HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

The outer Solar System contains trillions of small objects made of ice and rock; yet, few have been explored in near-ultraviolet wavelengths. The surface composition of trans-Neptunian objects (TNOs) is a relic of the early planetesimal disk, and studying them provides insight into the evolutionary history of the Solar System. In particular, the far to near ultraviolet holds potential for understanding how the ices and organic materials of minor planet surfaces are modified under the effect of UV and charged particles. Furthermore, carbonaceous materials are spectrally active in the ultraviolet as compared to in the traditional visible and near-infrared wavelengths; observing TNOs in the near-ultraviolet offers a unique avenue to study the composition of carbon-bearing surfaces.

Using data from the Canada-France-Hawaii Telescope (CFHT), we are studying TNOs in the first major near-UV survey of the outer Solar System. 165 objects spanning the full TNO population range have been observed in u ($\lambda \sim 370$ nm) from August 2014 to July 2019. The CFHT data has been acquired simultaneously with g , r , and J photometry from the Gemini-North telescope as part of the Colours of the Outer Solar System Origins Survey (Col-OSSOS). Our u -band survey is the first to have routine simultaneous photometry by two major observatories, yielding two-telescope data on 63 objects. Col-OSSOS has already shown that the cold classical Kuiper belt population occupy a unique colour space in the r - and z -band; further photometry of the Col-OSSOS sample enables expansion to a full set of pan-chromatic surface reflectance measurements. With Col-OSSOS data implying two separate surface classes of TNOs in the optical-IR region (Fraser et al., this meeting), the near-UV survey affords the opportunity to investigate if this bimodal classification continues in the u -band, or if additional colour classes are needed. Here, we present preliminary results from our analysis of this near-UV survey.
