Submitted on 26 Oct 2023

HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

HAL Authorization

INTRODUCTION

Wave propagations in liquid-filled pipe systems is a long standing research topic, having attracted significant research efforts for more than hundred years [Allievi \(1913\)](#); [Budny et al. \(1991\)](#); [Burmam \(1975\)](#); [Holmboe and Rouleau \(1967\)](#); [Joukowski \(1898\)](#); [Korteweg \(1878\)](#); [Résal \(1876\)](#); [Skalak \(1956\)](#). Several review papers can be found on this subject [Ferras et al. \(2018\)](#); [Li et al. \(2015\)](#); [Tijsseling \(1996\)](#) where it is established that the propagation of water-hammer waves is mainly governed by three coupling mechanisms : (i) Poisson coupling, (ii) friction coupling and (iii) junction coupling. (i) is related to the Fluid-Structure-Interactions (FSI) arising at the wave passage from the coupled deformations of the solid in the radial and axial directions (for axi-symmetric "breathing mode" vibrations). (ii) result from the viscous dissipation within the unsteady boundary layer propagating at the wave speed. (iii) results from the applied boundary conditions at pipes ends (for a single pipe). In fact, in the case of unconstrained pipes for which vibrations can arise at frontiers, FSI produce an additional elastic wave distinct from the fluid pressure wave into the pipe. This additional wave also called precursor wave, has a distinct propagating velocity from the fluid pressure one. Furthermore both waves, the fluid pressure wave and the elastic wave are coupled. This coupling is called "Poisson coupling" because it arises from off-diagonal coupling terms proportional to the Poisson coefficient in the general wave equation associated with the pressure/stress vector.

Given the complexity of this coupled waves system, and since the governing equations have been established from several decades (at least without considering friction coupling models), a large part of the literature has considered numerical solutions in time-domain either combining the Method of Characteristic (MOC) [Lavooij and Tusseling \(1991\)](#) or finite volume formulation [Daude and Galon \(2018\)](#) in the fluid with finite elements in the solid. On the other hand, explicit analytical solutions have been developed in more restrained configurations : single pipe, curved pipe [El-Raheb \(1981\)](#), extended blockage [Duan et al. \(2012\)](#) or simple three-like metric graphs [Yang et al. \(2004a\)](#) using the Transfer Matrix Method (TMM) [Aliabadi et al. \(2020\)](#); [Keramat and Duan \(2021a\)](#); [Keramat et al. \(2021\)](#); [Li et al. \(2002\)](#); [Liu and Li \(2011\)](#); [Zhang et al. \(1999\)](#) in

Laplace domain. However, TMM has seldomly been used for comparison and/or validation with time-domain numerical solutions. Since most numerical solutions are provided in time-domain (except those developed in Zhang et al. (1999)), they can indeed hardly benefit from comparison with TMM analytic solutions provided in Laplace domain. This is why a time-domain approach has recently been developed by Bayle and Plouraboué (2023b) using discrete mode decomposition of the FSI water-hammer. FSI effects can indeed significantly alter the high-frequency response of pressure signal Gerosa et al. (2021); Hosoya et al. (2012); Tijsseling et al. (2014) as well as the spectrum of the pressure (frequency shift) in elastic Duan et al. (2013); Henlik (2021); Keramat et al. (2020) as well as viscoelastic pipes Aliabadi et al. (2020); Covas et al. (2004); Gong et al. (2016); Keramat et al. (2021); Meniconi et al. (2012); Soares et al. (2008). The origin of those high-frequency component in the pressure signal comes from the Poisson coupling between the pressure and the longitudinal stress, so that when $\nu_s = 0$, no such phenomenon arise. On the contrary, when $\nu_s > 0$, the fast elastic wave propagation back and forth in the pipe produce high-frequency perturbations in the pressure signal. These high-frequency components of pressure signal can also be useful for other indirect purposes such as leak or defect detection in pipe systems Keramat and Duan (2021b); Keramat et al. (2021); Wang et al. (2021); Zanganeh et al. (2020)., Nevertheless, the link between time-domain analytical solutions and the more established TMM Laplace domain ones has not been discussed yet. In this contribution, we establish and discuss the relation between time-domain discrete mode decomposition solutions and the classical TMM approach. From the derived one-to-one mapping between these two approaches, we discuss how the resulting discrete mode spectrum can also be obtained from TMM solutions. This feature is useful for comparison with numerical predictions in specific configurations. Furthermore, for three specific sets of boundary conditions, the inverse Laplace-transform of the TMM solutions is performed and compared with numerical solutions. The paper is organized as follow. Parameters and governing equations are provided 2 (some additionnal informations are also given in Appendix 4). TMM Laplace domain solution for general boundary conditions are provided in 2. The inverse Laplace transform of these solutions are given in section 2 where the relation with the time-domain

78 discrete mode decomposition is also discussed. Three specific sets of boundary conditions are
 79 then considered in section 3 for which explicit Laplace domain and time domains solutions are
 80 obtained and compared with previous numerical solutions of the literature. Finally, convergence of
 81 the obtained solutions to mode truncation is finally analyzed in 3.

82 THEORETICAL FRAMEWORK

83 This section discusses the Laplace-domain TMM formulation of the water-hammer wave FSI
 84 problem for general classes of boundary conditions. TMM is hereby derived for the two-wave FSI
 85 propagating problem rather than the classical FSI four -equations one, but these two formulations are
 86 exactly equivalent as discussed in [Bayle and Plouraboué \(2023a\)](#). Here we nevertheless consider
 87 a less general formulation as the one considered in [Bayle and Plouraboué \(2023a\)](#) where a 2D
 88 unknown vector is considered for the pressure-axial stress 2D-vector $\mathbf{P} = (P, \sigma)$ and not a 4D one.
 89 This choice comes from considering boundary conditions independent on the velocity, so that, in
 90 this case, the general four equation FSI problems boils-down to equivalent and independent two-
 91 waves coupled propagation problems. This section discuss the relation between TMM solutions
 92 and time-domain analytical solution obtained in [Bayle and Plouraboué \(2023a\)](#) and their discrete
 93 spectrum of mode decomposition.

94 Governing wave-vector equation

95 Since governing equations and notations are the same as in [Bayle and Plouraboué \(2023a\)](#) there
 96 are not repeated here but given in appendix 4. The dimensionless water-hammer FSI wave-equation
 97 system with initial condition at rest (Cf (65) and (69) for more details) expressed in the eigenvector
 98 base reads

$$\left(\partial_\tau^2 - \mathcal{C}_{\mathcal{P}}^2 \partial_Z^2 \right) \mathcal{P} = \mathbf{0} \text{ , with, } \mathcal{P}(Z, 0) = \partial_\tau \mathcal{P}(Z, 0) = \mathbf{0}, \quad (1)$$

99 where the change of basis relations

$$\mathbf{\Pi} = \begin{pmatrix} \frac{2\nu_s \mathcal{D}}{c_-^2 - 1} & \frac{2\nu_s \mathcal{D}}{c_+^2 - 1} \\ 1 & 1 \end{pmatrix}, \quad \mathcal{C}_{\mathcal{P}}^2 = \begin{pmatrix} c_-^2 & 0 \\ 0 & c_+^2 \end{pmatrix} \equiv \mathbf{\Pi} \mathbf{C}_{\mathbf{P}}^2 \mathbf{\Pi}^{-1} \text{ , and, } \mathcal{P} = \mathbf{\Pi}^{-1} \mathbf{P}, \quad (2)$$

100 have been used. ν_s is the Poisson's modulus and \mathcal{D} the fluid to solid density ratio (provided in (64))

101 and c_{\pm} the eigenvalue velocity (68). The pressure-axial stress 2D-vector $\mathbf{P} = (P, \sigma)$ is transformed
 102 into a linear combination of those in 2D-vector \mathcal{P} from (2).

103 The initially coupled pressure/stress wave propagation problem now looks decoupled into two
 104 distinct wave propagation modes associated with 2D-vector \mathcal{P} . Nevertheless the coupling between
 105 \mathcal{P} 's components persists from the resulting coupled upstream and downstream boundary conditions
 106 associated with \mathcal{P} . For the sake of simplification let us introduce four 2×2 matrices \mathcal{N} , \mathcal{M} , \mathcal{Q} ,
 107 \mathcal{R} and $\mathcal{S}\delta(\tau)$ as a four-dimensional column vector corresponding to the perturbation with respect
 108 to the imposed steady-state ($\delta(\tau)$ being Dirac distribution). Boundary conditions can be formally
 109 written as a rectangular 8×4 linear system

$$\begin{pmatrix} \mathcal{N} & \mathcal{M} & \mathbf{0} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} & \mathcal{Q} & \mathcal{R} \end{pmatrix}_{8 \times 4} \cdot \begin{pmatrix} \mathcal{P}(0, \tau) \\ \partial_Z \mathcal{P}(0, \tau) \\ \mathcal{P}(1, \tau) \\ \partial_Z \mathcal{P}(1, \tau) \end{pmatrix}_{8 \times 1} = \mathcal{S}_{4 \times 1} \delta(\tau), \quad (3)$$

110 where $\mathcal{S}\delta(\tau)$ is a source term exciting the system for the impulse response. Specific sets of boundary
 111 conditions will hereafter be investigated and corresponding resolution using diagonalised vector
 112 wave-equation system (1), are handled in the Laplace domain in section 2.

113 Laplace resolution of the FSI wave equation

114 Let us introduce \mathcal{L} , the Laplace transform operator, s its Laplace variable and $\tilde{\mathcal{P}}$ the Laplace
 115 transform of \mathcal{P} :

$$\tilde{\mathcal{P}}(Z, s) = \mathcal{L}(\mathcal{P}(Z, t)). \quad (4)$$

116 The Laplace transform of (1) then leads to

$$\left(s^2 - \mathcal{C}_{\mathcal{P}}^2 \partial_Z^2 \right) \tilde{\mathcal{P}} = \mathbf{0}, \quad (5)$$

117 $\mathcal{C}_{\mathcal{P}}^2$ being diagonal given (2). A solution can be found for the spatial ODE system leading to

$$\tilde{\mathcal{P}}(Z, s) = \mathbf{E}(Z, s)\tilde{\mathcal{P}}^{\mathcal{D}}(s) + \mathbf{F}(Z, s)\tilde{\mathcal{P}}^{\mathcal{N}}(s), \quad (6)$$

118 with 2×2 diagonal matrices

$$\mathbf{E}(Z, s) = \begin{pmatrix} \cos\left(\frac{is}{c_-}Z\right) & 0 \\ 0 & \cos\left(\frac{is}{c_+}Z\right) \end{pmatrix}, \quad \mathbf{F}(Z, s) = \begin{pmatrix} \sin\left(\frac{is}{c_-}Z\right) & 0 \\ 0 & \sin\left(\frac{is}{c_+}Z\right) \end{pmatrix}, \quad (7)$$

119 and $\tilde{\mathcal{P}}^{\mathcal{D}}(s), \tilde{\mathcal{P}}^{\mathcal{N}}(s)$ 2D-vectors yet to be found. $\tilde{\mathcal{P}}^{\mathcal{D}}(s), \tilde{\mathcal{P}}^{\mathcal{N}}(s)$ provide the mode-dependent amplitude of
 120 $\tilde{\mathcal{P}}(Z, s)$ respectively associated with the Dirichlet or the Neumann boundary condition imposed at location
 121 $Z = 0$. This is a transposition of the transfer matrix method used by [Li et al. \(2002, 2015\)](#); [Tijsseling \(2003\)](#);
 122 [Zhang et al. \(1999\)](#), to the wave operator formulation. Combining the expression of (6) and (7) with the
 123 Laplace transform of the boundary condition system (3) (into which the Laplace transform of the Dirac
 124 distribution $\delta(\tau)$ being equal to one is used), leads to

$$\begin{pmatrix} \tilde{\mathcal{P}}^{\mathcal{D}} \\ \tilde{\mathcal{P}}^{\mathcal{N}} \end{pmatrix}(s) = \mathcal{B}^{-1}(s)\mathcal{S}, \quad (8)$$

125 with

$$\mathcal{B} = \begin{pmatrix} \mathcal{N} & is\mathcal{M}\mathcal{C}_{\mathcal{P}}^{-1} \\ \mathcal{Q}\mathbf{E}(1) - is\mathcal{R}\mathcal{C}_{\mathcal{P}}^{-1}\mathbf{F}(1) & \mathcal{Q}\mathbf{F}_k(1) + is\mathcal{R}\mathcal{C}_{\mathcal{P}}^{-1}\mathbf{E}(1) \end{pmatrix} \quad (9)$$

126 In the following development, the inverse of (9) is needed to find $\tilde{\mathcal{P}}$. It is interesting to note that the
 127 general solution for arbitrary closure law can easily be deduced from solution (8) by multiplying the hereby
 128 considered source term \mathcal{S} by the Laplace transform of the closure law. Alternatively, in time-domain, the
 129 general closure law solution are found from a convolution product with the impulse response solution as
 130 detailed in [Bayle and Plouraboué \(2023b\)](#). This is why the hereby considered impulse response is interesting
 131 to study as a generic solution. By introducing the adjugate matrix of \mathcal{B} , namely $\mathbf{adj}[\mathcal{B}]$ one can formally
 132 see that

$$\mathcal{B}^{-1}(s) = \frac{\mathbf{adj}[\mathcal{B}(s)]}{\det \mathcal{B}(s)}, \quad (10)$$

133 Let us furthermore introduce the two matrices

$$\mathbf{e}_1 = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{pmatrix}, \text{ and, } \mathbf{e}_2 = \begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}, \quad (11)$$

134 vector $\tilde{\mathcal{P}}(s, Z)$ can then be found using (6), (8) and (10) to reach

$$\tilde{\mathcal{P}}(s, Z) = \frac{\Phi(s, Z)}{\det \mathcal{B}(s)}, \quad (12)$$

135 with

$$\Phi(s, Z) = [\mathbf{E}(Z)\mathbf{e}_1 + \mathbf{F}(Z)\mathbf{e}_2] (\mathbf{adj} [\mathcal{B}] \mathcal{S}). \quad (13)$$

136 (12)-(13) is the formal solution for the 2D-vector $\tilde{\mathcal{P}}(s, Z)$ in the frequency domain. For specific sets of
 137 boundary conditions, this formal solution can be further developed. Nevertheless, there is one salient feature
 138 of this solution not yet discussed but of uppermost importance : this solution diverges for specific values
 139 of complex variable s . These locations are called the poles of function $\tilde{\mathcal{P}}(s, Z)$. These poles provide deep
 140 physical insights since they give the specific natural resonant frequencies of the wave system or, equivalently
 141 the specific oscillating modes of the solution in time-domain. The ensemble of these discrete resonant
 142 frequencies is called the spectrum of the solution. The reason for this equivalence is found from the inverse
 143 Laplace transform which is now discussed. Next section 2 also discusses how to establish the spectrum
 144 condition and how it is related to matrix $\mathcal{B}(s)$.

145 **Laplace inversion and time-dependent solution**

146 The pole of (6) are investigated in order to perform the inverse Laplace transform using Cauchy's theorem.
 147 Regarding the structure of (6), it immediately appears that the poles are located within the expressions of
 148 $\tilde{\mathcal{P}}^{\mathcal{D}}(s)$ and $\tilde{\mathcal{P}}^{\mathcal{N}}(s)$ and, consequently using (8)-(10), within the root of $\det \mathcal{B}(s)$. The adjugate matrix, by
 149 definition, does not contribute to the pole set of $\tilde{\mathcal{P}}^{\mathcal{D}}(s)$ and $\tilde{\mathcal{P}}^{\mathcal{N}}(s)$. The condition $\det (\mathcal{B}(s)) = 0$ is exactly
 150 similar to the spectrum condition derived in [Bayle and Plouraboué \(2023b\)](#) and leads to

$$\mathcal{S}_{\mathcal{P}} = \{s \in \mathbb{C} \mid \det \mathcal{B}(s) = 0\}. \quad (14)$$

151 The resulting transcendental equation for root s_k is specific to each boundary condition set and has to be
 152 computed numerically. In the following, three configurations are considered for which, in each case, the root
 153 s_k is purely imaginary, i.e.

$$s_k = i\lambda_k, \text{ with, } \lambda_k \in \mathbb{R}. \quad (15)$$

154 (15) provides the one-to-one mapping between the Laplace domain TMM solutions and the time domain
 155 ones provided in [Bayle and Plouraboué \(2023b\)](#) because each purely imaginary pole in the frequency domain
 156 $s_k = i\lambda_k$ provides the corresponding exponential $\exp(i\lambda_k\tau)$ in the time domain from Cauchy theorem, as
 157 now discussed. It is interesting to mention that purely imaginary poles are found for the three specific
 158 considered configurations examined in section 3, without stating that it is a general result. This remark goes
 159 along with the consideration obtained for the operator spectrum in [Bayle and Plouraboué \(2023b\)](#). The pole
 160 set of $\tilde{\mathcal{P}}(Z, s)$, \mathcal{S}_φ , being found, Cauchy's residue theorem is used to derive a time-domain solution for
 161 vector wave problem (1), leading to

$$\mathcal{P}(\tau, Z) = \mathcal{R}_e \left(\sum_{\mathcal{S}_\varphi} \lim_{s \rightarrow i\lambda_k} \left((s - i\lambda_k) \frac{\Phi(s, Z)}{\det(\mathcal{B}(s))} e^{s\tau} \right) \right). \quad (16)$$

162 (16) has been established using a closed contour being a semi-circle of infinite radius in the complex plane,
 163 the semi-axis of which being parallel to the imaginary axis with a strictly positive abscissa. This semi-circle
 164 has the imaginary axis included in it, and thus all poles [Duffy \(1994\)](#). Then, using the classical Taylor
 165 expansion of $\det \mathcal{B}(s)$ at poles $s_k = i\lambda_k$,

$$\mathcal{P}(\tau, Z) = \mathcal{R}_e \left(\sum_{\mathcal{S}_\varphi} \frac{\Phi(i\lambda_k, Z)}{\partial_s \det(\mathcal{B}(i\lambda_k))} e^{i\lambda_k\tau} \right). \quad (17)$$

166 The previous expression completes the frequency-domain analysis for the time-domain solution of (1). A
 167 variety of spatial boundary conditions is then investigated. The associated spectrum will be described and
 168 analyzed in detail. Natural frequencies, f_k , found from transcendental spectrum equation roots, s_k , read

$$f_k(\text{Hz}) = \frac{s_k c_p}{2\pi i L} = \frac{\lambda_k c_p}{2\pi L}, \quad (18)$$

169 where L is the pipe's length introduced in §1.

EXPLICIT SOLUTIONS FOR SPECIFIC SETS OF BOUNDARY CONDITIONS

Three sets of boundary conditions are analyzed: (i) the reservoir-pipe-anchored valve system (Fig. ??a), (ii) the reservoir-pipe-free valve system (Fig. ??b), (iii) pipe impacted by a rod (Fig. ??c). Explicit physical parameters associated with these test cases are provided in table 1.

The reservoir-pipe-anchored valve system: : case (i)

In the following configuration depicted in Fig. ??a, the pipe is supposed perfectly anchored both upstream and downstream. One thereby supposes an homogeneous Neumann condition for the axial stress at $Z = 0$ & $Z = 1$. Furthermore the reservoir impedes any pressure fluctuation upstream which can be interpreted as an homogeneous Dirichlet condition for the pressure field. Finally, downstream, the instantaneous valve closure is modeled with a Dirac distribution $\delta(\tau)$ acting on the axial pressure spatial gradient. The four boundary conditions thereby read

$$P(0, \tau) = 0, \quad \partial_Z P(1, \tau) = \delta(\tau), \quad \partial_Z \sigma(0, \tau) = \partial_Z \sigma(1, \tau) = 0. \quad (19)$$

Invoking the change-of-basis relationships (2) whilst introducing

$$\beta = \frac{c_+ c_-^2 - 1}{c_- c_+^2 - 1}, \quad (20)$$

the boundary condition matrices (3) can then be determined

$$\mathcal{N} = \begin{pmatrix} 1 & \frac{\beta c_-}{c_+} \\ 0 & 0 \end{pmatrix}, \quad \mathcal{M} = \begin{pmatrix} 0 & 0 \\ 1 & 1 \end{pmatrix}, \quad \mathcal{Q} = \mathbf{0}, \quad \mathcal{R} = \mathcal{N} + \mathcal{M}, \quad \mathcal{S} = \frac{(c_-^2 - 1)}{2\nu_s \mathcal{D}} \begin{pmatrix} 0 \\ 0 \\ 1 \\ 0 \end{pmatrix}. \quad (21)$$

183 The boundary condition matrices are useful to derive an expression for cornerstone matrix \mathcal{B} . Invoking the
 184 definition of the latter in (9), one finds

$$\mathcal{B} = \begin{pmatrix} 1 & \frac{\beta c_-}{c_+} & 0 & 0 \\ 0 & 0 & \frac{is}{c_-} & \frac{is}{c_+} \\ -is \frac{\sin\left(\frac{is}{c_-}\right)}{c_-} & -is \frac{\beta c_-}{c_+} \frac{\sin\left(\frac{is}{c_+}\right)}{c_+} & is \frac{\cos\left(\frac{is}{c_-}\right)}{c_-} & is \frac{\beta c_-}{c_+} \frac{\cos\left(\frac{is}{c_+}\right)}{c_+} \\ -is \frac{\sin\left(\frac{is}{c_-}\right)}{c_-} & -is \frac{\sin\left(\frac{is}{c_+}\right)}{c_+} & is \frac{\cos\left(\frac{is}{c_-}\right)}{c_-} & is \frac{\cos\left(\frac{is}{c_+}\right)}{c_+} \end{pmatrix}. \quad (22)$$

185 The determinant of $\mathcal{B}(s)$ can be easily found leading to

$$\det(\mathcal{B}(s)) = -is^3 \frac{c_- \beta - c_+}{c_+^3 c_-} \left[\beta \sin\left(\frac{is}{c_-}\right) \cos\left(\frac{is}{c_+}\right) - \sin\left(\frac{is}{c_+}\right) \cos\left(\frac{is}{c_-}\right) \right], \quad (23)$$

186 and,

$$\partial_s \det(\mathcal{B}(s)) = 3 \frac{\det(\mathcal{B}(s))}{s} + s^3 \left(\frac{c_- \beta - c_+}{c_+^2 c_-} \right)^2 \left[\frac{c_+ \beta - c_-}{c_- \beta - c_+} \cos\left(\frac{is}{c_-}\right) \cos\left(\frac{is}{c_+}\right) - \sin\left(\frac{is}{c_+}\right) \sin\left(\frac{is}{c_-}\right) \right]. \quad (24)$$

187 Let $s_k = i\lambda_k$, with $\lambda_k \in \mathbb{R}$, be a root of (23). The spectrum associated with the reservoir-pipe-anchored
 188 valve configuration arises from λ_k transcendental equation

$$\mathcal{S}_{\mathcal{P}} = \left\{ \lambda_k \in \mathbb{R}, \beta \sin\left(\frac{\lambda_k}{c_-}\right) \cos\left(\frac{\lambda_k}{c_+}\right) = \sin\left(\frac{\lambda_k}{c_+}\right) \cos\left(\frac{\lambda_k}{c_-}\right) \right\}. \quad (25)$$

189 As previously stated (25) exactly matches with the spectrum condition found by [Bayle and Plouraboué \(2023b\)](#)
 190 for the very same configuration within a time-domain approach. It remains to establish the expression of
 191 $\Phi(s, Z)$ in (13) to provide \mathcal{P} in (17). After considerable algebra efforts (cross-checked with symbolic
 192 computation) one finds

$$\text{adj}[\mathcal{B}(s)] \mathcal{S} = \frac{s^2 (c_-^2 - 1)}{2\nu_s \mathcal{D}} \begin{pmatrix} \frac{\beta}{c_+} \left(\cos\left(\frac{is}{c_-}\right) - \cos\left(\frac{is}{c_+}\right) \right) \\ -\frac{1}{c_+ c_-} \left(\cos\left(\frac{is}{c_-}\right) - \cos\left(\frac{is}{c_+}\right) \right) \\ \frac{1}{c_+^2} \left(\beta \sin\left(\frac{is}{c_-}\right) - \sin\left(\frac{is}{c_+}\right) \right) \\ -\frac{1}{c_+ c_-} \left(\beta \sin\left(\frac{is}{c_-}\right) - \sin\left(\frac{is}{c_+}\right) \right) \end{pmatrix}. \quad (26)$$

193 At this stage, the solution of the vector wave equation (1) can be expressed in either frequency-domain,
 194 combining (23) and (26) in (12), or time-domain, combining (24) and (26) in (17). When evaluating the
 195 derivative of the determinant (24) at $s = i\lambda_k$, it turns out to be purely imaginary while the term $\text{adj}[\mathbf{B}(s)]\mathbf{S}$
 196 in (26) turns out to be real, as matrix $\mathbf{E}(Z, s)$ and $\mathbf{F}(Z, s)$ in (7) do. In other words, when performing the
 197 inverse Laplace transform over $\tilde{\mathcal{P}}$ only the temporal sinus mode in (17) contributes and read :

$$\mathcal{P}(Z, \tau) = \frac{(c_-^2 - 1) \sum_{\lambda_k \in \mathcal{S}_{\tilde{\mathcal{P}}}} \sin(\lambda_k \tau)}{2\nu_s c_+^2 \mathcal{D}\lambda_k \left(\frac{c_- - c_+}{c_+ c_-} \right)^2 \left[\frac{c_+ \beta - c_-}{c_- \beta - c_+} \cos\left(\frac{\lambda_k}{c_-}\right) \cos\left(\frac{\lambda_k}{c_+}\right) - \sin\left(\frac{\lambda_k}{c_+}\right) \sin\left(\frac{\lambda_k}{c_-}\right) \right]} \left[\left(\cos\left(\frac{\lambda_k}{c_-}\right) - \cos\left(\frac{\lambda_k}{c_+}\right) \right) \left(\beta \cos\left(\frac{\lambda_k Z}{c_-}\right) \right) + \left(\beta \sin\left(\frac{\lambda_k}{c_-}\right) - \sin\left(\frac{\lambda_k}{c_+}\right) \right) \left(-\frac{c_+}{c_-} \cos\left(\frac{\lambda_k Z}{c_+}\right) \right) \right] \left[\left(\sin\left(\frac{\lambda_k Z}{c_-}\right) \right) - \frac{c_+}{c_-} \sin\left(\frac{\lambda_k Z}{c_+}\right) \right]. \quad (27)$$

198 Pressure/stress components can then be deduced from (27) using base-change (2). Figures 1 & 2 illustrate
 199 both time-domain solution and its spectrum. It is interesting to observe in Figure 1a the influence of the
 200 Poisson coupling coefficient onto the rise of high-frequency components of the pressure signal in the case
 201 $\nu_s = 0.3$ (orange continuous curve of Figure 1a). It is important to stress that these high-frequency peaks
 202 do not result from some numerical noise nor computational approximation. They result from accurate
 203 computation, the underlying physics relying onto the fast bouncing of elastic wave modes into the solid.
 204 Since each traveling mode has its own velocity being much faster than the main pressure wave, they manifest
 205 themselves into small pressure overshoots the number of which depends on the number of bouncing of
 206 each elastic mode each having its own amplitude. The richness of this signal is interesting since it carries
 207 important informations about the system's mechanical properties and boundary conditions. The inspection
 208 of Figure 2 illustrates how well the hereby presented analytical solutions match with previous numerical
 209 results. Also visible in Figure 1a and 2a are small overshoots arising both for [Mei and Jing \(2016\)](#)'s solution
 210 as well as ours, at the edge of each wave-front at discrete time $\tau \simeq 2, 4, 6, \dots$. These small overshoots result
 211 from the aliasing effect resulting from high-frequency cut-off of the Laplace transform as encountered from
 212 Nyquist frequency cut-off in Fourier transforms.

213 **The reservoir-pipe-free valve system : case (ii)**

214 Figure ??b configuration is now investigated. Upstream, the same conditions (19) are applied, with
 215 homogeneous Neumann condition for the axial stress and homogeneous Dirichlet condition for the pressure.
 216 Downstream, the static equilibrium of forces at the valve location combined with velocity continuity leads to

$$\alpha(2 + \alpha)\sigma(1, \tau) = P(1, \tau), \quad (28)$$

$$\partial_Z P(1, \tau) + \mathcal{D}\partial_Z \sigma(1, \tau) = \delta(\tau). \quad (29)$$

217

Considering change of basis (2) whilst introducing parameters

$$\kappa_{\pm} = \mathcal{D} + \frac{2\nu_s \mathcal{D}}{c_{\pm}^2 - 1}, \quad (30)$$

$$\gamma = \frac{\alpha(2 + \alpha) - \frac{2\nu_s \mathcal{D}}{c_{+}^2 - 1}}{\alpha(2 + \alpha) - \frac{2\nu_s \mathcal{D}}{c_{-}^2 - 1}}, \quad (31)$$

218

the boundary condition matrices (3) can be found leading to

$$\mathcal{N} = \begin{pmatrix} 1 & \frac{\beta c_-}{c_+} \\ 0 & 0 \end{pmatrix}, \quad \mathcal{M} = \begin{pmatrix} 0 & 0 \\ 1 & 1 \end{pmatrix}, \quad \mathcal{Q} = \begin{pmatrix} 0 & 0 \\ 1 & \gamma \end{pmatrix}, \quad \mathcal{R} = \begin{pmatrix} \kappa_- & \kappa_+ \\ 0 & 0 \end{pmatrix}, \quad \mathcal{S} = \begin{pmatrix} 0 \\ 0 \\ 1 \\ 0 \end{pmatrix}. \quad (32)$$

219

Using definition (9), \mathcal{B} can be found as

$$\mathcal{B} = \begin{pmatrix} 1 & \frac{\beta c_-}{c_+} & 0 & 0 \\ 0 & 0 & \frac{is}{c_-} & \frac{is}{c_+} \\ -is \frac{\kappa_-}{c_-} \sin\left(\frac{is}{c_-}\right) & -is \frac{\kappa_+}{c_+} \sin\left(\frac{is}{c_+}\right) & is \frac{\kappa_-}{c_-} \cos\left(\frac{is}{c_-}\right) & is \frac{\kappa_+}{c_+} \cos\left(\frac{is}{c_+}\right) \\ \cos\left(\frac{is}{c_-}\right) & \gamma \cos\left(\frac{is}{c_+}\right) & \sin\left(\frac{is}{c_-}\right) & \gamma \sin\left(\frac{is}{c_+}\right) \end{pmatrix}. \quad (33)$$

220

With parametric relation

$$\frac{\kappa_-}{\gamma \kappa_+} = \frac{c_+}{\beta c_-}. \quad (34)$$

221

The determinant of $\mathcal{B}(s)$ and its derivative with respect to s are

$$\det \mathcal{B}(s) = -\frac{2s^2 \beta \kappa_-}{c_+^2} + s^2 \frac{\kappa_+}{c_+^2} \left[\beta \cos\left(\frac{is}{c_+}\right) \cos\left(\frac{is}{c_-}\right) \left(1 + \left(\frac{\kappa_-}{\kappa_+}\right)^2\right) + \sin\left(\frac{is}{c_+}\right) \sin\left(\frac{is}{c_-}\right) \left(1 + \left(\frac{\beta \kappa_-}{\kappa_+}\right)^2\right) \right], \quad (35)$$

222

$$\partial_s \det \mathcal{B}(s) = is^2 \left(\chi_+ \sin\left(\frac{is}{c_-}\right) \cos\left(\frac{is}{c_+}\right) + \chi_- \cos\left(\frac{is}{c_-}\right) \sin\left(\frac{is}{c_+}\right) \right) + \frac{2 \det \mathcal{B}(s)}{s}, \quad (36)$$

223

with

$$\chi_{\pm} = \frac{\kappa_{\pm}}{c_{\pm}^2} \left(\frac{1}{c_{\pm}} \left[1 + \left(\frac{\beta \kappa_{\mp}}{\kappa_{\pm}} \right)^2 \right] - \frac{\beta}{c_{\mp}} \left[1 + \left(\frac{\kappa_{\mp}}{\kappa_{\pm}} \right)^2 \right] \right), \quad (37)$$

224 Let $s = i\lambda_k$, with $\lambda_k \in \mathbb{R}$, be a root of (35). The spectrum associated with the reservoir-pipe-free valve
 225 configuration is governed by the following λ_k transcendental equation,

$$\beta \cos\left(\frac{\lambda_k}{c_+}\right) \cos\left(\frac{\lambda_k}{c_-}\right) \left(1 + \left(\frac{\kappa_-}{\kappa_+}\right)^2\right) + \left(1 + \left(\frac{\beta\kappa_-}{\kappa_+}\right)^2\right) \sin\left(\frac{\lambda_k}{c_+}\right) \sin\left(\frac{\lambda_k}{c_-}\right) = \frac{2\kappa_-}{\kappa_+}. \quad (38)$$

226 Figure 3 illustrate the obtained spectrum (more precisely the first 24 eigenvalues) found from solving the
 227 transcendental equation (38) both versus the Poisson coefficient and the dimensionless pipe thickness. These
 228 results are interesting for providing explicit values for the natural frequencies when varying the FSI parameter
 229 ν_s and the pipe thickness. Here again, the cumbersome determination of $\mathbf{adj}[\mathcal{B}(s)]\mathcal{S}$ is performed with the
 230 help of symbolic computation and leads to

$$\mathbf{adj}[\mathcal{B}(s)]\mathcal{S} = -is \begin{pmatrix} \frac{\beta}{c_+^2} \left(c_- \sin\left(\frac{is}{c_-}\right) - \gamma c_+ \sin\left(\frac{is}{c_+}\right) \right) \\ -\frac{1}{c_-c_+} \left(c_- \sin\left(\frac{is}{c_-}\right) - \gamma c_+ \sin\left(\frac{is}{c_+}\right) \right) \\ -\frac{1}{c_+^2} \left(\beta c_- \cos\left(\frac{is}{c_-}\right) - \gamma c_+ \cos\left(\frac{is}{c_+}\right) \right) \\ \frac{1}{c_-c_+} \left(\beta c_- \cos\left(\frac{is}{c_-}\right) - \gamma c_+ \cos\left(\frac{is}{c_+}\right) \right) \end{pmatrix}. \quad (39)$$

231 From this, the solution of the vector wave equation (1) can either be expressed in frequency-domain,
 232 combining (35) and (39) in (12), or in time-domain, combining (36) and (39) in (17). In time domain, the
 233 solution reads

$$\begin{aligned} \mathcal{P}(Z, \tau) = & - \sum_{\lambda_k \in \mathcal{S}_p} \frac{\left(c_- \sin\left(\frac{\lambda_k}{c_-}\right) - \gamma c_+ \sin\left(\frac{\lambda_k}{c_+}\right) \right) \begin{pmatrix} \beta \cos\left(\frac{\lambda_k Z}{c_-}\right) \\ -\frac{c_+}{c_-} \cos\left(\frac{\lambda_k Z}{c_+}\right) \end{pmatrix}}{\lambda_k c_+^2 \left(\chi_+ \sin\left(\frac{\lambda_k}{c_-}\right) \cos\left(\frac{\lambda_k}{c_+}\right) + \chi_- \cos\left(\frac{\lambda_k}{c_-}\right) \sin\left(\frac{\lambda_k}{c_+}\right) \right)} \sin(\lambda_k \tau) \\ & + \sum_{\lambda_k \in \mathcal{S}_p} \frac{\left(\beta c_- \cos\left(\frac{\lambda_k}{c_-}\right) - \gamma c_+ \cos\left(\frac{\lambda_k}{c_+}\right) \right) \begin{pmatrix} \sin\left(\frac{\lambda_k Z}{c_-}\right) \\ -\frac{c_+}{c_-} \sin\left(\frac{\lambda_k Z}{c_+}\right) \end{pmatrix}}{\lambda_k c_+^2 \left(\chi_+ \sin\left(\frac{\lambda_k}{c_-}\right) \cos\left(\frac{\lambda_k}{c_+}\right) + \chi_- \cos\left(\frac{\lambda_k}{c_-}\right) \sin\left(\frac{\lambda_k}{c_+}\right) \right)} \sin(\lambda_k \tau). \quad (40) \end{aligned}$$

234 Here again, pressure/stress components can then be obtained from (40) using base-change (2). Figure 4
 235 illustrates the time domain solution (40), with again very good comparison with previous numerical results.

236 **The impact induced water hammer : case (iii)**

237 The third configuration of Figure ??c is now investigated associated with the over-pressure produced
 238 from the impact of a steel rod on a closed liquid-filled pipe system. This ingenious experiment was designed
 239 by Vardy and Fan (1986) to reveal intrinsic FSI coupling occurring in liquid-filled pipes while minimizing
 240 external disturbing contributions. This system has been analytically investigated in Li et al. (2002, 2003). At
 241 the upstream pipe end, a steel rod impacts the pipe sleeve producing an over-stress which propagates within
 242 the fluid/solid system. While the impact time of the rod over the upstream sleeve is supposed negligible,
 243 one nevertheless considers the sleeve's inertia, as illustrated in Fig. 10 of Tijsseling and Vardy (1996) which
 244 shows measured "impact times".

245 The dynamic equilibrium of forces along with the velocity continuity at both pipe's upstream and
 246 downstream ends leads to

$$m_0 \mathcal{D} \partial_Z \sigma_{zz}(0, \tau) = \mathcal{F}_r \delta(\tau) + \alpha(2 + \alpha) \sigma_{zz}(0, \tau) - P(0, \tau), \quad (41)$$

$$\mathcal{D} \partial_Z \sigma_{zz}(0, \tau) + \partial_Z P(0, \tau) = 0, \quad (42)$$

$$-m_L \mathcal{D} \partial_Z \sigma_{zz}(1, \tau) = \alpha(2 + \alpha) \sigma_{zz}(1, \tau) - P(1, \tau), \quad (43)$$

$$\mathcal{D} \partial_Z \sigma_{zz}(1, \tau) + \partial_Z P(1, \tau) = 0. \quad (44)$$

247 where

$$m_L = \frac{M_0}{\pi \rho_f R^2 L}, \quad (45)$$

$$\mathcal{F}_r = \frac{F_{rod}}{\pi \rho_f c_p V_{rod} R^2}. \quad (46)$$

248 Considering change of basis relations (2) and introducing parameters

$$\eta_L^0 = \frac{m_L \mathcal{D}}{\alpha(2 + \alpha) - \frac{2\nu_s \mathcal{D}}{c_s^2 - 1}}, \quad (47)$$

$$\mathcal{F} = \frac{\mathcal{F}_r}{\alpha(2 + \alpha) - \frac{2\nu_s \mathcal{D}}{c_s^2 - 1}}, \quad (48)$$

the boundary conditions matrices (3) can be determined

$$\mathcal{N} = -\begin{pmatrix} 0 & 0 \\ 1 & \gamma \end{pmatrix}, \quad \mathcal{M} = \begin{pmatrix} \kappa_- & \kappa_+ \\ \eta_0 & \eta_0 \end{pmatrix}, \quad \mathcal{Q} = -\mathcal{N}, \quad \mathcal{R} = \begin{pmatrix} \kappa_- & \kappa_+ \\ \eta_L & \eta_L \end{pmatrix}, \quad \mathcal{S} = \begin{pmatrix} 0 \\ \mathcal{F} \\ 0 \\ 0 \end{pmatrix}. \quad (49)$$

Cornerstone matrix \mathcal{B} can now be evaluated using (9)

$$\mathcal{B} = \begin{pmatrix} 0 & 0 & is\frac{\kappa_-}{c_-} & is\frac{\kappa_+}{c_+} \\ -1 & -\gamma & \frac{is\eta_0}{c_-} & \frac{is\eta_0}{c_+} \\ -is\frac{\kappa_- \sin\left(\frac{is}{c_-}\right)}{c_-} & -is\frac{\kappa_+ \sin\left(\frac{is}{c_+}\right)}{c_+} & is\frac{\kappa_- \cos\left(\frac{is}{c_-}\right)}{c_-} & is\frac{\kappa_+ \cos\left(\frac{is}{c_+}\right)}{c_+} \\ \mathcal{B}_{41}(s) & \mathcal{B}_{42}(s) & \mathcal{B}_{43}(s) & \mathcal{B}_{44}(s) \end{pmatrix}, \quad (50)$$

with

$$\mathcal{B}_{41}(s) = \cos\left(\frac{is}{c_-}\right) - \frac{is\eta_L}{c_-} \sin\left(\frac{is}{c_-}\right), \quad \mathcal{B}_{42}(s) = \gamma \cos\left(\frac{is}{c_+}\right) - \frac{is\eta_L}{c_+} \sin\left(\frac{is}{c_+}\right), \quad (51)$$

$$\mathcal{B}_{43}(s) = \sin\left(\frac{is}{c_-}\right) + \frac{is\eta_L}{c_-} \cos\left(\frac{is}{c_-}\right), \quad \mathcal{B}_{44}(s) = \gamma \sin\left(\frac{is}{c_+}\right) + \frac{is\eta_L}{c_+} \cos\left(\frac{is}{c_+}\right). \quad (52)$$

Introducing parameter ψ as

$$\psi = \beta \left(\frac{\kappa_-}{\kappa_+}\right)^2, \quad (53)$$

the determinant of $\mathcal{B}(s)$ can be evaluated

$$\begin{aligned} \det \mathcal{B}(s) &= s^2 \frac{\eta_0 \eta_L (\kappa_- - \kappa_+)^2 s^2 + c_-^2 \kappa_+^2 (1 + \psi^2)}{c_-^2 c_+^2} \sin\left(\frac{is}{c_-}\right) \sin\left(\frac{is}{c_+}\right) \\ &+ is^3 \frac{\kappa_+ (\kappa_- - \kappa_+) (\eta_0 + \eta_L)}{c_- c_+^2} \left(\psi \cos\left(\frac{is}{c_+}\right) \sin\left(\frac{is}{c_-}\right) - \cos\left(\frac{is}{c_-}\right) \sin\left(\frac{is}{c_+}\right) \right) + 2s^2 \frac{\psi \kappa_+^2}{c_+^2} \left(\cos\left(\frac{is}{c_-}\right) \cos\left(\frac{is}{c_+}\right) - 1 \right), \end{aligned} \quad (54)$$

so does its derivative

$$\begin{aligned}
\partial_s \det \mathbf{B}(s) &= \frac{2 \det \mathbf{B}(s)}{s} - s^3 \cos\left(\frac{is}{c_-}\right) \cos\left(\frac{is}{c_+}\right) \frac{\kappa_+ (\kappa_- - \kappa_+) (\eta_0 + \eta_L)}{c_- c_+^2} \left[\frac{\psi}{c_-} - \frac{1}{c_+} \right] \\
&+ \frac{is^2}{c_- c_+^2} \cos\left(\frac{is}{c_+}\right) \sin\left(\frac{is}{c_-}\right) \left[\psi \kappa_+ ((\kappa_- - \kappa_+) (\eta_0 + \eta_L) - 2\kappa_+) + \frac{\eta_0 \eta_L (\kappa_- - \kappa_+)^2 s^2 + c_-^2 \kappa_+^2 (1 + \psi^2)}{c_- c_+} \right] \\
&+ \frac{is^2}{c_+^2} \cos\left(\frac{is}{c_-}\right) \sin\left(\frac{is}{c_+}\right) \left[\frac{\eta_0 \eta_L (\kappa_- - \kappa_+)^2 s^2 + c_-^2 \kappa_+^2 (1 + \psi^2)}{c_-^3} - \kappa_+ \left(\frac{(\kappa_- - \kappa_+) (\eta_0 + \eta_L)}{c_-} + \frac{2\psi \kappa_+}{c_+} \right) \right] \\
&+ s^3 \sin\left(\frac{is}{c_-}\right) \sin\left(\frac{is}{c_+}\right) \frac{\kappa_- - \kappa_+}{c_- c_+^2} \left[\frac{2\eta_0 \eta_L (\kappa_- - \kappa_+)}{c_-} - \kappa_+ (\eta_0 + \eta_L) \left(\frac{1}{c_-} - \frac{\psi}{c_+} \right) \right] \quad (55)
\end{aligned}$$

Furthermore $\mathbf{adj} [\mathbf{B}(s)] \mathbf{S}$ is evaluated and reads

$$\mathbf{adj} [\mathbf{B}(s)] \mathbf{S} = -s^2 \mathcal{F} \begin{pmatrix} \frac{[-is\eta_L \kappa_+ (\kappa_- - \kappa_+) \sin\left(\frac{is}{c_+}\right) + c_- \kappa_+^2 \psi \cos\left(\frac{is}{c_+}\right)] \cos\left(\frac{is}{c_-}\right) + c_- \kappa_+^2 \left[\sin\left(\frac{is}{c_-}\right) \sin\left(\frac{is}{c_+}\right) - \psi \right]}{c_- c_+^2} \\ \frac{\kappa_-}{\kappa_+} \frac{[is\eta_L \kappa_+ (\kappa_- - \kappa_+) \sin\left(\frac{is}{c_-}\right) + c_- \kappa_+^2 \cos\left(\frac{is}{c_-}\right)] \cos\left(\frac{is}{c_+}\right) + c_- \kappa_+^2 \left[\sin\left(\frac{is}{c_-}\right) \sin\left(\frac{is}{c_+}\right) \psi - 1 \right]}{c_+ c_+^2} \\ \frac{[-is\eta_L \kappa_+ (\kappa_- - \kappa_+) \sin\left(\frac{is}{c_+}\right) + c_- \kappa_+^2 \psi \cos\left(\frac{is}{c_+}\right)] \sin\left(\frac{is}{c_-}\right) - c_- \kappa_+^2 \sin\left(\frac{is}{c_+}\right) \cos\left(\frac{is}{c_-}\right)}{c_- c_+^2} \\ \frac{\kappa_-}{\kappa_+} \frac{[-is\eta_L \kappa_+ (\kappa_- - \kappa_+) \sin\left(\frac{is}{c_+}\right) + c_- \kappa_+^2 \psi \cos\left(\frac{is}{c_+}\right)] \sin\left(\frac{is}{c_-}\right) - c_- \kappa_+^2 \sin\left(\frac{is}{c_+}\right) \cos\left(\frac{is}{c_-}\right)}{c_-^2 c_+} \end{pmatrix}. \quad (56)$$

In time domain, the transformed pressure/stress 2D vector \mathcal{P}

$$\mathcal{P}(Z, \tau) = - \sum_{\lambda_k \in \mathcal{S}_p} \frac{\lambda_k^2 \mathcal{F}}{\partial_s \det \mathbf{B}(i\lambda_k)} \sin \lambda_k \tau \mathcal{P}'(Z) \quad (57)$$

where $\partial_s \det \mathbf{B}(i\lambda_k)$ is given by (55) and vector $\mathcal{P}'(Z)$ components are

$$\mathcal{P}'(Z) = \begin{pmatrix} \lambda_k \eta_L \kappa_+ (\kappa_+ - \kappa_-) \sin \frac{\lambda_k}{c_+} \cos \frac{\lambda_k (Z-1)}{c_-} - \left(\frac{\kappa_+}{c_+}\right)^2 \left(\psi \cos \frac{\lambda_k}{c_+} \cos \frac{\lambda_k (Z-1)}{c_-} + \sin \frac{\lambda_k}{c_+} \sin \frac{\lambda_k (Z-1)}{c_-} + \psi \cos \frac{\lambda_k Z}{c_-} \right) \\ \frac{\kappa_-}{c_+ c_+^2 \kappa_+} \left[\lambda_k \eta_L \kappa_+ (\kappa_- - \kappa_+) \sin \frac{\lambda_k}{c_-} \cos \frac{\lambda_k (Z-1)}{c_+} + c_- \kappa_+^2 \left(-\psi \sin \frac{\lambda_k}{c_-} \sin \frac{\lambda_k (Z-1)}{c_+} + \cos \frac{\lambda_k}{c_-} \cos \frac{\lambda_k (Z-1)}{c_+} - \cos \frac{\lambda_k Z}{c_+} \right) \right] \end{pmatrix} \quad (58)$$

Finally, as previously noted the pressure and longitudinal stress components can be found from applying the

base-change matrix $\mathbf{\Pi}$ defined in (2) to vector $\mathcal{P}(Z, \tau)$. The spectrum associated with this configuration is

found using (55) from solving transcendental equation $\det \mathbf{B}(s) = 0$. The spectrum numerical evaluation is

carried-out to investigate the shift of natural frequencies caused by the geometrical parameter α in figure 5b

for a wide range of dimensionless pipe thickness parameter α . The natural frequencies are also compared

in Fig. 5a with the ones found by Zhang et al. (1999). Again a very good match is found from comparing

analytical results with the natural frequency of the previous numerical simulations. This results also illustrates the importance of considering the sleeve masses in such systems. The fourth and eighth frequencies are considerably affected by the oscillations of the pipe's end masses.

Modal convergence analysis

Even if the hereby presented solutions are analytical, they can only be numerically approximated since the spectrum's eigenvalues needs to be numerically computed and a finite number of node can only be evaluated, out of the theoretically infinite series. This is why this section investigates how much mode are needed in order to produce a sensible approximation of the exact solution. The mode truncation convergence of our analytical solution is checked by evaluating the quadratic error E

$$E = \frac{1}{N_Z N_\tau} \int_0^1 \int_0^{\tau=5} (\mathcal{P}_{M_{tr}}(z, t) - \mathcal{P}_{ref}(z, t))^2 dz dt, \quad (59)$$

where $(N_Z, N_\tau) \equiv (1000, 5000)$ are the space and time numerical uniform grid point number whereas $\mathcal{P}_{ref}(Z, \tau)$ is a reference solution with very-high mode truncation (2000 modes). For each configuration analyzed the analytical solution is truncated to M_{tr} modes (with $M_{tr} \ll 2000$). Figure 6 shows a linear convergence of mode truncation, i.e the \mathcal{L}_2 -norm of the error E decays as $E \sim M_{tr}^{-1}$. Furthermore figure 6 indicates that both in case (i) and (ii), the \mathcal{L}_2 -norm can be as small as $2 \cdot 10^{-9}$ when taking only the first hundred modes. This illustrates that albeit high frequencies are needed in order to describe the sharp time variation of the pressure solution, they are not contributing much for most of the pressure signal shape. Furthermore, in practice, since any real "impact time" has a finite time decay, not every high frequency mode can be excited, providing physical relevance to mode truncation.

SUMMARY AND CONCLUSION

The paper considers analytical solutions for FSI wave propagation in liquid-filled pipes using TMM method in frequency-domain. Transposing the TMM method to the 2×2 wave system associated with the pressure/stress coupled unknown, the formal solution in frequency-domain is provided for general (linear) sets of boundary conditions. The poles of this frequency-domain solutions give the natural vibrating frequencies of the system, i.e the discrete spectrum of the vibrating modes. The spectrum has been found associated with the zeros of the determinant of a transfer matrix (denoted \mathcal{B}) which encapsulates both FSI and boundary conditions couplings. The resulting spectrum is found consistent with the one found

292 previously using time-domain analysis. Considering three sets of boundary conditions, the diagonalized
 293 pressure-stress wave equation has been analyzed by a frequency-domain Laplace transform approach. For
 294 all configurations investigated, an explicit transcendental spectrum equation has been obtained. A detailed
 295 analysis of the spectrum variations versus constitutive parameters, i.e. the Poisson modulus or the pipe's
 296 thickness radius ratio α) has then been carried out. The determined natural frequencies were successfully
 297 compared with previous contributions found in the literature. For the pipe-reservoir-valve (free or not)
 298 system, a straightforward time dependent solution has been derived and compared to numerical benchmarks.
 299 The modal convergence of the time dependent solutions have been analyzed showing a good convergence to
 300 mode truncation. We hope that these analytical solutions providing the explicit natural frequency spectrum
 301 dependence upon mechanical and geometrical parameters can be useful for testing and validating FSI
 302 numerical methods. Also, this contribution provides a one-to-one mapping between frequency-domain
 303 solutions and time-domain ones. It should then permit to find explicit natural frequency spectrum using
 304 TMM method in frequency-domain in more complex configurations.

305 Appendix

306 Notations regarding the pipe geometry and mechanical properties are given in this appendix. A cylindrical
 307 tube having inner radius R_0 , wall thickness e , length L , is considered so that the dimensionless pipe thickness
 308 α can be defined as

$$\alpha = \frac{e}{R_0}. \quad (60)$$

309 The tube is entirely filled with a fluid having density ρ_f , bulk modulus \mathcal{K}_f . The elastic solid response is
 310 associated with Young's modulus E , Poisson's modulus ν_s , and density ρ_s . [Tijsseling \(2007\)](#) derived the
 311 classical pulse wave speed within the fluid, c_p , distinct from the elastic pulse wave speed within the solid, c_s

$$c_p^2 = \frac{1}{\rho_f \left(\frac{1}{\mathcal{K}_f} + \frac{2}{\alpha E} \left(\frac{2(1-\nu_s^2)}{2+\alpha} + \alpha(1+\nu_s) \right) \right)}, \quad c_s^2 = \frac{E}{\rho_s}, \quad (61)$$

312 their respective ratio being

$$C_s = \frac{c_s}{c_p}. \quad (62)$$

313 The perturbed fluid pressure P^* , and axial solid stress σ^* (in the following we use σ^* to denote the longitudinal
 314 stress component σ_{zz}^*), are re-scaled by the [Joukowski \(1898\)](#)'s over-pressure, i.e. $O(\rho_f c_p W_0)$ where W_0 is

315 the flow variation applied within the pipes, so that their dimensionless counterparts are denoted

$$P = \frac{P^*}{\rho_f c_p W_0}, \text{ and, } \sigma = \frac{\sigma^*}{\rho_f c_p W_0}. \quad (63)$$

316 The physical time t is furthermore re-scaled with respect to the fluid acoustic advective time scale, i.e.
 317 $\tau = t \frac{L}{c_p}$, whereas the axial coordinate is non-dimensionalised by the pipe's length, i.e. $Z = z/L$. Finally,
 318 the dimensionless density ratio is introduced

$$\mathcal{D} = \frac{\rho_f}{\rho_s}. \quad (64)$$

319 The derivation of the wave-vector equation governing the space-time distribution of the dimensionless
 320 perturbed pressure P and dimensionless axial stress σ has been provided in [Bayle and Plouraboué \(2023b\)](#) so
 321 that it is not repeated here. It results in the following wave-operator acting on the pressure/stress 2D-vector:

$$\left(\partial_\tau^2 - \mathbf{C}_\mathbf{P}^2 \partial_Z^2 \right) \mathbf{P} = \mathbf{0}, \quad (65)$$

322 where

$$\mathbf{C}_\mathbf{P}^2 = \begin{pmatrix} 1 & 2\nu_s \mathcal{D} \\ \frac{2\nu_s}{\alpha(2+\alpha)} & \frac{4\nu_s^2 \mathcal{D}}{\alpha(2+\alpha)} + C_s^2 \end{pmatrix}, \text{ and, } \mathbf{P} = \begin{pmatrix} P \\ \sigma \end{pmatrix}. \quad (66)$$

323 As mentionned in the introduction, it is interesting to notice that the off-diagonal terms of matrix $\mathbf{C}_\mathbf{P}^2$ are
 324 proportional to the Poisson coefficient ν_s so that the fluid pressure and the solid stress decouple as $\nu_s \rightarrow 0$.
 325 Furthermore, as $\nu_s \rightarrow 0$ the remaining diagonal terms are 1 and C_s^2 , the two eigenvalues of the resulting
 326 diagonal matrix. These eigenvalues are providing the two distinct wave-velocities of the uncoupled limit:
 327 1 which is the dimensionless pressure pulse velocity c_p whereas C_s^2 is the dimensionless elastic wave solid
 328 one. When $\nu_s \neq 0$ the eigenvalues of matrix $\mathbf{C}_\mathbf{P}^2$ provide the velocities of the coupled system. The vector
 329 homogeneous wave-equation resolution will be handled within the eigenvectors basis of $\mathbf{C}_\mathbf{P}^2$ as in [Zhang et al.](#)
 330 [\(1999\)](#). The eigenvalues of $\mathbf{C}_\mathbf{P}^2$, denoted $c_\pm^2 > 0$, associated with diagonalized matrix $\mathcal{C}_\mathbf{P}^2$ correspond to the
 331 wave speed mode propagation. They are the solution of the following polynomial characteristic problem

$$c_\pm^4 - \left[1 + C_s^2 + \frac{4\nu_s^2 \mathcal{D}}{\alpha(2+\alpha)} \right] c_\pm^2 + C_s^2 = 0, \quad (67)$$

332 the solutions of which are

$$c_{\pm}^2 = \frac{1 + C_s^2 + \frac{4v_s^2 \mathcal{D}}{\alpha(2+\alpha)} \pm \sqrt{\left(1 + C_s^2 + \frac{4v_s^2 \mathcal{D}}{\alpha(2+\alpha)}\right)^2 - 4C_s^2}}{2}. \quad (68)$$

333 The fluid pressure and the axial solid stress as well as their respective time-derivatives will be assumed
334 initially at rest so that

$$\mathbf{P}(Z, 0) = \mathbf{0} \quad , \quad \partial_t \mathbf{P}(Z, 0) = \mathbf{0}. \quad (69)$$

443 **List of Tables**

444 1 Physical parameters associated with the three configurations depicted in Figure ?? 26

[Physical properties and configuration for case (i) & (ii)]
Anchored and free valves (i) & (ii) Fig. ??ab

Fluid (water)	Solid (steel)
$\rho_f = 1000 \text{ kg} \cdot \text{m}^3$	$\rho_s = 7900 \text{ kg} \cdot \text{m}^{-3}$
$\mathcal{K}_f = 2.1 \text{ GPa}$	$E = 210 \text{ GPa}$
	$\nu_s = 0.3$
	$R_0 = 0.395 \text{ m}$
	$e = 0.008 \text{ m}$
	$L = 20 \text{ m}$

[Physical properties and configuration for case

Impacting rod system (iii) Fig. ??c

Fluid (water)	Solid (steel)	rod & sleeves (steel)
$\rho_f = 999 \text{ kg} \cdot \text{m}^3$	$\rho_s = 7985 \text{ kg} \cdot \text{m}^{-3}$	$M_0 = 1.312 \text{ kg}$
$\mathcal{K}_f = 2.14 \text{ GPa}$	$E = 168 \text{ GPa}$	$M_L = 0.3258 \text{ kg}$
	$\nu_s = 0.29$	$F_{rod} = 9.4 \text{ kN}$
	$R_0 = 0.02601 \text{ m}$	$V_{rod} = 0.1175 \text{ m} \cdot \text{s}^{-1}$
	$e = 0.003945 \text{ m}$	
	$L = 4.502 \text{ m}$	

TABLE 1. Physical parameters associated with the three configurations depicted in Figure ??.

445 **List of Figures**

446 1 Time-domain result and spectrum solution of test case (i). (a) Pressure response
447 with FSI ($\nu_s = 0.3$ continuous brown lines) and without FSI modeling ($\nu_s = 0$ black
448 dotted lines) versus Mei and Jing (2016)'s theoretical solution (which does not take
449 into account FSI effects, i.e. for which $\nu_s \equiv 0$). (b) Spectrum (32 first eigenvalues)
450 associated with Dirichlet/Dirichlet boundary conditions (19) versus the Poisson
451 modulus ν_s (blue dots for $\nu_s = 0$ are Mei and Jing (2016)'s spectrum and red dots
452 are the pure elastic modes the union of which compose the spectrum (25). As ν_s
453 varies, some eigenvalues come close to one-another, but a careful inspection shows
454 no cross-over between the depicted eigenvalues. 30

455 2 Time-domain and frequency-domain results of test case (i). (a) Comparison between pressure field
456 analytical solution at valve location (continuous brown lines) with MOC solutions provided by
457 Tijsseling (2003) (dashed blue lines). Non-FSI solutions (i.e $\nu_s = 0$) are provided for illustration in
458 black dotted lines. Insets provide a zoom for detailed check. (b) Comparison between Yang et al.
459 (2004b)'s pressure prediction in frequency domain at valve position (continuous black line) and
460 discrete spectrum eigenvalues obtained from transcendental equation (25) depicted in dotted (blue)
461 lines. 31

462 3 Spectrum of case (ii). (a) first 38 eigenvalues evaluated from (38) versus the Poisson modulus ν_s .
463 (b) first 21 eigenvalues versus the dimensionless pipe's thickness α . As α varies, some eigenvalues
464 come close to one-another, but a careful inspection shows no cross-over between them. 32

465 4 Time-domain and frequency-domain results of test case (ii). (a) Comparison be-
466 tween pressure field analytical solution at valve location (continuous brown lines)
467 with MOC solutions provided by Tijsseling (2003) (dashed blue lines). Insets pro-
468 vide a zoom for detailed check. (b) Comparison between Zhang et al. (1999)'s pipe
469 velocity spectrum at valve and eigenvalues obtained from transcendental equation
470 (38) 33

471	5	Spectrum of case (iii). (a) Comparison between Zhang et al. (1999)'s pipe velocity	
472		spectrum at valve and eigenvalues obtained from the root of (55). Investigation of	
473		natural frequencies with (blue dashed line) or without (red dotted line) considering	
474		the sleeves masses is depicted. (b) first 21 eigenvalues versus the pipe's thickness	
475		/ radius ratio α . As α varies, some eigenvalues come close to one-another, but a	
476		careful inspection shows no cross-over between the depicted eigenvalues.	34
477	6	Log-log plot of the truncation error E defined in (59) versus mode truncation M_{tr} for the analytical	
478		solutions of case (i) and (ii). A linear convergence M_{tr}^{-1} is depicted in (red) continuous line.	35

Fig. 1. Boundary condition sets investigated for the liquid-filled pipe problem.

Fig. 2. Time-domain result and spectrum solution of test case (i). (a) Pressure response with FSI ($\nu_s = 0.3$ continuous brown lines) and without FSI modeling ($\nu_s = 0$ black dotted lines) versus **Mei and Jing (2016)**'s theoretical solution (which does not take into account FSI effects, i.e. for which $\nu_s \equiv 0$). (b) Spectrum (32 first eigenvalues) associated with Dirichlet/Dirichlet boundary conditions (19) versus the Poisson modulus ν_s (blue dots for $\nu_s = 0$ are **Mei and Jing (2016)**'s spectrum and red dots are the pure elastic modes the union of which compose the spectrum (25). As ν_s varies, some eigenvalues come close to one-another, but a careful inspection shows no cross-over between the depicted eigenvalues.

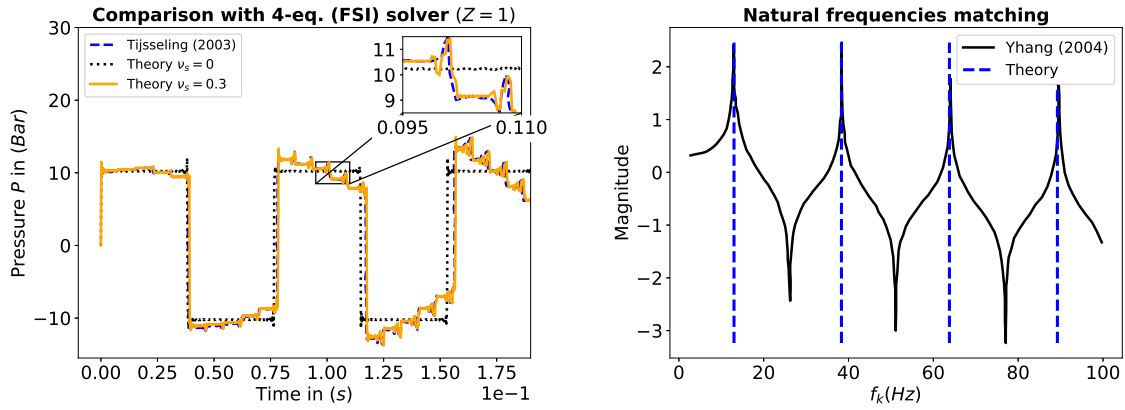

Fig. 3. Time-domain and frequency-domain results of test case (i). (a) Comparison between pressure field analytical solution at valve location (continuous brown lines) with MOC solutions provided by Tijsseling (2003) (dashed blue lines). Non-FSI solutions (i.e. $\nu_s = 0$) are provided for illustration in black dotted lines. Insets provide a zoom for detailed check. (b) Comparison between Yang et al. (2004b)'s pressure prediction in frequency domain at valve position (continuous black line) and discrete spectrum eigenvalues obtained from transcendental equation (25) depicted in dotted (blue) lines.

Fig. 4. Spectrum of case (ii). (a) first 38 eigenvalues evaluated from (38) versus the Poisson modulus ν_s . (b) first 21 eigenvalues versus the dimensionless pipe's thickness α . As α varies, some eigenvalues come close to one-another, but a careful inspection shows no cross-over between them.

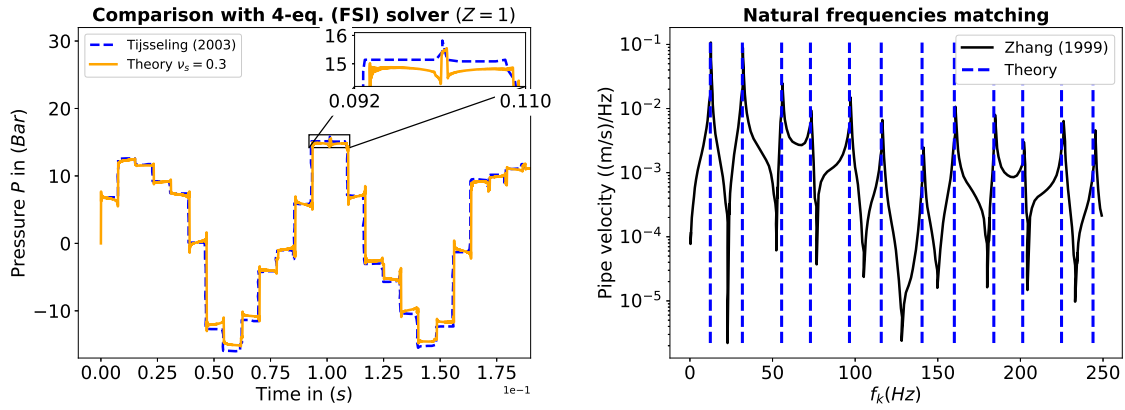

Fig. 5. Time-domain and frequency-domain results of test case (ii). (a) Comparison between pressure field analytical solution at valve location (continuous brown lines) with MOC solutions provided by [Tijsseling \(2003\)](#) (dashed blue lines). Inset provides a zoom for detailed check. (b) Comparison between [Zhang et al. \(1999\)](#)'s pipe velocity spectrum at valve and eigenvalues obtained from transcendental equation (38)

Fig. 6. Spectrum of case (iii). (a) Comparison between Zhang et al. (1999)'s pipe velocity spectrum at valve and eigenvalues obtained from the root of (55). Investigation of natural frequencies with (blue dashed line) or without (red dotted line) considering the sleeves masses is depicted. (b) first 21 eigenvalues versus the pipe's thickness / radius ratio α . As α varies, some eigenvalues come close to one-another, but a careful inspection shows no cross-over between the depicted eigenvalues.

Fig. 7. Log-log plot of the truncation error E defined in (59) versus mode truncation M_{tr} for the analytical solutions of case (i) and (ii). A linear convergence M_{tr}^{-1} is depicted in (red) continuous line.
