## abstract

The thermal conductivity (TC) and strength trade-off has been a long-standing dilemma for developing high TC alloys. Here a novel high TC and cost-effective die-cast Mg<sub>2.8</sub>Al<sub>3.8</sub>-La<sub>0.4</sub>Nd alloy was developed with enhanced yield strength (YS) at room temperature (RT) and high temperatures (HT), compared with the commercially widely used die-cast AE44 magnesium alloy. The new alloy provided the TC of 104.0 and 125.9 W/(m\$K) separately at RT and 300 °C. Compared with AE44 alloy, the TC was improved by ~13.5%. The new alloy also delivered an excellent YS of 137.1 MPa, ultimate tensile strength (UTS) of 240.2 MPa and elongation of 8.8% at RT, and the YS of the new alloy was enhanced by 6.3% at RT and 9.8% at 300 °C, compared with AE44 alloy. The new alloy only has a 1.3% increase in raw material cost compared with AE44 alloy, offering a relatively cost-effective alternative. The lamellar (Al,Mg)<sub>3</sub>RE and Al<sub>11</sub>RE<sub>3</sub>, the needle-like Al<sub>2.12</sub>RE<sub>0.88</sub> and the blocky Al<sub>10</sub>RE<sub>2</sub>Mn<sub>7</sub> intermetallic phases were identified. With the optimizing addition of Al and La, the Al solute amount in the matrix was reduced remarkably by 42% and then contributed to the improvement of TC. The major (Al,Mg)<sub>3</sub>RE phase at grain boundaries (GBs) contributed heavily to the enhancement of YS. This study elucidates the importance of the transfer of Al from the matrix to form higher content and novel Al-based intermetallic phases at GBs, for achieving die-cast Mg-Al-based alloys with excellent TC and strength.

## 1. Introduction

The increasing development of alternative energy vehicles, 3C telecommunication products and relative fields has increased the quantity and layout density of electromagnetic devices with high-power densities, and the resulting high temperatures can lead to a decrease in the operational stability and reliability of the devices [1e3]. Therefore, improving device thermal conductivity (TC) in a lightweight context is an extremely urgent issue. Due to their low density, magnesium alloys could replace conventional thermally conducting alloys [1,4]. However, the widespread application of magnesium alloys needs to consider two key issues: application performance and cost. According to the current research on magnesium alloys, a reasonable optimization of the alloying in magnesium alloys is an effective way to balance performance and cost [5e7]. In addition, low unit-cost high-pressure die casting (HPDC) is ideal for quantity production [8,9]. Therefore, the die-cast thermally conductive magnesium alloy that combines performance and cost is the aim of this investigation.

In general, the solid solution, the crystal structure and defects and the intermetallic phase determine the TC of the alloy [10e12]. The subsequent heat treatment or deformation produces microstructural changes, such as changes in solid solution, grain size and Intermetallic size, which also affect the TC [13,14]. Dilute atoms can cause lattice distortion in the matrix due to solid solution, shortening the mean free path for electron and phonon transfer and thus decreasing TC [12]. Grain boundaries (GBs) or intermetallic phases on GBs can also impede thermal conduction [15]. Solution heat treatment can increase the number of solution atoms in the matrix, thereby decreasing TC [1,16]. In contrast, artificial ageing heat treatment reduces the solute amount, thereby reducing the precipitation of solute atoms and increasing TC [12]. In addition, deformations such as extrusion positively affect the TC of certain alloys [1,17]. Within these factors, the solid solution of solute atoms is usually considered to be the main factor contributing to the deterioration of TC [1,12].

Al is often used in alloys to improve the castability of magnesium alloys, so most currently applied commercial die-cast magnesium alloys are Mg-Al-based alloys [6,18]. However, Al has a high equilibrium solid solution in magnesium of 12.7 wt% at 437 °C [19]. Excessive addition of Al can increase Al solute in a matrix, thus affecting TC. The TC of the common die-cast AZ91D, AM60, MRI230D and AE44 alloys are still at a low level, 51, 61, 77 and 91.4 W/(m\$K), respectively [20e22]. AE44 alloy has the highest TC. However, it cannot be compared to the widely used die-cast A380 alloy (96 W/(m\$K)) [22]. Therefore, reasonable control of the Al content is a critical concern in developing high TC Mg-Al-based alloys. In previous studies, we have successfully developed a HPDC Mg<sub>3.2</sub>Al<sub>4.4</sub>La<sub>0.4</sub>Nd alloy with excellent mechanical and thermal properties [7]. However, it

performed poorly on the cost compared to AE44 alloy. Therefore, it was concluded that there was a need to develop an alloy with improved TC and mechanical properties compared to AE44 alloy at the exact cost.

The methods and strategies used in this study will be consistent with our previous study [7]. In this work, we have developed a new highly TC and cost-effective die-cast Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy with an improved yield strength (YS) at room temperature (RT) and high temperature (HT) and compared it comprehensively with commercially representative die-cast AE44 alloy and previous developed high TC Mg<sub>3.2</sub>Al<sub>4.4</sub>La<sub>0.4</sub>Nd alloy. The design strategy, microstructure, thermal properties, tensile properties, and strengthening mechanisms of new alloys were investigated in depth.

## 2. Experimental

Pure ingots of Mg, Al and Zn and Mg-30 wt%La, Mg-25 wt%Nd and Mg-5wt.%Mn ingots were used to produce developed Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy and previously developed Mg<sub>3.2</sub>Al<sub>4.4</sub>La<sub>0.4</sub>Nd alloy [7]. The pure magnesium ingots were melted in electrical resistance furnaces fitted with steel liners, and then the other ingots were inserted into the pure magnesium melt. Subsequently, the melt was agitated three times to homogenise the composition and eliminate the impurities. The melt prepared was maintained at 720 °C for 30 min before pouring. The compositions of prepared melts were exhibited in Table 1, measured with Inductively Coupled Plasma-Optical Emission Spectrometry (ICP-OES). For comparison, AE44 alloy samples were die-cast using commercial ingots.

The HPDC experiment proceeded with a 4500 kN cold-chamber Frech machine [23]. Circulated oil preheated the die to 230 °C, and the compressed water preheated the shot sleeve to 180 °C. The casting pressure was 320 bar. Alloy melts were poured into the shot sleeve to prepare die-casting at 715 °C. One plate with a thickness of 4 mm for the TC test and eight round bars with a gauge size of Ø6.35 mm x 50 mm for the tensile test were cast under each shot [24].

The TC was determined by  $1/\alpha \cdot \rho \cdot C_p$ , where  $\rho$  was the density,  $\alpha$  was the thermal diffusivity (TD), and  $C_p$  was the specific heat capacity (SHC) [1,25]. The Archimedes method was applied to determine the RT density, while the thermal expansion was measured using a Shimadzu TMA-50 instrument to determine the HT density. The TD was tested on a Netzsch LFA-427 machine with the laser-flash method. The SHC was assessed with a differential scanning calorimeter (Netzsch 404C). Tension tests were conducted on Instron test machine. The tension tests were separately conducted at strain rates of 1 mm/min and 0.0002/s for RT and HT. The samples were held at a specific HT for 40 min before tensile tests. Three thermal and six tensile samples were tested to get mean thermal and tensile properties, respectively.

Table 1 e Composition (in wt. %) of die-cast Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy and the commercial AE44 alloy measured by ICP-OES.

Alloy	Al	La	Ce	Nd	Zn	Mn	Mg
Mg <sub>2.8</sub> Al <sub>3.8</sub> La <sub>0.4</sub> Nd	2.78	3.76	e	0.41	0.21	0.30	Bal.
AE44	3.70	1.11	2.19	0.40	0.11	0.31	Bal.

X-ray diffraction (XRD), scanning electron microscopy (SEM), and transmission electron microscope (TEM) were utilized to characterize the microstructure. The XRD analysis was performed in the  $20^{\circ}$  to  $100^{\circ}$   $2\theta$  range using a D8 diffractometer. Backscattered electron SEM (BSE-SEM) was performed on a Zeiss SUPRA machine outfitted with Energy-dispersive (EDS) after mechanical polishing. Ion polishing on a Gatan 691 was applied to prepare the TEM samples with a thickness of 50 nm. TEM was conducted on an FEI Tecnai G2. The ImageJ software was used to measure phase area fraction based on at least 10 SEM images and grain size distribution by using a linear intercept method.

### 3. Results

#### 3.1. Alloy design by thermodynamic calculation

A quantitative design strategy of high TC die-cast Mg-Al-based alloys based on non-equilibrium Scheil model calculations has been presented in our recent work [7]. According to this strategy, high TC of die-cast Mg-Al-based alloys can be achieved by minimizing the Al solute amount in the matrix. Minimizing the Al solute amount can entirely inhibit the  $Mg_{17}Al_{12}$  phase formation during solidification. In the current research, the alloy design followed this quantitative strategy. Fig. 1a shows the thermodynamic calculations for  $Mg_{3.7}Al_{10.4}Nd-x(La+Ce)$  alloy system. As described in our recent work, AE44 alloy also belongs to this system [7]. The thermodynamic calculations were carried out at 700 °C to RT and atmospheric pressure. It was calculated that a volume percentage of 0.857% of the  $Mg_{17}Al_{12}$  phase could be formed in AE44 alloy with 3.3 wt% mixed metal of La and Ce. It indicates that AE44 alloy is not in the ideal state of high TC. To achieve high TC in  $Mg_{3.7}Al_{10.4}Nd-x(La+Ce)$  alloy system, at least 6.0 wt% misch metal needs to be added to minimize the Al solute amount and ultimately suppress the  $Mg_{17}Al_{12}$  phase. However, this is inconsistent with the underlying aim of cost control. Therefore, based on the high TC alloy development strategy, alloying of Mg alloys needs to be further optimized to achieve a balance between performance and cost.

An appropriate reduction of Al and, thus, the addition of matching RE to achieve high TC and cost-effectiveness is considered an alternative method to designing die-cast Mg-Al-based alloys. Furthermore, La has proven to be the most efficient element for TC among the common RE elements (La, Ce, Nd, Pr, Gd, Y, Sm) due to its low equilibrium solubility in Mg [26]. Moreover, the price difference between pure La and Ce/La enriched mixed metals is insignificant in the current market. Therefore, the  $Mg_{2.8}Al_{10.4}Nd-yLa$  alloy system was proposed in the present work. Fig. 1b displays the thermodynamic calculations for the  $Mg_{2.8}Al_{10.4}Nd-yLa$  alloy system, in which at least 3.5 wt% La addition is required to suppress the  $Mg_{17}Al_{12}$  phase completely and achieve an optimized high TC. Considering combustion losses of La, the nominal composition of the high TC and cost-effective die-cast Mg-Al-based alloy of the present invention was designed and patented as  $Mg_{2.8}Al_{13.8}La_{0.4}Nd_{0.2}Zn_{0.3}Mn$  [27], which was expressed as  $Mg_{2.8}Al_{13.8}La_{0.4}Nd$  in the rest of the text.

#### 3.2. Thermal properties

Fig. 2 presents the thermal properties of die-cast  $Mg_{2.8}Al_{13.8}La_{0.4}Nd$  alloy from 20 °C to 300 °C and compares with the commercial die-cast AE44 alloy and previously developed  $Mg_{3.2}Al_{14.4}La_{0.4}Nd$  alloy [7]. The TD, SHC and TC increased with increasing temperature while the density decreased almost linearly. The TD and TC of  $Mg_{2.8}Al_{13.8}La_{0.4}Nd$  alloy were significantly higher than AE44 alloy and slightly lower than  $Mg_{3.2}Al_{14.4}La_{0.4}Nd$  alloy. The SHC of  $Mg_{2.8}Al_{13.8}La_{0.4}Nd$  alloy was slightly less than AE44 alloy below 150 °C, higher than AE44 alloy above 200 °C, but both were lower than  $Mg_{3.2}Al_{14.4}La_{0.4}Nd$  alloy. The density of  $Mg_{2.8}Al_{13.8}La_{0.4}Nd$  alloy was slightly higher than AE44 alloy and lower than  $Mg_{3.2}Al_{14.4}La_{0.4}Nd$  alloy.

The TD of  $Mg_{2.8}Al_{13.8}La_{0.4}Nd$  alloy increased from 60.8 to 65.9  $mm^2/s$  and TC from 104.0 to 125.9  $W/(m^2K)$  as temperature increased from 20 °C to 300 °C. For comparative alloy AE44, the TD increased from 51.9 to 58.9  $mm^2/s$ , and the TC increased from 91.4 to 111.2  $W/(m^2K)$  within an identical thermal range. At 20 °C, the TD and TC of  $Mg_{2.8}Al_{13.8}La_{0.4}Nd$  alloy were 17.2% and 13.7% higher than AE44 alloy. At 300 °C, the TD and TC of  $Mg_{2.8}Al_{13.8}La_{0.4}Nd$  alloy were 12.0% and

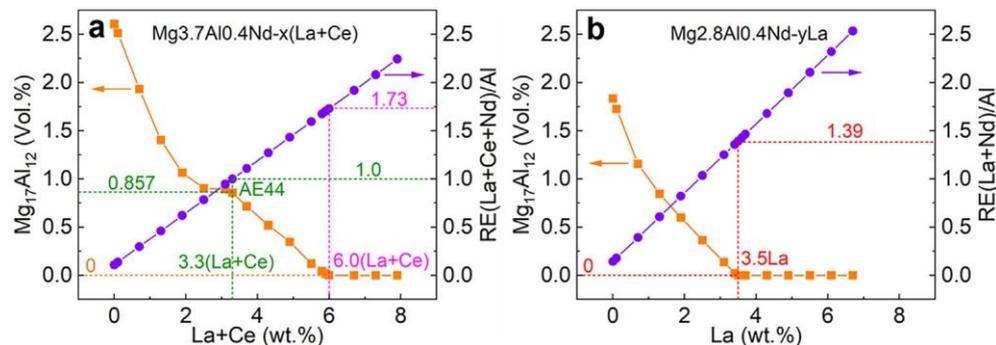

Fig. 1 e Thermodynamic calculation results of the volume percentage of the  $Mg_{17}Al_{12}$  phase under non-equilibrium Schell mode. (a)  $Mg_{3.7}Al_{10.4}Nd-x(La+Ce)$  alloy [7], (b)  $Mg_{2.8}Al_{10.4}Nd-yLa$  alloy system that newly developed die-cast  $Mg_{2.8}Al_{13.8}La_{0.4}Nd$  alloy belongs to.

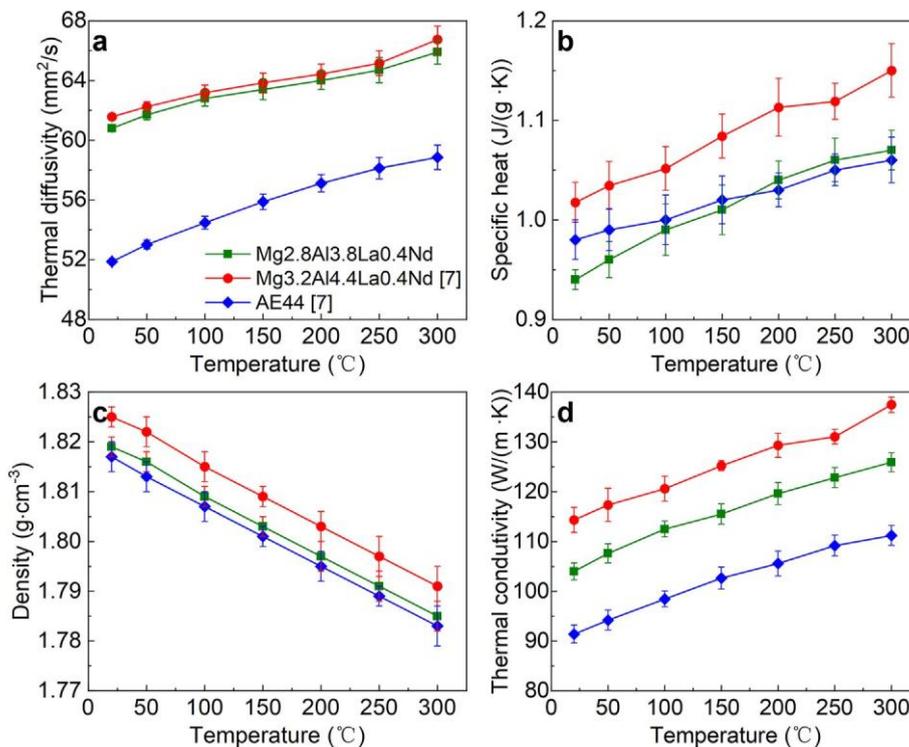

Fig. 2 e Thermal properties of die-cast Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy from 20 °C to 300 °C and in comparison with commercial die-cast AE44 alloy and previously researched Mg<sub>3.2</sub>Al<sub>4.4</sub>La<sub>0.4</sub>Nd alloy [7]. (a) TD, (b) SHC, (c) Density, and (d) TC.

13.2% higher than those of AE44 alloy. The improved TD was the main contributor to the improved TC. Table 2 and Supplementary Table S1 provided natural thermal properties data at RT and HT, respectively. It should be noted that the raw material cost of Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy is only 1.3% higher than comparator AE44 alloy and 1.4% lower than previously developed Mg<sub>3.2</sub>Al<sub>4.4</sub>La<sub>0.4</sub>Nd alloy, as shown in Supplementary Table S2.

### 3.3. Enhancement of yield strength

Fig. 3aee displays the tensile curves of die-cast Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy at RT, 150 °C, 200 °C, 250 °C and 300 °C compared with commercial die-cast AE44 alloy and previously developed Mg<sub>3.2</sub>Al<sub>4.4</sub>La<sub>0.4</sub>Nd alloy [7]. Fig. 3feh shows the YS, ultimate tensile strength (UTS) and elongation of the three alloys at varying temperatures. Detailed data on tensile properties are presented in Table 3. Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy can provide 137.1 MPa YS, 240.2 MPa UTS and 8.8% elongation at RT. Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy and previously developed Mg<sub>3.2</sub>Al<sub>4.4</sub>La<sub>0.4</sub>Nd alloys have higher YS and UTS at RT than comparator AE44 alloy, while lower elongation. Compared to AE44 alloy, Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy had a 6.3% enhancement in YS at RT. At 150e300 °C, Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy and previously developed Mg<sub>3.2</sub>Al<sub>4.4</sub>La<sub>0.4</sub>Nd alloy exhibited higher YS, UTS and elongation than comparative AE44 alloy. The YS, UTS and elongation of Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy at 300 °C were 72.5 MPa, 80.5 MPa and 37.1%, respectively, 9.8%, 8.5% and 144% greater than AE44 alloy. Therefore, Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy had a stronger YS at RT and a superior tensile property at HT

than AE44 alloy. Incorporating the thermal and tensile properties from Tables 2 and 3, Fig. 3i shows that Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy provides enhanced YS and TC at RT compared to commercially available die-cast AE44 alloy and is cost-effective compared to previously developed Mg<sub>3.2</sub>Al<sub>4.4</sub>La<sub>0.4</sub>Nd alloy.

### 3.4. Microstructure

#### 3.4.1. XRD pattern

Fig. 4 exhibits the XRD pattern of die-cast Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd and AE44 alloys under as-cast conditions.  $\alpha$ -Mg, Al<sub>11</sub>RE<sub>3</sub> and Al<sub>2</sub>RE phases were detected in AE44 alloy, which agreed with the reported phase constitution of AE44 alloy [28,29]. Al<sub>11</sub>RE<sub>3</sub> phase was also detected in Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy. However, different from AE44 alloy, a significant presence of (Al,Mg)<sub>3</sub>La phase was detected, while the Al<sub>2</sub>RE phase was hardly detected in Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy. It should be noted that small size or volume fraction phases are typically difficult to detect using XRD.

#### 3.4.2. SEM morphology

Fig. 5a and b displays BSE-SEM micrographs of commercial AE44 alloy under the as-cast state. The AE44 matrix exhibited a typical die-cast Mg alloy microstructure comprising  $\alpha_1$ -Mg nucleated inside sleeve and  $\alpha_2$ -Mg nucleated inside chamber [5,23]. With a relatively high cooling rate, the dimension of  $\alpha_2$ -Mg was smaller than  $\alpha_1$ -Mg in the cavity [23,30]. In consistency with the previous reports [28,29], three intermetallic phases were found in AE44 alloy, i.e., the lamellar Al<sub>11</sub>RE<sub>3</sub>, the blocky Al<sub>2</sub>RE and Al<sub>10</sub>RE<sub>2</sub>Mn<sub>7</sub> phases, and Al<sub>11</sub>RE<sub>3</sub> was the major

**Table 2 e** Thermal properties at RT and raw material cost of die-cast Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd and in comparison with die-cast AE44 alloy and previously researched Mg<sub>3.2</sub>Al<sub>4.4</sub>La<sub>0.4</sub>Nd alloy.

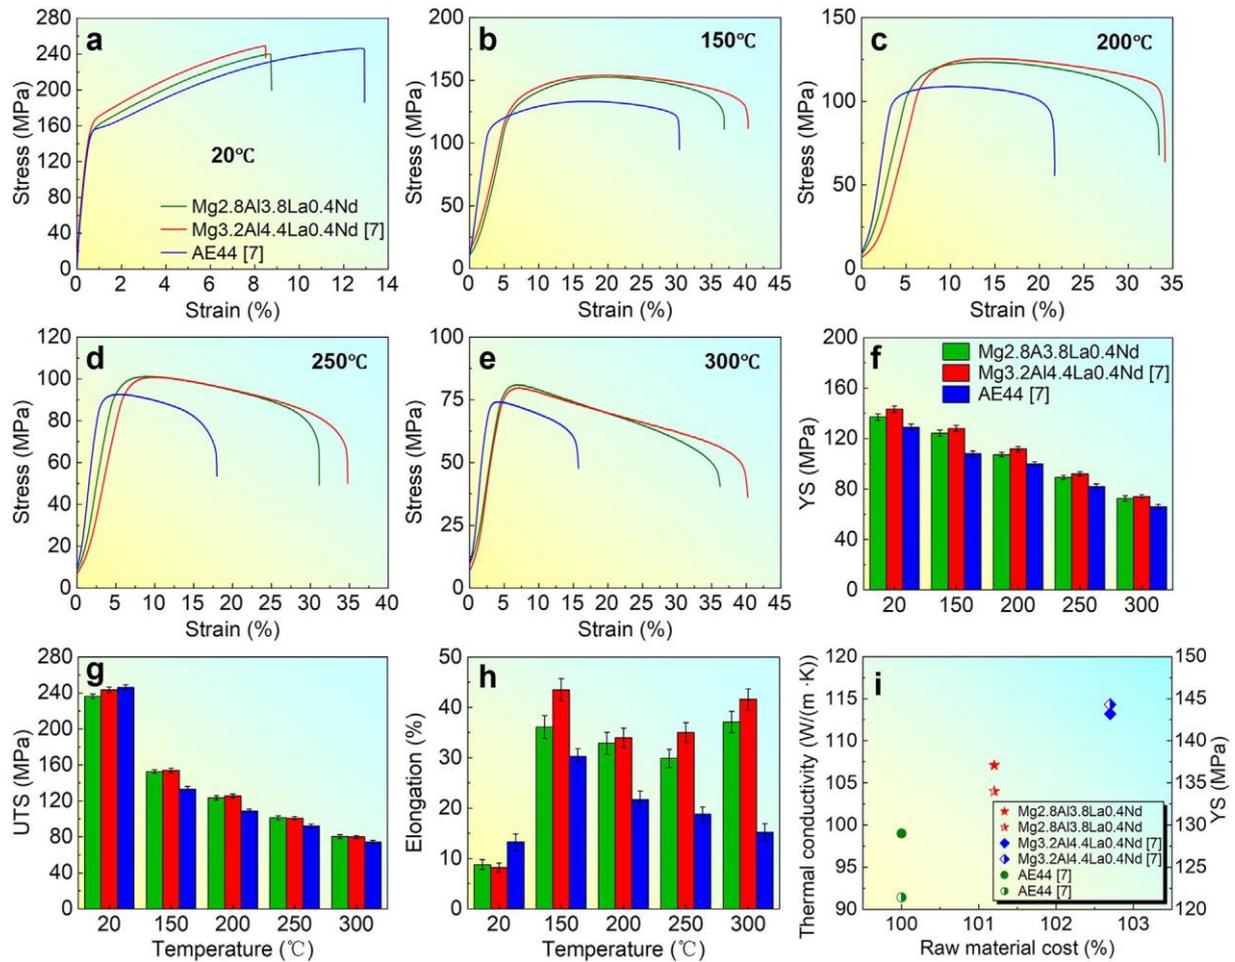

Alloys	Thermal diffusivity $\alpha/\text{mm}^2\text{s}^{-1}$	Special heat capacity $C_p/J\text{ (g}\text{\$K)}^{-1}$	Density $\rho/\text{g}\text{\$cm}^{-3}$	Thermal Conductivity $\kappa/W\text{ (m}\text{\$K)}^{-1}$	Raw material cost	Ref
Mg <sub>2.8</sub> Al <sub>3.8</sub> La <sub>0.4</sub> Nd	60.8 ± 0.2	0.94 ± 0.01	1.819 ± 0.002	104.0 ± 1.7	101.3%	This work
Mg <sub>3.2</sub> Al <sub>4.4</sub> La <sub>0.4</sub> Nd	61.6 ± 0.2	1.02 ± 0.01	1.825 ± 0.002	114.3 ± 2.5	102.7%	[7]
AE44	51.9 ± 0.1	0.97 ± 0.01	1.817 ± 0.003	91.4 ± 1.8	100.0%	[7]

intermetallic phase, while Al<sub>2</sub>RE and Al<sub>10</sub>RE<sub>2</sub>Mn<sub>7</sub> were the minor intermetallic phases, as shown in Fig. 5b.

Fig. 5c and d presents BSE-SEM morphology of die-cast Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy under the as-cast state. Different from AE44 alloy, in Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy, the lamellar (Al,Mg)<sub>3</sub>RE phase substituted for Al<sub>11</sub>RE<sub>3</sub>, a major intermetallic phase, while Al<sub>11</sub>RE<sub>3</sub> was relegated to a minor one. In addition, a small amount of the needle-like Al<sub>2.12</sub>RE<sub>0.88</sub> phase and the blocky Al<sub>10</sub>RE<sub>2</sub>Mn<sub>7</sub> phase were observed in Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy, and XRD did not detect these two intermetallic phases due to their small quantity. The four intermetallic phases in Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy were determined by TEM in the following text.

### 3.4.3. TEM confirmation of (Al,Mg)<sub>3</sub>RE and Al<sub>11</sub>RE<sub>3</sub>

Fig. 6a presents the scanning TEM (STEM) micrograph of (Al,Mg)<sub>3</sub>RE and Al<sub>11</sub>RE<sub>3</sub> intermetallic phases in die-cast Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy under as-cast state, and Fig. 6b shows the mapping results of STEM-EDS of distribution elements in Fig. 6a. Al<sub>11</sub>RE<sub>3</sub> and (Al,Mg)<sub>3</sub>RE phases were enriched in Al, La, Nd, Mn and minor Zn, while the contrast difference between Al<sub>11</sub>RE<sub>3</sub> and (Al,Mg)<sub>3</sub>RE on Mg indicated the Mg presence in the (Al,Mg)<sub>3</sub>RE phase. Fig. 6c displays the bright-field TEM micrograph of (Al,Mg)<sub>3</sub>RE phase in Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy, and the corresponding indexed selected-area electron diffraction (SAED) pattern in Fig. 6d confirmed the lamellar

**Fig. 3 e** Tensile properties of Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy at RT and HT and in comparison with commercial AE44 alloy and previously researched Mg<sub>3.2</sub>Al<sub>4.4</sub>La<sub>0.4</sub>Nd alloy [7]. Representative tensile curves at (a) RT, (b) 150 °C, (c) 200 °C, (d) 250 °C and (e) 300 °C; (f) YS; (g) UTS; (h) elongation; (i) enhancement of YS and TC of cost-effective Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy at RT compare with commercial AE44 alloy and previously researched Mg<sub>3.2</sub>Al<sub>4.4</sub>La<sub>0.4</sub>Nd alloy.

**Table 3 e** YS, UTS and elongation of Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy at RT and HT, compared with commercial AE44 alloy and previously researched Mg<sub>3.2</sub>Al<sub>4.4</sub>La<sub>0.4</sub>Nd alloy.

Alloy	Tensile properties	20 °C	150 °C	200 °C	250 °C	300 °C
Mg <sub>2.8</sub> Al <sub>3.8</sub> La <sub>0.4</sub> Nd	YS (MPa)	137.1 ± 2.6	124.2 ± 2.4	107.2 ± 1.9	89.2 ± 1.7	72.5 ± 2.1
	UTS (MPa)	240.2 ± 2.5	152.6 ± 2.1	123.4 ± 2.5	101.1 ± 2.3	80.5 ± 2.0
	Elongation (%)	8.8 ± 1.0	36.1 ± 2.3	32.9 ± 2.2	29.9 ± 1.8	37.1 ± 2.1
Mg <sub>3.2</sub> Al <sub>4.4</sub> La <sub>0.4</sub> Nd [7]	YS (MPa)	143.2 ± 2.6	128.0 ± 2.3	111.7 ± 2.0	92.0 ± 1.8	74.1 ± 1.5
	UTS (MPa)	243.6 ± 3.0	157.1 ± 2.4	125.7 ± 2.1	100.9 ± 1.9	79.9 ± 1.5
	Elongation (%)	8.2 ± 0.9	43.5 ± 2.2	34.0 ± 1.9	35.0 ± 2.0	41.6 ± 2.1
AE44 [7]	YS (MPa)	129.0 ± 2.4	108.0 ± 2.2	99.9 ± 1.8	82.1 ± 2.0	66.0 ± 1.6
	UTS (MPa)	246.5 ± 2.5	133.3 ± 2.7	108.9 ± 1.9	92.4 ± 2.1	74.2 ± 1.7
	Elongation (%)	13.3 ± 1.6	30.3 ± 1.5	21.7 ± 1.7	18.8 ± 1.4	15.2 ± 1.7

phase was (Al,Mg)<sub>3</sub>RE phase (Orthorhombic,  $a \frac{1}{4}$  0.4336 nm,  $b \frac{1}{4}$  1.8867 nm,  $c \frac{1}{4}$  0.4424 nm, C222<sub>1</sub>) [31]. High-resolution TEM (HRTEM) micrograph in Fig. 6e and the corresponding fast Fourier transform (FFT) pattern in Fig. 6h confirmed the (Al,Mg)<sub>3</sub>RE phase. As reported, the (Al,Mg)<sub>3</sub>La formation might be relevant with the singular addition of La and/or the ratio of La and Al [31,32]. The bright-field TEM image in Fig. 6f and the SAED pattern in Fig. 6g verified the presence of the Al<sub>11</sub>RE<sub>3</sub> phase (Orthorhombic,  $a \frac{1}{4}$  0.4431 nm,  $b \frac{1}{4}$  1.3142 nm,  $c \frac{1}{4}$  1.0132 nm, *I*mmm) in Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy [32,33]. Different from SEM, the Mg matrix under TEM is marked as Mg rather than a<sub>1</sub>-Mg or a<sub>2</sub>-Mg, as it is hard to identify a<sub>1</sub>-Mg or a<sub>2</sub>-Mg under the high magnification of TEM observation.

#### 3.4.4. TEM confirmation of Al<sub>2.12</sub>RE<sub>0.88</sub>

Fig. 7a shows the STEM image of the needle-like Al<sub>2.12</sub>RE<sub>0.88</sub> intermetallic phase in die-cast Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy under the as-cast condition, and Fig. 7b presents the mapping results of STEM-EDS of elements in Fig. 7a. The Al<sub>2.12</sub>RE<sub>0.88</sub> phase was enriched in Al, La, Nd, Mn and minor Zn, and Mg was hardly present in the Al<sub>2.12</sub>RE<sub>0.88</sub> phase. The SAED pattern in Fig. 7c verified that the needle-like phase in die-cast Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy was Al<sub>2.12</sub>RE<sub>0.88</sub> (Hexagonal,  $a \frac{1}{4}$   $b \frac{1}{4}$  0.4382 nm,  $c \frac{1}{4}$  0.4349 nm, *P6/mmm*) [31]. The HRTEM image in Fig. 7d confirmed the Al<sub>2.12</sub>RE<sub>0.88</sub> phase in Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy.

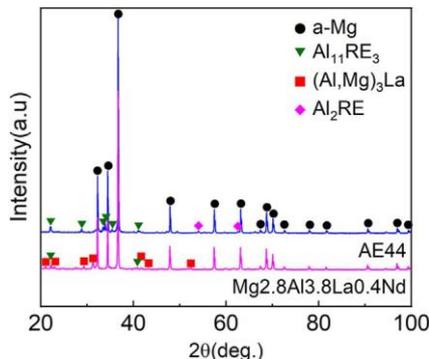

#### 3.4.5. TEM confirmation of Al<sub>10</sub>RE<sub>2</sub>Mn<sub>7</sub>

Fig. 8a presents the STEM image of the blocky Al<sub>10</sub>RE<sub>2</sub>Mn<sub>7</sub> intermetallic phase in die-cast Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy under

an as-cast state. Fig. 8b shows the mapping results of STEM-EDS for the elemental distribution in Fig. 8a. The Al<sub>10</sub>RE<sub>2</sub>Mn<sub>7</sub> phase was enriched in Al, La, Nd, Mn and minor Zn. The SAED pattern in Fig. 8c verified that the blocky phase in die-cast Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy was Al<sub>10</sub>RE<sub>2</sub>Mn<sub>7</sub> (Hexagonal,  $a \frac{1}{4}$   $b \frac{1}{4}$  0.9049 nm,  $c \frac{1}{4}$  1.321 nm, *R-3m*) [34,35]. The STEM-EDS result in Fig. 8d agreed well with the composition of Al<sub>10</sub>RE<sub>2</sub>Mn<sub>7</sub>, which further supported the presence of the Al<sub>10</sub>RE<sub>2</sub>Mn<sub>7</sub> phase in Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy.

#### 3.4.6. Fracture morphology

Fig. 9a-e shows the SEM images of the fracture surface of die-cast Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy at RT, 150 °C, 250 °C and 300 °C, sequentially. In the RT tensile fracture, dimples can be easily found, while the cleavage planes were also observed, which indicated the coupling of the ductile and cleavage fracture mechanisms, and this was consistent with the moderate elongation of 8.8% at RT. The tensile fracture at 150 °C, 250 °C and 300 °C mainly comprised the dimples, and this demonstrated the ductile fracture mechanism at the HT of 150e300 °C. The tear ridge was observed in the tensile fracture at 150e300 °C. Moreover, the tear ridge at 150 °C and 300 °C was more evident than at 250 °C, which agreed with higher elongation at 150 °C and 300 °C than 250 °C.

**Fig. 4 e** XRD results of die-cast Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy under as-cast conditions compared with commercial die-cast AE44 alloy.

## 4. Discussion

### 4.1. Mechanisms of thermal conductivity improvement

#### 4.1.1. Effects of solid solution in Mg matrix

Solute amounts in the matrix were treated as a major factor in TC reduction [1]. The dissolved solute atoms can cause lattice distortion and reduce the mean free path of electrons and phonons [36], thus affecting heat transfer [12]. Al was the dominant solute in die-cast Mg-Al-based alloy owing to its high equilibrium solid solution of 12.7 wt% in Mg at 437 °C [19]. The SEM/TEM-EDS measured Al solute amount in matrix of AE44 alloy was 0.69 wt%, while the Al solute amount in matrix of Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd is 0.40 wt%, a 42% reduction. The overall RE(La,Ce,Nd), Mn, and Zn solute amounts in matrix of Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd and AE44 alloys were similar, as shown in Fig. 10. In contrast, previously developed Mg<sub>3.2</sub>Al<sub>4.4</sub>La<sub>0.4</sub>Nd alloy had a relatively lower content of Al solute in matrix, while total RE, Mn and Zn solute amounts were comparable to that of Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy [7]. Therefore, minimizing the Al

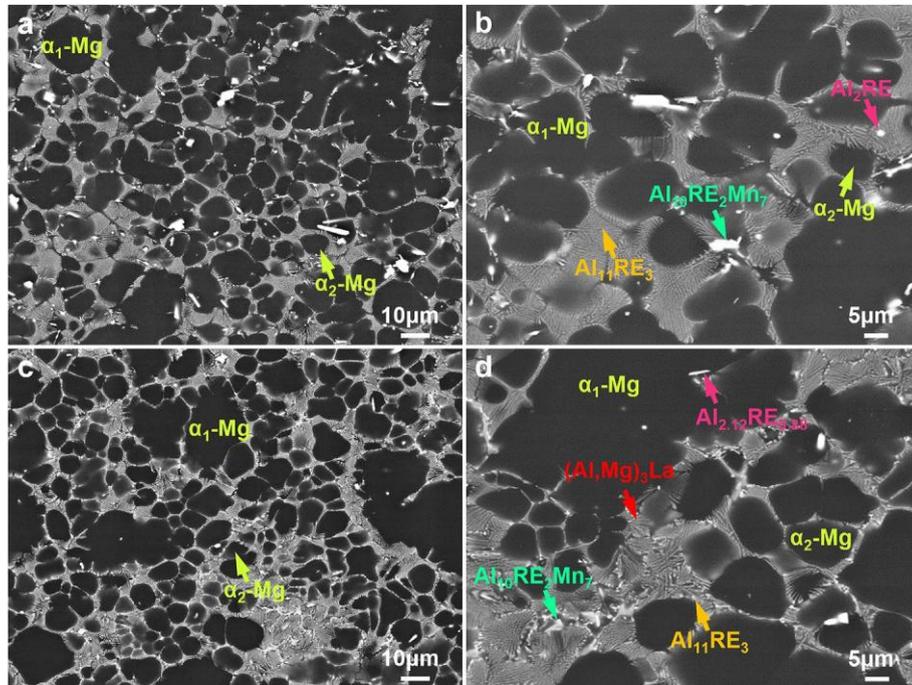

Fig. 5 e BSE-SEM micrographs of die-cast Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd and AE44 alloys under as-cast state. (a,b) AE44; (c,d) Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd.

solute amount in the matrix by completely suppressing the Mg<sub>17</sub>Al<sub>12</sub> phase contributed significantly to improving TD and TC. It also validated the alloy design strategy mentioned in Section 3.1. It can be concluded that the newly developed

Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy matrix had a lower content of Al solid solution compared to the AE44 alloy based on the high TC magnesium alloy development strategy and the optimization of the Al and corresponding RE additions, resulting in better TC.

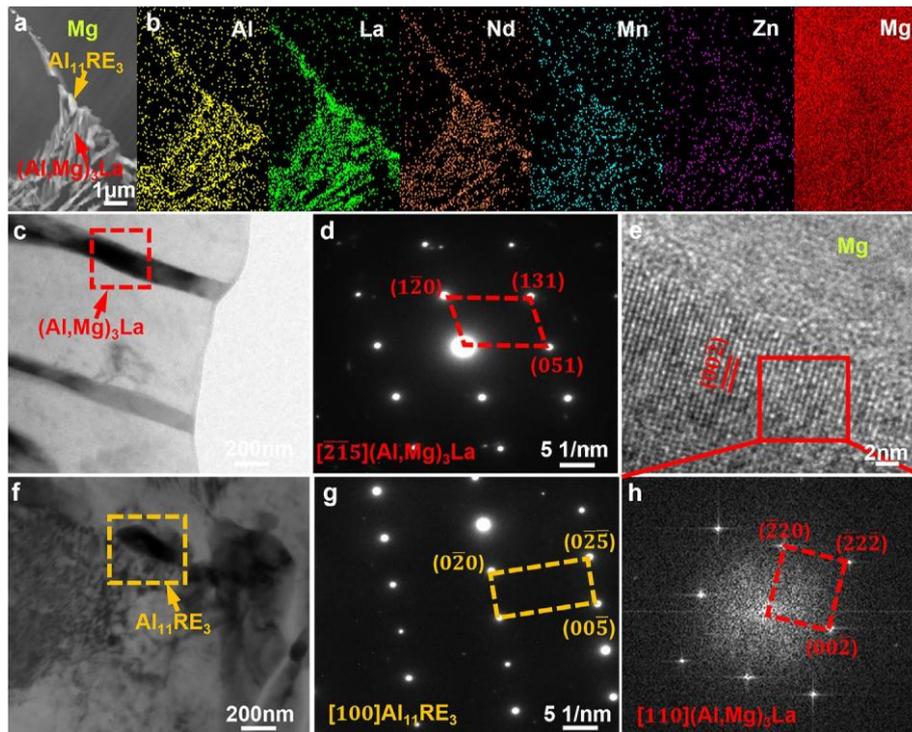

Fig. 6 e TEM confirmation of (Al,Mg)<sub>3</sub>La and Al<sub>11</sub>RE<sub>3</sub> intermetallic phases in die-cast Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy in as-cast condition. Fig. 7 e TEM confirmation of  $\text{Al}_{2.12}\text{RE}_{0.88}$  intermetallic phase in die-cast  $\text{Mg}_{2.8}\text{Al}_{3.8}\text{La}_{0.4}\text{Nd}$  alloy at the as-cast condition. (a) STEM image of  $\text{Al}_{2.12}\text{RE}_{0.88}$  phase; (b) STEM-EDS mapping of (a); (c) SAED of  $\text{Al}_{2.12}\text{RE}_{0.88}$  phase observed along  $[0001]$  zone axis; (d) HRTEM image of  $\text{Al}_{2.12}\text{RE}_{0.88}$  phase with the corresponding FFT pattern as the insert.

#### 4.1.2. Effects of intermetallic phases at GBs

The GBs and intermetallic phases at GBs also affect heat transfer [15,37]. Fig. 11a and b exhibit grain size distribution of die-cast AE44 and  $\text{Mg}_{2.8}\text{Al}_{3.8}\text{La}_{0.4}\text{Nd}$  alloys, respectively.

Fig. 11c displays the statistical average grain size (AGS) and area fraction of intermetallic phases in AE44 and  $\text{Mg}_{2.8}\text{Al}_{3.8}\text{La}_{0.4}\text{Nd}$  alloys. The AGS of  $\text{Mg}_{2.8}\text{Al}_{3.8}\text{La}_{0.4}\text{Nd}$  alloy was slightly higher than AE44 alloy, which should contribute faintly to improving

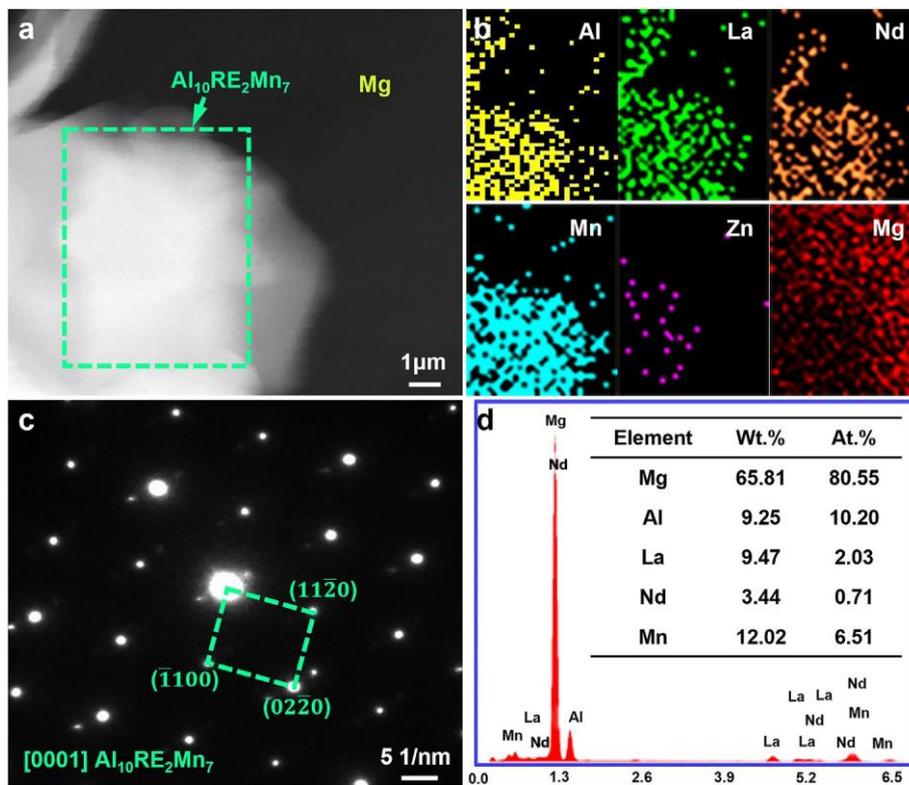

Fig. 8 e TEM confirmation of  $\text{Al}_{10}\text{RE}_2\text{Mn}_7$  phase in die-cast  $\text{Mg}_{2.8}\text{Al}_{3.8}\text{La}_{0.4}\text{Nd}$  alloy at as-cast condition. Fig. 9 e SEM images presenting the tensile fracture of die-cast Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy at RT and HT. (a) RT; (b) 150 °C; (c) 250 °C; (d) 300 °C.

the TC in Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy due to the decrease of the heat transfer block at GBs. The average area fraction of intermetallic phases in Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy was also slightly higher than in AE44 alloy. It should be mentioned that different from AE44 alloy, (Al,Mg)<sub>3</sub>RE replaced Al<sub>11</sub>RE<sub>3</sub> as the major intermetallic phase in Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy. However, (Al,Mg)<sub>3</sub>RE had the same orthorhombic crystal structure as the Al<sub>11</sub>RE<sub>3</sub> phase [32]. In addition, the substitution formation of major (Al,Mg)<sub>3</sub>RE phases in the Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy has not reduced the misfit or strengthened the thermal transmission from the intermetallic phase at the GBs to Mg matrix based on

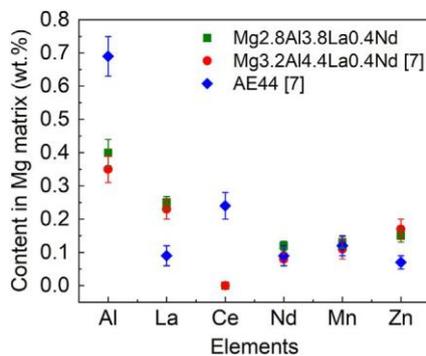

Fig. 10 e Solute amounts of the various elements in matrix of die-cast Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy under as-cast conditions and compared with commercial die-cast AE44 alloy and previously researched Mg<sub>3.2</sub>Al<sub>4.4</sub>La<sub>0.4</sub>Nd alloy.

the misfit analysis of (Al,Mg)<sub>3</sub>RE/Al<sub>11</sub>RE<sub>3</sub> and Mg [7]. Therefore, the grain size and the major (Al,Mg)<sub>3</sub>RE intermetallic phase formed at GBs should have a limited impact on TC improvement compared with AE44 alloy. The improvement of TC in the Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy can be explained by minimizing Al solute amount in the matrix via optimizing Al and RE addition.

#### 4.2. Mechanisms of enhancement of yield strength

According to Section 3.3, the YS of Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy at RT and 300 °C was enhanced by 6.3% and 9.8%, respectively, compared with AE44 alloy. It is well known that the strengthening of alloys is generally determined by solid solution strengthening ( $s_{ss}$ ), grain refinement strengthening ( $s_{gr}$ ), second phase strengthening ( $s_{sp}$ ) at GBs, precipitation strengthening and deformation strengthening [38e40]. Precipitation and deformation strengthening can be neglected at room temperature. Thus, the strengthening YS can be expressed by the following equation:

$$Ds_{Mg2.8Al3.8La0.4Nd} \approx \frac{1}{4} Ds_{ss} + \frac{1}{4} Ds_{gr} + \frac{1}{4} Ds_{sp} \quad (1)$$

The multi-solid-solution model presented by Gypen and Deruyttere [41] can be used to express  $Ds_{ss}$  effect on die-cast Mg alloys:

$$Ds_{ss} \approx \sum_i k_i^{1-n} C_i^n \quad (2)$$

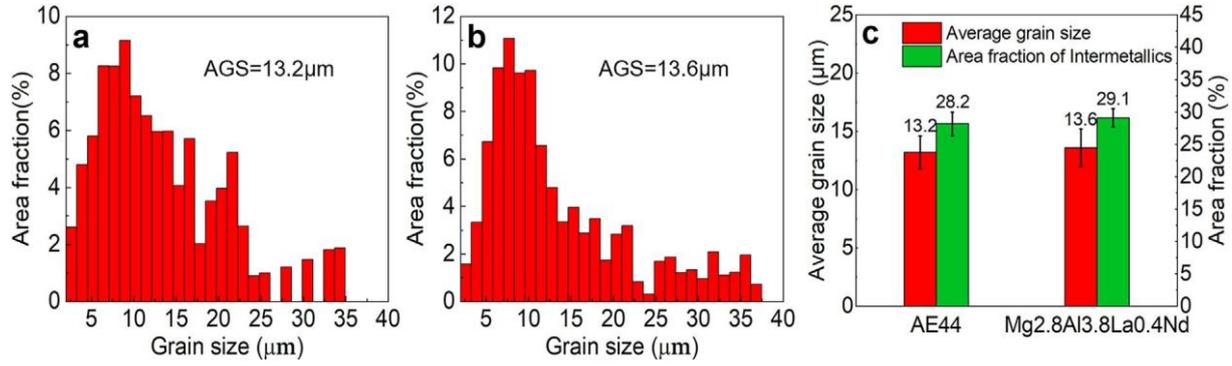

Fig. 11 e The AGS distribution and area fraction of intermetallic phases in die-cast Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd and AE44 alloys at as-cast conditions. Grain size distribution of (a) AE44 and (b) Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloys; (c) AGS and area fraction of intermetallic phases in die-cast Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd and AE44 alloys.

where  $k_i$  is a constant that depends on the alloying element and temperature,  $C_i$  is the solute amount, and  $n$  is a constant equal to 1/2, 1, 2/3 [41,42]. According to Fig. 10, the RE, Mn and Zn content was similar in Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy and AE44 alloy. Therefore, the difference in  $s_{ss}$  was mainly due to the Al solute amount.  $K_{Al}$  ( $\frac{1}{4}118 \text{ MPa (at.)}^{-1/2}$  and  $196 \text{ MPa (at.)}^{-2/3}$ ) was the strengthening rate of solid solution based on binary alloys with  $n$  of 1/2 and 2/3, respectively [43,44]. Thus, the  $s_{ss}$  of the Al dissolved in the matrix to Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy was 7.5 MPa and 4.9 MPa, respectively. The lower solid solution Al content in Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy resulted in smaller  $D_{s_{ss}}$  than in AE44 alloy, approximately  $-2.3 \text{ MPa}$ . In contrast, the need for the high TC alloy development strategy made the strengthening effect produced by Al solid solution in Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy have less impact on the YS.

The Hall-Petch equation [30,45] can be used to express the  $D_{s_{gr}}$ :

$$D_{s_{gr}} \propto \frac{1}{2} K d^{-1/2} \quad (3)$$

$K$  is the constant for Mg ( $280e320 \text{ MPa/mm}^{1/2}$ ), and  $d$  is the AGS [46,47]. Calculated from Fig. 11b, the effect of  $s_{gr}$  on the YS of Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd was approximately 101 MPa. From Fig. 11c, the AGS of Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy was higher than AE44 alloy. Al-RE phases, such as Al<sub>2</sub>RE, have been reported to act as heterogeneous nucleation sites to refine grains [31]. However, there is no evidence that the Al<sub>2.12</sub>RE<sub>0.88</sub> phase in Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloys can refine grains as a heterogeneous nucleation site as the Al<sub>2</sub>RE phase in the AE44 alloy. In addition, the formation of the Al-RE phase at grain boundaries was considered to prevent grain growth [31]. However, due to the generally small grain size in HPDC Mg alloys, the difference in grain size between the Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy and the AE44 alloy is insignificant. Thus, it was apparent that the  $s_{gr}$  for Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy was lower than AE44 alloy, but the difference was minor, approximately  $-1.3 \text{ MPa}$ .

Considering that  $s_{ss}$  and  $s_{gr}$  have a lower effect on Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy than on AE44 alloy, the increase in YS was mainly determined by the  $s_{sp}$ . Integrating the results of  $s_{ss}$  and  $s_{gr}$ , the effect of  $s_{sp}$  on Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy was approximately 28.6 MPa. According to Table 3, the experimental difference in YS between the two alloys was approximately

8 MPa. Integrated  $D_{s_{ss}}$  and  $D_{s_{gr}}$ , the  $D_{s_{sp}}$  was considered to have a higher contribution to Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy than AE44 alloy, with a value of approximately 11.6 MPa. As shown in the analysis of intermetallic compounds in Section 3 and Fig. 11c, the most significant difference was that Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy had a higher fraction of the formed (Al,Mg)<sub>3</sub>RE phase than the dominant Al<sub>11</sub>RE<sub>3</sub> phase in AE44 alloy. Therefore, it was evident that the increase in YS of Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy compared to commercial AE44 alloy was mainly due to the contribution of  $s_{sp}$ . The decrease in room temperature ductility was expected to be related to the different deformation mechanisms of (Al,Mg)<sub>3</sub>RE and Al<sub>11</sub>RE<sub>3</sub>, hopefully providing cutting-edge in-situ deformation facilities for research shortly. Furthermore, lower Al solute in matrix reduced the precipitation of the low melting point Mg<sub>17</sub>Al<sub>12</sub> phase, improving YS at HT. Also, the high content of the major (Al,Mg)<sub>3</sub>RE phase formation in GBs should contribute significantly to the enhancement of YS at HT. In addition, Fig. 3h shows that the Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy has excellent plasticity at HT. In general, a-Mg was more deformable at HT as more slip systems were activated, resulting in increased HT plasticity. In addition, the major intermetallic (Al,Mg)<sub>3</sub>RE, Al<sub>11</sub>RE<sub>3</sub>, and Al<sub>10</sub>RE<sub>2</sub>Mn<sub>7</sub> phases formed in the Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy were all thermally stable phases. The (Al,Mg)<sub>3</sub>RE phase was reported to remain at 500 °C for 100 h without significant morphological changes [32], Al<sub>11</sub>RE<sub>3</sub> had no visible decomposition at 450 °C [48], and the Al<sub>10</sub>RE<sub>2</sub>Mn<sub>7</sub> phase had a melting point of about 1150 °C [49]. Thus, the major intermetallic phases of the Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy can remain stable at up to 300 °C, thus pinning grain boundaries and impeding grain sliding. Therefore, the Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy obtained excellent mechanical properties at HT mainly due to the thermal stability of the major intermetallic phases.

## 5. Conclusions

A novel high TC and cost-effective die-cast Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy was successfully developed with the enhancement of YS at RT and HT, compared with AE44 alloy, and the major conclusions are as follows:

- (1) Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy can provide the TC of 104.0 W/(m·K) at RT and 125.9 W/(m·K) at 300 °C, which are improved by 13.7% and 13.2%, respectively, compared with AE44 alloy. Importantly, the raw material cost of Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy is only 1.3% higher than AE44 alloy.
- (2) Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy can deliver an excellent YS, UTS and elongation of 137.1 MPa, 240.2 MPa and 8.8% at RT. Compared with AE44 alloy, the YS of Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy was enhanced by 6.3% at RT and 9.8% at 300 °C.
- (3) Four intermetallic phases were identified in Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy, i.e., the lamellar (Al,Mg)<sub>3</sub>RE and Al<sub>11</sub>RE<sub>3</sub> phases, the needle-like Al<sub>2.12</sub>RE<sub>0.88</sub> phase and the blocky Al<sub>10</sub>RE<sub>2</sub>Mn<sub>7</sub> phase. Different from AE44 alloy, (Al,Mg)<sub>3</sub>RE formed and replaced Al<sub>11</sub>RE<sub>3</sub> as the major intermetallic phase in Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy.
- (4) The improvement in TC was mainly due to the decrease of Al solution in the matrix via optimizing Al and RE addition. The Al solute amount in the matrix of the Mg<sub>2.8</sub>Al<sub>3.8</sub>La<sub>0.4</sub>Nd alloy was decreased by 42% compared with AE44 alloy. The substitution formation of the major (Al,Mg)<sub>3</sub>RE intermetallic phase at GBs enhanced YS at RT and HT.
