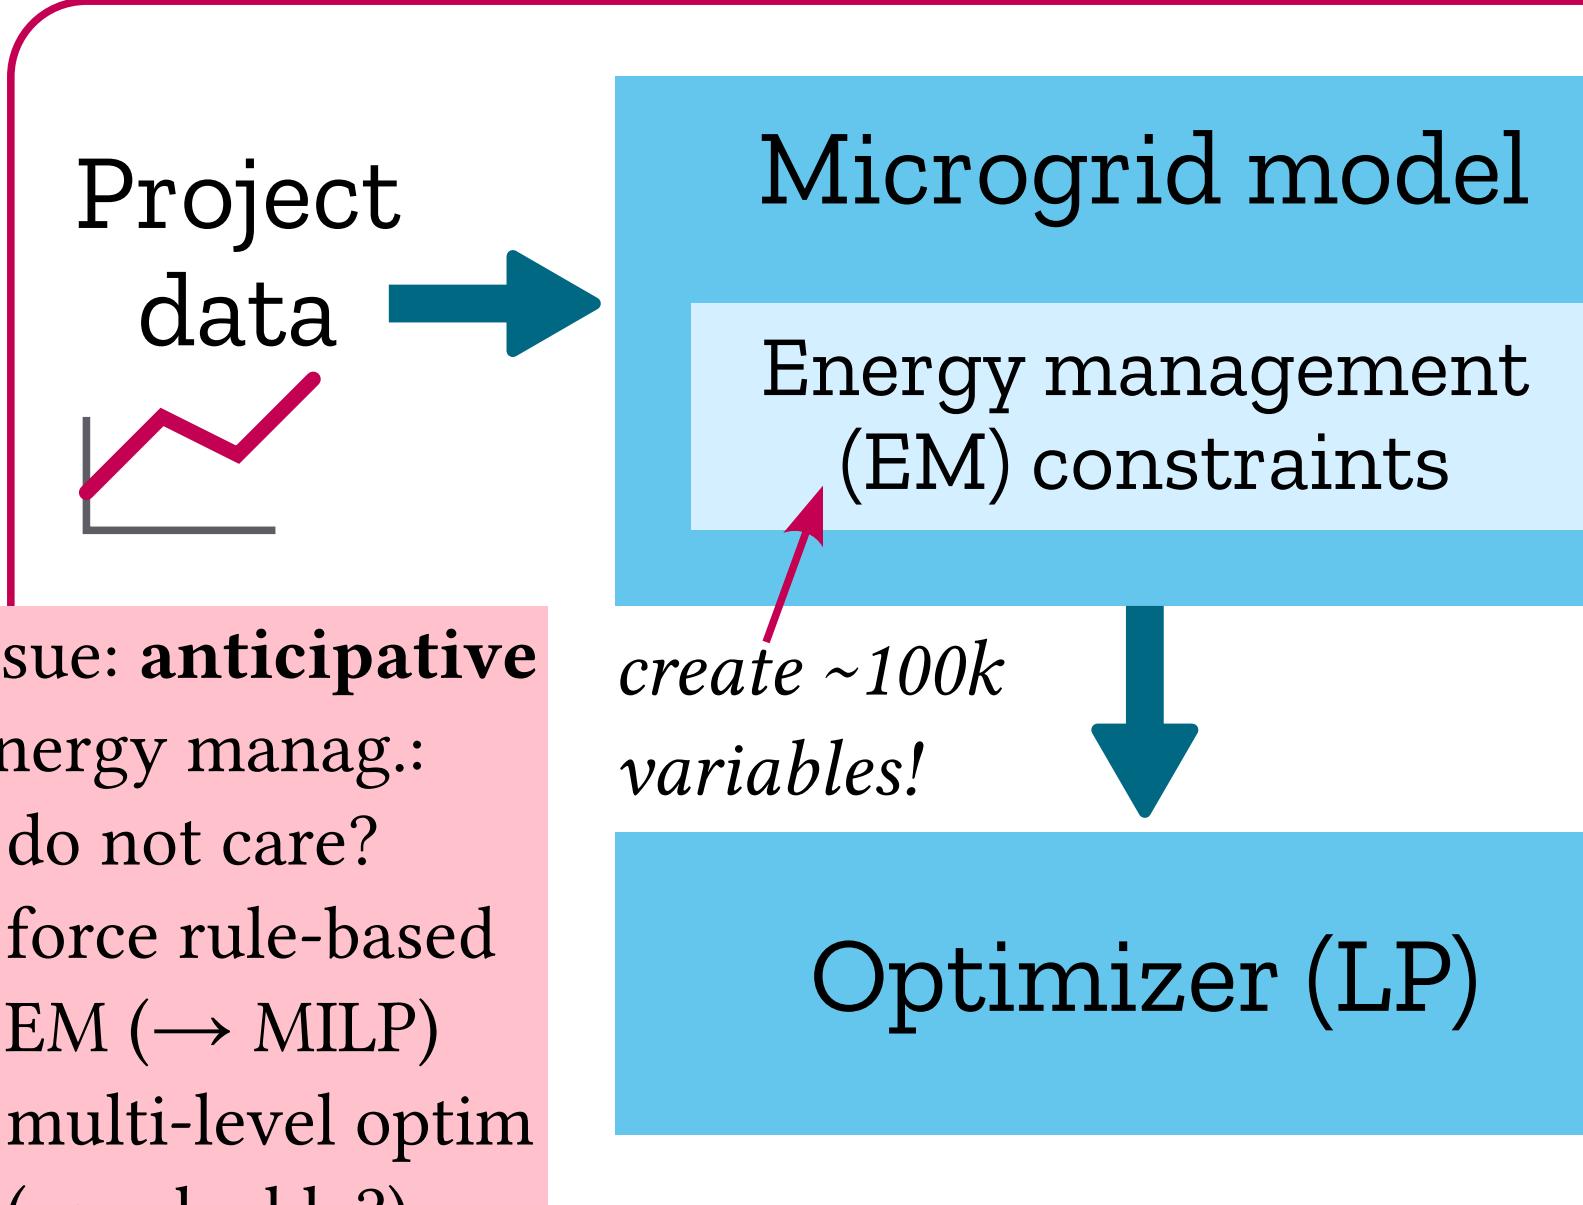

#### Q: Tuning relaxation amount ε ? → Compromise: more accurate model ↔ easier convergence

Microgrid model: **acausal** & algebraic  
 Simulator: sizing  $\leftrightarrow$  KPIs

Fact: convexity allows **reliable convergence**

- o Need to linearize models (for Linear Prog.)
- o Tools: JuMP.jl + LP solver (Clp...)

### Tools

<https://pierreh.eu/Microgrids-X/>  
 Github: Microgrids-X/Microgrids.jl  
 Operational & economic simulation of Microgrids  
 - with simple rule-based energy management  
 - with sizing optimization example

Simulator performance in three languages:  
 Julia 0.15 ms Matlab ~0.5 ms Python 11 ms  
 inside VM inside VM no JIT compilation!

### Conclusions

#### Choice of optimization approach

- o **Derivative free BB**: more physical model ☺, non anticipative ☺ but simplistic ☹ Energy Management
  - o **Gradient-based BB**: discontinuities require smoothing, faster convergence ☺, but multistart needed?
  - o **Algebraic (Linear Prog)**: guaranteed convergence ☺, but simplified physics ☹, not so fast with 100k variables and anticipative EM yields “overoptimistic” design ☹
- No clear winner, all are useful!

### Perspectives

For blackbox optimization:

- Study effect of **more optimization variables** for mid-project resizing (**recourse** against **uncertainty**: a few  $\rightarrow$  dozens of variables): ranking of BB algorithms unchanged?
- Add more algorithms in benchmark (GAs, PSO... often used in literature)
- Test **multi-objective** optimization algorithms

For algebraic optim.: is there an efficient way to enforce **non anticipative** Energy Management?
