What is new and relevant in the proposed term of postlocative art that we are defending is that, beyond overcoming the psychogeography and the contextualization of information with georeferencing, its terminology clearly includes moving beyond the preceding spatial orientation model, which has been exhausted. This contemplation of what beyond locative means requires informational and spatial territorialization in perpetual motion, in which the position of humans, as the creative engine and manager of the meaning of geosemantic discourse, is not that important and – moreover – is shared with non-humans. Postlocative art would therefore also be an art that points to the posthuman in the sense of moving beyond humanism, in its last dichotomous throes, characteristic of modernity (according to Latour in his critique of the separation between nature and society, or between technology and politics). It would also point to the cosmopolitical as it critically confronts the blind anthropocentric (and capital-centric) claims of the territorializing project of modernity. The postlocative struggle for the enunciation and representation of informational meaning in hybrid space is not determinant of a fixed, definite and universal *axis mundi*, rather it is the assimilation of the existence of many personalized and moving centers encrypted in the software code. Nodal centers around which we determine our experiential, cognitive, sociopolitical and identitarian context, associated with the relative, fluctuating, invigorated positions produced by our interactions with other nodes.

Postlocative Strategies for a Non-Anthropocentric World

Postlocative art works arrange the interrelationship between what the image/map coding leaves out or does not leave out, between what is decided to be represented or not, and what the purpose of the instrumental and operational logic delegated to AI in a network is, and whom it serves. They emphasize public use, high interactivity and the exploration of the unknowns that make up the representation of non-humans in artistic devices. An aesthetic-political commitment that would move away from the coordinates of private use, low interactivity and reaffirmation of the confirmation bias determined by the bubble filter that, through algorithmic predictions, selects all information that corroborates all of our beliefs and opinions in accordance with what is already known, stated and/or represented. Applying these characteristics, we identify five postlocative art strategies [34], which we briefly describe below:

First, we observe how in projects such as “Dead Pixel in Google Earth (2008-2010)” by Helmut Smits, “Street Ghosts” (2012-2017) by Paolo Cirio or “Map” (2006-2019) by Aram Bartholl, among others, we find a clear interest in establishing a direct dialogue, contingent upon its inclusion in the digital representation programs of the geobrowsing networks. These are projects that clearly assume that human interaction with the same territory occurs, is formed and induced, if we define territory as a habitable interface where the *infor*g can still leave warnings for browsers. These warnings would leave a double footprint, as a site-specific intervention (in the physical territory) and as a medium-specific intrusion (into the informational territory).

Other projects such as “9 eyes (2008)” by Jon Rafman, “Postcards from Google Earth (2010)” by Clement Valla, “The Driver and the Cameras” (2012) by Emilio Vavarella or “Dutch Landscapes” (2011) by Mishka Henner, for example, document informational products of a visual nature that present interferences, failures, censorship or certain technical characteristics that humans are still capable of interpreting as singular signs of their current relationship with the machine. With different formal approaches, all of these projects use the same documentation methodology, which includes the reappropriation, intervention and exhibition of a series of digital images/maps that relocate and confront the human element within the instrumentalization carried out by and for the software code.

The projects of this third strategy, still clearly making use of the geographic location metadata, emphasize its use for representing non-humans in a public parliament shared with them, an issue we see clearly in projects such as “Pigeon Blog” (2006-2008) by Beatriz da Costa, “TrashTrack” (2009) of the MIT Senseable City Lab, “Wi-Fi Structures and People Shapes” (2009) by Dan Hill, or “Italian Limes” (2014-2016) of the Folder group. All of them arrange their artistic concepts over the representation of the postphenomenology of events – apparently not visible, graspable or quantifiable – of the complex coexistence that we establish with non-humans in the network of our symbiotic existence.

The fourth postlocative strategy has an evident probatory nature that is deployed through a “forensic aesthetic” exercise, to use the words of Eyal Weizman [35], centered on counter-enunciating and counter-visualizing the operative processes through which the data, discourses and images/maps hide, shield and convey the structural violence orchestrated by the official informational frameworks. Groups such as Forensic Architecture, or artists such as Trevor Paglen, focus their practices and research on postlocating the human factor to publicly bear witness to it as a material and informational victim. A victim that is treated as collateral damage, or disposable and/or exchangeable merchandise, in the framework of a global political and military system that is governed in large part by the criteria established by the techno-economy of global semiocapitalism (according to the approach of Franco ‘Bifo’

Berardi) [36]. Projects such as “Selected CIA Aircraft Routes and Rendition Flights 2001–2006” (2006) by Trevor Paglen, “Watching the Watchers (2013)” by James Bridle, and all the projects to date of Forensic Architecture, track and reveal high tech and mediated conflicts that increasingly blur the line between techno-military (and its business side) and civil matters. Projects that ultimately research the relationship that representation has with the manufacture of public truth.

Finally, we want to highlight the fifth postlocative strategy, which requires the biopolitical involvement of the artists in conscious and direct confrontation with the ubiquitous sensors that collect all kinds of data, images/maps and personal and geocoded footprints. Their projects deploy tactical operations aimed at hacking, modifying, transforming and/or disrupting the syntax of the software code with the aim of affecting its operation and its associated geosemantic processes. We found a clear precedent for this strategy in the project “BorderXing Guide (2001-2011)” by Heath Bunting, which established the commitment to information access both to the physical location and to the production policy for user/citizen activities in hybrid space. However, it is Simon Weckert’s project, “Google Maps Hacks (2020)” that updates this strategy based on a tactical action that seeks to produce a geosemantic backlog in Google Maps, thus pointing to the possibility of an action to empower *infor*g in the involvement of the delegated management processes of the information in hybrid space. This highlights the fact that hybrid space may be counter-represented and counter-mapped with performative art practices that, with tactics characteristic of an informational guerilla group, enables the capacity for action and liberation, which is ontologically denied to the *infor*g.

What all these strategies have in common is a discourse and a formalization/visualization that questions the extraction and mapping of information, and the importance of non-anthropocentric representation in which non-humans have the capacity to act as agents in artistic production. These are strategies to confront the apparently irreversible delegation of the production of meaning to AI (which is mainly in charge of managing the irreversibility of informational chaos, the destruction of the planet and even the extinction of human being). Strategies that imply a willingness to *be seen or revealed* to the post-panoptic machine, and to distinguish oneself in a permanent representational loop that moves between masking and deliberate and selective unmasking in hybrid space. This is a question that we can classify as situated thinking with the interpretive turn of the data delegated to AI. An openly critical and contingent position with the limits of knowledge, power and desire, inscribed in the image/map of the systemic device of current informational control societies.

Coda

It is tempting to think that artistic production with postlocative media (ubiquitous, omnipresent and assimilated symbiotically by the *infor*gs) can enable deterritorialization and reterritorialization processes (decoding and recoding) within the systemic arrangement. It remains to be seen whether it has the capacity to critically explore the limits – and possible escapes – from cynicism, insensitivity and disaffection with the politics implicit in the conditions of semicapitalism and the inertia of alienation in the perceptive, expressive and cognitive abilities in the current context of techno-spherical dependence.

Postlocative art is presented here as the art that follows a fixed reference that is already known and socio-technically determined, self-absorbedly local and anthropocentric, aggravatingly individualistic and short-term, situated in an illusion of a false personalized, watertight and immobile space-bubble. No such space exists. Everything is wonderful, dangerous and complexly interconnected and distributed. Hence, we now have the opportunity to move beyond that socio-technically predetermined self-location, to dynamically orient ourselves in a network where we can put automation processes into play to benefit everyone (including non-humans). And where we can project ourselves as a planetary interspecies that does something effective without thinking only of instant benefits, within a more lasting space-time scale of mixed coexistence.

Santiago Morilla is a multidisciplinary artist, PhD in Contemporary Art (UCM, Complutense University of Madrid) and specialised in New Media Art (Erasmus Scholarship at The Media Lab Media Lab, University of Art and Design UIAH Helsinki, Finland), researcher and lecturer at UCM Faculty of Fine Arts. He is currently part of the research groups "Artistic practices and new forms of knowledge" (UCM id: 588) and "Energy humanities. Energy and sociocultural imaginaries between the industrial revolutions and the ecosocial crisis" (CSIC, PID2020-113272RA-I00, ENERGEHUM).

Weaving Augmented Reality into the Fabric of Everyday Life

Anton Nijholt

Enschede, The Netherlands
a.nijholt@utwente.nl

Abstract

In 1997 Ronald T. Azuma introduced the now generally accepted and followed definition in Augmented Reality (AR) research. In short, it tells us that in AR we introduce virtual content into the real world, this virtual content needs to be aligned with real content, and a user of an AR environment can interact with the (dynamic) virtual and real content in real-time. This definition leaves open how virtual content is generated, which display technology is desired and which senses are addressed. This has advantages, but it is now becoming clear that these missing aspects lead to confusion, also because with the current smart technology in general and ubiquitous computing in particular, AR technology can no longer be considered in isolation. We present the arguments that lead to this conclusion. We will explain the arguments with examples in which the vision, auditory and olfactory senses play a role. Starting point and conclusion obtained is that AR eventually will become an everyday technology that will merge into reality.

Keywords

Augmented reality, multisensorial augmented reality, digital technology, ubiquitous computing.

Introduction

Although introduced a long time ago, augmented reality (AR) research usually still follows the 1997 AR definition [1] which tells us that in AR we introduce virtual content into the real world, this virtual content needs to be aligned with real content, and that a user of an AR environment can interact with the (dynamic) virtual and real content in real-time. This definition does not make references to a particular sense that is being addressed by the virtual content. Neither does it demand that the virtual content be digitally created. What is ‘virtual’ and what is meant by ‘interaction’ is not discussed. If the virtual content is not digitally created, should it at least be digitally controlled or mediated? By not being too explicit about these matters, the definition is practically workable, but at the same time, it has led to a vision-dominated interpretation of the concept of AR. Other senses might only be addressed in the

context of computer-generated images of objects, that must be aligned with real-world physical objects. From the perspective of a user whose most relevant interaction with the environment consists of changing his position and orientation this might be acceptable. However, it is not when either the user or the environment asks for more active involvement of the user in the environment.

The virtual layer that is superimposed on reality can contain content that addresses the traditional five senses (sight, hearing, taste, smell, and touch), but other senses can play a role as well. Virtual content can affect our proprioceptive sense, for example in a therapeutic application, and equally, we can think of applications that have virtual content that shows awareness of temperature changes or has been designed to cause pain or induce hunger in a user. If we want to go beyond vision-oriented AR, both for users and for virtual content, we need to look at multisensorial input and crossmodal effects. A virtual creature in a virtual layer should show multisensorial situational awareness and by doing so in a believable way it needs input for its assigned models of goals, intentions, knowledge, and emotions from various sense-related sensors. This is quite different from ‘just’ referring to the integration of computer-generated imagery with the real world as we can see mentioned in most observations on and research in AR.

AR, both its virtual and real content, will become embedded in smart environments in which we assume ubiquitous computing and sensors, processors, and actuators that are part of the Internet of Things (IoT) and that can feed the virtual content that is present in the layer that is superimposed on reality with their real-time information about the environment and its dynamics. Hence, the alignment, requiring whatever combination of senses, can be satisfied by information made available from the smartness embedded in the environment. This includes information obtained from multiple cameras, probably providing non-usual views that make it possible to visualize objects that are out of the user’s view, for example from a drone, from remote locations, and from other sensors that provide the user or the virtual content with perceptual enhancements that have no real-world counterparts.

In this paper, we survey the various views that can be held when considering the alignment of virtual content with an AR user’s real-world view. The aim is to investi-

gate how Azuma's definition of AR can be maintained if we look at other than computer-generated (imagery) 'virtual' content, addressing other senses than our sight sense, and whether we can maintain a distinction between 'augmented reality' and reality in a future where we can speak of ever-present AR integrated with the IoT and ubiquitous computing technology [2]. From the sight sense point of view, our focus is on optical see-through (OST) AR, rather than on hand-held AR. The assumption is that in the (near) future bulky head-mounted devices (HMDs) such as the HoloLens can be replaced by AR glasses with similar functionality and in a more distant future by AR contact lenses.

In Section 2 we start with a global view of AR. Such a view has the danger of having to enter philosophical considerations of how 'virtual' as it is used in a 'virtual layer' that is, a layer that is superimposed on reality, fits in discussions on material versus non-material, physical versus non-physical, and real versus non-real. We will not enter this discussion, but rather, in section 3, look at ways 'virtual' content can be generated and aligned with real-world content. AR as part of smart technology and ubiquitous computing is discussed in section 4. All these observations are given a more concrete basis in section 5 where we have a more case-study-oriented approach to the various issues that need to be considered when we want to integrate AR into our daily life activities. To do so we need to pay attention to AR that is multi-sensorial instead of being uniquely oriented on only the sight sense. Conclusions that take into account developments in AR devices follow in section 6.

Augmenting the Real World: From Street Signs to 'Mouth Glasses'

It makes sense to go back to the original definition of AR and comment on the parts of this definition that are usually taken for granted. But before delving into a technology-inspired AR definition, it is enlightening to review a somewhat more general view of augmentation of the real world and how to distinguish, if possible, purposely added changes from 'naturally occurring' additions and changes to real-world environments. This is the recurring theme in this paper and it will be discussed from different angles.

As mentioned by Miguel Sicart [3], reality has always been augmented. Streets have been given names, borders exist between countries, there are directional and road signs, et cetera. We align these names and signs with the real world. Egyptians engraved hieroglyphics on walls, and in Roman times places of business were identified by signs, and stone pillars provided directions and distances to cities throughout the empire. Devices to enhance our senses also date back to ancient times. A treatise on optics was written two thousand years ago. Visual aid devices for reading and observing such as magnifying glasses, eyeglasses, binoculars, and microscopes were introduced. Wearable eyeglasses appeared in Italy during the 13th century. The Claude glass was introduced in the 18th Century, a gray convex mirror that allowed users 'to view landscapes as if they were picturesque paintings' [4], that is, to make landscapes more beautiful than they were in reality.

In the 1890s George M. Stratton experimented with eyeglasses that inverted the visual field [5]. Technological devices were designed that allowed us to perceive and manipulate our perception of reality.

Nowadays we have artifacts designed and produced by humans all around us. We perceive, usually in a multisensorial way, we appropriate, and use them, they can be interactive, and they are aligned in appearance, behavior, and function with our three-dimensional world. It can be argued that these artifacts are superimposed on the real world, but they are not virtual or interactive from a human-computer interaction point of view, where we interact with digital content and control digital and physical processes. For example, in contrast, Pokémon GO is an interactive smartphone game where virtual animated characters can appear and move around superimposed on a user's view of the real world. The creatures are computer-generated and for that reason are called 'virtual'. While some researchers have expressed the opinion that Pokémon GO is not AR, others have hailed it as a breakthrough for AR. Sicart mentions " ... audiences worldwide are now aware of augmented reality as a way of engaging and playing with the world."

Other much-cited applications with which the name of AR is associated by the general public are the well-known Snap Chat selfies that augment a face with cat ears, Facebook apps that add elephant trunk and ears to your face, or a Google Play app that lets you put a virtual tiger or another animal on the table in your living room. And, of course, we can look at navigation and tourist applications where we see location-based information, usually presented in textual form on a handheld, about streets, buildings, and events, that is superimposed on two- or three-dimensional representations of a particular environment.

There are other examples of augmenting the real world and devices that are needed to perceive such augmentations. Augmentations are not necessarily digitally generated and viewers-users do not necessarily have to use technology to perceive these augmentations, whether they address vision, sound, touch, smell, or taste. We may have the opinion that vision is our dominant sense and most AR research is oriented towards augmenting what we can see with wearable devices, whether they are handheld (smartphones) or head-mounted (smart glasses), the other senses have also their AR equivalents, and maybe more importantly, multi-sensorial or crossmodal equivalents. While with vision-oriented AR we have a virtual layer superimposed on the real world that contains (digitally rendered) visual content, with audio-oriented AR we have a virtual layer containing digitally rendered sounds, and similarly we can look at superimpositions of virtual layers on the real world that are touch, taste, or smell oriented and therefore augment our tactile, gustatory, and olfactory system. Hence, we can perceive these augmentations but this perception may require specialized technology, just as we need specialized technology to perceive visuals superimposed on the real world. In his foreword to a book on augmented taste and smell, world-owned chef Andoni Luis

Aduriz Mugaritz [6] mentions that we need ‘glasses’ for the mouth and perhaps in the future they become as common as spectacle glasses.

Augmented Reality and Digital Technology

In the previous section, we already introduced many characteristics of AR that need to be included in a more formal definition of AR. The original and generally accepted definition of [1] goes like this: “*Some researchers define AR in a way that requires the use of Head-Mounted Displays (HMDs). To avoid limiting AR to specific technologies, this survey defines AR as systems that have the following three characteristics: 1) Combines real and virtual, 2) Interactive in real-time, 3) Registered in 3-D.*” Azuma also mentions that “*AR might apply to all senses, not just sight.*”

According to this definition, the real and virtual content is combined in a real environment, real and virtual content are aligned with each other, and the combined content (the AR environment) is interactive, in real-time, and in three dimensions. The definition is not supposed to be limited to sight, AR should apply to all senses. Nevertheless, since humans are primarily sight-oriented, sometimes tacitly, sometimes explicitly, independence of technology is often understood as independence of display technology that combines real and virtual view images [7], but clearly, we can talk about display technology for other senses, including hearing, touch, and smell, or, preferably, a combination of senses that allow a multisensory display of virtual content just as in real life real objects display multisensorial characteristics. Adding virtual content to our surroundings can have the consequence that some real-world objects are no longer perceivable by our senses (diminished reality) or are perceived in a different sensory way.

Technology is part of our world and it is part of our daily activities. So we can ask what is special about our world being augmented with AR technology compared with other (human-made) technology. Is our television set, our smartphone, and our Internet, part of the ‘real’ world or are they augmentations of the ‘real’ world? What about our wearables, are smartwatches more AR than our digital or mechanical watches? We have prescription glasses and hearing aids that enhance our perception of reality and (sun)glasses and hearing aids that, respectively, reduce light and block external sounds. We can also diminish reality by closing our eyes and having our sight sense take over by active touch and discovering and experiencing an object in a quite different way than just looking at it.

Azuma restricts his definition to ‘combining’ the real with the virtual, and his examples are vision-oriented: “This definition allows other technologies besides HMDs while retaining the essential components of AR. However, this definition does allow monitor-based interfaces, monocular systems, see-through HMDs, and various other combining technologies.”

The technologies that are mentioned do not refer to anything other than the visual sense for combining virtual and real content. We may ask why using this AR technology provides us with a different view of our world than using

glasses that enhance our vision, batteries that provide us with energy that allow us to use our smartphones, connect with the Internet and communicate with friends, and enhance our perception of the world. Technology is not something that is added to our world, it is part of our world. Moreover, AR technology is not restricted to vision-oriented technologies as we can see in Azuma’s definition and it has to function in a world that is full of ‘traditional’ and digital technology. If we want to look at AR that addresses not only the sight sense we need to look at the ‘various other combining technologies’ that are mentioned by Azuma. AR functions in an already technology-impregnated society and in particular a ‘real world’ that consists of domestic and public environments with processors, sensors, and actuators that know about a user’s AR view and assist in interpreting and dealing with this view. In a seminal paper [8], Steve Mann introduced other ways to look at AR and made it part of a device-independent view of what he called ‘mediated reality’.

Let us, in this section, continue to focus on Azuma’s desire not to limit AR to a specific technology such as an optical see-through HMD. Indeed, various forms of AR have been introduced such as spatial AR, mirror AR, monitor-based AR, and handheld AR, which, although vision-oriented, do not require an HMD and where the conditions of this definition are satisfied. It is also mentioned that AR might apply to senses other than sight and that view is also generally accepted and there are many examples of systems that address senses such as touch, taste, smell, and sound by adding or manipulating stimuli that address these senses. That is, in AR we can overlay the real world with layers that contain augmentations of more than one of our senses. In this way, we have a multisensorial augmentation. For example, a virtual object can be provided with a tactile component, an animated object can be provided with sound, tactile properties of a real object can be changed. However, rather than having the AR cluttered with virtual content, we need an alignment of the virtual content with the real world. It needs to be anchored in the real world such that it appears to be a part of the physical environment. This attunement must meet an underlying desired goal of the augmented world, its designer, its owner, or its user. AR has many application areas. In medical education, it will make different demands on plausibility than in a theme park or an artistic installation.

It is quite possible that while wanting to avoid limiting AR to a specific technology Azuma nevertheless might have in mind other digital technology that could enable registration and real-time interaction. And nowadays it is hardly possible to think that digital technology will not be used whenever we want to create, control, mediate and experience stimuli that address our senses. On the other hand, unlike computer-generated Imagery that stimulates our sight sense, touch, taste, smell, and sound stimuli are not necessarily computer-generated and the delivery of these stimuli is not necessarily digitally controlled. Taste and smell are considered to be ‘chemical’ senses that require stimuli that can be digitally modulated but not re-

placed with digitally-generated stimuli that address receptors in the nose or mouth.

Hence, we might question what is the role of digital technology in this generally accepted AR definition. Can there be something ‘virtual’ that has not been created by digital technology? Or does ‘virtual’ only apply to something that has been created by digital technology?¹ Although we will return to this question in a later section, we may already decide, looking at other than the sight sense, that the answer is negative. The next question is how virtual content can be embedded in the real world. Does that always require digital technology? Again, the use of digital technology is obvious, we live in a digitally enhanced world, but that does not mean that it should be an essential part of an AR definition. The concept of real-time interaction does not necessarily require a special role for digital technology. Again, this role may be obvious, but not essential for an AR definition.

Augmented Reality and Ubiquitous Computing

According to the definition, in AR virtual content needs to be aligned with the real world. This assumes that in augmented reality we can perceive the real world, if not, the world around us would be an immersive virtual reality world. It also assumes that we can make a distinction between real and virtual content, at least from the point of view of an AR designer. Included in our real world is the technology that enhances our senses in dealing with the world, such as watches, glasses, hearing aids, smartphones, and other wearables. Smartphones are now an integral part of our lives. And so are social media. Navigation systems are integral parts of our cars. A car’s navigation system can provide information about what a driver will encounter further along the way. Street lights equipped with cameras can provide a motorist with see-through images on his front window (the car’s smart windshield) so that they can see around dangerous corners [10] and avoid collisions. While in the first decades of AR research it was oriented toward intrinsic issues, nowadays we cannot separate AR technology from smart digital technology, including all of our wearable technology, that exists in environments that have embedded sensors, actuators, and processors that are part of a ubiquitous computing world. This smart digital technology provides information that makes AR and interaction with AR more natural and smarter. It should be mentioned that neither in a recent article by Azuma [11] nor a “Grand Challenges for Augmented Reality” paper by Mark Billinghurst [7] there is mention of AR for other than the sight sense and the extrinsic issues of AR. But of course, humans are open to multisensorial stimuli, can predict these stimuli, cross-sensorially integrate these stimuli,

¹ In [9] Azuma’s definition is followed, but it is also mentioned that “AR supplements the real world with virtual (computer-generated) objects that appear to coexist in the same space as the real world.”

and act upon them. Hence, we want them also to be present in always-present AR.

Because of these observations, some questions arise. These questions can be considered from a human-computer-interaction-technological and a philosophical-technology point of view. The first view can be given a simple explanation. We design for a user who needs an application where they perceive their physical environment but designer-added content to their view makes the application more useful or more entertaining. In this case, the distinction between real and virtual is designer-made, that is, whatever the AR designer decides to integrate (that is, align) into an existing user-viewer environment. It will be perceived by this user/viewer and can be acted upon in their augmented world with whatever technology (if any) is necessary. This is a workable but also very opportunistic way to define the difference between real and virtual content in AR.

There is more to say, for example about the interaction between and the co-creation of the virtual and the real, not to mention many more insightful reflections on this difference from a more technology-philosophical point of view. But let us start by emphasizing how diverse the technology that is available to AR designers already is. While in the past AR technology could be distinguished in its use from other smart technology, ‘just’ focusing on the generation, display, and alignment of virtual content superimposed on reality, nowadays this distinction is hardly possible anymore. AR sensors and actuators are not that different anymore from what we expect to see in our wearables and the other way around. Various AR technologies exist: visual see-through, pass-through, optical see-through, mirror-AR, and spatial AR., each of them requiring technology such as miniature RGB and infrared cameras, wearable projectors, GPS, Bluetooth, head- and eye tracking, accelerometers, gyroscopes, barometers, magnetometers, depth sensors, et cetera, that we also need and use in pervasive and ubiquitous computing and require in the IoT.

Moreover, when we look at perceptual stimuli other than sight stimuli, we need to consider technologies that stimulate our auditory, touch, and haptic senses, and electric and chemical-based technologies that stimulate and change smell and taste experiences. Hence, in addition to the already mentioned technologies that are needed to generate and spatiotemporally control virtual content from the point of view of the user, we need to look at devices that provide electric stimuli to the tongue for taste experiences, tactile gloves, and ultrasonic transducers for touch and haptic experiences, directional microphones and in-ear sound monitors for auditory experiences, and scent projectors for smell experiences. Even when the stimuli are not digitally generated, in AR research their spatiotemporal characteristics are digitally controlled.

In ubiquitous computing, we have digital content realized by sensors, actuators, and processors, superimposed on reality. This digital augmentation is usually designed to increase efficiency in collecting, managing, and using information by those who own or are responsible for the en-

vironment but is also designed to increase the efficiency and positive experience of human users' use of smart environments. The positive experience may also be the result of being part of artistic, entertainment, or game environments. Ubiquitous or everyday-present AR is included in the smart environments that are realized with ubiquitous computing technology and cannot and should not be separated from other smart technology that is used to create these environments. And indeed, in [12] it is mentioned that "... *If AR is to become ubiquitous in consumer usage*" it requires a semantic understanding of the real world, an understanding that is only possible with having specific AR technologies embedded in ubiquitous computing technologies that aim to support users in whatever activities they are involved with.

Do these observations have consequences for the Azuma AR definition or perhaps require a completely different AR definition? There are many more observations to be made about the constituents of Azuma's definition before we can do so. These observations have to do with questions about how to distinguish virtual or digital from real, about interaction with virtual content, whether virtual content can change the real world, and with what we mean by the alignment of artificially generated or otherwise added content to a user's perception of the real world. Perhaps we should emphasize that in this paper we want to refrain from discussions about whether we need to distinguish between what is real, digital, or virtual. We will return to that in a future paper. But at this moment it is useful to look at a few examples of (not necessarily sight-oriented) augmented reality that help to shed new light on the constituent parts of the definition and on the consequences of having AR technology embedded in ubiquitous computing environments where there can be multiple AR users sharing augmented perceptions of reality. When discussing AR, we should also keep the well-known quote from Mark Weiser [13] in mind "*The most profound technologies are those that disappear. They weave themselves into the fabric of everyday life until they are indistinguishable from it.*"

Can we expect that AR technology will be weaved into the fabric of everyday life and is indistinguishable from it?

'Augmented Reality' and Public Space

In the early sections of this paper we looked at the various ways the real world can be considered as augmented and, in more detail on augmenting the real world using Azuma's AR definition. We discussed the supposedly needed digital technology to do so. Our aim in the previous section was to show that AR is a smart technology that will be part of ubiquitous computing making use of the Internet of Things. We mentioned Weiser's well-known observation about technology that weaves itself into the fabric of everyday life. This section aims to make these issues more concrete by discussing them in the context of an application that we can encounter as part of our daily activities in urban environments, entering or leaving a subway station.

Entering a Subway Station

Piano Stairs is an interactive musical stairway that has been introduced in cities around the world. Walking up and down the stairs is detected by sensors and a different tone is generated for each step. It became popular after it was included in the Volkswagen initiative called "The fun theory," a project that was meant to show that people's behavior can be changed for the better by making things fun to do [14]. The installation, using pressure sensors for each step, was created in 2009 in the Odenplan underground station of Stockholm. Subway commuters preferred to climb the stairs rather than ride the escalator.

Similar installations had already been introduced before, following a design of the artist Christopher Janney [15]. In his design, patented in 1985, different series of melodic and natural sounds were activated depending on ascending or descending the stair. For each step, a different sound is generated. Light sensors, one per step, detect an individual's position on the stairs. Other installations, usually following the piano stairs idea, and usually temporary, have been created in public spaces all over the world.

Staircase with Sound and Sight

Let us have a fresh look at regular stairways in public environments that we want to make more attractive by using augmented reality. Consider the situation of stairs where each step has a light sensor that detects whether someone steps at that particular step. After detection, a sound is played in the headphone of the person that climbs or descends the stairs. The sound that is played can be the note that belongs to a piano key that corresponds with a particular step. Black and white piano keys can be painted on the steps. The sound can not be heard by others not wearing a headphone, although they may wonder why the steps are painted like piano keys. According to the definition of Azuma, we have AR for the headphone user. That is, the virtual content is sound, not necessarily digitally recorded or (re)produced. The interaction between the user and (augmented) stairs is in real-time, and the virtual content is registered (or aligned) with the real-world objects. That is, the notes corresponding to the trodden step are played.

It can be enlightening to make a comparison between this sound-oriented AR with the vision-oriented AR approach where computer-generated images are superimposed on the real world that is perceived through an OST device. In vision-oriented AR we have sensors in our wearables, in particular, cameras that sense the real world and that provide a view of the real world that can be overlaid with virtual content, that is, computer-generated imagery. But other sensors are also needed to provide information that helps in aligning the virtual content with the real world from the point of view of the AR user. For example, in OST AR we need to sense the position and head orientation of the user to align the virtual content with the real-world view of the user. Notice, that the virtual content could as well be directed sound, perceived from a particu-

lar location in the real-world view that is provided by the OST device. In that case, the virtual content addresses the hearing sense. Virtual content that addresses other senses (touch, smell, taste) is possible as well. How virtual content is generated and aligned with real-world content is not an issue in Azuma's AR definition, although we often tacitly assume that it is done with digital means.

In the case of the piano stairs' implementation considered here, we need to sense sounds aligned with our position in the world as well. Sensors in our headphones can cancel environmental noise, so we have a 'diminished reality', and they can focus on sound coming from a particular location or person and the sound can be adapted to a listener's hearing capabilities. In the case of our piano stairs implementation, this sensor technology can add to the proper alignment of the keynote sounds to the position of the user, for example, by taking care that the sounds not only align with the particular step on the stairs the user is making but also that the sound is coming from the direction from that step, from below, rather than being ambient (not coming from a particular location).

Rather than using light sensors, we can think of an implementation with pressure sensors. It does not change the virtual layer, only how the position of the user is sensed, and the sound that has to be played in the user's headset. A stairs implementation in a smart public environment can have other sensors as well to provide a user with a personalized AR experience that addresses one or more of their senses, perhaps creating cross-modal effects.

Going back to our example, whether realized with light, pressure, or other sensors, if there is more than one user on the stairs, all of them wearing headphones that allow them to hear the sounds that are produced when interacting with the stairs, they can share their augmented world and they might try to play together. How should we look at a situation where the sounds can be triggered and heard by everyone who uses the stairs without needing a headphone? That is, the usual piano stairs designs as they have been implemented in indoor and outdoor public spaces? Should we call it shared AR? If we make an AR installation public by not requiring a personal device that displays virtual content aligned with the real world, is it still AR? With spatial or projected AR and monitor-based AR we use projectors, cameras, and additional technology, but the user is not necessarily required to have a personal device to perceive the augmented world. Azuma's definition of AR does not exclude perceiving AR without wearing a personal device. We can compare this public sound-oriented version of the piano stairs with spatial and vision-oriented AR implementations that address the alignment of projected visual content (computer-generated imagery) with real-world content, where real-world content ranges from museum objects to architectural or other objects that we can find in public spaces, for example, a three-dimensional front of a historical building.

We can turn the existing real world into an augmented real world by adding not yet present images, sounds, smells, tastes, or touch content, or by manipulating existing

content in a way that can be perceived by the user of the AR environment, whether or not a digital or other device is needed for perceiving the additions. Neither does the added content have to be digitally generated. Added auditory and touch experiences can be generated, controlled, and aligned in a non-digital way and this is certainly true for smell and taste. Digital technology can play a role or be needed in generating and aligning content and being able to interact with the augmented world. However, we conclude that Azuma's AR definition cannot be maintained if we want to include anything other than the sight sense and other than computer-generated content. If we want to maintain this definition, we should accept that we cannot always make a distinction between what we consider real and what we consider augmented. An elevator with glass walls is nicely aligned with the ground and other floors, it provides multi-sensorial experiences (auditory, visual, proprioceptive, smell) that are not present with traditional stairs, and its interactivity (where to go, going back on decisions because of requests from other floors, detecting children below a certain age, excessive weight, or door-closing obstructions), make such an elevator interactive as well. When we introduce such an elevator, we augment the existing world with multisensorial experiences that can be shared, from different perspectives, and that are not available for non-elevator users.

Perhaps we should say that this example is not about augmented reality because we do not need a wearable device to perceive the augmentation and its alignment with the real world. But this contradicts Azuma's device-independent AR definition. In addition, we may think of AR applications (spatial AR, mirror-based AR) where users do not need a device to perceive the AR display. And, as mentioned above, AR devices can be embedded in a ubiquitous or IoT computing environment that allows us to have a personalized augmented view of the world since the environment can recognize us, our context, our history, and our preferences, and therefore the (smart) environment can provide us with a view of the augmented environment that despite being shared, nevertheless provides us with a personalized view and corresponding (multisensorial) experiences. Our view of the augmented world might be different from the views of other users sharing the augmented reality world, in whatever way the augmentations have been realized, and whatever senses are addressed.

While in the Piano Stairs observations we made above, artificial sounds had to be aligned with passers-by stepping on its steps, to make it (sound-oriented) augmented reality, previous paragraphs and subsections already alluded to other than sound-oriented augmented reality. We made the comparison with vision-oriented augmented reality. In that case, we have computer-generated imagery that has to be aligned with a user's real-world perspective. Also, in the case of computer-generated imagery we can distinguish between individual (and personalized) AR, shared AR, and AR that has become part of reality. One or more AR users can have a personalized view of computer-generated imagery as virtual content superimposed on reality. An OST

device is required to view this content, aligned with the real-world content. Rather than having virtual content displayed on a user's OST device, we can have it displayed and embedded in a user's AR view of the environment. In projected or spatial AR, we have computer-generated imagery superimposed on real-world objects such as walls and buildings. Such projections can become part of ever-present augmented reality, not requiring a device to perceive the augmentation of reality.

Augmenting with Scent

Sensors, actuators, and wearables in a smart environment can provide its human inhabitants with augmented reality experiences, making the environment an AR environment. We can further illustrate this with smell-oriented AR and provide similar piano-stairs-like observations as we had above for sound and vision. The smell can be added to an existing environment by having it entered with smell-emitting objects such as flowers or making changes to the environment by starting cooking. These smells are generated chemically, not digitally. Digital technology can be used to manage the distribution and context-aware manipulation of natural or chemically produced scents, but the content is, unlike what we encounter with computer-generated imagery that has to be aligned with reality, not computer-generated. Papers that follow Azuma's AR definition and mention that it as well includes other than the visual sense, do not elaborate on this definition.

In various papers, scent-augmented realities have been discussed. The scent is usually delivered from fragrance oil cartridges. These cartridges can be present in a user's environment or a wearable display device, for example, attached to an OST HMD that displays visual virtual objects and have scents attached to them. The scent has to be delivered to the user we want to give an augmented reality scent experience. This is easy when the cartridges are near the user's nose and mouth, otherwise a directional stream has to be created, targeted at the user. Alignment (as mentioned in Azuma's definition) requires spatiotemporal control of the scent, which can be realized with fans that blow over an opened cartridge, scent projectors that make use of invisible air vortices [16], [17], or ultrasound [18]. If the scent-delivery system is not wearable, then the position of the user, in particular their nose, can be tracked with cameras that are present in the application area. Commercial olfactory displays that deliver directional olfactory streams are already on the market [19]. Hence, this way of scent generation (not digital) and (not necessarily digital) delivery to one particular person makes it an olfactory augmented reality experience.

We can argue whether a scent should be considered virtual. Unlike computer-generated imagery, the artificially added scent is not generated digitally and the alignment does not necessarily require digital technology. As in the case of computer-generated imagery where the aim can be to make it indistinguishable from visual reality in an AR application, we can think of sounds or scents that are indistinguishable from reality but this more or less requires also

considerations about the appropriateness of images, sounds, and scents that are added and perceived by the AR user, which again has to do with alignment. Another component of Azuma's definition is interaction in real-time. What does it mean to interact with scent? Smells can recall memories and influence our behavior. We can sniff a scent and actively look for different scents but that does not define human-scent interaction. Rather we can have the user exploring the environment guided by smells or acting on objects in the visual AR environment that have (augmented) smells associated with computer-generated visual virtual objects. From this point of view, we can say that Azuma's definition also covers a smell-oriented realization of augmented reality. Of course, interactivity is also present when an application requires the user to control the scent delivery system. For example by providing the user with a control panel or sensing the user's activity (gaze, gestures, et cetera) that triggers the scent delivery system.

We might think of a future scented version of the piano stairs where each step triggers a different scent. This certainly requires the quick switching and neutralizing of scents or their intensity. Rather we look at the next step we made when we discussed the transition from an individual AR experience to a shared AR experience, where 'shared' does not exclude the possibility that the AR experiences are personalized and depend on the position and orientation of the participants. Scents can be shared, whether their delivery and distribution are done by personal wearable delivery systems or by directional scent delivery systems (scent projectors) positioned in the environment. Sharing a scent-augmented environment can nevertheless provide inhabitants with different smells and smell intensities, similar to what we saw in the case of sounds in the sound-augmented environment of the Piano Stairs. Interactions between users based on their own or shared smell experiences are possible. Other inhabitants of the environment, not included in the scent-supported community, not having wearable scent delivery systems, or not being targeted by scent projectors, do not share the scent-enhanced reality.

We can, as we discussed in the case of Piano Stairs, make the scent augmentation of the real-world environment available for everyone in the environment, not needing a special device, although different locations can have different smells. Just like daily experienced Piano Stairs, the olfactory augmented reality has become a daily reality, that is, not experienced as augmented anymore. The people involved are becoming familiar with the scents, there is habituation. AR becomes reality, similar to what we saw in the other examples we presented.

Conclusions

Once our ubiquitous IoT computing becomes reality, including ever-present AR, it is not relevant anymore to distinguish AR from other digitally generated and controlled aspects of reality. To substantiate this conclusion we started with a global view of how the real world is already augmented and whether digital generated virtual content

can add to that from the point of view of Azuma's definition. AR does not necessarily require digitally generated content and having that aligned with real content. It depends on the senses that are addressed. Also, AR technology can not be isolated from other technology that makes ubiquitous computing possible.

We discussed an AR view on daily activity in public spaces, entering and leaving a subway station, and used it to explain our view on augmenting the real world with technology that provides us with an Azuma-like AR view but that does not necessarily distinguish between virtual and real and by looking at other modalities than vision only, not necessarily requires digitally generated content. We distinguished between individual, shared, and collective experiences. To have technology-supported personal experiences in the world the technology should be tuned to a particular user. That is true for a smartphone, a headset, or prescription glasses and it can be true for AR experiences. Every individual's beliefs (common sense and world knowledge), aims, actions to satisfy them, and emotions are unique. AR technology becomes part of unobtrusive technology in our wearables that communicates with our smart (urban, office, domestic) environments in a way that we prefer and get used to it. Following Mark D. Weiser [13], it disappears into the fabric of everyday life, including social life in public spaces and urban environments [2].

An OST HMD such as a HoloLens is not unobtrusive. It is inconvenient to wear, it has a limited field of (virtual content) view, and it covers regions of the face that are important for social interaction [20]. But, OST HMD devices, just like virtual reality devices, develop into all-day wearable light-weight glasses that cannot be distinguished from prescription glasses or sunglasses. They will be put on the consumer market by companies like Facebook, teaming up with Ray-Ban, Google, Apple, and Amazon [21]. AR contact lenses with image and motion sensors, connected to a smartphone, are also in development [22], [23]. We enter the world of Vernor Vinge's novel *Rainbows End*, where wearing computers is the norm, people choose cliques or 'belief circles' with which they share experiences, and use contact lenses that overlay what they see with virtual content that redresses their environment to their taste [24].

Abstract

AI.R Teletorium is an artificial intelligence-based collaborative storytelling system that offers children with inclusive needs an opportunity to participate in a remote interactive AI fairy tales storytelling experience while actively involving them in creating a story's narrative with their normal peers. We aim to provoke positive social interactions between children and help develop social, creativity and communication skills and improve their imagination and social competencies. AI.R Teletorium consists of a neural story generator and a doodler-based fairy tale visualizer. We design a character-centric bidirectional connection mechanism between the story generator and visualizer equipped with Contrastive Language Image Pretraining (CLIP). Thus, simple sketching enables kids to participate in the story generation process. Extensive experiments and user studies show that our system could generate and visualize meaningful and vivid fairy tales with limited training data and complete the entire interaction cycle under various inputs (text, doodler) through the bidirectional connection.

Introduction

While story provides an effective and concise way to share experiences, visual content acts as a more comprehensive and universal communication tool that transcends barriers between user groups with different cultural backgrounds and physical preferences. Learning for meaningful and coherent story visualization is thus becoming a popular yet challenging task among AI studies. This paper proposes AI.R Teletorium, an intelligent and artistic fairy tale visualizer that interacts with users in real-time. Furthermore, language and mental development are key aspects of early childhood education. Through the characters and virtues shown in the stories, fairy tales provide moral models for kids to follow and help develop their vocabulary by offering vivid illustrations. The majority of existing story visualization research ([7]; [13]; [16]; [18]; [29]) have relied on the combination of recurrent neural networks (RNN) and generative adversarial models (GANs). While achieving stunning results on constrained datasets like MS COCO ([17]), such end-to-end text-to-image

mapping could fail on composite scenes with multiple objects. Recently, ([9]; [10]; [21]) induce scene graph as an intermediate representation to support visualization of compound sentences. The Scene graph ([12]) describes things in a scene and their relationships, most commonly position relationships. Compared with raw text, scene graph conceptualizes scene contents as abstract semantic elements that are not bound by object class or relationship types, boosting text-to-image studies' flexibility and representation power. However, most existing visual language models are trained on massive real-life photos with captions. In fairy tale visualization, we still face the challenge of data shortage. On the one hand, fairy tale illustration conserves much artist labor; on the other hand, the illustration style usually varies from artist to artist, making learning more challenging. Based on this point, we combine a rule-based fairy tale parser with a neural sketch generator into an intelligent and interactive visualization system that specially focuses on fairy tale visualization.

In light of this, we propose a new AI fairy-tale co-creation system: AI.R Teletorium. It enables common creative experiences between groups of children with different physical preferences and at other locations. We aimed at offering an entertaining and imaginative platform for children to communicate with each other, improving their psychological health, especially under extreme circumstances such as the COVID-19 pandemic. The system is composed by two novel modules, a character-centric story generator and a visualizer in the form of doodlers. We connect those two modules by characters and build a bidirectional link to allow kids to interactively participate in the fairy tale creation process by simple doodling without vocabulary requirements.

We summarize our key contribution as follows:

- A novel multimodal fairytale co-creation interface based on interactive text-to-image transfer and vice-versa.
- The system presents a novel fusion method between a learn-based language model and a rule-based graph update, allowing for more flexibility in both story generation and visualization with limited data.
- Proposing a CLIP transformed story graph as an intermediate representation to transcend the barrier between digital storytelling content and insufficient illustration data (automatic AI fairy tales storytelling case).

This paper will first give a brief description of the AI.R.

Taletorium system. Then we explain our character-centric approach to fairy tale generation and visualization. Finally, we present the results from the performed experiments and demonstrate various applications to prove the generation flexibility of our proposed system.

Related Work

In the field of text to visual content(or, more specifically, image) synthesis ([7]; [9]; [13]; [14]; [16]; [20]; [26]; [27]; [31]; [36]; [38], [39]), early studies usually ground text to-image generation as a search problem. Given a text description, they search for words, representative images, and placement from an existing database that most match the description. They then adopt a graphics renderer to combine the search results into the same canvas. Despite the complex AI models (vision, language, and graphics) integrated into the system, such systems are usually incapable of generating new images.

With the rise of generative models([5]; [21]), researchers also explore combining RNN and GANs for text-to-image generation by learning directly from massive text-image pairs ([7]; [16]; [14]; [20]; [26]; [27]; [38], [39]). Such modelling enables the generation of new visual content from concise text descriptions. However, constrained by training data formation, they are generally incapable of modeling complex scenes with multiple objects.

Another stream of work adopts intermediate representations to deal with complex scenes. Johnson et al.([13]) firstly introduce scene graph for image generation and outperforms previous methods in generating an intricate image with multiple objects. They develop a graph convolution network to process the scene graph, which acts as a principal component for following scene graph-based image generation methods ([9]; [30]). In WordsEye ([3]) an automatic system for 3D scenes generation from text has been proposed.

Similarly, we use scene graph as the medium between fairy tale and visual contents to support sketched scene generation from fairy tale fragments with unusual objects and complex relations. Along with the generation of fairy tale fragments, we par each fragment in real-time into a scene graph containing characters and their relationships covered by the fragment. We then propose a conditional neural scene composer learned from human captioned natural images to compose sketched scenes from the parsed scene graph. As the story goes fragment by fragment, we update the scene graph according to fragment co-references ([32]).

Learning for Sketching

Doodling, or free-hand sketch, is a universal communication and art modality which combines convenience with expressiveness. As a high-level abstraction of real-world contexts, doodling endorses advantages for neural processing with its simplicity while suffers from the high sparsity and wide style diversity. Based on neural representations for sketch structure([8]; ([28]), a great amount of work has been done in doodle creation, recognition, retrieval, partial analysis and, abstraction, etc. We refer the audience to([35]) for a comprehensive review of learning for sketching.

With artificial intelligence becomes increasingly part in people's everyday lives, making researches on human-AI co-creation rather essential. Recently, ([22]) propose the positional idea to grounds the HRI design research on three touch-points: the roboticists as designers, the design features of the systems, and the users as co-designers. ([23]) explore four scenarios for collaborative human-human sketch co-creation, and shows that collaborative drawing with a third-party voting strategy leads to most creative sketches. Despite these pioneering works, the research in human-robot co-creation remains extremely limited. With AI.R Taletorium, we proposed an efficient human-robot co-creation scenario that utilize AI as a powerful interface.

The visualization system of AI.R Taletorium combines doodle creation with comprehension. It not only enables doodling from the story but also turns the user sketch interactively into the story.

Interactive Storytelling (IS)

Interactive storytelling plays an important role for for Early Childhood Education. AI learning companions, as either tutor or tutee role, provides an intelligent and responsive interface to support children's learning in a variety of contexts including language development, storytelling and scientific learning (Kanda et al. 2004; [23]; [6]; [11]). Compared with kindergarten teachers, personalized AI tutors/tutees could asses and automatically adapt to kid's knowledge level and physical needs. Previous studies([1]; [24]; [19]) have emphasized that the personalized instruction from robots could clearly augmenting the efforts of parents and teachers to help kids acquiring both academic knowledge and positive attitudes.

Storytelling, as an interactive process that facilitates imagination, creative thinking, language abilities, and cooperative learning, bringing a broad range of positive outcomes for primary education([4]) summarizes methodologies and enabling technologies used in building interactive storytelling system for kids. The In-Visible island project([33]) further pinpoints digital inclusion in IS systems. They designed an inclusive system to join visually impaired children and sighted kids together into a unified storytelling process, which on the one hand, accelerated the social learning curve of visually impaired children, on the other hand, educating sighted children to have more empathy towards their peers with physical limitations.

AI.R TALETORIUM System

AI.R Taletorium is a character-centric multi-modal AI fairy tale telling system aims at connecting users with different background and physical needs into a unified fairy-tale co-creation process with AI. The system consists of two intelligent components:

- Character-centric AI fairy tale generator.
- Intelligent doodling-based fairy tale visualizer.
- Collecting users' facial characteristics and selecting characters for the storyline based on predefined matching criteria.

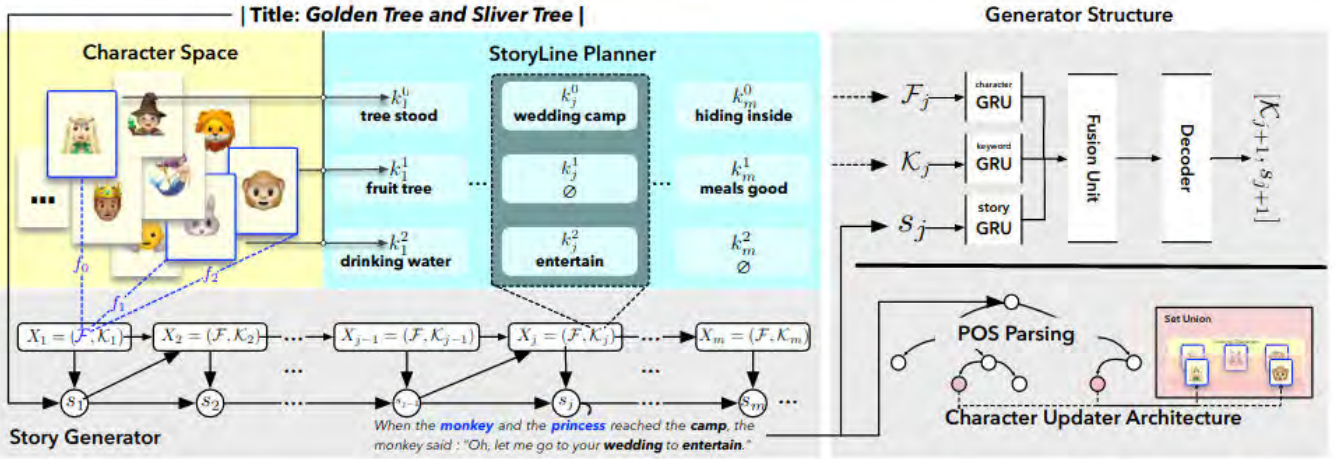

Figure 1: Character-centric story generation. We combine plan-and-write([37]) story generation framework with character features to compose each story fragment. We apply a dynamic generation strategy and plan for each fragment on the fly based on the previous story fragment and current character status. Such a character-centric generation scheme thus supports user co-creation with AI in storytelling by modifying characters.

- Interpreting users’ doodlers, they are added to the AI-generated fairy tale illustration and creatively implementing it in the storyline.
- Interpreting users’ doodlers, they are added to the AI-generated fairy tale illustration and creatively implementing it in the storyline.

With AIR Taletorium, we aim to intensify User-AI interaction in the joint act of creation by using users’ personal properties (face features and doodlers) and challenge artificial intelligence creativity to the highest level of imagination.

Character Centric Story Generation

We formulate the system input-output as follows:

Input: A character set $C = \{c_0, c_1, \dots, c_{n-1}\}$, a title $T = \{t_0, \dots, t_{k-1}\}$ that defines the main topic of the fairy tale and a storyline size m .

Intermediate output: We map characters onto the character embedding space as character feature vector $F = \{f_0, f_1, \dots, f_n\}$ as in (Liu et al. 2020). At each generation step $j \in [1, \dots, m]$, we generate storyline keywords ¹ $K_j = \{k_j^0, k_j^1, \dots, k_j^n\}$ for each character according to previous story fragment to define character actions at current step.

Output: A story $S = \{s_0, s_1, \dots, s_{m-1}\}$ composed with m story fragments, where $s_j = Merge(l_j^0, l_j^1, \dots, l_j^n)$ is merged from $n \leq \|C\|$ sentences ² generated from each character’s storyline keyword at current step. We follow a recurrent generation framework([37]) to generate the whole story (Fig. 1). Each fragment is generated based on previous fragment and current status $X_j = (F, K_j)$. We initialize the first fragment

¹We allow k_j^i to be empty, which means the character is not participating the current site

²We define $l_{ij} = \emptyset$ when $k_{ij} = \emptyset$, which means some characters might not be involved from the current generation step, and current fragment size n could be less than number of characters $\|C\|$.

as the given title:

$$s_{j+1} = (s_j, X_{j+1}), s_0 = T = t_0, t_1, \dots, t_k \quad (1)$$

As shown in Fig. 1, we initialize the characters by mapping user facial attributes, extracted with MXNet ([2]), onto 24 predefined fairy tale characters according to *Psychological & Cultural Stereotypical* rules, so the character with more features in common with the user will be choose.

Visualizing Fairy Tale

Most state-of-the-art text-to-image visualization methods are based on data-intensive transformer architecture, which generally suffers from insufficient training data, not to mention the domain gap of language styles and object categories between fairy tale stories and formal language descriptions. For example, while “A horse under a tree” could be a formal description for Visual Genome dataset([15]), in fairy tale stories it becomes “*The ferocious unicorn trapped in the tree*”. To tackle this problem, we introduce a doodler graph as an intermediate representation and adopt a two-stage generation framework to visualize fairy tale stories to interactive doodling interfaces. As shown in Fig. 2, we first parse the fairy tale fragment description into a doodler graph, then we adopt a GNN scene composer to compose doodler visualization from the parsed doodler graph. Similar to ([10]), the scene composer will first predict character layouts, then we adopt the SketchRNN ([8]) decoder to draw individual sketches according to the layout. By introducing the doodler graph as an intermediate representation, our visualization system is able to deal with more complex and abnormal scene structures such as fairy tale scenes. In the following, we will first formulate the doodler graph representation, introduce the scene composer architecture and demonstrate the doodler graph updating policy during the story generation process.

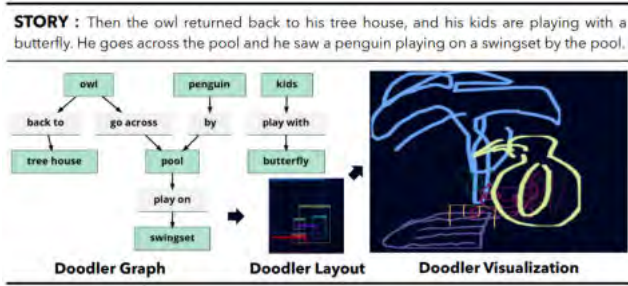

Figure 2: Fairy tale fragment to doodler visualization. Given a fairy tale fragment (top), we first adopt a rule-based parser to turn it into a doodler graph (left). Then we predict the doodler layout from the doodler graph (middle). Finally, we compose the doodler visualization according to the layout (right).

Doodler Graph Representation

Same as scene graph, doodler graph is a graph data structure that describes the contents of a scene ([12], [13]). We formulate the doodler graph as $G = (V, E)$, where vertexes $V = v_1, \dots, v_n$ refers to the set of characters, and edges E represents character relationships. Each doodler character $v_i = (o_i, c_i, w_i)$ is identified by its category o_i , color c_i and stroke weight w_i . Given a story fragment, we adopt a rule-based semantic parser to generate the doodler graph. Similar to ([13]; [34]; [31]), the parser will first parse the fragment into a syntactic dependency tree. Then a set of tree transformations is applied to the dependency tree to acquire characters (i.e., nouns), adjectives that describe character attributes, and verbs that identify character relationships. In practice, we assign doodling color and stroke weight to each character either based on their attributes (e.g., a red flower) or randomly choose one from a color palette.

Doodler Scene Composer

We train the doodler scene composer directly on the Visual Genome dataset (VG) ([15]). Considering the gap of characters and relationships between fairytale scenes and real-world scenes, we adopt a pre-trained text-encoder ([25]) to map the doodler graph into a scene graph according to the current story fragment. Specifically, we treat the matching problem as a zero-shot prediction problem. We replace each doodler entity in the story fragment with 81 candidate VG entities. We then encode candidate story fragments into text features $T_1, T_2, \dots, T_N, N = 81$ and calculate their scale cosine similarity with original story fragment feature T_0 , we choose the most similar entity to replace the doodler entity (Fig. 3). We adopt the same way to transfer doodler relations into casual relations. With transferred doodler entity and relation, we build a casual scene graph that suits the VG dataset.

After transferring the doodler graph to scene graph, we adopt a graph-neural-network-based layout predictor ([13]) trained on VG dataset to predict layout for doodlers. Given the layout bounding box, and layers for each object, we adopt a modified Sketch-RNN decoder (Huang and Canny 2019) to draw each doodler entity onto the canvas.

With this approach we managed to build a map between

Figure 3: Mapping doodler graph to VG scene graph. For characters and relationships presented in the doodler graph, we adopt a pre-trained text encoder ([25]) and search for the most similar VG ([12]) object based on the current story context.

real word and fairytale scenes which allow the net to learn how to build a reliable scene layout.

Character-centric Interaction System

With the doodler graph representation, we build a bidirectional connection to transform fairytale stories into drawings and vice-versa. In this way the user can influence the story generation by inserting new keywords or manipulating the characters inside the story by choosing at each generation step to remove characters and generating new ones thanks to the doodler recognition system. We decided to choose this system of interactions in order to create a more intuitive and children-oriented system instead of allowing the user to directly insert new fragments of the story.

The **story-to-drawing** transformation is based on neural correlation analysis and refreshes the doodler graph when a new story fragment comes. The co-reference system keeps track of pronouns in the system and matches the pronouns to nouns that existed in the previous context. We thus use the co-reference to link doodler characters in the newly generated fragment to the existing fragment. We analyze coreference between adjacent story fragments. After the coreference is resolved, we update the pronouns to their referenced nouns. With the updated doodler graph, we predict the layouts for new doodler characters and add each new character individually onto the canvas.

The **drawing-to-story** is similar to the story-based policy and is used to support user interaction. As a visualization medium, the doodler graph supports both transformings into/from story fragments and doodling. AI.R Taletorium is integrated with a doodler recognition system and allows users to add characters along with the generation. We will automatically parse the user sketch into story characters and update the scene graph based on doodler spatial relationships. We will generate the next story fragment based on the updated character set.

Experiments

In this section, we will first introduce the datasets we use and our implementation details in Sec . We then conduct the qualitative evaluation with story visualization and demonstrate user interactions under three scenarios in Sec.

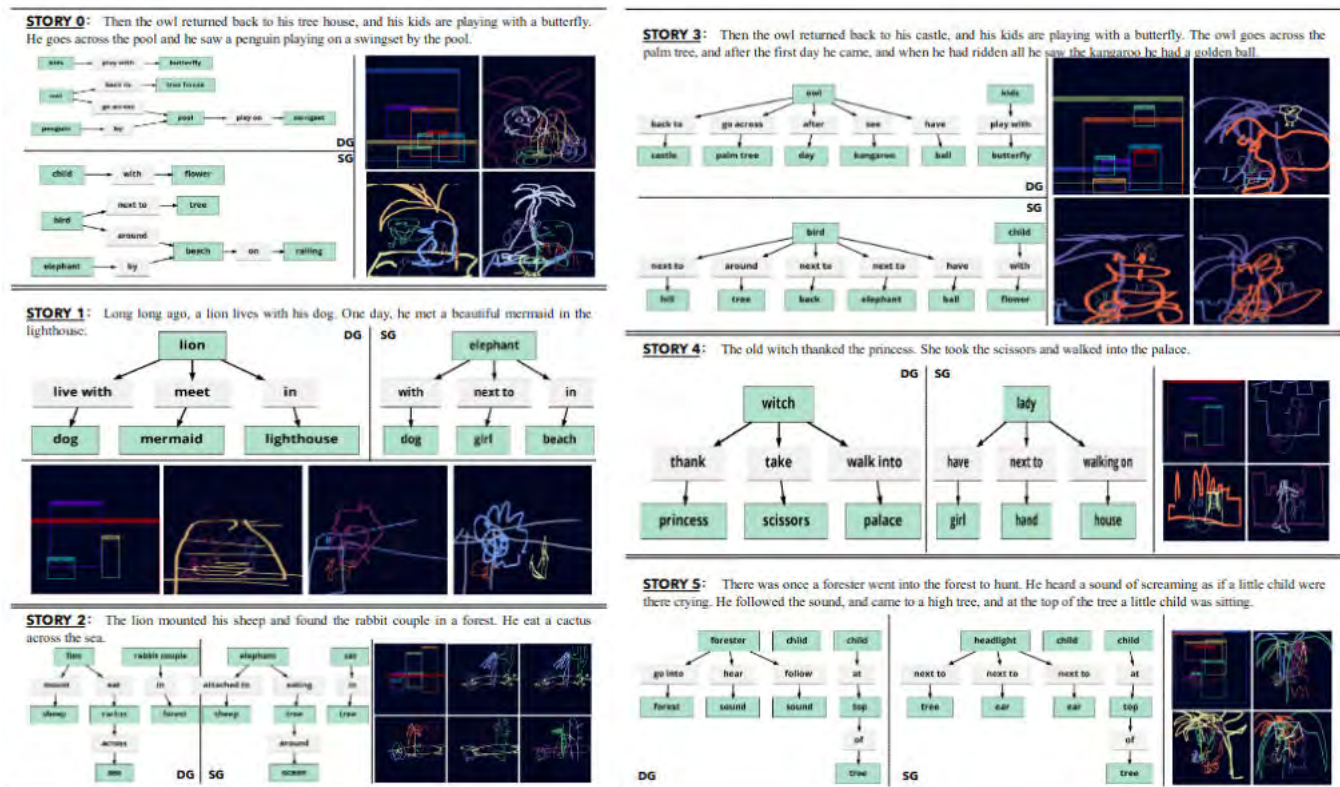

Figure 4: Doodler scene composition results. We demonstrate composed doodler scene examples for 6 stories. For each story, we show the parsed doodler graph (DG), the transformed casual scene graph (SG) based on the mapping strategy described in Sec. (Fig. 3) together with 4 composed scene examples. The result shows that with the doodler graph representation, we could handle complex scenes with multiple objects and relationships. Additionally, comparing STORY 3 with STORY 0, we further shows that our doodler graph representation could automatically remove redundant information and non-sense AI generated sentences like when he has ridden all. Meanwhile, as the mapping strategy automatically turn fairy tale objects to casual scene graph objects, we could also deal with rare scene descriptions including witch and forester.

Dataset and Implementation

Our system consists of three trainable modules: the AI fairy-tale generator, the doodler scene compositor, and the sketch drawer. We use the following datasets to train each module:

1. Fairy tale Dataset (FT890): We collect 890 fairy tale stories to train the AI fairy tale generator. We applied a modified RAKE algorithm([29]) to generate storyline keywords for each story. Firstly, we divide each story into an appropriate number of fragments (5 during the experiment). We then extract a set of keywords from a story and get their fragments id and score (indicates its importance calculated by RAKE). We select the top 4 characters to build the character feature space according to storyline keywords. We train the story generator with two 3090Ti for 20 hours and test with the 500 epoch checkpoint during inference.
2. We train the doodler scene composer on the Visual Genome Dataset ([15]) which contains 81 object categories. We process each ground truth scene graph with a graph convolution network (GCN) and train the GCN to predict the bounding box conditioned on the scene graph.

During inference, we map each fairy tale doodler to a scene graph object based on their similarity described in Fig. 3.

3. We train our doodler drawer on QucikDraw Dataset([8]) which contains 345 object categories. For fairy tale characters beyond the dataset, we assign the doodler that is semantically similar to the character as its representative doodler. We adopt a trained SketchRNN([8]) on the dataset to draw individual doodlers. We utilize TFJS integration for front-end sketching.

Fairy Tale Visualization

In the following, we first demonstrate the doodler scene composition results with parsed doodler graph, transformed casual scene graph and generated composition examples. We then analysis the efficiency of doodler graph updating policy among story fragments and perform ablation study on graph parsing w/o coreference resolution and scene composition with simple text guidance.

Doodle Scene Composition We demonstrate the visualization result for fairy tale fragments in Fig. 4. Compared with

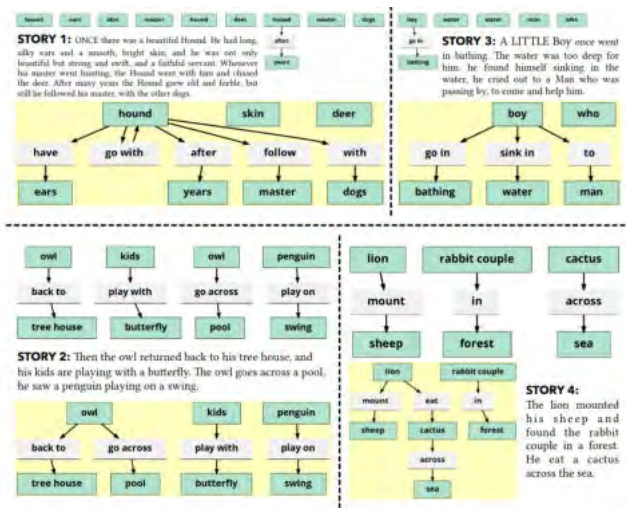

Figure 5: Graph parsing w/o coreference resolution. We demonstrate the graph parsing result on two types of text inputs: Aesop store (top) and AI-generated fairy tale (bottom). We label the coreferenced graph with yellow.

end-to-end text guided sketch composition methods([10]), with the doodler graph as intermediate representation, we are able to catch complex relations between multiple characters and scene objects, and identify correctly the layout for each object in the final composition with layered effects, i.e., the background scene could be correctly placed under character layers. For example, in the first story (story 0), there are 2 sentences with 7 scene characters/objects (green nodes), including an owl with his two kids playing with a butterfly and a penguin on swing-set by the pool, the doodler graph could correctly identify the relationships between characters and with the scene compositor we could align each character in a reasonable way (right).

The doodler graph representation also tolerates a certain degree of grammar mistake and nonsense descriptions, which is a common case for AI generated stories. For example, story 3 has relatively the same objects with story 0, except the additional description like when he had ridden all, the doodler graph automatically gets rid of the redundant information and the finally composited scene is similar to the original story (story 0 in this case)

AI Creativity plays an important rule in most generation tasks, especially in our case, when AI is acting as a co-creator for kids. During experiment, we find that the doodler graph representation also empowers the AI sketcher with certain degree of rational imagination by simple object/relation mapping to real world datasets (e.g. the VG dataset([15])). For example in story 5 (Fig. 4), while the forester seemed to be unfamiliar for most AI interpreters, we automatically map it to a headlight that is in the training dataset and favor the scene description.

Doodler Graph Update As the story is generated fragment by fragment, making it rather important to keep visualization consistency between story fragments. Instead of generating

new doodler graph for each story fragment, we automatically update maintain a single doodler graph for each story and update the graph based on neural coreference resolution across fragments. We assign for each character in the story a unique id and keep tracking of the character action in newly generated story fragments. In Fig. 6, we analysis the automatic doodler graph updating policy with both human-written Aesop Fable stories (left) and AI-generated fairy tales (right).

Aesop Fables are short stories composed by strongly connected fragments. In the example story, the FOX is identified as the main character who will lead the story in multiple story fragments. With coreference resolution (bottom graph with red nodes in each example in Fig. 6), we're able to track the same FOX within multiple story fragments and update it's action with multiple supporting roles (e.g. the cock)

Another problematic situation we dealt with the doodler graph updating policy is that the same character may perform in distant fragments. For example, though the farmer only comes in the first and last story fragments, we managed to keep him alive through the whole story, and identify he's the same farmer that the cock speaks to in the last story fragment.

The rational connection among AI generated story fragments are comparably weak than human-written stories, Fig. 6 (right). Though according to the AI generated story, the kangaroo performs multiple disconnected tasks among all scenes, with the updating policy, we could correctly track him as the main character of the story, and update supporting roles to the scene based on their relationships with the kangaroo

Applications

Text to sketch generation

Though targeting complex scene generation, in Fig. 7 we show that our visualization scheme could also deal with simple text guidance including only positional relations and achieve competing results with previous text-guided sketch generation methods([10]). This function could potentially help with AI-aided sketching with simple text instructions, with which we will further integrate into our interactive storytelling interface in future

Few-shot Visualization

We compare the generated doodler graph w/o coreference based updating in Fig. 5. The coreference resolution helps in two ways. First of all, it helps to identify cross-fragment character relations, and keep tracking of the character action for long stories. For example, in the first story, the original scene graph parser failed to identify the *hound's* activities and relations with supporting roles across the story while with the coreference resolution, we could correctly catch the *hound's* occurrence among the whole story to build the doodler graph. The same situation also suits for the boy in story 2 and the *lion* in the story 4. Secondly, the coreference resolution helps to identify the same character occurred in distant story fragments. Thus, avoid repeated visualization for the same char-

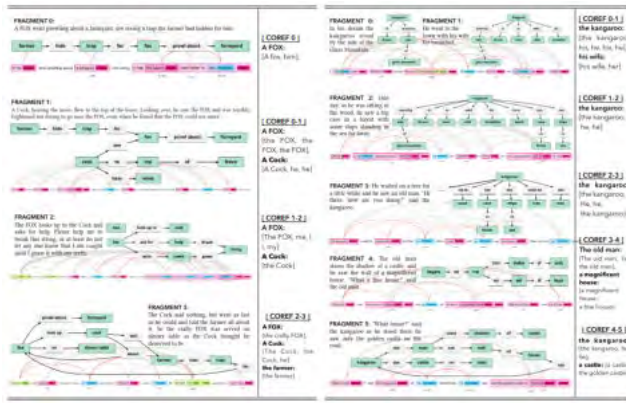

Figure 6: Story-based doodler graph update of Aesop’s fable story (right) and AI-generated story. Instead of generating a new doodler graph at each story fragment, we update the graph along with the generation to keep the visualization consistency (i.e., character consistency) within the same story.

acter, and keep the style consistency for each character during the whole story and meet the real-time needs for interactive story telling

Long-term Visualization

We compare the generated doodler graph w/o coreference based updating in Fig. 5. The coreference resolution helps in two ways. First of all, it helps to identify cross-fragment character relations, and keep tracking of the character action for long stories. For example, in the first story, the original scene graph parser failed to identify the *hound’s* activities and relations with supporting roles across the story while with the coreference resolution, we could correctly catch the *hound* is occurrence among the whole story to build the doodler graph. The same situation also suits for the boy in story 2 and the *lion* in the story 4. Secondly, the coreference resolution helps to identify the same character occurred in distant story fragments. Thus, avoid repeated visualization for the same character, and keep the style consistency for each character during the whole story and meet the real-time needs for interactive story telling. For example, while the original scene graph parser generates two owl characters, we correctly identify them as the same owl with coreference resolution, which also helps to build the relation that the same owl going across the pool and meet the penguin. We show examples of the composed scene for this story in Fig. 4 (story 0).

Conclusion

In this paper, we presented an intelligent visualization interface mainly focusing on fairy tales. Fairy tales, different from casual languages, have unique characters and relationships, which would generally lead to direct text-to-image visualization methods failing. We introduce the doodler graph as an intermediate representation based on this point. We fuse the rule-based language model with a learning-based generation model into a unified visualization system to allow for more flexibility during generation. AIR Taletorium can visualize

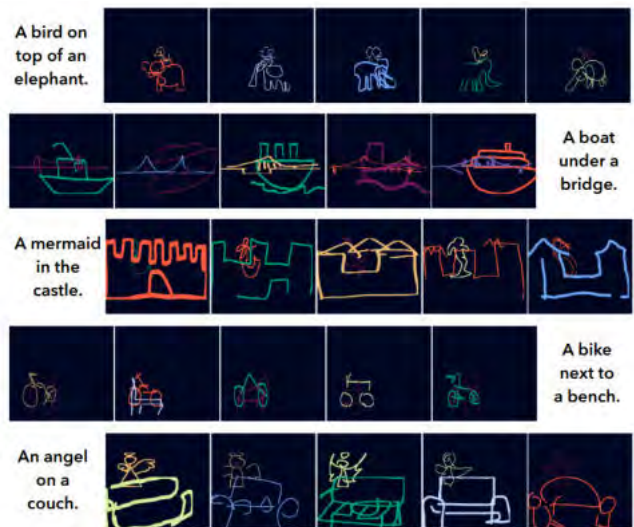

Figure 7: Visualization for a simple scene. Apart from the complex scene, our system also supports simple text-guided sketch generation.

complex fairy tale scenes with stylized characters and rare relationships with our fused framework.

The Process of Word Automation: From the Spoken Word to the Algorithm

Marta Pérez-Campos

UPV/EHU University of the Basque Country

Leioa, Spain

mperez272@ikasle.ehu.eus

Abstract

In this paper, I will trace a path in which the starting point will be the spoken word, made immortal through writing, and which will lead to the consideration of the word as the fundamental constituent part of today's algorithms. This analysis will be carried out without losing sight of the fact that we are within an artistic research, in which it is necessary to deal with concepts that belong to other disciplines such as linguistics or computer science. The process of transcription will be the thread that connects the spoken word with the written word, allowing me to analyze how this transcription and its intrinsic characteristics have been used in areas as disparate as the world of art and the development of programming languages.

Subsequently, I will analyze the creation and evolution of the idea of algorithm –from its beginnings centuries before the creation of the first computers– and the link between them and the world of art, through the presentation of works that propose the use of pseudo-algorithms. It will be the algorithms that will allow me to talk about digital computers and how the technology behind them has served as a source of inspiration for contemporary artists.

Algorithms, language, code poetry, artistic research, education

Introduction

The automation of the word is a phenomenon that in this paper will be understood as the participation of the word in those automatic processes in which it ends up becoming the basis that makes them possible. The clearest example of this are the algorithms, made up of written words on which any computer process is built. In these algorithms, we find how the word, which originally belonged to the oral tradition, has been transformed until it has become an immobile element both in its form (written) and in its meaning (univocal).

Transcription as the movement from the oral to the written word

The immutability of the word in its written form is produced thanks to transcription. This transition, in which the word changed from being a sonorous and intangible element to being physically represented by means of writing, meant its reification, its transformation into an immobile element [1] and a way of making it tangible and visible. Thanks to writing, it was possible to solve the problem of storing the information that previously had to be memorized. This way of understanding writing as an information storage system is also behind programming languages, understood as a precise method of communicating instructions from the programmer to the machine. This process – this connection between two entities– turns writing into a means of communication and transmission of knowledge by allowing a connection between the brain of the writer and the brain of the reader of the text, which can be either another person or a machine.

Interestingly, although writing is a communicative activity –insofar as it seeks to record certain information that will be read in the future–, it is normally carried out in solitude. However, this idea of writing as an individual activity was challenged in the art world by the surrealist artists, with the creation of the exquisite corpse (*cadavre exquis*) –both using texts and drawings– for which the collaboration of several people was necessary. In the world of computing, writing has also become a collaborative activity, as in the development of applications, where teams of several programmers are currently working together. Thus, we find that, both within the world of art and within the world of software development, writing ceases to be necessarily a solitary activity and becomes a process in which the end result is the contribution of several individuals.

The appearance of the text and the direction

One of the distinctive features of transcription as opposed to spoken language is that it made it necessary to adopt a direction when writing texts, either left to right or right to left, although there are exceptions such as the boustrophedon.

don style [2] in which both are combined. This complexity added by bidirectional reading was eliminated by restricting reading to a single direction: either left to right or right to left. Etymologically, the word letter derives from the Latin *littera* which in turn is believed to come from *linea-tura* and this from line, corroborating the need for a reading order in the text [3]. Obviously, this directionality is also applicable to programming languages, which are generally read from left to right. However, there are esoteric programming languages that do not respect this restriction, such as Befunge or MiLambda. These programming languages are considered two-dimensional since it is possible to control the reading direction in any of the four cardinal directions. Specifically, Befunge was designed to be as difficult to compile as possible [4], one of the factors influencing this complexity being that the program can be read in any direction. With this bidirectionality, it is sought -like the surrealists with their exquisite corpse- to experiment with the limits and characteristics that define writing and transcription.

Orality and programming languages

At first glance, the statement that Amalie E. Gnanadesikan writes in her book *The Writing Revolution: Cuneiform to the Internet* 'Writing is a way of expressing a language, it is not language in itself' [5] seems obvious, but in programming languages it is only possible to express an idea by writing it down. Within an algorithm there is no oral element that influences the transmission of the resulting message. This lack of orality may remind us of those letters that have no sound, such as the letter *aleph* in the Hebrew alphabet, or *h* in Spanish.

While it is true that orality may be present when we want to make a translation between the instructions we want to transmit to the computer -thought in our brain in pseudo-code- and the programming language we will use to transmit the instructions to the machine, from that moment on, communication becomes a silent transcription in which the computer compiles or interprets our code to make it understandable. We find that, in the case of programming languages, the machine does not require phonetic and phonological elements to be represented to communicate with it. This communication with the machine is possible thanks to the abstraction on the hardware that led to the creation of programming languages, which -to be more understandable to the programmer-make use of words that belong to natural languages. For this reason, actions in which the code becomes spoken speech are disturbing. Such was the case of the reading made in 2001 by the Italian philosopher Franco 'Bifo' Berardi of the source code of the *ILoveYou* virus at the D-I-N-A festival in Bologna. The text accompanying this reading began by asking whether the code of a virus can be read as a poem. A sort of revolutionary poem celebrating the defeat of operating systems within the capitalist society. It is worth mentioning that this computer virus was created in the year 2000, spread to infect 10% of the computers existing at that time and generated great

economic losses. Bifo gives a reading of *ILoveYou* in which the beginning is in a calm, almost machinic tone, to end up raising his voice in a way that, according to the organizers of the event, seems to bring it closer to political discourse. Another way of interpreting this reading is closer to the text itself and its loss of power when read. The potential power of this virus vanishes completely when it is expressed verbally instead of being executed inside a computer, it becomes a few paragraphs of harmless text.

Programming languages as notation

The reflection on the silence of programming languages, on their lack of orality, leads to the book *Lines: A Brief History* by Tim Ingold in which we find a revealing paragraph:

'It seems that when we listen to speech our understanding penetrates the sound to a world of verbal meaning beyond it. But, to continue with the same metaphor, it is an absolutely silent world; silent as the pages of a book, in fact. In short, while sound is the essence of music, language is mute.' [6]

This lack of sound, which Ingold associates with language, is perceived as necessary specifically within programming languages. This author also reflects on the relationship between writing and musical notation, questioning whether the transition from the spoken to the written word can be studied without considering the emergence of musical notation. He believes that writing should be considered as a form of notation. In both cases we find a transcription of the sound into graphic marks, but Ingold finds a key difference between them both. In the case of writing, the writer uses graphic marks to compose her work, while the composer uses musical notation to indicate the execution of his:

'Reading a piece of writing is an example of cognition, of assimilation of the meanings inscribed in the text; reading music is, on the other hand, an example of execution, of representation of the instructions inscribed in the score' [7].

Even though this division seems quite strict, there are cases in which it is not so clear whether we are dealing with an example of cognition or performance. Ingold exemplifies this with the case of poems written to be recited aloud. In this case, the musicality of the verses is of great importance, but it is still a verbal composition. In the case of the writing of algorithms, we would be dealing with an example of execution, a representation of instructions closer to the writing of scores than to the composition of a literary work, so that with its poetic use we would try to move these instructions away from *execution* and bring them closer to *cognition*.

Programming languages, algorithms and art

Talking about programming languages makes it necessary to talk about algorithms. Today, by algorithm we mean a text composed of a series of instructions by means of which a computer is able to solve a problem. A more gen-

eral definition of this term –in which it is not specified whether the computer is the subject of the action– would be that which understands by algorithm any process that can be automated and that requires a systematic calculation [8]. In both cases, the starting point is a problem to be solved after executing a sequence of instructions.

Two theories have been developed about the origin of the word algorithm. On the one hand, it is believed to come from the name of the 8th century mathematician, astronomer and geographer Al-Khwarizmi, who in the 9th century wrote an algorithm with which certain types of quadratic equations could be solved. On the other hand, it is believed to derive from the Late Latin word *algorismus* which is an abbreviation of the classical Arabic word for calculus using Arabic numerals. Whatever its true origin, both theories lead us to a first conclusion: the word algorithm has been with us for many more centuries than the computers that made it popular. Although computers are a twentieth-century invention, in Greece, in the fourth century BC, Euclid formulated what is now known as Euclid's Algorithm, used to find the greatest common divisor of any two numbers. However, the presence of algorithms is not limited to the world of mathematics and computing. A recipe is the example often used to explain what an algorithm is in a quick and simple way.

There are a number of conditions that must be met for a procedure to be considered an algorithm [9]. On the one hand, the procedure must be able to be written using a language –not specifically a programming language– and it must serve as an answer to a problem posed by some input data: the algorithm must solve this problem and the way to solve it must be step by step. It is also necessary that all these steps depend on the input data and on each of the previous steps: they must be interrelated. Finally, there needs to be a case, specified in advance, that functions as an output, so that it is possible to terminate the process at some point, preventing it from running to completion. In addition to these conditions, one of the remarkable features of the algorithms is the lack of ambiguity in the words used. In them, it is clearly defined what we are referring to at each step, leaving no room for interpretation. As mentioned, a cooking recipe would meet all of the above requirements. Another example of an algorithm can be found in the aforementioned musical scores, in which in order to hear the melody correctly it is necessary to play it exactly following the notations indicated in it and to know the musical notation.

The score: a link between algorithms and art

Within the art world, we find another type of algorithms and scores, those used in the world of action art and performance art. Through them, the artists, and sometimes the audience, have to follow a series of instructions in order to create a work of art. Nevertheless, these scores only fulfill some of the specifications that must characterize an algorithm. If we take as an example the score *Recorrer un cuadrado de todas las formas posibles* (1995), by the artist

Esther Ferrer, we find that the score is written in a specific language, indicates a series of interrelated steps that lead to the resolution of the problem and aims to serve as an answer to a given problem: to go through a square in all possible ways. Nevertheless, in its approach, it introduces the infinite by saying that all the ways in which the square is traversed are valid, with its indication 'toutes les versions sont valables' [10].

Another assumption that is not fulfilled is that each of the steps must be related to the previous one. This type of score leaves room for the performer's creativity and avoids being as restrictive as a true algorithm.

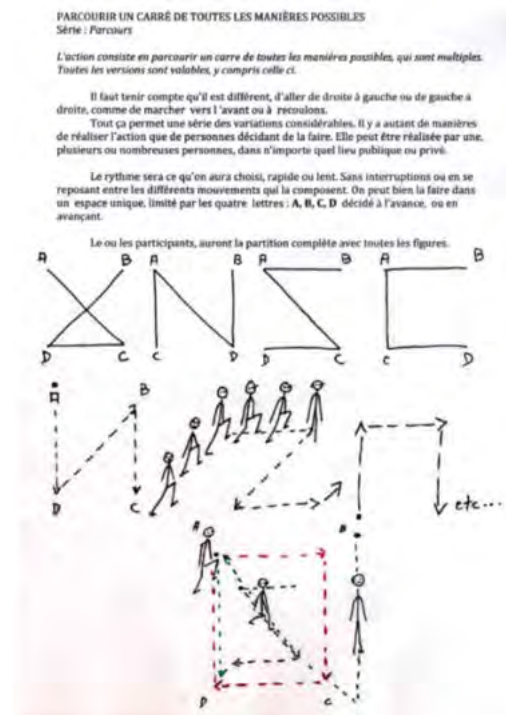

Figure 1. Score *Recorrer un cuadrado de todas las formas posibles* (1995)

The definition and concept of algorithm

Related to the definition of algorithm, we find a distinction made by the early 20th century mathematicians: the difference between the definition and the concept of algorithm. This interest in developing a description of the concept itself makes it possible to deduce which types of problems can be solved using an algorithm and which cannot. In this way, it is possible to abstract from the definition of algorithm - which has been deduced from its application - its relationship with other concepts, in this case belonging to mathematics. The first step towards the definition of the concept of algorithm was taken in 1904 by the mathematician David Hilbert and his attempt to translate mathematical formulas into logical sentences, although in 1931 Kurt Gödel demonstrated with his incompleteness theorem that there are some propositions within arithmetic that cannot be reduced to true or false, as required by logic. It would

be Alan Turing who in his article "On Computable Numbers with an Application to the Entscheidungsproblem" would formulate the first definition of the concept of algorithm using what is known as Turing's machine, which is a formalization of what we do when we execute a calculation using an algorithm [11]. In this article, Turing describes a theoretical machine capable of performing any computation, provided it is possible. This was the theoretical precursor of what we know today as a computer and at the same time was responsible for formally defining the idea of algorithm. With it, Turing was able to demonstrate the existence of problems that a computer cannot solve [12].

The Turing machine from the perspective of art: Roman Verostko, *A Universal Turing Machine as a Self Portrait*

The idea of the Turing machine is essential in computing, so much so that it was from it that it was possible to develop the concept of Turing complete, used today when a programming language can perform the same tasks as this machine. This idea has also been influential in the art world, serving as an inspiration, and more specifically in art made with algorithms, as found in the work of Roman Verostko: *A Universal Turing Machine as a Self Portrait*. This project starts from the premise that when a computer presents a simulation of a Turing machine, it is actually presenting a simulation of itself, since computationally they have the same capacity. The markedly conceptual character of this piece suggests us to consider the screen of our computer as a window into the inside of the machine itself. Visually, this project presents a series of lines composed of zeros and ones in a way that seems random, since we do not know the underlying logic behind them. On the artist's website there is a simulation of this work in HTML. Through the browser and using the tools that allow us to inspect the code with which the page is written, it is possible to see that each of the lines is composed of a predetermined series of ones and zeros, whose order or arrangement we do not know their origin. This project requires us to make an act of faith and trust that these ones and zeros are really related to a Turing machine and that they are not randomly placed numbers.

Verostko adds this text on his web:

'For me, the text of a UTM algorithm, like a medieval biblical text, radiates an aura of authority even though difficult to comprehend. As an artist I have written algorithms for illuminating a Universal Turing Machine (UTM) and to celebrate its impact on our culture. These illuminations are works of art and not exercises in computer science. [...] Like medieval Latin that transcended the vernacular and was universally understood by those schooled in Latin so also this algorithm speaks a universal tongue understood by those schooled in computer science' [13].

The last sentence is revealing about the previous statement: the algorithm can only be understood by those people with

knowledge in computer science, the rest will have to believe that behind those zeros and ones there is an algorithm that turns them into a Turing machine. Paradoxically, this fact takes it away from being what it pretends to be: a universal tongue.

From von Neumann architecture to the emergence of software

Turing machines are the conceptual basis on which computers began to be developed: electronic devices responsible for processing the information we provide them with in the form of bits and returning a result. After the creation of digital computers, a computer is considered to be composed of two parts: hardware and software. The hardware makes up the physical part of the computer and the software the intangible part, although the boundary between the two is not as clear-cut as it may seem at first. This difference arose with the development of the von Neumann architecture. Until John von Neumann developed this way of structuring a computer in the 1940s, which is still used today, computers performed only one task, the one for which they were created.

There were three main innovations that the von Neumann architecture introduced with respect to its predecessors. The first is that the computer has a memory in which both data and instructions are stored, without the memory distinguishing whether what it contains is of one type or another. The second is that this information can be accessed by specifying the address at which it is stored, facilitating interaction between the person and the computer. Finally, the execution of a program is carried out sequentially, processing one instruction after the previous one if no jumps or interruptions are specified [14]. All these allowed computers to be programmable, physically at first, until the idea of software was developed in parallel through the first programming languages. Although the development of the von Neumann architecture made it possible to distinguish between hardware and software, the first computers created using this architecture were programmed physically, by connecting and disconnecting wires. With the creation of these devices, which occupied entire rooms, the human-computer relationship began.

The EDVAC was the first computer for which a stored program was created, an advance that avoided the need to modify the wiring every time it was necessary for the computer to perform a different task. The first computer with a memory unit to store the first stored program was the Manchester Baby, developed at Manchester University and introduced in 1948 [15]. The interesting thing about this computer is that it was the first to use a 32-bit word length, which along with the 64-bit word length has become the most commonly used word length in today's processors.

The word and the page

The concept of word, in relation to computing and computer architecture, has existed since the beginning. A word is the natural unit of memory organization. The size of the word is generally equal to the number of bits used to represent an integer and the length of an instruction [16]. This definition is similar to the words we use to communicate in that they are units of representation with a specific meaning. Humans communicate using words, and words are the minimum unit for representing an instruction in digital computers. At this point, talking about bits and words has already produced the first level of abstraction with respect to the machine: to enter instructions it is no longer necessary to make physical connections in the machine, it is now possible to store and enter instructions using words made up of bits. This was the first step in the introduction of software into computing.

Apart from the word, there is another parallel with human communication, more specifically written communication, and that is the idea of a *page*. A page is a block of fixed size, each of these blocks possessing a certain block size. This is the way in which the virtual memory of a processor is organized, in blocks, providing the processor with a larger address space than if it had only physical memory [17]. We find that the relationship with the word and with writing appears in the very architecture of the first computers and continues to the present day with the creation and development of the idea of software. Although the first computers were programmed using the so-called machine code, which was reduced to instructions represented by ones and zeros, it did not take long for computers to appear that were programmed using what is known as assembly code.

A use of assembly language beyond programming: *Grasp all, lose all (La avaricia rompe el saco)*

The appearance of assembly language meant the addition of a first layer of abstraction on the computer, since the ones and zeros that make up the instructions at the lowest level could now be written using a combination of words and numbers. The building block for this translation is a program called an assembler. As its name suggests, an assembler is that which assembles something; an intermediary between an initial and final object. In this case, between the source program and the object program. This type of language is still at a level very close to the machine, which allows the physical characteristics of the machine to be explored, although it makes it difficult to read and understand. An example of this can be found in this brief composition written for the Intel 4004, the first microprocessor marketed on a large scale:

```
FIM 0 255
FIM 1 255
FIM 2 255
FIM 3 255
FIM 4 255
FIM 5 255
FIM 6 255
FIM 7 255
INC 0
INC 1
INC 2
INC 3
INC 4
INC 5
INC 6
INC 7
INC 8
INC 9
INC 10
INC 11
INC 12
INC 13
INC 14
XCH 0
```

To approach it, it is important to know that its title in Spanish is *La avaricia rompe el saco (Grasp all, lose all)*, a well-known popular saying, and that it seeks to be a literal implementation of it using a programming language. Although at first it seems to be an incomprehensible sequence of letters and numbers, it is not necessary to have extensive knowledge of computer science to understand it. The Intel 4004 is a processor with 15 registers, numbered from 0 to 14, in which it is possible to store a maximum number of 4 bits. These registers can be accessed in pairs, the pair 0 being the one composed of registers 0 and 1; pair 1 is the one comprising registers 2 and 3, and so on. In the first eight lines, we see that the FIM instruction is used, which allows accessing these registers in pairs and assigning them a certain value. In this case, the FIM instruction 0 255, what it does is that registers 0 and 1 both acquire the value 16. This is achieved because when we convert 255 from the decimal system to hexadecimal, we obtain FF. The letter F in hexadecimal is equivalent to 16 in decimal, so indicating the value 255 (or FF) makes both registers 0 and 1 acquire the value 16. After providing the maximum value to each of the pairs of registers, the next step is to increment the value of each of them by 1. To achieve this, the INC instruction is used. What this causes is a register overflow, causing the register to take the value 0. Subsequently, the XCH instruction is responsible for passing the value of register 0, although the value of any of the registers could be used, to the accumulator. The accumulator's function within the microprocessor is to store information temporarily, assuming an intermediate position between the registers and the memory. In this case, the accumulator ends up receiving the value 0, the same value it had at the beginning, although its registers have reached the maximum value. The idea of accumulator extends its meaning in the world of computing to the one assigned to it generically in the dictionary: that accumulates. Although, in this case, the accumulated amount is reduced to zero as a consequence of the excessive sum made in the registers, literally applying the proverb that gives the composition its title.

The automated word as an artistic expression: Nöel Arnaud, *Poèmes Algol*

After the development of assembly language, known as second generation (2GL), the third generation (3GL) or high-level languages followed. This type of language is easier for the programmer to read, but adds a layer of abstraction that distances it from the machine. Among the first high-level languages, developed between the 1950s and 1960s, we find FORTRAN, ALGOL or COBOL. The main characteristic shared by these languages is that they allow the programmer to focus on solving the problem, rather than on the details of the machine on which he is programming.

The fact that they are high-level languages, and therefore not directly linked to the internal architecture of a machine, made these languages popular and at the same time their ease of reading gave rise to experimentation. The French writer Nöel Arnaud, a member of the Oulipo literary experimentation group, published *Poèmes Algol* in 1968, a series of literary compositions based on the programming language of the same name.

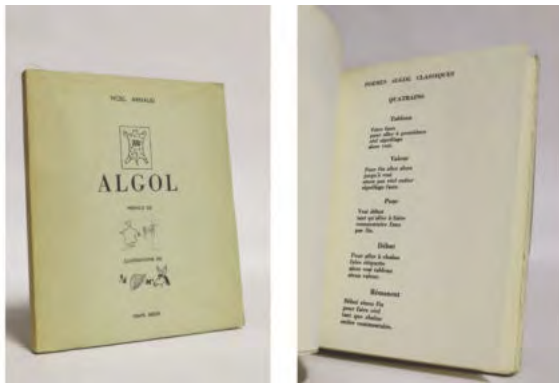

Figure 2. *Poèmes Algol* cover and one of Arnaud's poems

To compose his poems, Arnaud has used exclusively the French translation of the 24 words reserved in the ALGOL programming language: true, false, goto, if, then, else, for, do, step, until, while, comment, begin, end, own, boolean, integer, real, array, switch, procedure, string, label, value. Although they are based on ALGOL, they use neither its syntax nor its lexicon, since all the words have been translated into French, so that, evidently, the poems are not compiled by a computer. In this case, the use of the programming language is purely literary and serves as a restriction: only certain words can be used to write the verses. What is valuable about these poems is that starting from a language in which the reserved words have a very specific meaning and function, Arnaud returns them to natural language.

Subsequently, these third-generation languages evolved into what is known as object-oriented programming (OOP). This programming paradigm allows the constituent parts of a program to be divided into classes, which are

instantiated in objects, and the work is thus distributed among different programmers. What these programming languages bring to the 2GLs, apart from an additional layer of abstraction on the machine, is the possibility of dividing the code into objects and classes that can be worked on in parallel.

The 3GLs were followed by the fourth (4GL) and fifth generation (5GL) languages. These add a layer of abstraction over the previous ones, since they specify the task to be performed instead of how to perform it and are designed so that the computer solves the task instead of the programmer, respectively [18]. 4GL languages use sentences closer to the human language than 3GL and are mainly used in database programming [19]. The latter encompass both functional and logic programming and are considered a constituent part of the declarative programming paradigm. Like object-oriented programming, functional programming is also characterized by a series of its own concepts such as *currying*, *lazy evaluation* or the importance of the type of the function. This last point has been used in an expressive way in the following composition, *The Nothing Nothings*:

```
nothing :: a -> [a]
nothing x = [] ++ nothing x
```

The type definition is given by the first line in which the identifier *nothing* is separated by `::` from the expression indicating the type of the function in question. In this case, with the letter *a* we are indicating what is called a type variable, that is, a representation of any type of data, be it an integer, a decimal, a character, etc. This data type *a* symbolizes the input data of the function, which is separated from the output data `[a]` by `->`. In the output data, the use of square brackets means that we will get a list, a sequence, of items of type *a*. If we move to the second line, we find the definition of the function *nothing*. This definition indicates that if we write the word *nothing* followed by an element of any type (*nothing x*), we will obtain as a result (=) a concatenation (`++`) of the elements stated in the input. To achieve this concatenation of elements, a technique known as recursion is used in which a function calls itself. In recursion there is a base case, a condition that when fulfilled forces the function to stop calling itself to avoid an infinite loop. This type of loops is generated when, due to the absence of a base case or due to errors in the logic within the algorithm programming, the function calls itself indefinitely, until the computer runs out of memory. In the code fragment at hand, the function enters an infinite loop, since there is no base case to stop the algorithm. Thus, a list of elements is created which, precisely because of this infinite loop, does not generate any output information, making it appear that the algorithm is not doing anything, although in reality it is generating an *infinite* sequence of elements.

Conclusion

Having taken the spoken word as a starting point, this paper has traced how the spoken word itself and its intrinsic characteristics have been modified to lead to the written word and current algorithms. Both the idea of algorithms and the computer processes that they have brought about have served as a source of inspiration for contemporary artists, who have experimented with a language and a medium that is apparently far removed from artistic creation. This use of software in an artistic way helps to make understandable the functioning of certain processes and rules, which otherwise would be very difficult to understand for a person without computer knowledge.

The software, and with it the words that make it up, position themselves as the main tool that facilitates communication and interaction between people and machines, functioning as an interface, as a point of contact, at a lower level of abstraction than the command line interface (CLI) and the graphical user interface (GUI). Thanks to the experimentation and speculation that artistic creations allow, it is possible to bring the user closer to the hidden side of computing devices. Although this knowledge is not necessary to interact with the device, it can provoke reflections on the functioning of certain processes normally hidden from the user, but which condition our relationship with these devices.

Towards the Sonic Laboratory: Laboratories' creative potential

Laura Plana Gracia
UAL University of Arts London, United Kingdom
lauraplanagracia@gmail.com

Abstract

This research aims to define and establish the sonic laboratory, a hypothetical concept that has not been widely explored, although there are already some examples named as such. This research also investigates the sonic laboratory's creative potential. Analysing different typologies (science lab, media lab, hacklab, and others), this research presents an open and inclusive description of the laboratory that opposes a technoscientific perspective, following Lori Emerson's laboratory studies which state, "Labs have never been static, unchangeable, unitary entities with clear-cut histories. They are—and have always been—shaped by communities of people both inside and beyond their walls" [1].

Keywords

laboratories, hacklab, media lab, hackerspaces, makerspaces, laboratory studies, science and technology studies, sound art, art, science and technology, media art.

Introduction

This research aims to define and establish the sonic laboratory, a hypothetical concept that has not been widely explored, although there are already some examples named as such. Through this research, I aim to articulate a sonic laboratory's definition to investigate its creative potential.

This research inspects the definition, antecedents, and various typologies of what is generally understood under the term laboratory. This will entail a search for the historical precedents and consider the origins of the term laboratory. In doing so, I will explore what a laboratory used to be even before it was named as such, including not only spaces typically designated as laboratories but comprising also other typologies such as workshops and artists' studios. The research also explores the already established typologies of laboratories, such as academic laboratories, science laboratories, media labs, and hacklabs.

To achieve such a definition, I will pursue case studies that present examples of sonic practices developed in laboratory environments. The case studies are artsience labs and academic laboratories. I will show an example of sonic artist in artsience labs: Robertina Šebjanič. The contribution from artsience labs to this research is paramount and

analysing artists' practices in artsience labs through their methods and outcomes will help define the sonic laboratory. I will also examine the case studies of academic institutions that function as laboratories and develop sonic practices. The designation of sonic labs is shared through academia, and there are already some examples named as such. Although existing, the sonic laboratory has not yet been defined and articulated, and contrary to the media lab, it has not gained further acceptance. Through analysing sonic practices in academic laboratories, this thesis will enrich the sonic laboratory definition. The example chosen to research on academic laboratories is Sonics Immersive Media Lab (SIML, Goldsmiths, University of London).

Definition of laboratory

The laboratory's history cannot only be considered for those just named labs as it would be incomplete. The first known laboratory was in 1592, and the etymology for the concept laboratory comes from the Medieval Latin laboratorum, from Latin laborare (to labor) [2]. Historically, the word laboratory was elaboratory, but this use is now obsolete. Elaboratory comes from elaborare, the physiological role of some form of natural apparatus for elaborating any vital action product. Clara Bofill reaffirms that laboratorum refers to labour or work:

If we delve into the origins of this word, we find that the Latin laboratorum means a place for labour or work and that the verb laborare means to work, to produce, to cultivate. In the 18th century, for example, the word "laboratory" was used to describe the studios of painters, sculptors and printmakers, as well as, more generally, any place in which people made things with their hands. [3]

In searching for an inclusive definition of the term laboratory, I have studied Lori Emerson's works, which explore the concept of the media lab from a non-hegemonic perspective. Looking at the contextual situation of media labs, she explores the term laboratory and establishes a new concept for the "hybrid lab", including all other laboratory typologies, media lab and the science lab. The hybrid laboratory is an inclusive definition of the lab that con-

fronts a laboratory definition connected to the technoscientific paradigm. Here, Emerson offers a feminist perspective adopting a definition of the lab that includes non-human actors and female narratives. As labs are places where instruments and animals have a strong presence, the hybrid lab defies the patriarchal, colonial and objective perspective of the lab definition and opts for an inclusive definition that reconnects with feminists and posthumanist perspectives, including non-humans and women.

Moreover, Emerson introduces feminist studies into laboratory studies and the Marxist theory, following Henri Lefebvre, which defines the laboratory as an open concept, malleable, determined by the practices, contexts, and people that developed it. As she states,

Labs have never been static, unchangeable, unitary entities with clear-cut histories. They are—and have always been—shaped by communities of people both inside and beyond their walls, by these same communities' intellectual trajectories, and, of course, by the labs' physical locations and configurations. [4]

Furthermore, labs are places to work, but their definition is generally associated with the technoscientific paradigm and science world. However, a more contemporary laboratory description, following Emerson, provides the parameters to create a definition for the sonic laboratory, which aims this research. Associating at this stage the hypothetical idea of a sonic laboratory with Emerson's openness of hybrid labs allows me to compare the sonic laboratory to academic spaces and industrial labs and be established as places of experimentation and artistic practice.

Academic Laboratory

The laboratory's role in education is crucial to developing the modern academic laboratory, with origins in medieval monasteries, apothecaries, and kitchens. For Avi Hofstein and Rachel Mamlok-Naaman, academic laboratories are places to “develop students' abilities and skills.” [5] Some laboratory activities are to engage students individually, while others have sought to engage students in small or large groups. The academic laboratory connects with the world of science, which emerges thanks to workshops' central organising to focus on specific experiments. Laboratories are sites where to conduct investigations, and their development is through experimentation, which will be a constant feature of most laboratories.

In addition to this, researchers that focused on the study of digital humanities labs state that a digital humanities lab:

produces and is produced by a network of scholars, practices, institutions, epistemologies, ideologies, and cultures of STEM, the Humanities, higher education, and society.” [6]

Following this definition of a digital humanities lab, the authors also understand how

Labs must contribute to the legitimisation of lab practices and material products for particular epistemic cultures in the Humanities. [7]

This refers to the production of knowledge in humanities labs as a result of producing

documentation, contextualisation, and subjectification. DH scholars, DH journals, and DH audiences are as much an outcome of laboratory work as an artefact. [8]

This definition of humanities labs defines these spaces as epistemically active spaces. However, with this definition, the authors offer an alternative model of laboratory work, with a vision of

alternative disciplinary spaces where DH work can be practised, and alternative objects of DH research. [9]

The research considers the importance of these alternative laboratories to the hegemonic model of science. But there are other examples, such as the American academic laboratory born out of industry and academia's confluence. However, this model appears not as an alternative but subsumed in the scientific laboratory's hegemonic definition reaffirming the values that transform this laboratory into an industrial-military-academic complex. According to Emerson,

Most American universities founded in the mid to late nineteenth century were created in the spirit of entrepreneurialism. [10]

This section on academic laboratories describes how some laboratories are far removed from the scientific and hegemonic laboratory perspective (humanities and digital humanities laboratories). However, the research also shows how the American University laboratory model is still creating a laboratory's hegemonic view. Both examples will contribute to an extensive and inclusive definition of a laboratory by approaching and distancing from these academic labs' models.

Science Laboratory

There is a direct link between the academic laboratory and the science laboratory. This idea of a liaison is reinforced by tracing back to early apothecaries, which first developed towards academic-chemical laboratories, establishing an academic scientific laboratory model, which will exist until the present moment. Thus, there is a bridge between the laboratory in an educational environment and the science laboratory.

The origins of the science labs are in the chemical laboratories that appeared during the XVIII century in Europe. In her study, Klein presents as an example “the chemical laboratory of the Berlin Academy of Sciences [founded in] 1753” that A.S. Marggraf directed. [11] The origins of the science laboratory connect to the world of chemistry, early apothecaries, and academia. As Klein defends,

Laboratories, pharmaceutical and academic-chemical, were the institutions where manufacture (in the case of pharmaceutical laboratories) or technological inquiry (in the case of academic chemical laboratories) and inquiry into nature were firmly entwined. [12]

These academic chemical laboratories are the bases for the contemporary science laboratory.

Philip Bell also studies the development of laboratories in academic environments but only those related to scientific investigations. Through his text, he describes science laboratories as places for experimentation and "lab work", which are the basis for scientific investigations. [13] They also support teaching and building epistemological learning, primarily through the methodology of hands-on experimentation. Other methods in science laboratories

are embedded in a broader context of inscriptional work associated with the communication and publication of results. [14]

According to this, science behaves in a chain production from facts to literature, using experiments and registering simulations, and finally building black boxes, which impact social consequences.

Following this, technology has been created under a scrupulous dependence on hyperstructures (technoscientific laboratories, for instance), resulting in extremely hard to disbelieve, doubt, and dissent, leaving the confronters impressed, without power and resources to contest and dispute their authority. This is used in Bruno Latour's parable of "counter-laboratories". [15] Latour's critical analysis will be further explored in this research, adopting the actor-network theories and the feminist studies (in Lori Emerson and Donna Haraway) to help define and establish a sonic laboratory.

Media lab, hacklab and other typologies

The historic MIT Media Lab is one of the media labs pioneers and possibly where the name media lab was first popularised. The MIT Media Lab emerges from the late nineteenth-century laboratories model, a mix of academic laboratories, science, and industrial labs. Nevertheless, it "was a continuation of a long legacy of art and technology labs at MIT" such as the Centre for Advanced Visual Studies. [16] However, "the naming of the lab wanted to position itself as part of the lineage of private-sector technology labs", such as Thomas Edison Laboratory and Bell Labs. [17] The MIT Media Lab represents a continuation of the Thomas Edison Laboratory with the same values of countercultural status and interdisciplinarity, with the same unconventional methods and success.

At MIT Media Lab, interdisciplinary science and arts brought artists, scientists and engineers towards a unique aim which was to develop participatory and innovative technological practices. Moreover, after Thomas Edison Laboratory and Bell Labs, the MIT Media Lab's studies and practices with music represent a possible sonic laboratory's origins.

However, the media lab's history is extensive; other lab typologies emerged from the media lab. The hacklabs, hackerspaces, makerspace, FabLabs, and BioLabs are all variables of the media lab and began to appear in the middle of the 1990s. Their origins link to the emergence of the personal computer. First hackers collaborated with MIT

and founded the free software movement. One example is Richard Stallman, who launched the GNU Project, and the Free Software Foundation.

Hacklabs and hackerspaces are hackers' places, generally self-managed spaces, their interest is in technology, and their practice develops through meetings, sharing, and creating knowledge in collective and individual projects. Like hacklabs and hackerspaces, there are also tech shops, incubators or innovation labs, hubs, FabLabs, and makerspaces. Nevertheless, what makes them different is that hacklabs and hackerspaces are the origins of these communities. An indisputable feature of these hacklabs and hackerspaces is the use of open source software and hardware. Through sharing and free licences and methods such as forking, hackers' use of open source is seen nowadays as an alternative to the big five technological corporations' imperative and profit (Amazon, Apple, Facebook, Google, and Microsoft).

Following this alternative logic, many artists have joined hackers' practices, developing what Victoria Bradbury and Suzy O'Hara denominate the art hack practice. As both authors mention, the art hack practice takes place in other laboratories representing maker culture. Makerspaces interrogate issues around financial sustainability, staffing and office culture. According to these authors,

The concept for the lab grew out of a question of how a hack can be extended into a physical space that supports the kinds of practices that would occur in a more temporary space. (...) interruptibility, openness and generosity (...) sustain the lab environment. [18]

Makerspaces and FabLabs, also named Fully Automated Business (FAB) or Fabrication Laboratories, do not use uniquely open hardware, but they can provide precise machines. According to the dossier *Soberania Tecnologica*, they potentially do not opt for transforming the system, but for "a re-updating of capitalist production and consumption relations." [19]

Moreover, Tania Aedo provides some examples of sonic practices developed in these types of laboratories environments. In this context, Aedo states a reactivation of maker, hack, and DIY culture in the laboratory. Artists are makers who trespass the critical thresholds, crossing disciplinary boundaries. Even though Aedo provides sonic practices as examples, she reinforces the interdisciplinarity in these laboratories, integrating different disciplines such as media art, sound art, conceptual art, media archaeology, expanded cinema, new materialism, experimental electronic music and critical theory. Aedo presents examples of developing sonic practices in hacklabs that can become examples of a hypothetical sonic laboratory. One example is *Astrovandalistas*,

a decentralised laboratory in different locations in Latin America, such as Mexico and Brazil as well as in the United States, developing low-tech tools that enable new forms of communication and collective participation with open software and open hardware that can be easily replicated. [20]

The laboratories' creative potential: artists, institutions and exhibitions

This research searches to define a concept, sonic laboratory, that although it was used in academia, has not been widely explored. In doing so, this research will investigate the laboratories' artistic and creative potential, which will allow me to conceptualise the scope and nature of the sonic laboratory and explore its features. Thus, this research will investigate the laboratories' most creative side through examples such as art centres, festivals, exhibitions, virtual laboratories, and sound artists who establish their practice as a kind of laboratory. One example of this is the artist Simon Cacheux, developing sound art through technology and hacking practice, who states:

For me, a sonic lab is a lab where you research about sound in all its aspects. I like the idea of a broad interest in sound(s). There has been a lot of Art/Science connections in the past years: sound has a solid relationship with physics and science, so having sonic projects merging both art and science looks quite natural. The lab is almost inherent to the scientific aspect of sound, and the technology for manipulating sounds is recent (a century or so), and it is still connected to its scientific origins (first sound makers were engineers). [21]

Another example that contributes to studying the laboratories' creative potential is Hugh Davies' work at the Electronic Music Studio at Goldsmiths, University of London. Constituted in academia, the EMS is one of the laboratories that not named as laboratory functioned as such. Knowing that in the contemporary academic context, there are already existing examples of laboratories called sonic laboratory, such as the Sonic Lab at SARC, the EMS can be explored as a reference for the concept of the sonic laboratory but requiring exploration widely. Davies worked on self-built instruments. Thus, he could be considered as a pioneer through his DIY practice in modifying:

electronic sound apparatus in his early live electronic compositions (...), through the 'instrumental turn', represented by his first self-built instrument. [22]

Davies contributed through his sound art practice to define the laboratory concept in artistic and academic environments. In this sense, with his DIY approach, Davies contributed to teaching and learning in a more hands-on experience, applying learning-by-doing methodologies. These features are present in most media labs and hacklabs nowadays, which were not existing when Davies started practising with the self-built instruments.

Moreover, to present more examples of laboratories' creative practice, I give examples of laboratories that grow in art centres, such as Laboratorio de Investigación y Producción Musical in Argentina. There is also a tendency to fund laboratories inside the art institutions such as BANF, Canada, and Hangar, Barcelona. Still, these laboratories represent an autonomous economy that facilitates music-making and the making of sound devices in the whole of the institution. Indeed, specific laboratories ty-

pologies such as hacklabs and medialabs operate influenced by DIY, as seen in the recently inaugurated Sound LAB, in Litoral, Gijón:

the new media centre for the production, dissemination and exhibition of technological sonic art. Sound LAB is a space for experimentation in the various practices of contemporary sound art. [23]

Another example of an art institution that develops as a laboratory is the IRCAM LAB, part of IRCAM (Institute for Research and Coordination in Acoustics and Music), founded by Pierre Boulez in 1977 at the Centre Pompidou and the French Ministry of Culture. IRCAM is considered a laboratory because it is "one of the world's largest public research centre dedicated to both musical expression and scientific research." [24] Moreover, IRCAM is a place where artistic practice collides with scientific and technological innovation. This mixture of science and art is a feature present in some laboratories that develop through creative practice.

To contribute to this research, I also investigate those exhibitions that adopted the laboratory as a methodology to exhibit. For example, Joasia Krysa presented Erkki Kurenniemi (In 2048) at Documenta 13, a curatorial hybrid between new media curating and sound art to display computer techniques, archival material and original prototypes of Kurenniemi's handmade instruments. As Joasia Krysa notes, "such labs can address new institutional opportunities in humanities to engage with practice-based knowledge creation and extend their mission to include tools, techniques and a new curatorial scope." [25]

By analysing laboratories' creative potential, this research explores places not named laboratories but functioning as laboratories. Here, the laboratory definition includes many creative artists, institutions and exhibitions. Moreover, I can see certain art institutions as laboratories, although not being named as such. The research will explore artists' studios, institutions, and exhibitions as creative potential adopting laboratory methodologies to develop and innovate practices through engaging art, science and sound.

Sonic practices in artsience labs: Robertina Šebjanič at the Marine Institute Ireland

Robertina Šebjanič is an intermedia artist based in Ljubljana. She is an active participant at the Hackteria laboratory. Among other laboratories in which she participated, there are

Interactivos'12 Ljubljana: Obsolete Technologies of the Future at LJUDMILA digital media lab in Ljubljana (...), KSEVT – Cultural Centre of European Space Technologies (...), HackteriaLab Bangalore and (...) HackteriaLab Yogyakarta." [26]

Recently, Šebjanič has also participated at Aerial/Sparks, an artist-in-lab residence at the Marine Institute Ireland.

The Marine Institute Ireland is a “State agency responsible for marine research, technology development and innovation in Ireland.” [27] Among their facilities, there is the RV Celtic Explorer, a laboratory where to research marine acoustics. The RV Celtic Explorer is

Acoustically silent (ICES 209), which minimises fish avoidance and provides an ideal environment for the collection of high-quality acoustic data, dynamic positioning, acoustic transducers and other instrumentation, and large dry and wet laboratories.” [28]

Aerial/Sparks invites artists to produce “a series of compelling stand-alone artworks for exhibition and radio broadcast.” [29] Aerial/Sparks shows the result of this arts/science lab in the shape of an exhibition curated by Louise Manifold. The exhibition shows the artworks produced during the artists' residence at the laboratory through different media such as sound compositions and installations, prints, video works and performances. The seven participating artists, writers and composers are Ailís Ní Ríain (IRL), Carol Anne Connolly (IRL), David Stalling (DE), Kennedy Browne (IRL), Kevin Barry (IRL), Magz Hall (EN) and Robertina Šebjanič (SI). The exhibition takes place in different locations at the Inis Oírr, the smallest of the Aran Islands.

In this context, Šebjanič presents her sound art project *Selachophilia: Cetorhinus Maximus - Limaria Hians*. The artwork

weaves together mythologies and sciences, humans and non-humans, to speak of our ability to address challenges in the age of the Anthropocene. Stories unfold carried by the migratory Basking Shark (*Cetorhinus maximus*) and the flame shell (*limaria hians*), a small species endemic to the North Atlantic waters. Šebjanič had the opportunity to experience both sea creatures during her residency on the RV Celtic Explorer. This immersive audio installation intertwines sean-nós vocals with the narration of a storyteller and field recordings of above and below the depths of the Atlantic Ocean. [30]

In Šebjanič's words, she produces “art, science and technology relations and new media works, resulting from interference between fields that create a hybrid media.” [31]

Onboard the RV Celtic Explorer, the artist had the chance

to explore interactions between organisms and sediments through scientists' perspective, with tools and techniques from the vessel. The result was an art project with a sound centric component.” [32]

The artist presence on board encouraged collaboration and engagement with scientists, whose point of view highlights art and science common topics, such as being interested in the process and being based on observations. Šebjanič continues to explain her experience in art residences at laboratories, which are, according to her, places and spaces where scientists work and research is happening. During the Aerial/Sparks residency onboard the boat, the

artist had the opportunity to work with sensing tools. She became actively involved with the team through daily briefings that brought her close to the scientists' complex projects.

Šebjanič presents herself as a sound artist who, after 15 days on the boat, produced a sound work resulting from scientists' conversations. The audio installation resulting presents sean-nós vocals with the narration of a storyteller and field recordings of the Atlantic Ocean. The artist is interested in the relations humans have with sharks. From an ecological perspective, the inter-species connection between huge and small creatures (sharks and shells) produces an interaction affecting the environment (*ibid.*). The artist includes the anthropocentric perspective in the sound work through the recourse of the voice, and in doing so, she explores how sharks are connected to folklore, questioning how science can learn from folklore.

Šebjanič's methodology to produce this sound installation consists of:

- Observation and process, which are part of scientists' investigations.
- Sensing tools, which are scientific tools and technological sound apparatuses from the laboratory.
- Narratives and vocals, a humanities component, which includes human and non-humans.

Šebjanič's work illustrates the transdisciplinary relations between art and science in laboratories. These relationships are reinforced thanks to the dynamics of sharing methodologies, from science laboratories to arts practice, which is bidirectional - the scientists benefit from arts methodologies such as inclusive narratives, and likewise, artists can use scientific tools and methods. Moreover, the use of art methodologies such as field recording and developing narratives in laboratories can explain how the laboratory's role in science and technology is amplified, showing a laboratory from an open and inclusive perspective. The transdisciplinarity in Šebjanič's work demonstrates how the development of sonic practices in the laboratory contributes to defining the laboratory considering human and non-human relations in science and humanities. The mixture of the science laboratories and the sound artists practice will help determine the sonic laboratory as a laboratory-developed by artists to use sonic technologies through an inclusive perspective and humanities methods.

Another aspect to highlight from this example is about the exhibition as an outcome. The artists' practices in arts/science labs amplify the laboratory's chances to be a place to research and manufacture and exhibit. Bringing art methodologies, such as curatorial development, to the scientific laboratories is something that arts/science labs do, contributing to defining the laboratory as a place for humanities and not only dedicated to scientific research. Developing exhibition practice in arts/science labs is a characteristic feature that mixes art methodologies in scientific spaces. This contribution from art to science that is exhibiting could also be a feature that defines the sonic laboratory when exhibiting sound art.

The transdisciplinary methods applied in the laboratory and the outcomes such as sound installations and exhibitions will be fundamental to build up the sonic laboratory.

Academic labs - practical examples: Sonics Immersive Media Lab (SIML, Goldsmiths, University of London)

SIML is an “interdisciplinary, cross-departmental, world-class multi-media facility.” [33] SIML “research touches on the theory, practice, technique, and epistemologies of sound and image as a medium.” [34] The SIML facilitates “trans-disciplinary and multi-departmental” exchange, transforming the sonic lab into a media lab.

Both conceptual, as well as technological advances are present in the lab. The lab encourages us to perceive technology from a critical perspective, including the creative aspects of sonic and technological works' practical development. As a media lab, the SIML facilitates technical support, but this is combined with an artistic perspective of developing sound works.

This laboratory can contribute to a sonic laboratory definition from a position that includes the technological aspect of developing sound works in a transdisciplinary mediation. What is interesting from this case study is the critical dimension that the lab is opting to. The SIML uses the critical approach to technologies in his definition, and in doing so, it assimilates to practices typical from the hacklab. A technology's critical approach can be seen in hacklabs that use open-source hardware/software, which is not only in use in these types of laboratories. Most media labs use open software/hardware, as these are technical resources that contribute to creativity. The SIML can define the sonic lab exemplifying how the media lab has been used as a base where the sonic laboratory emerges, independently and within the subvert culture, as its critical component indicates. The SIML is an academic laboratory dedicated to the technological study of sound from a critical perspective, but it assimilates practices typically from the media lab, as transdisciplinary indicates. The SIML is a media lab that grows its interests in sonic technologies mixed with other disciplines. This example identifies the conditions that may be possible for a sonic laboratory, with shared features with a media lab but highlighting a critical perspective and their studies' interdisciplinarity.

Conclusions

Creating this survey, I must recognise that laboratories' wide diversity makes it impossible to generalise what a lab is. In Parikka's words:

The "inventing the future" sort of corporate brand of MIT Media Lab differs rather radically from these small-scale examples that could be even called humanities labs of our era, and they differ from the emergence of labs in rather different geopolitical locations such as the maker-lab ecosystems emerging in West Africa, for example in Agbogbloshie, Ghana, one of the hubs of e-waste dumping. [35]

Consequently, the laboratory definition may remain open and inclusive. The thesis adopts feminist theories and actor-network theories defining laboratory far from a vision regulated by the technoscientific perspective, derived from a rationalist, patriarchal, and colonialist objectivity model.

This survey chapter that works as a contextual review will support this thesis' aims and objectives to define and establish the sonic laboratory. Although the term has been used in academia and other fields, the concept has not been widely explored.

Understanding what a lab is and studying the already known labs allowed me to create this overview. I described different laboratory typologies (academic lab, science lab, media lab, hacklab and others), which approaching ones and criticising others would help define and establish the sonic laboratory.

Moreover, this survey shows that the term laboratory does not designate one place but presents heterogeneous sites with different activities and aims: knowledge production, manufacturing, researching, hands-on experimentation, and more. These are some of the laboratory's features and will provide this research with the essential details to define and establish the sonic laboratory.

The analysis of sound artists who have developed their practice in this type of artsience labs as case studies is paramount to the sonic laboratory definition because it establishes the bases to understand the sonic laboratory as a sound artists practice.

I also want to highlight from this survey that I have found the term sonic laboratory has already been used in academic and artistic fields. At this point, the survey offers some examples of laboratories dedicated to the exploration of sound, already named sonic laboratories, which confirms their existence. Although these examples, the sonic laboratory requires further investigation and examination. I have presented an academic laboratory introducing the sonic laboratory concept which studied as case studies will bring features and methods to understand the possibilities of the sonic laboratory.

This research aims to define and establish the sonic laboratory to understand their creative possibilities and reach through studying laboratories from a non-hegemonic and inclusive perspective.

The Last Play: A transmedia installation

Doros Polydorou

Cyprus University of Technology

Cyprus

doros.polydorou@cut.ac.cy

Abstract

This paper focuses on the methodology undertaken and the lessons learned, to create the location-based Virtual Reality (VR) story-telling experience. *The last play* was initially staged in Limassol as a student exhibition show in May 2021 and then again in September 2021 at the Animatikkon Festival in Pafos. The installation is for two people and takes place in two different sections, one physical and one virtual, and it can be experienced in either order. The experience aims to immerse and engage the users by utilizing mechanisms borrowed by immersive theatre and game-design such as spatial storytelling, agency, engaging multiple senses and telling the story through multiple mediums. The integration of these various practices seems to be an important element that complements the immersive qualities of the VR experience. Furthermore, the spatial storytelling methodology, the transmedia approach, and the integration of the various physical objects into the experience seem to positively contribute to the storytelling aspect of location-based VR installations.

Keywords

Transmedia storytelling, Virtual Reality, immersive theatre, location-based entertainment

Introduction

Background

“All cities are geological; you cannot take three steps without encountering ghosts bearing all the prestige of their legends. We move within a closed landscape whose landmarks constantly draw us toward the past. Certain shifting angles, certain receding perspectives, allow us to glimpse original conceptions of space, but this vision remains fragmentary. It must be sought in the magical locales of fairytales and surrealist writings: castles, endless walls, little forgotten bars, mammoth caverns, casino mirrors” (Chtcheglov, *Formulary for a New Urbanism*).

This paper outlines the process, key issues and initial findings relating to the location-based VR installation *The Last play*. Exhibition spaces, museums and galleries are always in the lookout to identify new ways to engage and immerse users in their exhibits. Framing knowledge and ideas in stories, is a technique used throughout the ages [1] and the power in narratives is certainly not a secret in the museum world and other similar exhibition spaces [2]. New technologies such as Virtual Reality offer new storytelling potentialities but also come with their own unique challenges. In this work, the author attempts to bridge knowledge from computer games and immersive theatre in order to propose

a new way to approach immersion and storytelling in the context of location-based VR experiences.

Overview

Time works for those who place themselves beyond time.

- Jacques Yonnet

The last play is a location based virtual reality installation, made in collaboration with students and researchers at the department of Multimedia and Graphics Arts, Cyprus University of Technology. It emerged as a research project that explores alternative and experimental story-telling techniques. The narrative revolves around themes of time travel and the passage of time within the confines of a theatre, beginning in mid-twentieth-century New Orleans and concluding in present times.

The experience is designed for two people so users are allocated to a pair before they are invited into the space. The first user is hooked up to the VR experience, where she/he gets to explore a theatre in New Orleans during the 1940s, which is just about to debut their last play before they are forced to close down. Through exploration and investigation, the user can piece together information on the history of the theatre, why it is about to shut down, as well as travel to two additional time periods that show how the theatre was re-purposed to a home and subsequently left to ruins. In the meantime, the second user sits comfortable on a couch and gets to read a journal presented in the form of an artbook, that details every single object, corridor and secret that can be uncovered in the three time periods of the VR experience. The journal is written from the perspective of a past participant that documented the experience by collecting photos, making drawings and character personas of the various protagonists you meet in the VR space. Furthermore, in this section, the user gets to explore physical items installed in the space which seem to have mysteriously “leaked” from the virtual world as well as witness, through a projection screen, the other participant exploring the VR space. Halfway through the experience, the users switch place. The whole installation is best experienced as a collaborative effort and the participants are encouraged to work together in order to best uncover and witness the secrets hidden away in the theatre.

Building on knowledge from immersive theatre [3, p.84], the users are initially treated to a pre-show with an online teaser experience. Before the day of their visit, the users are asked to visit a website, build around a 3d scene which can be further explored in the VR experience on the day, which provides enough information to provoke curiosity and introduces them to some characters of the world. This acts as an introduction/teaser to the experience, which essentially splits the narrative into three different mediums. The story of *the last play* is not “imposed” to the audience members through narration or descriptive text, but it’s told through environmental storytelling. The user discovers items such as

letters, bills and documents, old photographs, and scratches on the walls – making exploration of the space an integral part of the experience. The exploration is not limited to the online or the virtual space, but it extends into the physical space through various objects which seem to have escaped into reality. All the different elements are tied together into a narrative which is suggested in the artbook. The world was designed in such a way to allow each participant to pave their own path into the space(s) thus each participant walks away from the experience having drawn their own conclusion about the characters and the space itself.

Figure 1. The physical space of the experience. A participant is watching the second participant interacting in the space / reading the journal.

The Experience

The last play invites the participant to explore its world. There are no enemies to kill, no elaborate puzzles to solve and no mechanisms that can “kill” the player. Instead, the experience relies on the acts of exploration, discovery, and the narrative transportation initiated through the participants’ connection with the space and its objects. Just like games such as *Dear Esther*, *Gone Home* and *The vanishing of Ethan Carter* – I am purposefully avoiding to use the derogatory term “walking simulators” here – the last play draws from the theory of psychogeography.

Guy DeBord, wanting to explore how geography affected the emotions and behaviors of individuals, suggested a playful way to navigate the urban environment in order to examine its architecture and spaces. The *dérive* (drifting) is an exercise used to explore the hidden aspects of a city in both a physical and a psychological sense. The purpose of the experience is for a participant to take a walk that involves “playful-constructive behavior and awareness of psychogeographical effects.” [4]. In other words, the purpose of the walk is to let go of oneself and really see and feel the world by becoming consciously aware of all its effects, histories, characters and secrets.

The space, the objects and the story

The world of *the last play* is initially introduced to the participant through the online teaser. Upon navigating to the website¹, they are treated with a short introduction that introduces Raymond Douglas, the owner of the theatre and one of the main characters of the story. The participant then gets the opportunity to explore Douglas’ office, by clicking on the various items and documents located in on the desk and inside the drawers. The documents start to reveal some important elements of the story, such as hints that the theatre is about to close down as well as the part of the script of the

current performance. The items were carefully placed in order to provoke curiosity but not reveal too much. Furthermore, the aim here was to demonstrate the world building and the intricacies of the narrative.

Figure 2. Screen captures from the online teaser.

In order to create a believable world, one that would leave traces, histories and secrets for the participants to discover, the team followed a specific procedure. The first step was to construct the theatre. The architect from the team created era-accurate architectural drawings, which the level designers followed in order to build the space. Following from there, the script writers created the characters which would live in the space, each one with a specific backstory and how they ended up in working in the theatre. The next step was to create connections between the people, such as friendships, love affairs, jealousies, and tensions. The team then imagined how these scenarios would have played out in the space, adding various environmental indentations in the theatre to create a believable history. One example is the love affair between two young actors which can be witnessed through love notes and little markings on the toilet walls.

Figure 3. Capture from the VR world. Graffiti toilets

When the participants enter the VR world of *the last play*, they find a place frozen in time. As they walk down the corridors of the theatre, they realize they exist as a ghostly presence in a single “slice” of time. As the participant approach the motionless characters, they can hear echoes of their dialogues and/or thoughts, revealing pieces of the puzzle of the history of the place. Nick Papadimitriou calls it *deep time*, where the past echoes through the spaces and fills it with an intense spirit of place wrapped in quietude and a past (qtd. in [5]). The space is also filled with interactable objects, some of them embedded with special powers that can *shift* the slices of time. Uncovering one of these objects takes you to a different period, forward or backward in time. The familiar space is now transformed, showing the effects of the passage of time.

Figure 4. Captures from the VR world. Celeste with her child and the abandoned toilets of the theatre.

Celeste, the young aspiring actress is now a single mother living with her child in the under-stage of the theatre. Remnants of the past glories of the theatre remain in the space, some of them kept as mementos by Celeste, others as consequences of decay. The space is now repurposed and filled with traces of people and their stories. Psychogeography rejects the idea that there is one dominant interpretation of environmental stories and instead focuses on the aesthetics provoked in a succession of readings through a certain player (ibid). Most participants will not take the same path in the space and they will not witness and interact with the same objects. The experience is therefore an individual experience and each participant will form her/his understanding of the story. In *the last play* this mechanic is complemented with the investigative report that is available in the physical space of the experience. This report is written from the perspective of a spectator that got obsessed with the story. The unknown spectator, lived and re-lived the experience, explored every single corner, heard every dialogue, read every letter and documented everything in his journal. What fueled his curiosity even further, is the fact that one day he started discovering items that “leaked” from the virtual space into the physical space. The items, along with and the journal are available for the participants to witness in the physical space.

Figure 4. Captures from the Physical world. The “leaked” items and a participant interacting with them.

Bennet states that “within urban exploration there appears to be a reverence for objects – whether as art objects or nostalgic points of connection with the ghosts of the place” [6]. The team of *the last play* wanted to heighten these connections by making the important object available in both a physical and a virtual form. By giving the objects a materiality, with all the accompanying qualities of material objects, the virtual counterparts also get an elevated status.

They stay in the memory of the participant and act as anchors that further enhance the coherence of the three spaces.

Figure 6. The physical space of the experience. A picture of the artbook.

Immersion

As immersion and presence is studied and theorized by a plethora of disciplines, it is inevitably an elusive concept without a single definition. The application of the term, even if looked under the scope of digital games, it is as diverse as: general engagement, perception of realism, addiction, suspension of disbelief, identification with games characters and more [7, p.25]. What makes things even more complicated is that hybrid events, such as *the last play*, very rarely follow the same approaches and/or methodologies as other similar experiences so they are very difficult to homogenize under a specific framework. As *The last play* used elements of game design, immersive theatre and VR, therefore the immersion methodologies used in the experience were a combination derived from the said disciplines.

Machon, adapting Calleja’s reading of game theories proposed the concept of *Immersion as transportation*. She defines it as: “Where the audience-participant is imaginatively and scenographically reoriented in another place, an other-worldly-world that requires navigation according to its own rule of logic” [3, p.63]. She continues to differentiate between immersive theatre and games, explaining that game environments afford extranoetic habitation by recognizing and reacting to the presence of the player, where immersive theatre affords *actual*, physical cohabitation and contact between human bodies, thereby fusing imagination, interpretation and interaction (ibid). The world of *the last play* is composed of three inter-connected, self-contained spaces with their own rules and regulations and a consistent logic. As the participant explores the world and realizes that the objects and characters witnessed in the virtual space traverse into the physical space, the noetic understanding of the world is reinforced further with the physical presence offering to the participants a greater degree of believability to the completeness of the world. In order for this effect to take place, the participant has to discover the world and make the appropriate connections, essentially forming a noetic understanding of the space. This is achieved by allowing the participant to engage in exploration in order to advance a non-linear narrative, where space is the essential communication medium.

This methodology ties perfectly with Jenkins pivotal work “Game Design as Narrative Architecture” that proposes that environmental storytelling creates the

providing by (i) immersion into the narrative to unfold, (ii) embedding narrative information within the set, (iii) evoking pre-existing narrative associations, (iv) and providing resources for emergent narratives (Jenkins, 2004). The narrative of *the last play* is spread across three different mediums, but the story is never actually told to the participants. The story needs to be pieced together by uncovering the various hints, listening to the dialogues, and observing the environment. For example, one of the mysteries that surround the space, is a why the theatre had to close down in the first place. In order for the full story to be uncovered, the participant needs to find and read the letter from the city council, discover the death certificate (both available on the website), subsequently visit the theatre in the VR space, climb the stairs to the theatre's attic and unlock the memory that shows the accident that took place. Furthermore, signs of the accident can be seen in the space in the form of markings and dents on the floor.

The importance of forming a coherent world is also highlighted by Slater in his often-cited paper published in 1997. Slater proposed that a VR environment needs to satisfy the *illusion of plausibility* which makes a user believe that the place they are "visiting" is real. This illusion is broken down into three conditions: (i) The environment needs to respond to your actions (ii) Events in the world are addressed personally to you and (iii) events are following the expectations of the participants [8]. All three of these conditions are met to various degrees in the experience, as the world in *the last play* is developed to be interactive (items can be picked up, doors can be unlocked etc.), characters respond to the presence of the participant and the world is consistent across the various mediums. Slater has also proposed a second condition, the *place illusion* which can be met by allowing the participant to use her/his own body while immersed to perceive the world in the way that they normally would: for example, turn their head to look left and right, bend down to reach etc. This is further analyzed in the next section.

Interaction

Machon states that "Western theory has largely ignored the underlying series of proprioception and kinesthetic "hapticity" (the holistic focus on haptic sensation and perception)" [3, p.46]. Immersive VR experiences in galleries and museums are mostly following a similar approach, prioritizing visual and audio fidelity and conveniently accepting the current status of the "couch-potato player", commonly inviting the participant to step behind the curtain, only to discover a head mounted display and a single chair. Navigating the space and interacting with the various mechanisms are done through the controllers and a lot of these experiences have been optimized for seated players (limited exhibition areas are also, of course, another important factor for this decision).

Building on some previous VR work [9], *the last play* wanted to fully utilize the body as an immersive mechanism. Machon continues, "What is important in relation to embodied theorizing is the valorization of the whole body and its capacity for interpreting from holistic experience; a must when appreciating, analyzing and evaluating genuinely immersive events" [3, p.46]. As *The last play*, was a hybrid event taking place in both a physical and a virtual space, the team wanted to allow the participants to function along the familiar limits of our day-to-day interactions. Explore the space (both physical and virtual) by walking. Watch the other person player navigate the virtual space through a projector screen by sitting comfortably on a couch. Read the

journal by carefully holding the physical, decomposing book.

As the two participants entered the space, they found themselves in the foyer area. An actor handed them their tickets and urged them to proceed forward highlighting the two different paths that followed. One of the two participants was urged to follow the first path leading to the VR area and the other the second, leading to the investigation area. In the VR area, the participant was greeted with another member of the team that facilitated the "dive" into the virtual space. In the investigation area, the participant was free to roam and explore the space. On the right side, there was a table with the items that "leaked" out of the virtual world, with little notes describing where and when they were discovered. On the left, there was a small seating area allowing the participants to comfortably explore the investigative journal/artbook as well as observe, in real time, the "dive" of the other participant.

Char Davies, talking about her philosophy when designing *Osmose* states: "It is impossible to speak of immersive virtual space or of enveloping physical space without speaking of the body". It is only through the living organic body that we can access the world" [10]. While developing the VR section of *the last play*, the team wanted to minimize the interactions through the controller and utilize the body as much as possible. For this reason, the navigation of the space was conducted through a combination of the teleporter function and a room scale setup. That forced the participants to teleport to the area they wanted to explore and then subsequently explore the virtual space through physical movement of their body. The various interactions, such as picking up items and opening doors, were done through the trigger button of the controller. This set up proved to be quite successful as it had a very low learning curve and felt quite natural to the participants.

Audience Reaction and future work

The last play premiered in May 2021 at the Cyprus University of Technology, and in September 2021 at the Animatikon festival in Pafos. During the initial showing we have gathered a lot of positive feedback as well as some suggestions for improvements. Feedback, from 21 participants, was collected through informal discussions at the end of the experience and we are currently in the process to implement some changes based on the feedback for the two upcoming showings.

The participants have all enjoyed the online teaser and most of them said that was one of the main reasons why they wanted to attend the experience. The online 3d scene was "atmospheric" and provided "enough information to provoke their interest but not to give anything away". They found the graphics and the user experience very good but some of the participants commented on the heavy accent of the voice actor. A further interesting and unexpected observation was that audience members seemed to have enjoyed the experience even more when it turned social. The person outside the VR space would read a hint in the journal and guide their partner to explore areas or objects they might have missed. As the world is quite elaborate and there is not enough time for users to explore everything in a single session, this collaborative approach seemed to be an ideal way to experience more content. Furthermore, all users talked positively about the immersive qualities of the transmedia approach – how the multiple mediums helped them piece together the story- and the visual fidelity of the VR world. Most users have not experienced VR before, and a few stated that they felt uncomfortable with the locomotion

during certain areas of the experience. This was greatly improved in the second showing (Pafos) where teleportation and room scale were the recommended methods of navigation instead of the joystick (The joystick was kept only as an accessibility feature for people that needed/wanted to experience the VR sitting down).

The last play is an experience that builds on previous immersive VR installations by adding the physicality of objects and including additional world building mechanisms

such as the investigative journal and the transmedia approach of fragmented storytelling. The work has provided some interesting insights and raised some follow up questions, specifically on the use of physical objects as a mechanism to enhance environmental storytelling. As a follow-up to this work, the team wishes to explore location-based, augmented-virtuality [9] storytelling that completely eliminates the controller and encourages physical action and interaction through hand tracking.

Posthuman Rituals

Nina Rajcic, Jon McCormack

SensiLab, Monash University
Melbourne, Australia

nina.rajcic@monash.edu, jon.mccormack@monash.edu

Abstract

As we become increasingly entangled with digital technologies, the boundary between the human and the machine is progressively blurring. A posthumanist perspective embraces this ambiguity, giving primacy not to the individual agents that comprise a system, but to the relationships between them. In this hyperconnected age, our relationships with technology mediate and mould our perceptions of reality, and now they are beginning to define us. This research project explores new possibilities for human-machine relationships, moving away from relationships marked by habitual, unconscious behaviours towards those imbued with intention and meaning. Three works: *Mirror Ritual*, *Message Ritual*, and *Worn Ritual* take inspiration from the mutual entailment of matter and meaning in the dynamic configuring and re-configuring of self-identity. The proposed relationships are not intended to replace or imitate existing ritual practices among humans, but to inspire new forms of shared meaning in the human and non-human assemblages of contemporary culture.

Keywords

Posthumanism; Design; Human-Machine Relationships

Introduction

Today, the intimate couplings between humans and their technology are manifest. We are, at all times, surrounded by a network of interconnected devices that monitor, mediate, and mould our parallel and hyperconnected realities []. We have become entangled with technology in such a way that it's difficult to draw a boundary between human and machine. Artificial intelligence (AI), brain-computer interfaces (BCI), and bio-implants are just a few of the technologies gaining prominence that challenge the long-established epistemological and ontological approaches set in place by the humanist traditions.

With the rise of these entangled and intelligent technologies, traditional notions of identity, agency, and autonomy being put into question [21]: Who exactly is the 'user' [4]? Where exactly lies the interface? In response to this technological proliferation, posthumanist thinking has been proposed as an effective framework for reconsidering the research, design and creative practices underlying Human Computer Interaction (HCI) [15, 14, 31]. Posthumanism calls for the reconfiguration of human and non-human relations,

with the decentering of the human, and the relinquishing of dualist categories such as nature/culture, mind/body, and subject/object.

The shift towards relational ontologies reminds us that in the designing of 'interfaces' we are in effect designing the *relationships* between human and machine [28]. These relationships not only shape our behaviours and perceptions of reality, they underpin the very nature of our being. Their effect on society today is highly visible, most notably through social media networks and their real-time, AI curated content feeds. The intent of these algorithms is to maximise engagement, screen-time and click-through, with the relationships forged then being ones marked by unconscious behaviours, unreflective actions, and addictive tendencies [13].

In this paper, we call for a shift away from habit-based human-machine relationships and towards those imbued with intention and meaning. We present three projects: *Mirror Ritual*, *Message Ritual*, and *Worn Ritual*, which form a conceptually linked series of speculative propositions for future human-machine relationships. Each work utilises machine-generated poetry to produce a shared conceptual space between human and machine. The works investigate the role of language and ultimately narrative in the reconfiguration of identity, exploring the mutual entailment of the material and the discursive in one's open-ended becoming. Each work is in varying stages of development, uses differing scales of temporality, and addresses a distinct aspect of what constitutes the self. The realised designs serve to not only challenge the existing paradigms in HCI research, but to provide altogether new experiences and ultimately forge valuable and meaningful relationships between humans and intelligent machines. The *Ritual Series* aims not to simulate the ritual practices observed across societies past and present, but instead to offer new rituals that produce shared meaning in human and non-human assemblages; new rituals for an increasingly posthuman society.

Background

The notion of the Personal Computer (PC) began to take shape in the mid-twentieth century, with the dream that every individual could one day own their own computational device. Made possible by the advent of the microprocessor, computing gradually permeated into mainstream society, sparking what we know today as the third industrial revo-

lution. This necessitated a shift towards a more interactive form of computing, as proposed in the seminal paper *Man-Computer Symbiosis* [20]. Rather than simply processing tasks, the computer should additionally give and receive real-time feedback. More notably, Licklider envisioned a world in which humans and computers would be intimately coupled, forming a symbiotic relationship from which emerges a new kind of computer, and a new kind of human. Licklider's formative musings, among others, became the foundation of the field of Human-Computer Interaction (HCI) as we know it today. Computers first became commonplace in the workplace, and so the goals and methods of early HCI research concerned itself with functionality, productivity and efficiency. As computing gradually permeated from the workplace into the home, then from the home onto the body, HCI research began to explore more nuanced, subjective and distinctly human needs such as emotion, creativity, and loneliness [8, 9]. The epistemological processes within HCI research likewise shifted from engineering inspired positivism towards socially constructed and situated forms of knowledge production.

Human Machine Relationships

More recently, we are witnessing the increasing entanglement of people with their personal devices; the way in which they mediate and shape our shared reality is unprecedented. As the boundary between human and machine becomes more difficult to distinguish, the existing epistemological and ontological frameworks passed down from humanist traditions become strained. It no longer makes sense to treat the 'user' as ontologically distinct from their technology. With early roots in Donna Haraway's conceptualisation of the cyborg [18], we see the emergence of posthumanist and relational ontologies which challenge the anthropocentric and humanist values set in place by the secularist movements—that humans embody the locus of agency, morality, rationality, and individuality.

Under the posthumanist paradigm, humans and technology are ontologically inseparable, meaning that it is the relation between the two that defines their existence, rather than their individual properties. These ontologies emerge in part as a response to the proliferation and adoption of digital technologies. Posthumanist philosophies, in the broadest sense, call for a radical de-centering of the human, marked by a return to materiality [10]. Adopting relational ontologies leads us to the understanding that in the designing of 'interfaces', we are, in fact, designing the relationships between human and machine through which humanity continues to be shaped [28].

Barad's account of posthuman performativity [1] provides insight into how we might begin to understand human-machine relationships. According to Barad, the boundaries between human and machine are not predetermined, instead they are performed within a certain material configuration. These enacted boundaries, or *agential cuts*, must be applied at one scope or another. In applying Barad's framework to technology design, we do not feign to account for the 'whole' but rather acknowledge the enacted separations, and ultimately take a multiplicity of configurations into consideration. To draw these boundaries early in the design process is to neglect the fluid nature in which human and machine negotiate their respective agencies. Instead of designing technologies with

pre-established roles of 'user' and machine, we instead design for the relationship as a whole. This involves taking into account the user during their active engagement, along with the greater context of their situated relationship, and moreover how it develops in time.

Humans have already formed complex relationships with AI systems that have a profound impact on everyday life, such as the relationship one has with their smartphone. Social media sites have adopted AI for numerous applications, but most notably it is AI systems that curate, in real-time, the stream of content that one is exposed to. The goal of these algorithms are to increase engagement, and ultimately to maximise screen-time. The result is an invisible yet highly targeted system that affects behaviour change—working most effectively when one is unaware of their influence. The presence of agency within these algorithms is unmistakable. As such, social networks provide the ideal example of an assemblage of human and non-human agents, illustrating the posthuman reality of today. The algorithms are distinctly inhuman; they are indifferent to the humanist values of sovereignty, freedom, self-determination, and liberty. They are indifferent to whether or not the end-user is human at all [13]. The obtrusive nature of these non-human agents on human perceptions and behaviours is seen across many aspects of society. In the case of social media, the favoured behaviour of the algorithms, and hence the generated behaviour in users, is one of unreflective, reactionary engagement. Users are rewarded for their unceasing engagement through clicks, likes, comments, shares—in addition to the infinite scroll of hyperpersonalised content. The relationships engendered by social media networks are then, *by design*, habitual and largely unconscious [19].

Human-machine relationships that are grounded in habit are widely spread throughout much of contemporary society. Habits are, in the broadest definition, automatic and repetitive behaviours that are learned and enforced through action [22]. Habits can be both positive and negative, yet in any case markedly require little conscious thought or intention. Rituals similarly involve routines, yet can be differentiated by their intentionality, deep emotional involvement, and their 'socially shared meaning' [16]. Notably, rituals serve a societal function, in that they communicate and reinforce the shared values and identity within a culture [26]. Just as habitual behaviours can be intentionally encoded into the design of human machine relationships, so can ritualised interaction be placed at the core of design decisions. Human-machine rituals need not mimic nor simulate existing ritual practices commonplace in society. Instead, these new human and non-human assemblages carve a space in which novel forms of meaning-making become possible.

Posthuman Art and Design

Wakkary outlines the role of posthumanist thinking for design [31], arguing that the main arc of design over the last forty years has been to prioritise human values, conceptualised anthropocentrically through a series of paradigms such as human factors, ergonomics, embodied interaction and human-centred design. While these paradigms have been effective in propagating human-centric technologies, they have come

with significant environmental, social or cultural costs. In contrast, posthumanist thinking supports greater humility in design, shifting the focus away from ‘the power of self-reflexive human reasoning to situated, partial, and multiple ways of knowing.’ [31, p.2]. This mode of design explores what it is like to *design-with* humans and non-humans, rather than to *design-for* an idealised ‘user’.

This approach incorporates a variety of methods and tropes, including the *counterfactual artefact* [30] – a non-normative approach used to question design or technological conventions; *slow technology* such as *Olly* [23] which explores time and memory using technology to envisage a longer-term relationship with personal data, or *Long-living chair*, a rocking chair designed by Larissa Pschetz that records and displays its use over a period of ninety-six years, allowing the owner to observe long-term patterns of use [24].

Such methodologies are also common in media art. Artist Ana Rewakowicz made extensive use of Barad’s concept of “mattering” and, similar to our presentation here, presented a diffracted intra-action with three artworks that are part of the *Mist Collector project* – an installation that collects water from fog, produced in collaboration with scientists at l’École Polytechnique in Paris. Rewakowicz explored ethical considerations through the notion of the “inhuman”, something that “steps inside of ‘human’ in order to address human ‘ugliness’ within” [27].

Extended Self

The emergence of the posthuman is evidently relevant to our contemporary culture marked by our extensive entanglements with technology. Yet, according to Clark and Chalmer’s Extended Mind Thesis (EMT) [11], the human is already technically constituted. They argue that cognition does not happen exclusively within the confines of the brain and body, but extends out to include the manipulation of objects in the world. Offering the example of putting pen to paper, reshuffling letters on a scrabble board, or using a diary to remember events, Clark and Chalmers describe how such actions are so closely coupled with cognition that they in part constitute it. In this sense, the use of technology is already enmeshed in our thinking and operating in this world. The EMT in many ways aligns the field of cognitive science with posthumanist thought by acknowledging the materiality of the mind, as well as breaking down the mind/body duality.

In granting the materiality of the mind, we are lead to an understanding of self as too embedded in the physical world. In a 1988 essay, Belk proposes that the self is made up of not only the mental processes, ideas, and memories one has, but the things, places and people one finds themselves in assemblage with [5]. Personal possessions inform self-concept by offering concrete and continuous markers of memories and beliefs. In later work, Belk goes on to detail how the proliferation of digital technologies has dramatically shifted the discourse around materially constituted self-identity [6] to include the virtualisation of personal possessions and memories, the re-embodiment and multiplicity of self, and the public presentation of identity.

Language and the Self

Language is often placed in opposition to the material under representationalism, which adopts a binary of words and things; signifier and signified. Yet, as Clark describes, language itself has a materiality; we encounter “words in the air, symbols on a printed page” [12]. Language is not merely a vehicle through which we express our inner thoughts, but a form of computation in itself. The supra-communicative view of language, originally pioneered by Vygotsky [29], proposes that language is a tool that guides behaviour and structures action.

Under Barad’s posthuman performativity, language and matter are not placed at odds, rather “the relationship between the material and the discursive is one of mutual entailment”. Discourse, as Barad highlights, does not refer to merely spoken or written words, rather “discursive practices define what counts as meaningful statements” [2], enabling what can and what can’t be said. A material-discursive approach to understanding self-identity takes into account mutual significance of matter and meaning in one’s open-ended becoming. Within a performative and relational ontology, the self is not a rigid or singular identity, but an ever-emerging subject. This constitution of the material-discursive self forms the inspiration for the works described in detail in the sections that follow.

Mirror Ritual

Figure 1: Mirror Ritual

Mirror Ritual is an interactive installation that questions the existing paradigms in our understanding of human emotion and machine perception. The work appropriates an everyday object, the mirror, augmenting it with artificial intelligence to foster both literal and metaphoric reflection. Through AI generated poetry the mirror ‘speaks’ to the viewer, each poem unique and tailored to their machine-perceived emotional state.

Mirror Ritual looks and functions like a regular mirror, however it is ‘activated’ when a person approaches the mirror and stares at their reflection. A machine vision camera, embedded behind the glass, recognises human faces. As the viewer stares into the mirror, their current emotion is estimated based on facial expression and this detected emotion is converted into a ‘seed phrase’ which is then used to generate a unique poem using a version of OpenAI’s GPT-2 transformer network trained on a custom corpus of poetry (see Fig 2). The poem’s text gently fades onto the mirror and is displayed for as long as the viewer continues to stare at it. When the viewer looks away, the poem is lost forever; each new gaze into the mirror generates a new poem. The full technical details of *Mirror Ritual* can be found in [25].

The work is inspired by the theory of constructed emotion, which posits that the supposed basic emotions (such as anger, fear, and joy) have no have no biological or neurological essence [3]. Instead, emotion is constructed from a number of more basic psychological processes, such as language, past experience, and the agreed upon social reality. In contrast to prescriptive technologies that are founded on reductionist theories of emotion, this work’s real-time affective interface engages the audience in the co-construction of their emotion. The audience are encouraged to make sense of the mirror’s poetry by framing it with respect to their recent life experiences, effectively “putting into words” their felt emotion. This process of affect labelling and contextualisation works to not only regulate emotion, but helps to construct the rich personal narratives that shape human identity.

With this work, we aim to develop a human-machine relationship that provokes emotional reflection in viewers through the conceptualization of their affective state. These objectives are reflected in the physical design and construction of *Mirror Ritual*. The use of a mirror surface works symbolically to suggest that you must not only confront your physical self, but also that you may reflect upon your internal emotional state. In addition to the process of reading and interpreting the generated poetry, viewers are subsequently confronted with their momentary reactions. In this way, *Mirror Ritual* engages viewers in the iterative process of the co-construction of their emotional state – predictions made by the mirror are not intended to be direct representations of the viewer’s affective state, yet they can work to shape it.

The mirror is developed with a sustained engagement in mind; we intend that viewers incorporate *Mirror Ritual* into their daily routines, developing a meaningful relationship with the interface through multiple encounters over time periods of weeks, months or even years. For this reason, the mirror has been designed to assimilate easily into daily life, both in its aesthetic qualities (it appears as a standard round mirror), and in it’s dual function (it can simply be used as

The comfortable place

is not the one that we have vacated
we are always with you
clinging to your empty good time
your warm harbor in the dusk
we are always with you
(we are always)
and this good time
we call sacred
we provide a framework

Excited

I am trudging
in the wrong direction
The wrong footstep
A bon fire in a church
I repent
If only I knew
what confusion
is doing
In this slow wood
A crane landing
In the least invasive
Style
On a whisper
Of wind lifted
From a book
That I had not opened

You are elated and ecstatic

For three whole days
you have been praying
and fearing
and reveling in
the knowledge that now is the most
optimal time to embrace
your whole life story, including
the one you’ve been carrying around
in your mind, like a baby

Figure 2: Examples of generated poetry. For each poem, we present the associated facial expression as perceived by the mirror and the subsequent seed phrase (shown in **bold**), which is used to generate the poem using a custom GPT-2-345M neural network.

Figure 3: A CAD render of the *Message Ritual* lamp

a mirror). The mirror could be hung in a bathroom, living room, or hallway entrance, creating the space for viewers to pause and reflect on their mood as they transition between the moments of their day.

Early experimentation provided a number of insights about the relationship generated through engagement with *Mirror Ritual*. Participants largely found themselves able to emotionally engage with the mirror, often perceiving the device as possessing agency and intention. The mirror's poetry was best received when participants were able to connect it back to something tangible, framing the messages within the context of their life and recent experiences. In this way, *Mirror Ritual* presented participants with fresh concepts and imagery, occasionally bringing to the surface dormant emotions, beliefs or memories [25]. Meaning seemed to unfold between participants and the mirror, both over the course of one interaction, and over the extended period of engagement. The experience was generative, directing further thought and conversation. Furthermore, the relationship itself was found to define the respective roles of its constituents; both the participants and the mirror *becoming through* one another.

Message Ritual

Message Ritual is the second artefact developed in the *Ritual Series*. Comprising a bespoke table lamp and an AI backend, *Message Ritual* is an integrated system that encourages the re-framing of memory and identity through machine generated poetry. Appropriating a typical domestic object, the lamp is designed to have an ongoing presence in the home. While functioning as a regular table lamp, while turned on it also listens in on conversations occurring throughout the day via an embedded microphone array and on-board computer. Each night, the system analyses those conversations, reconstructing

the key themes and topics as a source for machine-generated poetry. A short, bespoke poem is then delivered back to individual members of the household as a text message upon waking. *Message Ritual* presents an alternative approach to traditional augmented memory systems – rather than focus on the sensing and quantification of external experiences or actions, we aim to construct meaningful, personal narratives through the use of machine-generated poetics.

As with *Mirror Ritual*, *Message Ritual* similarly utilises machine-generated poetry to foster reflection and introspection as the individual attempts to draw meaning from their delivered poem. But rather than grounding itself in the viewer's in-the-moment mood, *Message Ritual* draws upon an individual's recent memories to contextualise their poetry. The system is not attempting to improve the recollection of 'accurate' memories, rather it encourages the active framing and re-framing of personal events that contribute to one's overall life narrative. As with *Mirror Ritual*, the work is designed to be lived with over an extended period of time, with the poetry referencing the events of the previous day. This self-referential nature of the experience aims to provide some sense of continuity over the interactions, allowing people to develop a meaningful relationship with the system over an extended period of time (months, years).

Message

A smartphone was chosen to serve as an intervention to the typical habitual behaviours and gestures associated with the device. The morning SMS is designed to reach the participant in their first moments of the day, encouraging reflection and re-framing of the previous day's events. The daily reading and interpreting of the message contributes towards one's waking ritual, prompting the participant to proactively reflect and contemplate their life. SMS technology is utilized as it sits outside of social media applications, creating a conceptual division between *Message Ritual*, and other morning routines that are mediated through a smartphone.

Lamp

The design of the lamp itself is crucial to the overall experience, as it will be embedded into the homes and lives of participants. In line with the design of *Mirror Ritual* [25], the lamp serves both a functional and aesthetic role in participants' homes. Here, everyday domestic objects (e.g. furniture, crockery, plants, soft furnishings) are of interest as they have clear and well-defined roles in one's life, but they also distinctly lack a technological component. Technology providers push for the widespread integration of technology and everyday objects (the 'smartification' of the home) [7], generally aiming to augment both the function of the artefact itself, and to increase the connectedness of objects with each other (i.e. internet of things). In this work however, the use of everyday objects is chosen not to necessarily 'improve' an object's function, but rather to bypass any preconceived notions or behaviours that users may associate with traditional interfaces such as screens, smartphones or voice-assistants. In this way, the natural behaviours afforded by non-technological objects (i.e. switching a lamp on or off) are utilized in the interaction, allowing for the interface to

Figure 4: Message Ritual: the Lamp listens to conversations in the home and responds with poetic reflections of the day's conversations via text message (shown right) to members of the household the following morning.

escape common behavioural and gestural habits such as tapping, swiping, scrolling, refreshing, issuing commands, etc. The artefact blends into the domestic surroundings, so as to not interfere with natural conversation occurring in the household. Furthermore, the light from the lamp carves out a space for occupants to gather and converse, especially in the evening and night time hours.

Living with Lamp

In a 2 week long study, participants were asked to invite the lamp into their home. We found that the lamp aided in the reflection on and recollection of recent memories, offering transitory moments for quiet contemplation. Moreover, the lamp served as a social centrepiece, encouraging conversation and connection within households. More interestingly, however, is the common perception of the lamp as an extension of it's designer. Emotions experienced towards the device seemed to distribute across the entire assemblage of household members and researchers. It became impossible to decouple the experiences of any one participant. Instead the specific material configuration; the households, participants, designers, and researchers, altogether shaped the course of the lamps becoming. Again, only through the relationships that emerged through sustained engagement, did we come to further understand the influences, implications and possibilities of *Message Ritual*.

Worn Ritual

The third project of the *Ritual Series* serves as a counterpoint to the first two; taking inspiration from the narratives generated in relation to both *Mirror Ritual* and *Message Ritual*, but addressing the ephemeral nature of machine-generated poetry. Often such poetry is perceived as lacking significance

or meaning, in the sense that it is trivial to generate thousands if not millions of poems in a short period of time. Moreover, the poetry lacks an identifiable author and the traditional intentions of human poets. *Worn Ritual* is a response to the transient nature of machine poetry; by taking short excerpts from the generated poems and inscribing these into physical materials such as aluminium, steel, and textiles, the narratives behind the poetry are given a greater sense of value and permanence.

Worn Ritual is currently in the early stages of conceptualisation and development. In early experiments, the concept has been explored through the medium of hand stamped aluminium bracelets. Rather than using automation, a personalised poem is chosen through a manual curation process, from which an excerpt is hand stamped onto a bracelet that is then gifted to the participant. Examples of the chosen excerpts and associated bracelets can be seen in Figure 5. The curation process involves seeding the poetry model with a phrase that is meaningful to the participant, and generating several poems of which only one is selected. The selected poem in some way captures the participants recent experiences or reflects on the relationship between participant and designer. In one example, a bracelet was made as a parting gift to a participant leaving the country indefinitely, with the following associated poem (seed phrase in **bold**, stamped phrase in *italic*):

There is no unhappy ending here,
And if there was, it would be a different jungle.
We are thrust forth as the favored creatures
Of mythical beings and saintly heroes.
This is surely no happy accident.
It is a *spiraling arc*—the work of love.

Figure 5: Worn Ritual: aluminium bands with hand-stamped AI generated poetry (left) are shaped into bracelets (right).

Experimentation with jewellery as a medium has provided early insight into how these constructed narratives can be embedded into physical, static artefacts. Further experimentation will focus on how the chosen materials and context of the works influence the perceived value and meaning of machine poetry. We plan to explore a range of materials and techniques, such as machine engraving, embroidery and woven textiles. In addition to wearables designed for personal meaning, we will also experiment with larger scale pieces designed for domestic and public settings, allowing for the continued exploration of how machine-generated poetry can be imparted with social-shared meaning.

Conclusion

The three works presented in this paper are designed as a conceptually linked series of works that each propose a speculative future of sustained human-machine relationships. The works embody a critique on traditional approaches of the quantifying of self: the measurement of emotion; the outsourcing of memory; while at the same time offering positive and optimistic alternatives for human-machine relationships. The works also reject the typical focus of technology on accuracy, efficiency and speed: capacities that enforce the relentless ‘consumption of disappearance’ that define modern technological cultures [17]. Instead we turn to creating rituals that render time habitable – much like we furnish homes to make space habitable, rituals allow one to inhabit and linger in time. It is no coincidence that all the works in the *Ritual Series* encourage the emergence of long-term relationships over instant gratification, and that they work as personal or household objects, whose significance is earned rather than given.

The *Ritual Series* serves to not only challenge the existing paradigms in technology design, but to offer altogether new rituals and experiences, ultimately striving to forge intentional and meaningful relationships between human and machine. In response to the increasingly common tendency for technology to mould the human into a form that can be understood by a machine, or more recently the desire for the machine to be reconfigured for the human, the *Ritual Series* instead allows for their mutual unfolding. Neither precedes

the other, neither defined by the other, but through their relation emerges a continuous and open-ended becoming.

Abstract

Aerial images have become commonplace on the media landscape around us, in places like TV news, films, and digital maps. However, do we consider what these images represent, both in the artistic field and in society?

The aim of this project is to raise these and other questions in order to reflect on how drones are being inserted into the normality of everyday life and to question their vigilant scope. We ask how we as artists can act as hackers, disruptors and creators of new possibilities.

Our use of aerial images is not intended as surveillance, but rather as research on what is happening in certain areas where nature and worlds inhabited by humans coexist, most of them unknown to the majority of the local population.

Keywords

Drones, Hacktivism, Counter-surveillance, Environmental awareness, Augmented reality.

Introduction

Drones, also called Unmanned Aerial Vehicles (UAVs) are recent examples of flying machines used for modern warfare. They have the ability to travel into enemy lines, capture images and collect field intelligence. Created for military purposes, they demonstrate the technical prowess of one army over another. Whoever manages to climb higher and see the other from above, has more information about the opponent.

Recently, drones have also become entertainment machines, a new means of capturing images whether for newspapers, movies, commercial purposes or as a hobby. They appear to maintain their military descent as a surveillance tool, being used in cities to monitor the population. Often in the criticism of drones, the notion of “scopic regime” [1] is used, expressing a hierarchical, violent and asymmetrical power model that manifests itself in the forms of surveillance and drones.

Figure 1. *Frontiers || Territories, Timelessness-* Ars Electronica Campus Exhibition, 2019. Augmented reality project overlaying images captured by drone onto a satellite image map of the area. We used the Mapknitter software to match the drone images to the map.

Satellites are another example of aerial imaging devices that are out of our visual range and constantly record images of the Earth. These images are also used for reconnaissance. In both drones and satellites, the images they capture have an ever-increasing range and resolution. These machines are seeing for themselves, and are part of what Harun Farocki has titled operational imagery, images made by machines and which are "read" by machines. They are used to map the world and may not be treated impartially, thus changing the way we see and "do" things in the world, as Trevor Paglen has pointed out. [1]

Figure 2. Image capture from Google Maps edited to remove all natural spaces from the area under study.

Many of the images we see on digital maps today are aerial images that don't portray a stable ground, instead creating an assumption of what exists. Satellite images that we later see applied to digital maps, as in the case of Google Maps, are, according to Ana Peraica, landscapes that result from the "gluing" of various image clippings through the use of artificial intelligence. [1]

Beginning

In 2019, we presented publicly in Ars Electronica Campus the project *Frontiers || Territories*, it was in the research around this project that we awakened to this relationship of images captured from a point where we are far and in different positions from the camera. In this project, we became interested in looking for borders in the area where we live. When represented on maps, borders are just lines and do not have the same force as the concept in terrestrial terms can have. Even knowing that they are invisible, they manifest themselves in our behavior.

Another factor that brought us here was that already in this work we were interested in exploring ways of capturing aerial images that are made with Do It Yourself tools, created by us and that are documented for those who

come next and intend to do something similar or who can adapt to what they intend to do. So we started with the construction of a pole where a *GoPro* camera could be

attached and set to automatic mode, capturing images from the moment it was turned on.

These images were then uploaded into the open source "Mapknitter" software created by Public Lab. [12][13] It wasn't easy to reach the intended goal because of the weather conditions, with the wind impeding camera stabilization (Fig. 4). So, as a last resort, a drone was used to get results that fit the deadline we had to meet.

It was from this experience that we took the notion of size, weight and possibilities that drones have, as well as the number of models and sizes. We were able to ascertain their stability, susceptibility to certain flight conditions as well as the image quality, scope, detail and information that drone images can capture. We researched the current local airspace legislation that applies to the use of drones and we found the legally safe airspace for drone use as a tool for entertainment, commercial and artistic purposes.

Figure 3. Image capture from Google Maps edited to remove all built objects (houses, roads, etc.) from the area under study.

In *View From Above*, we once again use the drone as a means of capturing aerial images, in which we can explore the area where we live. This time trying to reinforce it with a way of doing hacktivism, which we had already started in this previous project

Figure 4. Composition with photos taken with a GoPro camera attached to the end of a long pole.

Artist as hacker

“The artist makes social conditions visible, the hacker highlights the weaknesses of the system. The hacker shows the open wounds of machines, or the computer world, making it clear that everything a machine achieves can also be nullified by it.” [3]

In this case, not only the computer world, but the world in general, since currently the virtual world intersects with the real world. From the point of view of this research, the hacker loses the connotation normally given to him, that of criminal, someone who steals or cheats, in hacker jargon these people are called crackers, someone who illegally and unethically breaks a security system.

Ethics is very important to define the hacker, so there are several manifestos referring to this topic, such as McKenzie Wark's in the book “An Hacker Manifesto”. Wark refers to the hacker as a producer of differences, who deconstructs technology and highlights differences in the positions of relationality and power. [4]

Hacker intervention is known as a gesture of transgression and rebellion against the established, especially in the technological environment. Although hackers act particularly through computation, it is understood that their manifestation is usually expressed through different means, even non-technological ones, and so we can include them in art. If the computer hacker goes in and changes codes, as artist hackers can we change the code of art?

Artists who identify with hacktivism intend to create a more open conscience and question the functioning of the norm. The confrontation with the relationships that sustain the economy, power and politics are very important for the activist hacker. The latter is thus represented as a participatory member in social and political issues.

As this project revolves around surveillance devices, the sovereign relationship of those behind these devices, which here focuses on drones, we have the possibility of questioning the look that comes from above and still looking at the one who looks from above, what Mirzoeff calls “countervisuality”. [5][9]

Figure 5. Image capture experiments carried out with the drone, using a mobile phone to preview what the drone is capturing.

Possibilities

“What if, instead of resisting the use of surveillance technology, we could harness it for the public good?” [6]

This project has a community aspect that starts from learning to fly a drone, collecting information and tricks in forums for sharing information related to drones. On the other hand, it is intended to give power back to people, to make known the area where they live, where they can have a critical view.

One of our main references is the #dronehackacademy project[7][8], defined by the creators as a prototype of a hacktivist school, a laboratory for citizenship science and the production of critical theory for the use of unmanned aerial vehicles, coordinated by Pablo de Soto and Lot Amóros. They worked together with the community of Vila Autódromo, in Rio de Janeiro, where they made use of the drone in favor of the community. Participants had the opportunity to see and locate their dwelling area and to have a new perspective on the space they live in. These people were watching the demolition of the houses where they lived and thus being able to compare with the houses in the past.

This is an example where technology becomes an asset for community use by dismantling the power of the gaze and appealing to the right to gaze.

In this project, Flone [10] is used, an example of a low-cost, open-source DIY drone, in which all the information about its functioning and construction is available to be improved and changed, in software and open hardware platforms. Flone is a technological device, similar to the drone, it is open source and therefore it is possible to replicate. On the project's website, you can find all the specifics for building a Flone. This is a hacker instrument, for the freedom of information, being available to anyone.

Another project that was a reference was DIY Forest and Surveillance Kit, in which DIY open-source video streaming boxes were used in a forest area for fire prevention.[11] In addition to questioning the capture of images by surveillance cameras, they draw attention to the fires that have been a scourge and to the repercussions that may result.

We < = > Drones

Drones see us and we see them back!? We should notice that drones are part of the technological world and despite our insistence that they "see" us, there's always a human operator behind the drone and technology in general.

In this project we invoke "countervisuality" as a form of hacktivism directed at the use of drones as technological platforms of power through surveillance.

In this hands-on research, we took it upon ourselves to use the drone and understand how it works. Bringing it into the field of performance art, we look and point towards the

drone in order to reverse the vertical hierarchy its operation naturally creates.

Figure 6. Top: commercial drone being used for experiments. Bottom: assembling a Flone DIY drone during an artistic residency.

Figure 7. *I see the drone and the drone sees me* (2021). Stills of Video-Performance.

We started by flying a very simple model, in order to understand its functioning and gaining flight experience. Then we moved onto a higher end model with built-in ability to capture high-quality images. This model has proved more challenging to fly, and we have been steadily gaining experience with it in order to be able to fly safely at greater heights and longer distances.

In parallel, we have been assembling our own Flone drone that will serve as a platform to allow us greater flexibility in the future to explore new image capture

technologies, on-board image processing and dropping or picking up of external payloads.

In *Drone Shadow* [12], James Bradley makes a 1:1 representation of the outline of a drone in chalk on the streets of several cities, recalling the outline that is also made in chalk at crime scenes.

At the same time, it's a way of reminding the public that drones are out there, up above. Its intention is thus to communicate both the physical reality and the apparent invisibility of the drone aircraft. Bridle follows the idea that you have to draw to better understand the world, because if you can't describe it, you can't act fully in it. Knowing it, it is possible to debate and criticize it. In 2013, James Bridle published the book "*Drone Shadow Handbook*", a guide to drawing models of the drones he made in public spaces, while also indicating their characteristics.

This guide is a way for Bridle to share with anyone interested in doing DIY versions of his project. This opens the door to free access to information, a characteristic present in the hacker community.

Where/Target

Our main target location for image capture is marked as a protected forest area. However, despite its protection status, it has suffered great devastation for the construction of large houses.

Unlike the #dronehackacademy project, our intention is not to fly over an area under deconstruction, but rather over an area in tension between deforestation and construction, where the house prices are the highest in the nation. We're telling the story of a place where protected trees are cut down to build real estate and then partially replaced by other kinds of vegetation in order to maintain privacy and define property limits.

How

The practical implementation of this project intends, on the one hand, to create a cartography of the area mentioned above, with images captured by the drone and displayed horizontally, on the floor where the public will walk and will be able to visualize details of certain points through augmented reality (figure 9). It is intended that the public can be from above looking down and with a tablet have the experience of looking from above.

The layers to be presented include research among the population which has recently begun to protest, given the increase in deforestation for the construction of houses.

Figure 8. Stills of the augmented content displaying the differences in the same zone but different years, in Cascais, Portugal. Image source: Geocascais, CM Cascais.

Figure 9. Mock-up of the Augmented Reality interactive installation that reveals the project visual content to the public.

Figure 10. Stills of the augmented content displaying the drone video overview nearby the natural park Sintra - Cascais, Portugal. The images are part of the video content we created as part of the View from Above interactive installation, where several similar instances are exposed.

Conclusions

This article presents the *View From Above* project, which aims to use the unique perspective of drones to expose the aforementioned process of prime real-estate encroaching into a protected forest area. It is thus a way of contributing the criticism of the “look” of drones to the artistic and technological community. Appealing to community work and freedom and exchange of knowledge.

In order to further develop this project, we will carry out flight studies in the area we are researching. Moving on to the next project stage in augmented reality, we are building a narrative with data that have been collected to better understand the area where we are acting.

In tandem we are building an online platform that details the project’s artistic and technical research, to make our work known to hacktivist platforms and communities that want to fly over areas where the good conditions of natural spaces are being questioned.

Inhaling Quantum-Consciousness: Ecological Vibrational Possibles

Clarissa Ribeiro, Ph.D.

University of Fortaleza / Roy Ascott Studio / UCLA Art|Sci Center and Lab

Fortaleza, Brazil

cr@clarissaribeiro.com

Abstract

Navigating the contemporary debate on the Vibrational Theory of Olfaction (VTO) as a quantum mechanism, there is a rising hope it can lead us to an understanding of the biological world more as ‘energy interchanging in charged playgrounds’ and less as related to molecules’ shape-dependent trades. This can teleport our understanding of the biological as ‘moist’ to the biological as ‘molist’ – crossing scales in complementary moves from the molecules-atoms-bits’ realm of *moistmedia* to the charged ‘scale free’ panpsychist realm of *molmedia*. As the third move in a series of works that starts as invitations to explore humans’ body molecular informational exchanges with the microbial, the paper presents and discusses the genesis of the installation ‘Inhaling Quantum-Consciousness’ in a direct dialogue with Hélio Oiticica’s appropriation of Russian Suprematism aesthetics and structural principia, expanding the use of the pure pigment to an experiment in biochemical art.

Keywords

Vibrational Theory of Olfaction (VTO), Biochemical Art, Moistmedia, Molmedia, Pure Pigment.

Introduction: Immersed in data

“So, as multimedia give way to moistmedia, and interactive art takes on a more psychoactive complexion, consciousness remains the great mystery, just as intelligent artificial life remains the great challenge.” [1]

Human olfactory receptors are members of the G-protein coupled receptor superfamily. G-protein-coupled receptors (GPCRs) are the largest and most varied group of cells’ membrane receptors in eukaryotes acting like an inbox [2] for messages that inform cells of the presence or absence of life-sustaining light or nutrients in their environment, or conveying information sent by other cells. These molecular receptors can receive information in the form of proteins, lipids, sugars, peptides, light energy and help regulating a massive number of bodily functions – from sensation to hormone responses. The human sense of smell uses these receptors to discriminate between an astonishing variety of odorants. Nevertheless, the exact mechanism [3] by which an odorant activates a receptor is still unclear.

Luca Turin was pioneer in suggesting that [4] inelastic electron tunneling has a big chance of being the method by which vibrations are detected by the olfactory receptors within human nose. In fact [4], the vibrational theory of olfaction is a tentative description of a possible mechanism for olfaction that offers researchers a set of principles that authorize predictions allowing for structure-odor relations.

In a paper published in 2013, Turin and a group of collaborators [3] describe and discuss experiments using isotopomers (an odorant) in a possible test of shape versus vibration mechanisms. The researchers assert that testing for odor character differences between deuterated and undeuterated odorant isotopomers can be effective in helping to prove the validity of the vibrational mechanism, considering deuterated and undeuterated odorant isotopomers have different vibrational modes, despite having identical ground-state conformations. What is behind the contemporary Vibrational Theory of Olfaction (VTO) is a quantum mechanism.

Howard Wiseman and Jens Eisert believe that [5] considering the growing importance of quantum mechanics in biology, all the suspected cases of nontrivial quantum effects in biology must be examined with caution. Beyond the vibrational bonds related to the mechanisms of olfaction (or better saying, a chemical presence we perceive as odor) the understanding of consciousness as a biological elementary level phenomena starts being by some means illuminated by quantum mechanics.

Hameroff and Penrose [6] back in 1996 navigate historic references to discuss the problem of incorporating the phenomenon of consciousness into a scientific worldview. They recall a set of philosophical positions addressing the problem – bringing an understanding of consciousness as a fundamental component of physical reality such as panpsychism [6] in which it is a quality of all matter, having atoms and subatomic particles elements of consciousness.

Among all philosophical positions the researchers mention in this seminal paper [6], the one of Alfred North Whitehead has elements that can be most directly applicable in the effort of understanding consciousness from a quantum mechanics perspective. As pointed by Hameroff and Penrose [6], Whitehead describes the ultimate concrete entities in nature as being ‘occasions of experience’, bearing a quality similar to our notion of ‘feeling’. From Whitehead point of view, consistent with panpsychism, even temporal events in the career of an electron [6], have a sort of ‘protomentality’, a ‘protoconsciousness’. The researcher’s intention is “[...] to regard experiential phenomena as also inseparable from the physical universe, being deeply connected with the very laws which govern the physical universe.” [6]. Recalling Penrose arguments in his ‘Shadows of the Mind’ [7], they ponder there is a necessary non-computability in consciousness thought processes that must be inherent in the phenomenon of quantum state self-reduction. The researchers argue in this debate that the gravitational induced collapse of the wave-function is ultimately related to the phenomenon of consciousness and micro-tubules forming the cytoskeleton of neurons should be the right place to look for such state reductions.

From Moist to Molmedia and backward

Navigating the contemporary debate on the Vibrational Theory of Olfaction (VTO) as a quantum mechanism, there is a rising hope it can lead to an understanding of the biological world more as ‘energy interchanging in charged playgrounds’ and less as related to molecules’ shape-dependent trades.

This can teleport our understanding of the biological as ‘moist’ to the biological as ‘molist’ crossing scales in complementary moves from the molecules-atoms-bits’ realm of *moistmedia* [1] (Figure 1) to the dry and charged ‘scale free’ panpsychist realm of *molmedia* [8] ruled by quantum traffic.

Mole is defined as the amount of substance containing the same number of discrete entities (ions, atoms, molecules) as the number of atoms in a 12 g sample of pure 12C. Mole, in molmedia, denotes not the quantitative amount of substance but the embedded chemical information. From a quantum mechanics point of view, *the embedded information can be seen as the vibrational information of a chemical entity that influences its possible bonds and its impacts when received by other entities in different scales* – as when a G-protein-coupled receptors (GPCRs) acts like an inbox for messages that inform cells of a chemical event. Media, in molmedia, refers to the *information circulation and exchange processes at elementary entities level* (molecular, atomic and subatomic) within a given system – the chemical is message.

from the immaterial to the re-materialisation of art

Figure 1. Roy Ascott “Moist Chart.” 2000 [1].

Figure 2. “Molmedia Chart” 2021 (by the author).

Exploring the understanding of consciousness from the perspectives discussed and elaborated here, the piece ‘Inhaling Quantum-Consciousness’ (2021-2022), as homage to Hélio Oiticica/Kazimir Malevich and Roy Ascott, bridges the Brazilian Neo-Concrete Movement (1959–61) and contemporary biochemical art. The work dialogues with ISEA 2022 subtheme ‘Human and non-Human’, encapsulating questions related to the quantum nature of life as a cosmological phenomenon that extends far beyond Planet Earth, elaborating on how we become bodies in the world, construct, and gain knowledge from a cross-scales perspective. *The Possibles are quantical.*

‘Inhaling Quantum-Consciousness’ (2021-2022), is the third configuration that the initial artist’s intentions assume in a self-organizing and adaptive creative processes. The work can be understood as an emergence in a process that starts in 2016 with the project “Ulysses Pact: Metagenomic Entanglements”, presented at the 22nd International Symposium on Electronic Art ISEA2016 in Hong Kong, exploring chemical informational trades within human body and between human body and the environment. This understanding of the creative process in multimedia arts as a CAS (Complex Adaptive System) having emergent qualities is fully elaborated in the author’s Ph.D. thesis “Instants of Metamorphosis: The Collective as Process; the Process as System” (available at LABS Leonardo Abstract Service online database). From a deeper understanding, there is the intent of meditating on how the notions of *moistmedia* and *molmedia*, in a spiraling two-way dialogue, transcends multimedia as structural to the poetics.

Art as the Living – the Living as the Chemical

“Art no longer cares to serve the state and religion, it no longer wishes to illustrate the history of manners, it wants to have nothing further to do with the object, as such, and believes that it can exist, in and for itself, without “things” (that is, the “time-tested well-spring of life”).[9]

In a moment we start understanding that even the molecular fragments of dead lactobacilli in a baked bread can influence human behavior when we eat it (figure 3) the concerns about the impacts that dysbiosis can have in mental states rises. Caused by the deprivation of contact with non-urbanized environments abundantly populated by microbes, dysbiosis can be potentialized by the social distancing rules imperative during Covid-19 pandemic.

Figure 3. “Psychobread” (2020-2021) baked using donors’ saliva (containing salivary microbiome samples) mixed with honey following Indigenous Australians’ traditional recipe. Workshop for the UCLA SciArt Summer Institute 2020 and 2021 lead by the author. (Photo by the artist).

In the pre-pandemic version of the series, considering possible integrations and information exchange between above-ground trees’ microbiota and the human respiratory and digestive system, the invitation that was placed to the audience was to inhale samples of trees’ bark microbial populations, welcoming these contaminants inside the human body. The artist’s intentions were to play with instinctive reactions of the audience to consider stimulate a reflection on our vital relation with nature’s microbial molecular information.

Inhaling Consciousness (2019)

Considering the audience reaction in the first time the work was installed in 2019 in Porto, Portugal, for the

Consciousness Reframed exhibition ‘Sentient States: Bio-Mind and Techno-Nature, it was interesting to observe how open to the experience all showed to be. In its very first configuration, the work consisted of a transobject from the appropriation and adaptation of a nebulizer – a medical Cool Mist Inhaler and Accessories (Tubing, Cup, Mask), a reservoir bag and a dust/particles sensor system attached (Arduino, sharp dust sensor, LCD 16x2), having a cork oak bark excerpt inside, extracted by the artist’s uncle from her grandfather lands in the village of Folgoso, Raiva, Portugal.

Figure 4. Inhaling Consciousness (2019) at 21st Consciousness Reframed Conference exhibition “Sentient States: Bio-Mind and Techno-Nature”, 6-9 June 2019, Universidade Católica Portuguesa, Porto, Portugal. (Photo by the artist).

For Inhaling Consciousness (2019) an additional intention was to meditate on how chemical substances, by encapsulating information, can help preserving nature’s heritage, especially in times we face unprecedented deterioration and devastation of planetary ecosystems due to climate change and the impact of humans’ actions.

The Brazilian Neo-Concrete Movement concept of a transobject, relates to the intension of incorporating an ordinary object into an idea, making it part of the genesis of the work without losing its previous structure. The apparatus in this first version of the work, adapted from a medical inhalation breathing system, has an intentional aesthetic and conceptual relation with two references – Hélio Oiticica’s [10] [11] B50 Bólido Saco 2 Olfático, 1967 plastic, rubber and coffee 65,0 x 52,0 x 2,5 cm, and Barbarella (1968) movie’s giant hookah which dispenses ‘Essence of Man’ [12].

Considering the audience openness to the experience – wearing the nebulizer’s mask and breathing from the vapor chamber containing the cork oak tree bark excerpt, inhaling it microbial population molecular information – raises the question of how could the individual suppress the protection against stimulation.

Carefully avoiding depicting Oiticica’s art as something pathological, Inge Hinterwaldner observes that in works such as Oiticica’s “B 50 Bag Bólido 02 Olfatic” “[...] the open arrangement should meet participants ready to open themselves up [...]” [13] The researcher points that, from a psychoanalytical point of view, we can understand “stimulus barrier” as a defense mechanism against stimulation. Hinterwaldner [13] mentions that the understanding brought by Shelley Carson and Jordan Peterson, as an example, consider a possible connection between the personality peculiar openness to experience, or a reduced filtering of stimuli, and creativity.

Inhaling Consciousness (2020)

In its second configuration, the transobject assumes a portable arrangement – as an apparatus one can have in a backpack or bag to ‘inhale’ trees aboveground microbial populations “on the go”, addressing ecological issues from a perspective that can be seen as close to panpsychism.

For these versions of the work, the dust/particles sensor GP2Y1014AU0F was placed inside of the vapor chamber attached to the breathing mask, measuring the total dust density inside of the chamber. As in the first version of the work, the total of particles measured by the sensor includes the concentrations of 1-micron particles, 2.5-micron particles, 10-micron particles. In both versions, the information is visualized in a small LCD attached to an Arduino, bringing together the phrase “inhaling consciousness”.

The series of works places the human body, dissolved in its molecular, atomic and subatomic nature, as central to the poetics. The human body as a quantum-ruled complex and the environment’s chemo-informational inhabitants are melted, amalgamated, entangled as parts of a cross-scale biochemical choreography.

Figure 5: Inhaling Consciousness (2020) in its portable version, presented at ISEA2020 ‘Why Sentience?’ (live on Zoom). (Photo by the artist).

Inhaling Quantum-Consciousness (2021-2022)

From the microbial world and the molecular information, it embodies, we shift to an incursion in the subatomic subtleties of informational exchange referring to the dynamics of vibrational conversations that encapsulates nature’s quantum heritage. Including the bio in all that is chemical – so all is *life* – the invitation to the audience is to enjoy the presence of gentle aerosols produced by water atomization – vaporizing the water contained in twined glass bottles to which is added, for each one of the bottles, the pigments extracted from flowers of two variations of the Ipê – term that refers to seven different tree’s species within the genus *Tabebuia* [14] original of the tropical forests of Central and South

America also known as Golden and Pink Trumpet trees. As in the precedent versions, a dust sensor is attached, and the measurement (number of dispersed particles) is displayed in a small LCD together with the phrase ‘inhaling consciousness’ (Figure 6).

Figure 6: Inhaling Quantum-Consciousness (2021-2022) transobject from the adaptation and subversive use of tragicomic ‘Made in China’ plastic bottle with animals heads on the top through which a straw passes releasing Ipê flowers’ pigment in the vapor produced by the water atomizers attached to the bottles, (Photo by the artist).

Water atomization produces dry fog using a surface acoustic wave transducer (a piezoelectric disk) – the high frequency mechanical vibration produces a cloud of small particles of liquid. The linear mean diameter of the mist was about 5 μm measured in an experiment in which the researcher was testing an atomizer that could be suitable for miniaturization feeding very small amount of mist to control atmospheric conditions.

Ipês massive trees can reach heights of 150 feet, and its flowers became Brazil’s National Flower after the publication of Law no. 6,507, in 1978. Ipê is not an evergreen – the tree drops its leaves before producing large clusters of exuberant flowers in colors that includes [14] white, golden yellow, lavender, bright pink, and red. The name Ipê, of Tupi origin (one of the Brazilian native’s mother languages), means ‘thick bark tree’ [15]. Healing properties are attributed to the Yellow Ipe in popular Brazilian medicine considering the essence of its flowers to have revitalizing properties, balancing internal energy flows in human body.

For “Inhaling Quantum-Consciousness” (2021-2022) the choice was to have yellow and pink Ipê flowers (Figures 7 and 8) collected from trees at the University of Fortaleza’s Campus gardens, where the artist teaches, from September to October 2021 – in a moment the schools start teaching at classrooms after almost 1 year and a half following Covid-19 pandemic restrictions.

Figure 7: extracting the pigment from Yellow Ipê flowers and testing pigmenting water (image by the author).

Figure 8: extracting the pigment for Purple Ipê flowers (image by the author).

The Supremacy of the Chemical

In ‘Inhaling Quantum-Consciousness’ (2021-2022), the transobject has a direct conceptual dialogue with Hélio

Oiticica’s “B22 Glass Bólido 10 Homage to Malevich Gemini 1”, 1965 [16] (Figure 10) not only referring to the fact it reproduces its arrangement (*twinned glass bottles filled with colored liquid, one translucent pink, one translucent yellow*) but relating to the fact the ‘pure pigment’ plays a central role both in Oiticica’s poetics and is structural to ‘Inhaling Quantum-Consciousness’.

Considering the pigments used for the water pigmentation were extracted by the artist from the Ipê flowers, it is interesting to remember that natural pigments used to be the base for oil paints until the 19th century before synthetic pigments were introduced. Nowadays, a crescent community of artists choose to use natural materials as they are environmentally friendly.

Irene Small [17] [18] in an analysis that rather than subscribing to either a center-periphery flow Eurocentric discourse or to a romanticized narrative of indigenous autochthony, considers that the use of raw pigment by Hélio Oiticica and Yves Klein was conditioned by a self-conscious relationship to a history of modernist art [17][18]. She observes that Oiticica’s early works demonstrate a clear engagement with Suprematism [9], even rehearsing Malevich’s stylistic tropes in gouache paintings.

Small observes that [17] [18] Oiticica’s “B22 Bólido Vidro 10 Homage to Malevich, Gemini 1”, 1965 (Figure 10), suggests an intimate artistic dialogue with the aesthetic essence of Russian Suprematism – *twinned glass bottles filled with colored liquid, one transparent blue, one opaque yellow* [17] [18]. Meanwhile, Yves Klein framed his relationship with his avant-garde precursor in an ‘aggressive reversal’ [17] [18] – publishing in 1954 a pamphlet containing color plates supposedly representing a series of his own monochrome paintings, but which simply referred to the miniature tabs of paper themselves and, four years later, he drew a cartoon, labeled “Position of Malevich in relation to me,” depicting the Russian artist anachronistically painting a still life of one of Klein’s own monochromes.

Irene Small [17] [18] points that, when both Oiticica and Klein arrived at the use of raw pigment—Klein with the 1957 Dry Blue Pigment in a Wooden Tray [19] and Oiticica in 1963 with a nested glass sculpture titled B7 Bólido Vidro 1 (Figure 9) — they did so have full awareness of their own position in relation to the historical avant-garde [17] [18].

Figure 9: Hélio Oiticica B7 Bólido Vidro 1 (1963) [20].

In his considerations about Oiticica’s Bólidos or ‘meteors’, Ferreira Gullar points that simple contemplation is not sufficient to reveal the meaning of the works – the action

Abstract

This paper is dedicated to the analysis of two works produced by two contemporary artists, more specifically "*Rachael is not real*" by Matthias Winckelmann and "*Machine Hallucination*", by Refik Anadol, having as convergence point the generative method of production employed in both. The article describes both works using, as theoretical foundation, the most widely accepted definition of Generative Art and reveals nuances of both works that might not be fully comprehended by the current theory. Finally, the article looks at some of the most recent technological advances and their impact on the art world, such as Artificial Intelligence, which have been used to create art, and proposes a reflection on the importance of re-visiting theoretical definitions in order for them to be able to keep up with the technical evolution of art.

Keywords

Generative Art, Generative art theory, Artificial Intelligence, Generative Methods, Artbot

Introduction

Nowadays, visual artists increasingly use technological equipment and unconventional methods that go far beyond cameras and computers to produce images. The technological revolution has expanded the knowledge and visibility of the arts to the world. Artists have found in technology a way to diversify and disseminate their art through mass media, such as TV, photography, cinema, and more recently the Internet.

However, the devices, techniques, and effects used by artists to produce and display their work are not inert. On the contrary, they are embedded with meaning, and present artists with the challenge of overcoming the technological determinism embedded in machines and devices. This is particularly true when it comes to Generative Art.

Generative Art is created when an artist cedes some degree of control to an autonomous system that creates, or is, the art itself. The various implementations of these "generative" processes produce a range of results, from works that are rigidly ordered to those that rely heavily on elements of chance and randomization.

The act of generating a piece apparently taking precedence over the final product is a defining characteristic of this art form. This precedence of process may or may not be discernible in the final work. Many of the works of Generative

Art have a very close relationship with science or technological advances that have become so popular and pervasive in our lives, such as Artificial Intelligence (AI).

Art and science have always been intrinsically linked. This creative, interdisciplinary collaboration has existed since the Western world began to distinguish reason from mysticism. Currently, several research institutions, such as Harvard, Oxford and Sorbonne Universities, Massachusetts Institute of Technology (MIT), University of California at Los Angeles (UCLA), among others, promote projects integrating art and science. The results of this connection are diverse, and have resulted in the creation of artistic works with fully scientific concepts that reach museums and contemporary art galleries with works that range from Data Visualization to the use of AI and robotics.

In this article, we will approach the contemporary art production through the spectrum of Generative Art by analyzing two current works produced by two contemporary artists, more specifically *Rachael is not real*, by Matthias Winckelmann and *Machine Hallucination*, by Refik Anadol. The point of convergence of the analysis is the generative method of production employed in both. The main objective is to contrast the two analyzed works with the theoretical background in order to identify possible points of divergence between the current artistic production and the theoretical definition dedicated to Generative Art.

Theoretical Background

The term "Generative Art" refers to art that was developed entirely or partially by an autonomous system. In this context, an autonomous system is one that is not human and can independently choose aspects of a piece of art that would otherwise demand decisions made by the artist. The human creator may claim that the generating system symbolizes his or her own artistic idea in some circumstances, and that the system takes on the role of creator in others.

Generative Art is a contemporary form of artistic expression in which not necessarily the artwork or final product is at the center, but the process of creation and the underlying ideas. The work is created by processing a procedural invention, i.e. a set of rules created by the artist or a recorded program in the form of, for example, natural language, musical language, binary code or mechanism.

Celestino Soddu [16], one of the pioneers in the that field,

states that Generative Art is not a technology, not just a computer tool, but a way of thinking a possible world, a way of bringing your own creativity to life. According to Soddu, Generative Art constructs possible worlds by creating evolutionary rules that produce events that, if on the one hand are unpredictable and surprising, on the other hand they mirror the identity and the ability to recognize the idea, they are the natural representation of it.

The term “Generative Art” can be seen simply as a reference to the way the art is produced, making no claims about why the art is being produced that way, or even about its content. Generative Art is dissociated from any specific technology, and can be highly complex or not. It is emphasized, therefore, that a system that moves an art practice into the field of Generative Art must be well defined and complete enough to operate autonomously [16].

In the most widely cited theory of Generative Art, Philip Galanter [8] describes generative art systems in the context of complexity theory. In particular, Murray Gell-Mann and Seth Lloyd’s [9] notion of effective complexity is cited. In this view, highly ordered generative art minimizes entropy and allows maximum data compression, and highly disordered generative art maximizes entropy and does not allow significant data compression. Generative Art, in complex terms, combines order and disorder in a manner similar to biological life, and in fact, biologically inspired methods are most often used to create complex Generative Art.

Another effort to understand Generative Art was undertaken by Abraham Moles [14], for whom complexity in art increases with disorder, while its value also increases. The book *Information Theory and Aesthetic Perception* is, as its title suggests, an attempt to apply information theory to the analysis of aesthetic perception, using concepts familiar from communication theory as well as from the psychology of perception. According to Moles the human receiver does not always prefer massive amounts of information. If a greater degree of information (of difference) signifies a possibility of change, a greater degree of intelligibility (of similarity) may promote continuity and safety. It is in this sense that information appears, in Moles, associated with a notion of value. Following this line of thought, one can see that the intelligible is less complex and, therefore, more banal. As the etymology of the word, *interligere*, reminds us, to be intelligible means to establish the maximum number of possible connections. It is, therefore, about the most ordinary or, as Moles assures us, generally speaking, intelligibility varies inversely as information does [14].

Case Studies

Rachael is not real by Matthias Winckelmann

According to Matthias Winckelmann “*Rachael is the world’s first fully automated autonomous 3D design Influencer on Instagram*”¹. *Rachael* is a real time software, or rather a bot, designed by media designer and artist Winckelmann. Since May 2020 this bot has been creating 3D renderings every day and automatically posting these images on the Instagram

¹<https://www.mwinckelmann.com/rachaelisnotreal>

account @rachaellic. *Rachael* is designed to create attractive randomly generated images with the goal of gaining as many followers as possible. With *Rachael*, Winckelmann deconstructs the mechanisms behind social platforms like Instagram and critically examines the consumption of contemporary images on such fast-paced social media platforms.

Figure 1: 3D rendering from the art project *Rachael is not real*. The bot *Rachael* generates an image and publishes on Instagram everyday, based on randomization of various design parameters. © Matthias Winckelmann.

From a technical standpoint, *Rachael* is relatively simple: a series of scripts (algorithms) that automate tasks. The images are generated based on rules pre-established by the artist and the results, although random, follow an aesthetic pattern rigorously defined by the creator. There is no curation or selection of results, nor use of machine learning and AI [7], but there is the use of algorithms in the creation of the system that generates and publishes images [20].

Machine Hallucination by Refik Anadol

Machine Hallucination is a multimedia installation using the largest set of raw data ever assembled for a single work of art, resulting in a cinematic experience derived from representations of urban memories re-imagined by AI [1]. The experience, lasting approximately 30 minutes, was generated using machine learning algorithms trained on over 100 million public domain images and broadcast recordings of the actual sounds of New York City available on social media. The images and sounds are treated by the artist as collective memories and hidden layers of history seen from different perspectives. The final product suggests a mirrored dialogue between the city of the future and the present, performed in the format of a high-tech immersive message, thus pointing the way to an imaginary near future when machine intelligence could

expand the urban inhabitant's ability to dream. The work, an immersive three-dimensional screening projected onto the walls, floors and ceilings of a gallery connotes both night-clubs and nightmares.

Figure 2: *Machine Hallucination*, exhibited at Artechouse NYC in 20218. © Refik Anadol.

Refik Anadol used several algorithms for this project. The main one is called StyleGAN [11], an innovative adversarial network introduced by researchers at graphics processing unit company Nvidia in December 2018 and made public in February 2019. Visitors became participants in the narrative, taking a step into the story rather than simply observing it on the walls, allowing them to intuitively understand the ways in which memory can be experienced spatially. Anadol's work therefore orbits at the threshold of the normally separate domains of architecture, film, and performance art.

Both works in the light of Generative Art theory

Although both works selected for analysis are quite different, there are a series of details that narrow the relationship between them. These details, if analyzed through the spectrum of the most widely accepted theory about Generative Art, aims to answer the research question that guides this article: considering the theoretical definitions about Generative Art and given the similarity of the processes employed in both works analyzed, how can both be classified according to the theory that approaches Generative Art?

So, we will start by observing the similarities between both works from the point of view of their production and not necessarily of their results, especially if we consider that, in Generative Art, the process seems to have as much or more relevance than the result.

The most obvious relationship between the two works focuses on the use of technology to produce art. Although the vast majority of contemporary art production involves the adoption of technology during production or even as an integral part of the final result or performance, the use of technology in art production is not and has never been an absolute and unquestioned demand when it comes to Generative Art. Galanter notes that given the use of visual symmetry, pattern and repetition by the oldest known cultures, Generative Art is as old as the very notion of art as we conceive it [8].

Although Winckelmann and Anadol make exhaustive use of different types of technology and seek to break new fron-

tiers in their respective fields, both go beyond technology by raising questions and proposing discussions. This is another characteristic that brings them both together. Winckelmann defines *Rachael Lery* as the world's first autonomous 3D design Influencer. As if this definition was not strange enough, the artist goes further by stating that he made a point of not revealing publicly that *Rachael* was in fact a bot who published visually appealing works on a daily basis. This, in turn, never stopped thousands of people from following Rachael's profile and liking her daily posts. For Winckelmann, what is at discussion is precisely the dichotomy between creation and value. More specifically, what constitutes creative value?

The reflection proposed by the artist is not only valid, but current and important, especially for the means of consumption adopted by the artist and that, by the way, is an integral part of the work: the social media. More specifically, Instagram, a type of social media designed for immediate and rapid consumption of images, something already preconceived decades ago by Susan Sontag in her seminal book "On Photography" [17]. Sontag stated that "today everything exists to end in a photograph" and one of the most tangible materializations of this statement is precisely Instagram. The artist's provocation refers not only to the impulse to "enjoy" images without any appeal or depth, but also and above all the act that the very space where the work is displayed and consumed compels people to do so in an almost mechanical way. The images, in turn, have an aesthetic structure that, according to the artist, represent visual languages popular on the platform [20].

Refik Anadol, on the other hand, proposes a series of reflections on the potential and limits of technologies such as AI. The artist creates an art form that uses data as a primary element and sculpts it to form a sequence of fluid and hypnotic images exploring the concept of hallucination, memory, and the tension between humans and machines. Complex images, with deep and personal meaning, grouped, overlaid and presented almost inseparably from one another, as in a kind of pointillism ruled by AI. The question that orbits the artist's work and more specifically *Machine Hallucination* is: if machines can learn, then can they dream or hallucinate? Anyone with the slightest knowledge of how AI works knows that the answer to both questions is categorically and simply: no. Anadol knows this too, but still there is a tendency, even if speculative, that machines can actually create an output that looks like a dream or a hallucination based on memories that we give it.

For Anadol, there is a remarkable similarity in how humans operate. Human experiences and memories are a form of input, while dreams and hallucinations can be understood as outputs. Starting from this concept, the artist builds intricate sequences of images, sometimes recognizable, sometimes absolutely surreal, of public spaces having as input, collective memories (i.e. photos, videos, sounds) and as output, the result of the application of machine learning algorithms. Here there is a clear contradiction between what is real and unreal, or hallucination, what is physical and what is virtual. This virtual space, this hallucination created by the machine, can be appreciated, although not often understood by the audience. The virtual transforms the fragments created by the human

imagination into a constructed universe, potentially unlimited, but restricted to the set of human perceptions at a given moment in time. The same effect is perceived if we compare a work of art, or photography, to cinema, which amplifies, in the connection of senses and emotions, the universe imagined by the receiver of the message. At this point, Anadol's work gives the viewer a synaesthetic experience by combining cinema, painting, and architecture in an absolutely innovative and immersive way. However, when we take a closer look at the work and its generative production process, some details help us understand the role of the technologies applied in its production. On his website, Anadol reveals a little about how each algorithm was applied without giving more details about what exactly each one does, although it is clear that there are a series of them performing very distinct functions such as capturing images from the internet, grouping images, generating new images from parts of existing images, etc. The most remarkable thing is not exactly the technology employed, which is open source and was not developed by the artist, but his mechanistic definition of dreams or hallucinations: data enters, memories are formed, dreams come out. Perhaps the choice for extreme simplification reflects a technical limitation in reproducing dreams (or hallucinations), something still impossible for machines. However, the detail to notice is the abundance of preexisting rules to operate the algorithms, most of them requiring a massive amount of data for previous training, which denotes some degree of control by the artist.

This brings us to another similarity between both works: the definition of rules defined by the artist, even if the system itself has autonomy to generate results. According to Galanter [8], rule-based art is not necessarily synonymous of Generative Art, as for example, the case of an artwork generated from the imposition of restriction rules that prevent the use of certain colors or shapes. According to the author, this kind of art is not generative because the restriction rules are not constructive. That is, by themselves they do not state what should be done, only what cannot be done. Here the theory postulated by Galanter creates rules, but also exceptions that can make such a view limiting when it comes to understanding current art production, even if such postulates are still able to cover much of the current Generative Art production.

In Winckelmann's case, at a first glance, there seems to be no restrictive rules or anything that speaks against the generative nature of the work. What happens is exactly the opposite. There is a system (algorithm) that automates the task of generating and publishing the images, which in turn are generated based on pre-established rules. These rules do not seem to be limiting, given the randomness and diversity of the results, which follow an aesthetic pattern rigorously defined by the creator. There is no curatorship or selection of results, but there is a hegemony in the compositions, which although random, follow a pattern that respects rules such as limits, grids, colors, lighting and symmetry. If we consider that the artist's intervention in a first moment demanded the establishment of design and composition rules, and these rules are not clear to anyone outside the artist's production circle, we can suspect that the process is not generative if we consider Galanter's theory, even if there are several elements advocated by the

author. To get an idea of how complex and blurry is the line between Generative Art and other art forms, Galanter cites the case of Jackson Pollock, whose best known works are apparently random. According to Galanter, due to the lack of introduction of means outside himself, these works cannot be considered generative. No movement made by the artist to create his works can be truly generative, although it has been proven that the artist's paint marks are fractal in nature due to Pollock's in-depth learning [19]. In this way, the result of the work is premeditated and calculated rather than randomly generated. At this point it can be said that Winckelmann's work is indeed generative, as it employs various randomization techniques, tracking methods to evaluate surface areas, and general probabilities of spawning. Due to its algorithmic nature, Rachael is able to generate an infinite number of images, each with a unique combination of shapes and colors based not only on rules of design and composition, but also on weighted randomization of different parameters that regulate the generation of the images.

An example that helps to clearly understand a generative work is the sequence of paintings by Harold Cohen [18], materialized through AARON, an AI painter created in 1973 by the artist, coded in a software that autonomously develops several paintings [5]. The result are prints with real fabric paints (instead of pixels), in which the artist "teaches" the machine to mix colors and compositions by providing it with imagination (input) that allowed it to paint human figures or still lifes without any visual references or human intervention. The autonomy of the system makes clear the main characteristic of Generative Art, although there are rules and, in this case, "learning" of the machine.

AARON is very reminiscent of Winckelmann's *Rachael* in that it is a machine that creates, but it is also reminiscent of Anadol's work in that it is a machine that learns to create. The use of AI as a dominant part of its construction is not just a detail, but a fundamental part to be observed.

Combining AI and art may sound like the ultimate embodiment of futurism. Having machines producing art was most likely the dream of many technology enthusiasts centuries ago, and right now, part of this dream is materializing. In fact, science fiction has been so far ahead of the actual evolution that concepts such as post-digital art may already seem a bit dated. Given its penetration in the arts and its impact, one can consider AI from two perspectives: one is how it serves as a tool to enhance art that extends to algorithms, being able to create art objects autonomously, and the other, how artists contemplate and choose to represent a society where AI will dominate more and more venues, both for the better and for the worse of society.

With *Machine Hallucinations* Anadol seems to try to propose both discussions at once. Anadol takes as a starting point the concept of a type of shared intelligence that arises from the collaboration of many individuals in their diversity, originated by the habit of registering and sharing experiences, a concept known as Collective Intelligence [13], and by the way, much older than any form of technology. This intelligence is distributed everywhere, in which all the knowledge is in humanity and raised to another level with the use, by the artist, of AI. The fundamental concept behind Collective In-

telligence can be summed up by the maxim that no one knows everything, but everyone knows something. Anadol's work goes beyond and seems to propose a new dimension to this Collective Intelligence, adding to the universe of data that feeds the experiment a kind of cognitive cartography, with new experiences generated not only by people, but also by algorithms.

These algorithms reconstruct urban memories using different perspectives from individual points of view, but also reimagine and build new images from previous knowledge, just as humans do when acquiring new experiences from the experiences of others. The use of various algorithms in the construction of the system and how the final experience is generated are evidence of some of the main characteristics advocated by Generative Art. In the case of *Machine Hallucinations*, there is not only the use of machine learning techniques for the selection, filtering and clustering of images, but also the generation of new images from the data, used here as raw material for the construction of landscapes that sometimes remind real places, sometimes take the audience to diatopic worlds. The use of algorithms by itself does not determine that the art is, in fact, generative. That is why it is important to take a step back and try to understand how the literature understands the use of several more recent techniques of artistic production and if, in fact, such techniques that propose to generate art can in fact be comprehended by the current theoretical framework.

There is a neuralgic point in the theory that deals with Generative Art and refers to the digital art, more specifically the use of computers. Margaret Boden and Ernest Edmonds [2] agree that generative art need not be restricted to art made using computers, and that some rule-based art is not generative. They have gone further and proposed a technical vocabulary that includes Ele-art (electronic art), C-art (computer art), D-art (digital art), CA-art (computer-aided art), G-art (generative art), CG-art (computer-based generative art), Evo-art (evolution-based art), R-art (robotic art), I-art (interactive art), CI-art (computer-based digital art), and VR-art (virtual reality art).

The problem with such definitions is precisely the attempt to distinguish artistic production based solely and exclusively upon technology, that is, the medium or support, and not necessarily upon the process of artistic production, which, by the way, takes precedence over the result, medium or support [8]. And none of them seems to be good enough to fully describe the works of Matthias Winckelmann and Refik Anadol, not only because they are works that blur the boundaries between man and machine, but also because they have characteristics where sometimes the artist and sometimes the machine play roles at different levels and intensity. Another problem with this approach lies in the inexorable fact that technologies were made to be overcome and will fatally become obsolete, as will the definitions that are based on such technologies.

Conclusion

Since Marcel Duchamp's claim that a porcelain urinal is a work of art a century ago, the definition of art has become elusive to the point that anything, and consequently nothing,

can be considered art. What does it mean when a data scientist develops an algorithm that allegedly creates art? How can we even judge something that we cannot effectively define? It is becoming increasingly difficult to avoid the question that most people realize can have a hugely painful answer: what does humanity entail and to what extent is it replaceable? What does it mean to be human now? Is the technology capable of replacing humans when it comes to creating art in the same way that it already replaces manual labor?

As uncomfortable as these questions may seem, they need to be asked, and this is the ideal moment to do so given the technical development before us that seems to make clear the need for a re-thinking of our artistic order and classification. Aesthetic rules can be codified rigidly, helping us to decide what art is and how to classify it, which is something our predecessors were already able to clearly articulate, but they cannot be immutable, especially if we consider the technical advances and their impacts on artistic production.

The reason for the urgency in revising theoretical definitions can be explained by impressive examples, such as *Edmond de Belamy*, a rather dark portrait of a man painted in a blurred style. The work is part of a set of generative images called *La Famille de Belamy*, developed by the art collective *Obvious*, which was the first artificial painting created by the AI that sold on the Christie's auction house in 2018 for USD 432,500 [3]. In another impressive example *Beeple*, artistic name of Mike Winkelmann, has achieved an incredible accomplishment: in two months he has achieved the status of the third most expensive artist, second only to big stars such as Jaspers Johns, Gerhard Richter, Damien Hirst and Jeff Koons, after having sold at Christie's auction house a set of 5,000 images for USD 69,346,250.00. The sum represents the third highest amount ever paid for a work of art by a living artist [12].

The fundamental difference between Mike Winkelmann, Matthias Winckelmann and Refik Anadol lies in the fact that the work of the first has nothing at all generative about it, but the body of work is not something that needs no analysis or should be ignored. A Times critic accuses the artist of "violently eradicating human values" and of "childish amusement". To defend him, Noah Davis, a Christie's expert, has put his reputation on the line by comparing him to the Duchamp readymades [4].

Anyone minimally familiar with Duchamp's work will know that the comparison seems rushed and difficult to understand. If we examine the procedures, we find no features that could support any proximity between *Beeple's* collage and the readymades. When Duchamp created the readymades, he did so in the condition of a recognized artist, who participated and knew deeply the art system, contributing to the main debates and art movements of his time. *Beeple*, on the other hand, is a newcomer in the art world, who undoubtedly performed a remarkable achievement by reaching the top in just two months, participating in an event led by the art market - and the new financial context - promoted by cryptocurrencies.

Analyzing the procedural and aesthetic side, there is no possible comparison between both. The aesthetic neutrality in the choice of the pieces that compose the readymades, as well as the absence of manufacturing by the artist, are the

main rules conceived by the French artist. The distance between the readymades and any of the images from the work *Everydays: The First 5000 Days* lies precisely in the fact that, to exist, the first implies the appropriation of an industrial object, while each of the pieces that make up Beeple's assemblage is a virtuoso image, carefully crafted by the artist's hand. The presumably kitsch aesthetic that guides Beeple's work sharply contrasts with the aesthetic indifference in the choice of the pieces that make up the readymades. The confusion in the classification of the artwork is something that, once again, reinforces the need for a better classification and interpretation of what we are producing in terms of art at this time.

However, even if Beeple does not produce Generative Art and seems, therefore, out of the scope of analysis of this paper, it is important to analyze what is behind his remarkable achievement. The project, at first sight without major consequences, of making a drawing every day, and posting it every day on Instagram reveals, above all, the desire for dissemination and recognition, therefore, a communication strategy of Winkelmann. His success and recognition are absolutely undeniable, given that it is necessary to communicate well to justify the more than 2 million followers on his profile. Deleuze, in a lecture about cinema, states that "art has nothing to do with communication". On the other hand, he says, "there is a fundamental affinity between the work of art and the act of resistance" [6].

One can observe that from the moment the 5,000 thousand images were gathered in a single file, forming, by juxtaposition, an irregular grid, a new concept, unnoticed until then, becomes evident in Beeple's project: time. Deleuze states that what is embedded, in the creative activity, is the constitution of space-times. Beeple has shown incredible obstinacy in keeping alive a project in progress, day after day, for more than fourteen years.

On Instagram, the images cause impact, but the distraction that social media provokes due to its superficial nature and ephemeral interactions, end up covering up an important detail: the time and effort of the human behind the project. Both Mark Winkelmann and Matthias Winkelmann use social media, but their processes, although different, result in basically the same type of outcome, which ultimately has its intensity or effectiveness reduced to mere "likes". However, art is more than patterns created to capture and awaken the interest of a potential audience, and in this aspect, the works of the two artists analyzed in this paper are close. Both Matthias Winkelmann and Refik Anadol use patterns and automatization, which can result in images without any connotation or depth of content. Often the overlapping of elements and the speed with which these elements are repeated eliminates any possibility of comprehension or absorption by the audience.

The question that should really be asked has little to do with any process or technology. After all, what should most interest those who study contemporary art is precisely how relevant is the work created by a machine? What would be the perception of humans about what the machine is capable of creating and would the art created by a machine be more relevant than the art created by humans?

Some studies help to understand a little about people's per-

ception of art and the artistic value of works created by machines and humans. Hong and Curran [10] published a study in which they subjected participants (n = 288) to two types of artworks created by AI and by humans. After viewing images of six works of art, participants were asked to rate their artistic value using a scale commonly employed among art professionals. The study concluded that artworks created by humans and AI were not considered equivalent in their artistic value. In another study, Ragot et al. [15] present an experiment with 565 participants invited to evaluate paintings that were created by humans or AI and rate them on four dimensions: liking, perceived beauty, novelty, and meaning. The paintings perceived to be created by humans are rated significantly higher than those perceived to be made by AI.

What both studies show is that the perception of value when comparing something created by a machine or by humans differs radically, and at the same time, even with all the technical advances we are experiencing, reveals that the artist has not only responsibility, but also recognition of his importance and, consequently, relevance of his work.

Technological development is a perpetual evolution since the invention of the wheel and is designed to go on forever. Most, if not all, art forms include aspects of technology and always have, since art and technology have something in common: the need to renovate, to discover limits and overcome them. However, the role of the artist should be to control technology, not the other way around, since technology should remain an extension of us.

But one thing is already clear: AI will permanently change the way we create, curate, absorb and mediate art, and will certainly permeate the philosophical discussion about what and who really is the creator.

Abstract

This paper presents the software autonomX that is designed for intuitive artistic creation with complex dynamical systems. After a discussion on artistic and technical precedents, the paper demonstrates how autonomX responds to the necessities of artists thanks to an original framework of signals, generators, and drawing. An overview of the software is given. Finally, we discuss case studies of artistic practice with complex systems that led to the development autonomX and the experience of workshop participants discovering the software for the first time.

Keywords

Complex systems, machine agency, software instrument, artificial life, cellular automata, neural networks, temporal dynamics, lighting design.

Introduction

autonomX is an “open-source desktop application [that] allows multimedia artists and students to easily and quickly experiment with lifelike processes via a graphical interface in order to generate dynamic, emergent and self-organizing patterns and output these patterns via OSC to control light, sound, video, or even robots in real time” [1].

The article begins by presenting the background that motivated the production of autonomX. In particular, we describe some histories of artistic and lighting practice involving stochastic systems and the role of vitality in the time-based arts.

We follow with the presentation of the three core design paradigms of autonomX: *generator*, *signal*, and *drawing*. The *generators* are the algorithmic encapsulation of complex dynamical systems (systems that model the temporal evolution of a deterministic set of parameters) in a format that gives rapid and intuitive access to their parameters, without resorting to coding, and visualizes the inner workings of these algorithms on a 2-dimensional lattice. The generators send and receive time varying *signals*

from the implemented algorithms in real time, making the system appropriate for temporal expression and interaction with any computer-driven media. The manipulation of signals is made intuitive to the user by *drawing* directly on the visualization lattice so that they can easily specify which parts of the system serve as signal inputs and outputs.

The article then gives an overview presentation of the current version of the software by discussing the main elements of its interface.

Finally, we offer a discussion on concrete artistic creations with complex systems that led to the development of autonomX and on the results of an online workshop held during ISEA 2020 in which participants discovered the first prototype of the software.

Background

The background of the project derives from a three-year research project called “Dynamic Light,” funded by the Fonds de Recherche du Québec Société et Culture (FRQSC). The goal of the Dynamic Light Project is to think about light and lighting design like we think about music: as the composition of complex and dynamic patterns, rhythms, phrases, and gestures that take place over time. The project is inspired by the work of the 20th century Greek-French composer Iannis Xenakis who argued in the 1960s that due to new technologies “We understand that a new art of light is at our doorsteps, one that is not painting, nor frescos, nor theater, nor ballet, nor opera” because “light occupies time, for its effect depends on rhythm and duration while music shapes space.” [2]

Despite Xenakis’s proposal, the history of lighting design since the introduction of gas and later, electrical lighting into the theater at the end of the 19th century, has been seen to “tremendously modify the perception of space” [3]. Theater artists like Adolph Appia and Gordon Craig who were seen as the first “lighting designers” working with new technologies like electric lighting focused predominantly on

the manner in which light could emphasize “the plasticity of the performers and their space” (Appia). Later, theater lighting designers such as David Belasco focused on light as images, in particular, how to use different lighting instruments to create spatial atmospheres that evoked specific dramatic moods. This tradition of light seen as sculptural and plastic is one that has carried into the work of theater scenographers such as Josef Svoboda (what he termed “psychoplastic space”) and Robert Wilson in the later 20th century.

At the same time, despite the rapid development of new hardware technologies (LEDs, computer controlled moving heads and lighting consoles) and networking protocols that incorporate real time sensor data (ARTNET, ACN), the conceptual-technical paradigm of lighting control in the performing arts is still situated in the 1950-60s: a lighting desk, a series of dimmers which control a series of individual instruments and a “cue-based” system of fixed instruments that are organized by a set of cues that follow dramatic action on stage. Lighting desks, while increasingly sophisticated in terms of microprocessor control and storage, are still principally based on these cue control/scene paradigms and few (if any) allow real-time input (or influence) from data derived from the exterior world. Moreover, the programming of sophisticated temporal behaviors is restricted to standard cookie-cutter tricks such as “chasing” (sequencing of one light after the other in a series), bumping (flashing) or similar. Indeed, despite the rapid evolution of LEDs which produce a “time response” that is closer to human visual perception than any previous lighting instrument, it is nearly impossible to expressively compose with light in and over time with existing tools and current control technologies.

The development of the autonomX software is thus guided by two principles: (1) the fact that dynamics—the production of shifting, temporal changing rhythms, motions and gestures—creates strong emotional “vitality affects,” (Stern) that indicate the manifestation of being alive and (2) new technological advances in hardware (LEDs, sensors) and computational paradigms from machine learning and simulation-based complex systems introduce new possibilities of working with time as a material in lighting design or media composition, in general.

Conceptually, autonomX is guided by the need to produce what psychiatrist Daniel Stern called “time profiles” or “temporal contours” without the need to explicitly produce such behaviors. Stern, an American psychiatrist based in Switzerland till the end of his life, had focused on what he called dynamic subjective experience and vitality, as it was revealed in psychotherapy and the arts. As Stern argued, the “time-based arts, namely music, dance, theater and cinema move us by the expressions of vitality that resonate in us” [4]. At the same time, such “vitality affects” are not only reserved for humans. The dynamic flows of time in objects and processes like light, sound, and vibration outside of us also sweep us up into dynamic moments of intensity.

Another conceptual underpinning to the autonomX software is Simon Penny’s argument that an “aesthetic of

behavior” marks the difference between contemporary artworks that can respond dynamically to their environment versus traditional static forms that remain fixed in time. Such an aesthetic emerges from the “possibility of cultural interaction with machine systems” [5]. Penny’s argument applied to light directly challenges the mainly object-based, static histories of what has been called “light art” [6] in the visual arts. Artists such as James Turrell, Robert Irwin, Maria Nordman, Doug Wheeler, Dan Flavin, Otto Piene and more recently, Rosalie (aka Gudrun Müller) and Olafur Eliasson (among others) have mainly focused on the spatial or volumetric dynamics of light—what Turrell called “sensing space.” While time did enter light art through the work of Thomas Wilfried, Moholy-Nagy and later Nicolas Schoffer, Heinz Mack, Otto Piene and the ZERO group as well as collectives such as Gruppo T [7,8], the vast majority of this work was linked to either early 20th century cinema or kinetic sculpture which embedded light into and as an object but didn’t focus on complex temporal patterns within the lighting fixture or environment itself. At the same time, as Penny references the histories of the media arts, while new technologies from computer science such as Alife, agent-based control and more limited machine learning have historically been used in artistic works involving robotics and machines (Kac), or computer-generated animations on screens (Ray, Sims, OpenEndedGroup, Memo Akten) these techniques are just being recently deployed in lighting design.

autonomX Framework

autonomX emerges from the “Dynamic Light” research project to propose a practical tool enabling artists, students, and researchers to experiment with the temporal dimension of cutting-edge scientific computational processes from areas such as Artificial Life and machine learning, and to use these processes to express their “vitality” through light and, more generally, any computationally controlled media. As the “Dynamic Light” project engages with both academic research and concrete artistic production, autonomX materializes the theoretical and practical knowledge developed during the research project in the form of an open source desktop application.

autonomX is guided by the fact that temporal dynamics create strong “vitality affects” to be experienced sensibly [3], and that new technological advances in computational paradigms, in particular Artificial Life and machine learning, introduce new ways of working with time, in lighting as well as other media.

The computational techniques that autonomX is concerned with are part of the family of complex systems. That is to say, temporally dynamic systems composed of large arrays of interacting elements that generate emergent global behaviors out of local interactions. Such systems which are found in a wide variety of natural and physical phenomena, from the motion of celestial bodies, the division of cells, the firing of biological neurons, or the growth of human and animal populations, possess autonomous, self-

organizing, and emergent properties that generate behaviors that are sometimes impossible to predict from the understanding of the initial state of the system. In programming terms, the behaviors expressed by such complex systems escape their reduction to code and ask us to develop new methodologies and instruments responding to the challenge posed by computation systems that escape human prediction and understanding.

To this end, autonomX aims at fostering an approach to complex systems—rooted in experimentation and observation by providing an intuitive and stable software instrument that (1) encourages the manipulation of parameters and expression of temporal dynamics in different media—as opposed to spending time writing, compiling, and debugging code—, and (2) is adapted to the constraints of artistic production—that includes a seamless integration with other software, run-time stability, and simplicity of manipulation.

autonomX proposes an original framework of *generators*, *signals*, and *drawing*. This framework is directly inspired from well-established media practices, in particular those of sound and video synthesis, with the aim to maintain a form of familiarity and to simplify the entry in the world of complex systems.

Generators

The core of autonomX consists in its *generators*, “a grid-based wrapper for an AI and/or Alife algorithm” [9]. Those generators are defined by the different algorithms they encapsulate; as of release 1.0, a Spiking Neural Network, Wolfram Cellular Automata, and John Conway’s Game of Life. The generators provide a 2-dimension visualization of the algorithm, give access to its parameters, and process the input and output signals that enable the communication between the algorithm and other multimedia software.

The *generators* are inspired from sound and video synthesis practices in which modules such as oscillators, filters, and time-based sequencers can be manipulated intuitively thanks to carefully designed expressive parameters. Similarly, autonomX’s generators enable the manipulation of specific parameters relevant to the temporal behavior of the algorithms. This choice of design aims at freeing the user from programming considerations to instead focus on the expressive qualities of the algorithmic material.

Signals

autonomX frames lifelike computer processes around the concept of *signals*, that is to say time varying information that is extracted from and fed back into the algorithms.

The processes autonomX is designed for are complex dynamical systems, which are temporally evolving systems which consist of large arrays of interacting elements that generate global, sometimes unpredictable behaviors out of local interaction. Despite a history of musical composition with dynamic, complex, and chaotic systems that express their temporal dynamics through sound synthesis [10], most artistic applications focus on the rendering of aesthetic visualizations of such systems [11]. More recently, the *Wekinator* software proposed an approach to live artistic performance using neural networks by placing machine learning processes within a framework focused on intuitive training and easy communication with other software through standard Open Sound Control (OSC) protocols [12].

autonomX’s *signal* paradigm moves away from the visualization of the system at the global scale, frequently in the form of 2D or 3D visualization software, and toward a paradigm of time varying signals sampled from and fed into different parts the system, from the local activity of a single element to the mean global activity of the system and everything in between. These signals can then communicate with other software through the OSC protocol.

By preferring an artistic framework of time varying signals inspired from computer music contexts, autonomX is particularly suited for exploring real-time interactions with performers, public, and environments, and for the expression of temporal dynamics within multimodal media environments.

Drawing

The generation and distribution of signals from and to the generators is made intuitive thanks to a principle of *drawing*, which involves the manual drawing of rectangular shapes over the visualization lattice in order to specify the cells that will be sampled and stimulated.

Since complex systems consist of large arrays of interconnected elements that possess self-organizing and emergent properties, their visualization on a 2-dimension lattice aims to display the relations between local interactions and global activity that are characteristic of such systems. The principle of *drawing* that is core to the manipulation of autonomX enables users to intuitively experiment with the various scales of complex systems, from local to global activities. By drawing the regions of the system that sample output signals and the ones that receive input signals, they can creatively interact with the emergent properties of the algorithms.

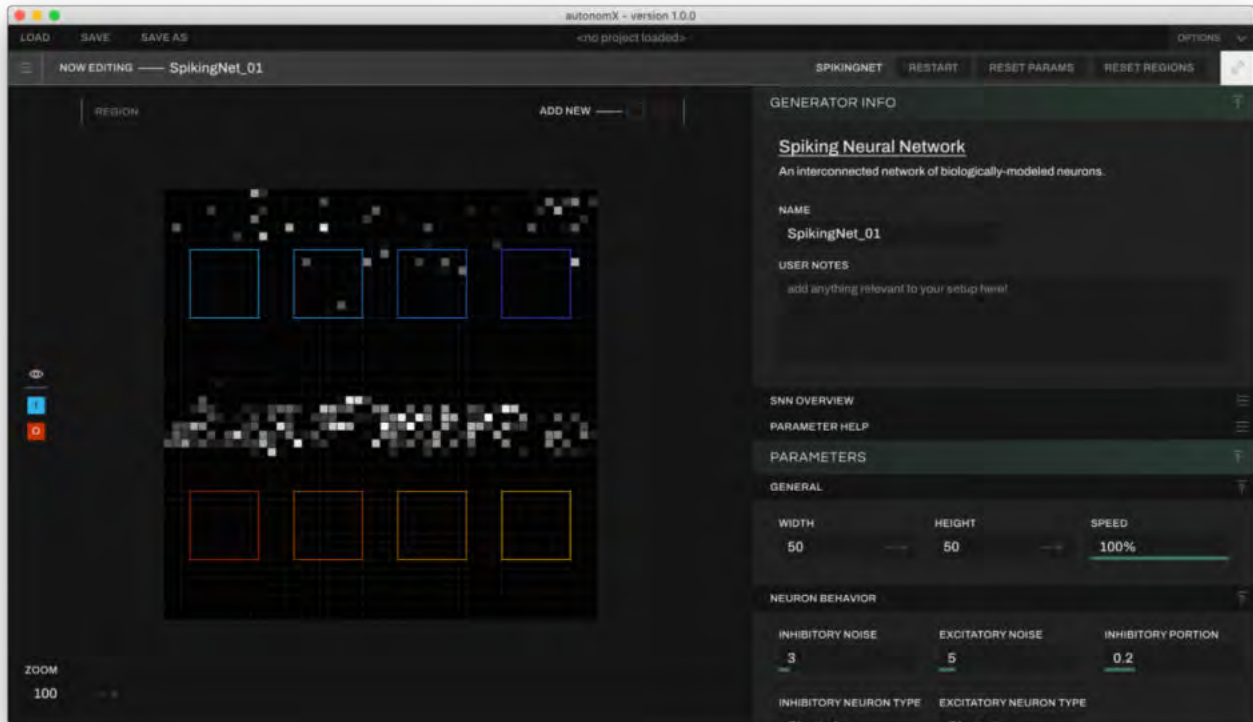

Figure 1. autonomX’s interface. The generator currently selected is a Spiking Neural Network. The different parameters of the generator are visible in the right side’s *generator info* column.

Software Description

The following section describes the functioning of autonomX through an overview of its interface and main functions. We describe how the generator, signal, and drawing concepts of the software are concretely implemented and accessible to the user. The following description focuses on the framework of the software and does not describe the individual algorithms encapsulated in the generators¹.

Interface

autonomX’s interface (Figure 1) centers around a 2-dimension visualization lattice that displays the real-time activity of the generators.

To the left, a collapsible panel gives access to the list of generators currently running in the software (Figure 2). An *add* and *delete* button allows users to freely add generators and choose their type, or delete existing ones.

To the right, a panel gives access to the parameters of the generator currently selected. While some parameters are common to every generator, the majority are specific to each generator (that is, algorithm) type.

Finally, at the top of the software, a horizontal menu gives access to the save and load functions as well as the parameters of the OSC engine of autonomX.

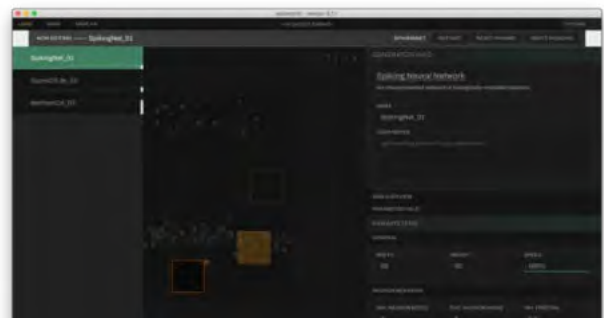

Figure 2. autonomX’s left side collapsible panel serves to add and delete generators.

¹ The source code of autonomX, alongside its documentation and guideline for the implementation of new algorithms, can be found on lab Xmodal’s github: <https://github.com/Xmodal>.

Generator Parameters

The right-side column, *generator info*, of the software is dedicated to the different parameters of the generators. They consist of two kinds of parameters: *general* ones that correspond to attributes common to all generators, and *specific* ones that correspond to the specific algorithm implemented in the generator.

The *general* parameters consist in the *height* and *width* of the 2-dimension rendering lattice and the *speed* at which the generator runs. Three *restart*, *reset parameters*, and *reset regions* functions are also present. Those parameters and functions are present for every generator.

All other parameters are specific to each generator type and vary depending on the algorithm they implement. For example, they can control the *pattern type* of Conway's Game of Life (Figure 3), or the *neuron type* and *inhibitory portion* of a Spiking Neural Network (Figure 1).

The different parameters allow users to interact in real time with the algorithms without having to intervene in their code.

Figure 3. autonomX running a Conway's Game of Life generator.

Lattice Visualization

The 2-dimension lattice that occupies most of autonomX's interface real estate serves a dual purpose.

First, the lattice displays the activity of the generator's algorithm in real time. The dimension of the lattice is controlled by the *height* and *width* parameters and is specific to each running generator.

Second, the lattice serves as the background on which the input and output regions can be drawn. The direct superposition of the input and output regions on the visualization lattice allows the user to intuitively configure how the input and output signals relate to the algorithms.

Input and Output

The input and output regions consist of colored rectangles, blue for the inputs and orange for the outputs, that can be added, deleted, moved, and resized at will by the user (Figure 4).

The output signals are sampled out of the lattice cells situated inside the orange output regions. Each sampled region generates a unidimensional stream of float numbers that corresponds to the mean average activity of all the cells present in the region. The user can sample any part of the system by choosing the size and position of each region, from the activity of a single element to the local activity of a few cells or the global activity of the whole system.

Each input region receives a signal consisting of a unidimensional stream of float numbers that it distributes to the cells it covers. By default, the signal received is uniformly added to the current values of all the cells.

The default behavior of the input and output can be rewritten in the implementation of a generator so that a more appropriate or original adaptation of the signal framework can be proposed by a contributing programmer.

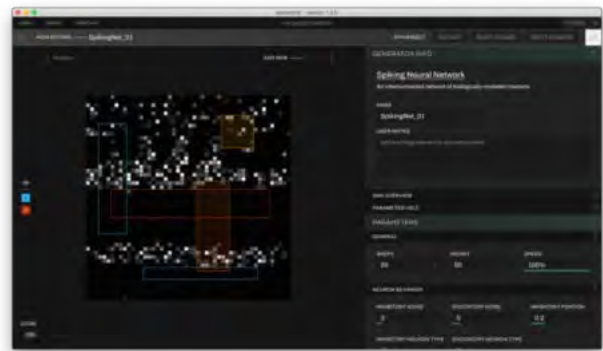

Figure 4. Multiple input and output regions of different size and location arranged by a user over a Spiking Neural Network generator.

OSC

Each input, output, and parameter of the generators can communicate and be controlled through the Open Sound Control (OSC) protocol [13]. This choice was made to allow a flexible integration of autonomX within a range of multimedia software environments (Processing, Open Frameworks, Touch Designer, Max/MSP) used by artists, designers and those working in the area of creative computing.

The OSC signature mirrors the software interface in a consistent fashion and all signals are normalized so that autonomX can run as a stand-alone application and communicate with multimedia applications supporting OSC.

Discussion

The following section briefly discusses the genesis and necessity of the autonomX software, its reception by workshop participants, its limitations, and its future development orientations.

Artistic Practice with Complex Systems

autonomX is one of the outcomes of the research-creation project Dynamic Light that inquiries into practices of lighting design that employ cutting edge computing technologies for the expression of temporal behaviors with light. One of the motivations of the project was to explore how to produce new forms of temporal action (and hence, new “vitality affects”) that currently would be impossible to code as individual events in standard lighting control systems. Moreover, while such systems are routinely coded in higher-level software languages for a wide range of scientific applications, such programming is extremely difficult for those without the sufficient mathematical knowledge of such systems. In other words, our need to harness the types of temporal actions that are generated by complex systems, ranging from so-called “periodic” (occurring at regular intervals) to what is called in physics “quasi-periodic” behaviors (oscillating between periodic and unpredictable) for driving the actions of light for expressly aesthetic/artistic purposes (for example, exploring the perceptual limits of patterns or constructing systems that oscillate between order and disorder for observers) was one of the main motivating factors for the autonomX software development.

From an artistic perspective, the dynamic light project produced artistic outcomes that employed various complex dynamical systems (i.e., Spiking Neural Networks, genetic algorithms) as well as unsupervised machine learning in order to produce complex patterns in light. For example, the earliest artistic result was a large-scale commission called *Totem*² which resulted in an autonomous light sculpture that demonstrated the temporal evolution of artificial neural networks in relation to their environment. A second set of projects also sought to harness Spiking Neural Networks (essentially, a mathematical model of firing neurons) as co-partners in a series of performance works. *SNN #1: The Speed of Thought Itself*³ is a performance for two human performers and eight Spiking Neural Networks interacting with one another to reenact a series of 19th century mental chronometry experiments dating back to the work of the Dutch psychologist Franciscus Donders. A second work using spiking neuron models entitled *SNN #2: Light/Space/Prop*⁴ was a light performance for a network of 15 Spiking Neural Networks that, through their self-organization, could control a series of moving head lighting instruments in a public space (Barcelona). *SNN #2* aimed to reconstruct Laszlo Moholy-Nagy’s 1924 light prop for an electric stage but at city scale, by creating a choreography of light in public space. As these projects all focused on creating performative and agential lighting systems capable

of exhibiting a wide range of temporal expressions, the subsequent development of autonomX was directly built on the demand for a set of expressive tools that could produce a rich range of behaviors. In other words, the forms of technical practice demanded by these artistic projects (shown in high-profile institutions and festivals in Europe) and the production experience gained by working with complex dynamical systems during the creation of those artworks directly led to the development of autonomX.

From concrete production conditions, certain ways of understanding the relationship between technical and artistic practice quickly became apparent. First, the development process of each work revealed that the emergent *behaviors* generated by Spiking Neural Networks, Genetic Algorithms, and machine learning techniques cannot be deduced from their algorithmic implementation alone. On the contrary, each intervention in the programming of complex systems requires extensive periods of observation that reveal their transformations over different time scales, from a few seconds to minutes and hours, in order to stay attuned to their temporal modulations and develop a perceptual and sensorial understanding of the system’s configuration [14].

Second, the production of the artistic works demonstrated that the constraint of writing and compiling complex software code that is demanded by the implementation of such systems steals time away from observing and experiencing their activity (as both artists and spectators) and from developing meaningful interactions with the rest of the artwork ensemble, in particular with sensing and sequencing systems.

Third, the temporal and scalar characteristics that are produced by complex systems revealed that injecting and sampling temporal signals to and from parts of a system has the potential to generate meaningful behaviors. The use of a signal, rather than the visualization of the whole system, is particularly suitable for artistic practices that rely on small numbers of instruments—a few musical instruments to relatively low numbers of lighting devices.

The artistic work on which autonomX emerges from thus allows us to understand that creation practices with complex systems require extensive periods of observation and experimentation in order to reveal self-organizing and emergent behaviors that cannot be deduced from the structure of the algorithms alone. The strong sensitivity to initial conditions that characterize such systems as well as the improvisational nature of working with them in real time require practical, quick, and easy tools that foster both intuitive experimentation with parameters and interactions, and observation. In the context of multimedia artistic creation, the use of lighting and sound as expressive material

² *Totem* is an artwork by Chris Salter in collaboration with Takashi Ikegami, Sofian Audry, Alexandre Saunier, and Thomas Spier. It was commissioned by the Barbican Center in London as part of their touring exhibition *AI: More Than Human*.

³ *SNN #1: The Speed of Thoughts Itself* is a performance by Chris Salter and Alexandre Saunier premiered in 2019 at Impakt Festival (Utrecht, NL).

⁴ *SNN #2: Light/Space/Prop* is a multimedia installation by Chris Salter and Alexandre Saunier premiered in 2020 at Llum BCN (Barcelona, ES).

revealed that the use of time-varying signals extracted from and fed into complex systems can generate meaningful behaviors out of a limited number of instruments. This practical knowledge developed during the Dynamic Light research-creation project is thus critically-technically (Agre) materialized in autonomX's *generator*, *drawing*, and *signal* frameworks [15].

Collaborating Over Controlling

To test the software with potential user groups, autonomX was used in different workshops open to both artists and students that had no previous exposure to the software. In particular, autonomX's prototype, release 0.1, was the object of a workshop entitled "Dynamics of Perception" held online during ISEA 2020. Together with the technical and creative team, several collaborating anthropologists participating in the Dynamic Light project were also present to participant-observe and discuss with the participants their experience while going through activities that involved the generation of various sounds using the Spiking Neural Network (SNN) generators.

When interviewed about their experience, participants described a sense of *collaborating with*, successfully or not, the SNN system and described experiencing a form of "machine agency" that resulted from the autonomous activity of the neural networks [16]. They contrasted these descriptions with the feeling of *control over* that is usually experienced with more traditional control systems that consist in explicitly programmed sequences of events with neither self-organizing nor emergent properties.

This feeling of collaboration was accompanied by what participants characterized as *observing* and *learning* the behaviors expressed by the system. In other words, they stressed the importance of spending time listening to the sonic material being modulated by the SNN in order to become attuned to the patterns being expressed and to slowly make sense of the system's different parameter combinations. Importantly, they remarked that this process of *observing* and *learning* was not related to their *understanding* of the inner workings of the SNN. These discussions showed that despite the computational nature of the technique employed, the intertwined relations between sensorial perception and hands-on experimentation behind the participant's observation and learning process felt to them more conducive to artistic creation than any rational understanding of the algorithmic implementation of the SNN.

While the "Dynamics of Perception" workshop was limited to the manipulation of a single type of generator (the Spiking Neural Network), the points highlighted by the participants offer insights that remain relevant for artistic creations using other kinds of complex systems. In particular, they show that systems that possess autonomous, self-organizing, and emergent qualities might be better addressed through notions of *observing*, *learning*, and *collaborating*, rather than of *understanding* and *control* that can be associated with systems such discrete state machines more commonly employed by artists. Artistic

experimentation with complex systems thus suggests that fostering material and sensorial engagement as an integral part of computational disciplines would prove beneficial to the study of complex systems, not only in the arts but also in the larger context of scientific practice. This preliminary conclusion has large-scale ramifications for how humans will relate to the agential structure and actions of such systems, particularly as their implementation will continue to be black boxed in ever more sophisticated wrappers by industrial concerns, even as such adaptive and behavioral technologies enter into most of our everyday experiences.

Conclusion

autonomX is an open-source software that encourages artists and students to quickly and intuitively manipulate complex dynamical systems in order to experiment with the generation of temporal dynamics in various media, from light to sound and robots, that such systems make possible. Because complex systems possess autonomous, self-organizing, and emergent properties that produce global behaviors from the local interactions of large ensembles of simple entities, they offer a challenge to the traditional forms of understanding and control present in multimedia software. Instead, complex systems invite us to move toward principles of observation, learning, and collaboration that acknowledge their temporal dimension and their potential for expressive agency.

autonomX builds on the knowledge acquired during the research-creation project "Dynamic Light" that intertwined concrete artistic practice and anthropological observation of the creation process. This original approach has led to the development of a framework of *generators*, *signal*, and *drawing* that fosters an intuitive and multimodal engagement with complex systems. autonomX embodies these principles in the form of a software instrument intended for real-time artistic creation and composition.

As of the writing of this paper, the release 1.0 of autonomX is freely accessible on lab Xmodal's github repository [1]. Future developments will go in the direction of expanding the application's technical possibilities, furthering the anthropological understanding of complex systems, and supporting artistic creation with a larger international community of scientists and artists.

The current version of autonomX supports a limited number of processes, namely, Spiking Neural Networks, a full implementation of Stephen Wolfram's Cellular Automata, and Conway's Game of Life. This implementation offers a small repertoire of techniques that will be expanded in the future in collaboration with international collaborators in the fields of the computation arts and artificial life. We aim to implement a large variety of techniques including boids, reaction-diffusion systems, and recurrent neural networks such as reservoir and transformer models.

Additionally, artistic productions have demonstrated that interconnecting multiple complex systems together yields striking expressive possibilities. We wish to extend the

current possible complexity of the software by allowing for intuitive internal connections between generators.

Second, at the methodological level and in relation with the “Dynamic Light” research project, autonomX will be used in the design of experiments on the sensorial perception of the temporal dynamics expressed by complex systems. Those experiments, held in relation with a team of anthropologists of the senses and focused on participant observation, will focus on how observers perceive the kinds of “vitality effects” [4] produced by light and sound behaviors driven by autonomX. The aim of these experiments will be to develop a qualitative understanding of complex systems based on the sensorial perception of their behaviors.

Finally, the long-term objective of autonomX is to support artistic practices with cutting-edge technologies and contribute to the development of not only the media art scenes but also the cross over space between computational technology-augmented artistic practices and the performing arts. In the coming years, lab Xmodal’s team will conduct workshops for artists and students. We will also use autonomX in new artistic projects that might also fulfill the long sought after goal of the 20th century Indian art historian Ananda Coomaswamy—to create art as an “imitation of nature in her manner of operation.”[17]

Écosystème(s): a self-interactive sound installation

Estelle Schorpp

Université de Montréal, CIRMMT (McGill University)

Montréal, Canada

estelle.schorpp@gmail.com

Abstract

This article presents the creation process of *Écosystème(s)*: a self-interactive installation. This work is based on an ecosystemic approach to sound creation. Such an approach aims at creating aesthetic, technical and conceptual links between ecology and sound art practices. In the context of *Écosystème(s)*, it is expressed through the sharing of a sound and sensitive experience of fragile living systems. This perspective considers and practices listening as a means of understanding and confronting the ecological crisis, while attempting to convey it through an interactive work. This approach proceeds through the use of algorithmic processes for the fabrication of artificial sound environments that integrate, cohabit and underline existing natural sound relationships, in a dialogue between artificial technologies and natural ecosystems, while setting up a context for attentive listening. A great deal of room is left to intuition and imagination in this creative process, through the desire to seek a balance between concept and expression of interconnected subjectivity.

Keywords

Sound installation – sonic environment – interactive technology – sonic ecosystems – sound art – sound ecology – insects – non-human communication.

Introduction

Écosystème(s) is a self-interactive sound installation whose behavior and sound identity are inspired by the communication techniques of orthopteran insects. The term "self-interactive" is used here to emphasize that the device is self-regulating (the device listens to the sound it produces and adapts its behavior according to the result). The device takes the form of a wooden desk in which are embedded seventeen speakers of different models. Two cardioid microphones are suspended above the speakers and pick up the intensity level of the sound environment. Simultaneously, these levels are sent to *Max/Msp* and control the triggering, localization and duration of about fifty sound samples in *Ableton Live*. This piece marks a personal turning point in my practice and research, as it is the first work using digital interactive technologies. The main objective in the creation of *Écosystème(s)* is to conceive a sound piece inspired by various behaviors of natural systems, in order to provoke a posture of silent and attentive listening through interactive technologies. This text presents, first, the different steps that led to the creation of *Écosystème(s)*. In the second part, the text will examine

the technical, aesthetic and conceptual aspects that characterize the work.

The animal world

Starting from a field recording practice, the animal sound world has become a favorite playground for the composition of electroacoustic pieces for several years. In fact, for centuries, it has been a playground for many composers who, for aesthetic and/or poetic reasons, imitate, describe or represent various natural phenomena¹. For example, the use of onomatopoeia in Clément Janequin's 1520 polyphonic song *Le chant de l'alouette* is a mimicry effect. Moreover, the animal sound world occupies a significant place in the genre of the symphonic poem, as in the *Carnival of the Animals* composed by Camille Saint Saëns in 1886. Moreover, Olivier Messiaen's well-known fascination with birdsong led him to study and transcribe it. Finally, with the invention of electroacoustic recording and reproduction technologies, composers of musique concrète are able to record, analyze and use the sounds of the animal world in their compositions. In the footsteps of Murray Schafer, artists such as Hildegard Westerkamp, Chris Watson or Bernie Krause, to name but a few, show a great interest in the acoustic signatures of a place and the living beings that compose it: field recordings are obviously characteristic materials of their electroacoustic compositions.

However, the animal sound world is not only fascinating for aesthetic reasons. With the rise of general ecology and more specifically sound ecology, interest in the "natural" sound world has increased considerably. As the Norwegian composer and sound artist Espen Sommer Eide explains, the romantic vision of the solitary artist in front of a sublimated nature is outdated; in the face of contemporary challenges, it is important to find new ways to represent and articulate interactions between the artist and nature. The artist is no longer an observer separated from the object of their observation, but an agent inscribed in living networks:

"The starting point, for the artist or the composer, is not the outing in nature to find inspiration, followed by the translation of this experience into music [...] Can we describe in another relevant way the interactions between the artist and nature? As in Uexküll's stories, the artist is already present in a scene of sensory activity, but he is also part of a larger network of sensations and structures that act and react: the human senses, those of living beings, but also plants, molds, bacteria, stones, soil and wind." [1]

As Eide points out, some artists are interested in the fragility of these systems. For example, the work of composer and bioacoustician Bernie Krause², and more recently that of

¹ In his book *Le poème symphonique et la musique à programme*, Michel Chion explains that the symphonic poem is the genre par excellence which narrates, describes, evokes a landscape, through

various compositional processes: imitation, description, representation. (Chion, 1993).

² See, among others, the exhibition "Le Grand Orchestre des Animaux" organized by the Fondation Cartier pour

natural sound environments, aim to make the listener aware of the imbalance between biophony, geophony and antropophony. These three terms, invented by Krause to categorize the sounds that coexist simultaneously on Earth, make it possible to identify various ecological issues, such as the disappearance of animal species and biodiversity. Namely, they are geophony, which includes geophony includes all sounds of non-biological origin such as wind, water, earth movements or rain; biophony, which includes the sounds of living organisms; and finally, antropophony which includes sound sources of human origin.

With ecological thinking, sounds are not reduced to abstractions detached from their habitat. On the contrary, they archive testimonies relative to the specific inventions of living species that interact in constant coevolution with their environment, which is also ours. These species are then considered as agents that create the sound environment. This same thought implies a movement of approach and integration in the sound environment: rather than observing it (or recording it) only for its aesthetic qualities, we experience it in a lived and affective way. From this point of view, the expression of a "living network" substitutes itself to the term "environment" and invites the human ear to lend a listening to the sound networks of the living: "the organized sound of life itself." [2]

Numerous contemporary philosophers have examined the "puissance d'agir"⁴ of living beings, and more particularly of animals. In line with the Gaia Hypothesis, these philosophers of the living⁵ offer new and inspiring models of thought for artists: interdisciplinary and collective re-research-creation projects, in the form of workshops, contemporary art exhibitions, and living art events, aiming to explore a variety of alternatives and to nourish reflection on our relationship with the living. For example, the exhibition *Critical zones: Observatories for Earthly Politics* organized at the Zentrum für Kunst und Medientechnologie in Karlsruhe (ZKM) in August 2020, based on an idea by Bruno Latour, invited artists to explore new modes of coexistence between different forms of life⁶; similarly, the company *Zone Critique*, directed by Frédérique Aït-Touati, has been developing modes of theatrical writing since 2004 questioning scientific and ecological imaginaries. The last performance, entitled *Viral* (2021), is part of the "earth trilogy" and proposes to rethink our material dependencies in a co-evolution with viruses⁷. Finally, the University of Lausanne recently invited the philosopher of science Vinciane Despret for a cycle of meetings and collective experimentation around the notion of a narrative of possible futures; the event concluded with a presentation of her latest work *Autobiographie d'un poulpe* (2021), in which the author imagines, among other things, a future in which scientific research would allow us to communicate with animals⁸. It is in this context, at the convergence of science, philosophy and artistic practices that the sound installation *Écosystème(s)* has matured.

l'art contemporain in 2016:

<https://www.fondationcartier.com/expositions/le-grand-orchestre-des-animaux>.

³ See, among others, the Fragments of extinction project: <https://www.fragmentsofextinction.org/>.

⁴ In his book *Face à Gaïa : huit conférences sur le nouveau régime climatique*, Bruno Latour uses the term "puissance d'agir" to translate the term agency and "avoid the horrible 'agentivité'" [3]

⁵ Examples include Vinciane Despret (*Habiter en oiseau*, 2019), Baptiste Morizot (*Manières d'être vivant*, 2020), and Donna Haraway (*Manifeste des espèces compagnes*, 2019).

The idea of *Écosystème(s)* was born after reading the article *L'univers sonore animal: Rôle et évolution de la communication acoustique* written by Yvelines Leroy in 2002. The author details how in order to recognize each other and to isolate signals from the background noise, different species cohabiting in the same environment use various methods of frequency, spatial and temporal exclusion: some sing at different times of the day and occupy a distinct territory, others occupy a certain frequency range, or use all these strategies. The signal repertoire, intrinsically linked to environmental influences on the animals' bodies, is the result of a long evolution of the species' transmitter organs. This information suggests a direct relationship between the evolution of the environment and the auditory sensory system, confirming that listening is ecological, interactive and changing. Finally, the article explains that the language of each zoological group innovates in a particular way: the orthopteran insects (locusts and grasshoppers) introduce repetition, discontinuity, sequence, regular or irregular pattern; the amphibians, formant and its nuances; the birds, for their part, invent melodic line. Leroy's text summons an ecosystemic thought of the animal sound world while using a musical vocabulary to talk about language innovations: it is thus possible to take advantage of both the concept of self-regulation and the typomorphological suggestions for sound composition. Starting from the idea of a natural musical ecosystem, the project develops on three organizational principles, namely the choice of sound materials, a self-regulated communication system, and a listening device. In this regard, the communication techniques of orthopteran insects have been a source of inspiration both from the point of view of sound materials and algorithmic logic.

The sonic material

The choice of insects is not insignificant: from an aesthetic point of view, they offer a fertile ground of materials, including noisy and high-pitched sounds arranged in more or less regular rhythmic patterns. Buzzing, rubbing, stridulation, clicking : the insects' song blurs the boundaries between the perception of an artificial or natural sound, and a machine sound or an animal sound. Cultivating this ambiguity with regards to sound sources combines the machine and the organic, creating cyborg sounds⁹. In large quantities, the effect is that of a dense and rich accumulative mass, as a solitary insect pierces the ambient sound web: just disturbing enough to notice, just banal enough to ignore. Because of their antiquity (more than 400 million years), their number (they constitute 85% of animal biodiversity) and their differences, the choice of insects allows us to weave conceptual links with ecology. Considered strange

⁹ A term referring to the concept developed by Donna Haraway in *A Cyborg Manifesto*. A cyborg sound is a sound that deconstructs the Nature/Culture duality (Haraway & Wolfe, 2016).

world, they embody the "other that counts" – if we take Donna Haraway's formulation – with whom we cohabit. Moreover, their relative invisibility for the human eye refers directly to the perceptive field of the listening: omnipresent and invisible, as the sounds, they are acousmatic beings, or rather *acousmètres*¹⁰.

For the production of sound materials, the first source gathers insect sound recordings from field recordings; a filtering process then allows the isolation of the different species according to their frequency range. Subsequently, electronic sounds is made to imitate different parameters of insect song behavior, such as spectrum, envelope, articulations, or rhythmic patterns. The goal is to create an environment that oscillates between naturalism and fantasy - in reference to the sound universe close to that of the film *Nausicaa and the Valley of the Wind* by Hayao Miyazaki, for example¹¹. This work gave rise to more than fifty samples, which were classified into four groups: natural insects, artificial insects, birds and signals (fig.1). Overall, the first two groups constituted the majority of the samples; after which the work consisted of making these sound species cohabitate.

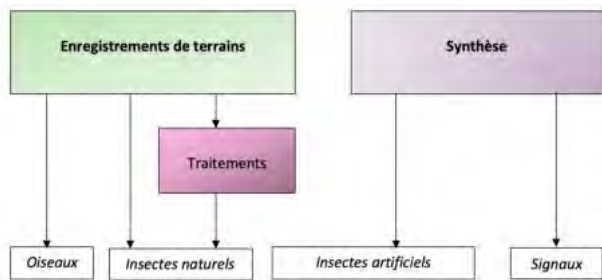

Figure 1. Graphic illustrating the process of creating sound materials for *Écosystème(s)*.

System development: autonomy and biophonic writing

According to Évelyne Leroy's article, each species occupies a specific physical and spectral space: there is a sound and territorial organization of biophony. This observation recalls Bernie Krause's first experience in Kenya in 1980: an event that he describes as close to a spiritual revelation. At nightfall, after the generators had been turned off and all the team members had withdrawn, the sounds of the forest were finally revealed. Krause sets up his microphones in front of his tent, and lying down in his sleeping bag, listens. He writes:

"No longer a cacophony, it became a partitioned collection of vocal organisms—a highly orchestrated acoustic arrangement of insects, spotted hyenas, eagle owls, African wood owls, elephants, tree hyrax, distant lions, and several knots of tree frogs and toads. Every distant voice seemed to fit within its own acoustic bandwidth—each one so carefully placed that it reminded me of Mozart's elegantly structured Symphony No. 41 in C Major, K. 551." [4]

¹⁰ The exact term to talk about insects would indeed be "acousmètre". In the cinema, the latter designates a character in a film that is only perceived in a sonorous way: insects are therefore "acousmètres" of the sound environment.

¹¹ This film, in addition to having an aesthetically interesting soundtrack in its ambiguity between natural and artificial sounds, is one of the most ecological films of the director. In a world

spectrograms from his recordings. As the images scroll by, the structure of the soundscape is revealed, showing distinct forms, which Krause likens to musical notation: from the bat singing in the highest frequency range, to the elephants occupying the lower end of the "biophonic score. [5] Rather than listening to sounds in a dissected manner, Bernie Krause notes that together they form a singular, unique, and surprisingly musical organization. This remark is of capital interest, in that it proposes a significant link between the music and the sound environment via the organization of the elements.

From the outset, the objective for the composition of *Écosystème(s)* was to avoid the process of linear writing: there was no question of elaborating a soundscape based on a hierarchical order that would determine which sound would come after or before another. On the contrary, the idea was that the soundscape should generate itself by taking up the principles of communication of the orthopteran insects, that is to say to make it analogically "alive". From then on, the question had to be rephrased as follows: how do insects organize, adapt and self-regulate in their environment? They listen, they distinguish themselves, they recognize each other. Logically, it was necessary that the sound samples could listen to each other to organize themselves. Two microphones were therefore added to the system, becoming the receiving organs of the ecosystem. To complete it, the loudspeakers took the role of transmitting organs, and the algorithm that of the brain. In general, it was a question of engaging pseudo-cognitive mechanisms, even if minimal, which make the devices both sensitive (thanks to the sensors — the microphones —, the system receives and perceives the sound environment) and capable of acting accordingly, with the help of a processing and analysis of the sounds, the motor of the action responsible for triggering the process. This feedback structure finally gives the device the ability to self-regulate, i.e. to listen to itself and to feedback.

The autonomous dynamic system is the second characteristic of the "living" in electroacoustic performance according to Agostino Di Scipio; the first being the human agent. In this case, the capacity for action and perception is controlled by the human performer, who becomes the only element capable of operating the self-regulation of the device and its interaction with the environment. As a comparison, in the case of an interactive installation, it is possible to replace the term performer by listener. Indeed, in the majority of the interactive installations, the public is the key agent of the loop; in this perspective, this one is in front of a linear system (fig.2). The second notion of the "living" is more about the technical agent, where the whole is not only a performance or an interaction with humans, but an autonomous dynamic system. From a procedural point of view, we are approaching artificial intelligence, where the devices composing the device are endowed with a capacity for action — the abovementioned power to.

"The conditions are thus put in place so that the performative device can prove to be able to produce, all by itself, sufficiently dynamic and varied sound flows over the short and long term. The device becomes a potentially

asphyxiated and contaminated for thousands of years by industry, a few human communities survive between a desert and a vast toxic forest to which the "Omus" (literally "insect-kings" in Japanese) have adapted and of which they are the protectors.

2008a, 2008b]. [6]

Thus, the "internal medium" (the machine) is coupled to the "external medium" (the environment) and the human agent, in the background, is no longer indispensable to the functioning of the system. (fig.3)

Figure 2. Diagram of a linear sound system.

Figure 3. Diagram of a retroactive sound system.

Figure 4. Spectrogram of an extract from *Écosystème(s)*.

Although Di Scipio is particularly interested in performance, the reflection is quite applicable to the interactive sound installation: physically, *Écosystème(s)* receives, analyzes and sends only acoustic data. Technically, the intensity level and envelope once analyzed, triggers, locates and determines the position of each sample. So to speak, it is enough to initiate the system by snapping your fingers near the microphones; once started, the system regulates itself by reintegrating its own emissions and those of the environment. A spectrogram shows the organization of the sound samples (fig.4).

One parameter remains important: How can the system be made to distinguish its own emissions from those of the environment?

The device: the importance of furniture in the induction of interactive postures

interactive with acoustic data, it was obvious that the sound environment and the audience would also be taken into account. The essential thing was to mark the sound presence of the listener, which produced a perceptible impact on the behavior of the ecosystem, which, once disturbed, tried to find a balance in order to spread out. The function of aesthetics, beyond the notion of pleasure, is decisive when it comes to predicting the social behaviors it induces. In this sense, the choice of the form and the aesthetics of the device must take into account the type of behavior that the artist wishes to engage with the listener. To this end, the first idea was to conceive an immersive installation of the environmental type: a space in which the listener evolves. Unfortunately, this kind of immersive device curbed the recognition capacity of the system which could no longer distinguish itself from the environment; the behavior then became chaotic, which was not the desired effect.

Consequently, the device is integrated into a specific piece of furniture in which to embed all the speakers (fig.5). Such a device allows to concentrate in turn the acoustic energy and the attention of the listeners. Since the loudspeakers are located below the microphones, the sensitivity level is limited to a distance close enough to obtain a minimum of control over the system's behavior. This arrangement also greatly reduces the difficulty of separating the system's own emissions from those of the environment. Now that the object had taken on the dimensions of a piece of furniture which, by its shape, informs the orientation of consultation, it was important to concentrate the listener's attention in one locus; rather than an itinerary, to invite them to adopt a listening posture with respect to a sound microcosm.

At this scale, in addition to solving a technical problem, the device was consistent with the ecological dimension of the project, insofar as listening to a smaller and more fragile world intuitively arouses a desire for discretion.

Figure 5. View of the installation *Écosystème(s)* exhibited at the Festival International de Musique Actuelle de Victoriaville, 2021, © Estelle Schorpp.

Silence is necessary to listen to each other, to give space, and to share the sound environment equally. Noise and noise pollution have been a concern since the industrial revolution – although the term has only been used since the 1970s. By their number and intensity, industrial sounds crush the diversity of sound signatures of living beings cohabiting in the same space; as Vinciane Despret reminds us, "there is no way of inhabiting that is not first and foremost 'cohabiting'". [7] This domination creates a profound imbalance and becomes the source of several problems. First of all, it is a social problem, since not everyone is with regards to exposure to the noise¹². Silence in the sonic cohabitation between humans — in other words the urban sound environment — is almost non-existent, and the little that remains is unequally distributed: the quality of listening between humans and non-humans decreases. This posture of partial deafness or hypoacusis gives way to the second problem, of an ecological nature, which the imperial domination of noise engenders. The complex exchanges between animals that emit signals in order to communicate with their congeners are critical : indeed, they allow, among other things, to attract a partner during the mating period, to defend a territory, to signal the presence of a predator or a prey. However, many of these signals are masked by urban anthropophony, which disrupts the fragile ecosystem of animal communications. Recently, a 2018 study by environmental science students at UQTR (Université du Québec à Trois-Rivières) demonstrated that some bird species adapted their song frequency to no longer be masked by traffic noise (Roca et al., 2016). Moreover, following containment measures related to the COVID-19 pandemic, a new ecophony is entering urban areas. Recently, a study — entitled Silent Cities — has been collecting sound recordings from urban environments around the globe that document changes that took place during and after the containment period. Started in mid-March by scientists from France and the United Kingdom, this project relies as much on the voluntary participation of researchers as on anyone able to make the required recordings (Descoteaux, 2020). These parameters are reminders of primordial issues regarding the ability of human societies to get along. *Écosystème(s)* operates in this vein, seeking to rebalance the human sound presence and to redeploy space among the living for an alternate collective organization of the sound environment.

On the one hand, the installation interacts with its sound environment and thus with the sound presence of the public: indeed, if the ambient noise is too high, the system will no longer perceive its own emissions, which will be masked and will no longer be able to self-regulate. On the other hand, as explained above, the audience is not an essential agent for the system to function properly: the system reacts to its presence, but does not need it to self-regulate. This is why *Écosystème(s)* is described as self-interactive: the installation is autonomous. In this case, what role do the

role. The question that emerges is: what level of interactivity and awareness is desired, or even necessary?

On some occasions, the process of interacting with an object or environment diverts attention from the original message or content and directs the listener's activity towards pure entertainment. In other situations, the subtle adaptation of sound is an appropriate response, where the simple audible feedback of the interaction with a microphone is enough to enrich the experience without necessarily being noticed. It is towards this second, almost unnoticed or unremarkable interaction, i.e. towards an interactive aesthetic of the unspectacular, that the artistic objectives of *Écosystème(s)* tend. The interaction as such is considered in its relationship with silence. Reacting to sound intensity, the system's behavior is disturbed when the ambient sound signature exceeds its own signal: unable to regulate itself, the ecosystem then stops evolving and goes into a loop. So, what is the desired level of interactivity? The answer is simple: the sine qua non condition for listening to the audience is silent attention. It is in such conditions, where the sound environment is equitably shared, where the communication of the insects is not masked by human noise, that *Écosystème(s)* manages to self-regulate and that musical motifs emerge.

Conclusion

The ecosystemic approach to sound creation is intrinsically linked to cultural, technological and environmental contexts marked by the ecological crisis. It reflects the increasing accessibility and ubiquity of technology and media in our environment, while emphasizing the need for the arts to define their role in the face of the ecological crisis.

The process of creating *Ecosystem(s)* has allowed for the practical application of various issues related to an ecosystemic approach. More specifically, the conceptual universe of the work is based on a systemic understanding of sound environments, which considers them as an open set of interdependent dynamic interactions. On the other hand, the algorithmic approach offers precious tools to model the behavior of sound systems and to musicalize them. Moreover, this method allows to work in real time with complex environments, and to adapt the algorithm to the broadcasting framework. Finally, the choice of sound materials, as well as their organization in time and space, are aesthetically inspired by natural sound systems; the device applies different strategies to guide the listeners towards a sensitive and intellectual encounter with the work.

In short, the systemic approach is reflected both in the creative process and in the experience of the work. In the case of *Écosystème(s)*, thanks to an interactive device that aims to produce a silent encounter, a reflection is initiated around the sonic cohabitation between humans and non-humans, redirecting the attention of the listeners towards the complex communication systems that surround us and to which it is essential to give a fair place in our living spaces.

¹² Work conducted by the Direction régionale de santé publique du Centre intégré de santé et de services sociaux du Centre-Sud-de-l'Île-de-Montréal (DRSP) in collaboration with the Université de Montréal and the Institut national de la santé publique du Québec (INSPQ) has revealed, since 2010, that nearly half of the population of the Island of Montreal (46%) with a family income

of \$40,000 or less is exposed to noise levels (LAeq24) greater than or equal to 60 dBA. This proportion decreases with increasing family income.

Author(s) Biography(ies)

Estelle Schorpp holds a masters degrees from École Nationale Supérieure des Beaux-Arts de Paris. She also graduated from Université de Montréal with a masters degrees in Sound Creation and Composition during which she wrote a thesis entitled : *Sonic interactive environments: an ecosystemic approach*.

She uses sound installation, music composition, writing, performance and new technologies to put together projects that both embrace and criticizes our daily relationship with our sonic environment. She is interested in sound ecology, hybridity between nature and technology, and the attention to the unremarkable. Her projects often consist in form of hybrid environments giving space to non-human narratives and to many imaginaries about soundscapes.

Recently, she has been inspired by natural ecosystems and explores the potential of algorithmic systems through interactive sound installation.

Her work has been presented in festivals such as Prix Ars Electronica (AT), MUTEK (MX, CA, AR, JP), FIMAV (CA), Exhibitronic (FR, GER), MuTeFest (FIN) and in group exhibitions at the Centre d'Exposition de l'Université de Montréal (CA), Palais des Beaux-Arts de Paris (FR) and Exhibition Laboratory (FIN). She has participated in study days and symposiums at CIRMMT (CA) and EHESS (FR). In 2016 she received the first Exhibitronic award for her electroacoustic composition *Bagdad 9ème siècle*. She is the recipient of several research-creation grants.

Nonhuman Creativity in Generative Art: Beyond the Anthropocentric Paradigm

Stella Sofokleous

National and Kapodistrian University of Athens

Athens, Greece

stellasof@phs.uoa.gr

Abstract

This paper explores fresh insights into the ways we negotiate our ideas about nonhuman creativity, emphasizing the need to recast traditional notions of what it means to be an artist today. In the prospect of the existence of entirely autonomous nonhuman agents of art production in the following decades, an attempt is being made to question the exegesis of the artificial creativity of generative art from an anthropocentric point of view. Through the observation of four art projects, the first part sheds light on the interaction of artists with generative art-making systems in order to demonstrate that the concept of assemblage between living and non-living agents is currently emerging. The second part attempts a *new* ontological exploration of algorithmic systems as a possible path for essentializing their creative agency. The discussion extends to whether these aspects can operate as a foundation of the ontological definition of nonhuman creativity.

Keywords

Nonhuman creativity, generative art, assemblage, new ontology

Introduction

In recent decades, within the theory of art discourse, there is an attempt to understand and define an emerging trend of artistic production, which derives from the ability of generative systems and algorithms to express themselves artistically with a certain degree of autonomy. The debate over the potentially autonomous artistic production of a nonhuman agent is a complicated one, partly because it brings back the modernistic concern that the machine will displace the artist from the creative process leading to a dystopian technological totalitarianism.

Artificial creativity can hardly be explained through the rigid behavior of algorithms, so it is often approached throughout the interpretation schemes we have created to explain human creativity. However, the inexperience of our human species in comprehending creative “others” and the fear of losing our most human quality, constitutes a serious setback for an impartial understanding of the creativity of nonhuman agents. In order to avoid constraining the discussion to outdated and romantic theories of human creativity, leading back to an almost metaphysical talent of a genius human artists, the analysis attempts to question the exegesis of the nonhuman creativity of generative art through the anthropocentric paradigm. In doing so, nonhuman creative systems are approached as an ontological *otherness*, as agents *per se*.

The first part of this paper discusses the interaction of artists with generative art-making systems, by referring to

examples of projects from 1968 onwards. These examples demonstrate how human and nonhuman creative agents operate as an assemblage [1] in order to jointly explore new artistic possibilities. In the second part, the analysis deals with the ontological overview of the algorithms used in the artificial systems of creating art. The fresh examination of these algorithms aims to highlight the less rigid manifestations of their behavior. This examination serves as a gateway to an ontological exploration of the nonhuman creativity.

Assemblages of human/nonhuman creative agents

It is simply carbon fascism to argue that only biological creativity is worth studying
— Alison Pease & Simon Colton

In both the Renaissance and the Early Modern era, artists such as Leonardo da Vinci, Albrecht Dürer and Johannes Vermeer took advantage of technology in their artistic quests. By the end of the *quattrocento*, Da Vinci created the first android robot, named “mechanical knight”. Around 1800, the first “automata”, anthropomorphic moving mechanical devices were created. These machines were able to hold in their information capacity certain simple representations which they could repeat on paper. [2] By 1804, Joseph Jacquard invented a loom which was controlled by punched paper cards for weaving intricate designs and portraits. [3] Later, during the late 19th century and the first half of the 20th century, the avant-garde used many elements of the flourishing computing culture of the era, both in terms of materials and concepts. Art movements such as Surrealism, Dada, Fluxus, OULIPO, conceptual and abstract art were inspired by fundamental principles of programming and algorithms, such as formal instruction, randomness, interactivity and automation. [4]

By the mid-20th century, art was significantly influenced by cybernetics, “the study of control and communication in the animal and the machine”. [5] Many artists influenced by cybernetics [e.g., Gordon Pask, Robert Breer, Roy Ascott, Jean Tinguely] shifted the emphasis of art from object-oriented notions to its understanding as a complex dynamic system that provokes a dialogue between the act of creation, the artist and the public. [6] From the 1980s onwards, the digital revolution [7] brought about a dynamic change in the way contemporary culture was synthesized, which sparked, on the one hand a useful critique of the algorithmic culture [8] [9] [10] and, on the other, especially in art, contributed to a slow but profound shift in the definition of what it means to be an artist today.

Today, the current trends in which the literature refers to as “generative art”, “artificial intelligence art”, “algorithmic art”, “robotic art”, “artificial creativity” or “computational creativity” (CC), define in many cases a nonhuman agent as the foremost creator of works of art. Research on productive visual arts using artificial systems is gaining more and more interest and this is evident from a series of conferences held in the second half of the 20th century: [International Conference on Computational Creativity (ICCC); Design Computing and Cognition (DCC); Creativity and Cognition (C&C); International Conference on Design Creativity (ICDC); International Workshop on Creative Agents (IWCA)].

Artists/programmers who engage in this kind of artistic creation often define their systems as autonomous entities for the generation of art, based on the argument that they are able to create novel works. [11] [12] Due to the possibility of autonomous function of such systems, a large number of artists and programmers approach their relationship with their machines as a collaboration, a kind of an assemblage of living and non-living entities to achieve common artistic goals. [13] According to Joanna Zylińska: “Naturally, artists do not construct these machines just to get ‘help’ but rather to probe the limits of the human idea of creativity and of human-machinic assemblages. These works are thus described as collaborations between the artists and the robotic systems those artists have designed”. [14]

Examples of art creation systems date back to 1968, when the artist Harold Cohen created AARON (the artist’s Hebrew name), a machine he designed and trained to imitate his own artistic style. In the five decades of his collaboration with the artist, AARON gradually went from creating simple, black-and-white, representational forms to more complex, color works that resembled those of Cohen. Although any new idea had to be coded and fed into the system, the program could compose an almost infinite number of distinct works of art on its own. AARON’s ability to “make decisions” was made possible through Cohen’s choice to install a random number generator at the heart of the program, creating an illusion of autonomy and of agency.

Cohen stated that the relationship he had developed with AARON was similar to that of the Renaissance artist with his assistants in the studio. [15] Until his death in 2016, Cohen claimed that the artistic capability of AARON was based not on his innate skill and creativity, but on his special collaboration with the artist himself. [16] However, as Simon Colton aptly points out, “It is over-simplistic to say that AARON has been developed to paint in the style of Cohen, as he has been influenced himself by feedback from the software, so the process has been somewhat circular”. [17] Over time, his relationship with his system seems to have taken the form of an assemblage, with AARON exploring and pointing out to the artist new manifestations of the latter’s artistic style. [18] As Cohen himself admitted, “It slowly dawned on me that I could use the machine to investigate some of the things that I thought I hadn’t been able to in painting, that had made me very discontented with my painting”. [19]

Following Cohen’s contribution, early 21st century ventures into the field of artificial creativity had as their primary goal to explore the potential of developing a “personal” artistic style deriving from the systems themselves, thus moving away from the imitation of pre-existing forms. In 2005, Simon Colton, with a team of scientists at Imperial College London, developed an artist-machine called The Painting Fool. According to their website, they started the

creation of The Painting Fool in order to investigate whether an artificial system can be described as “creative artists” in its own right and if so, under which conditions. On The Painting Fool website, the visitor encounters also the following quote: “I’m The Painting Fool: a computer program, and an aspiring painter. The aim of this project is for me to be taken seriously - one day - as a creative artist in my own right. I have been built to exhibit behaviours that might be deemed as skilful, appreciative and imaginative.” For this reason, The Painting Fool does not copy the style of a pre-existing visual style or artist, but creates works through its interaction with the stimuli of its environment.

One of The Painting Fool’s first works was the composition of portraits of visitors of the gallery where the system was on display. The results were then presented in the *You Can’t Know My Mind* exhibition in 2013. Colton, wanting to avoid random number generators and differentiate himself from Cohen, decided that the current “mood”, which would inspire the creation of a portrait would be activated in the machine based on the daily news presented in the press. Painting Fool therefore scanned daily articles from the Guardian and modified its “feeling” according to how positive or negative were the news of the day. [20] The Painting Fool, similarly with AARON, functions based on a certain level of randomness. In this way, the programmers provided the system with a kind of “random logic” and “emotional autonomy”, in the sense that they could not predict the state of the algorithm. [21]

It is also important to mention that Colton’s action in the emerging field of artificial creativity is not limited to the programming of The Painting Fool. In collaboration with Alison Pease, they implemented the Turing Test, to evaluate artificial creativity. However, as they themselves state in the findings of this experiment “...the Turing Test is largely inappropriate for the purposes of evaluation in Computational Creativity, since it attempts to homogenise creativity into a single (human) style...”. [22] In this sense, the inability of the game of imitation to evaluate the creativity of productive systems makes it necessary to design procedures for evaluating artificial creativity as creativity itself and not as a simulation of the human.

As the examples of AARON and The Painting Fool demonstrate, in the early decades of the advent of artificial creativity, the algorithms chosen as the most suitable in art production systems were the stochastic algorithms, whose functions steps depend on random choices made during their execution. Unlike deterministic algorithms, the steps of stochastic algorithms in their execution are neither defined nor unique, but they can change and produce unexpected results. This is either because the developer has included a random number generator in the code or because the algorithms themselves are able to receive inputs from their ever-changing external environment. At first glance, the argument that randomness can be equated with the autonomy of a machine in artistic performance seems simplistic and inadequate, mainly because the former gives the illusion of spontaneity and uncontrollability, but is judged inferior to the *per se* creative procedure.

Therefore, from the end of the 20th century onwards, the artists/programmers of the productive art choose to work with more complex algorithms such as those used in artificial neural networks or swarm intelligence. An attempt to define neural networks is as follows: A neural network is a massive parallel distributed processor consisting of simple processing units, the neurons, which have the natural tendency to store empirical knowledge and make it available for use. They resemble the brain in two ways: 1. The net-

work acquires knowledge from the environment through a learning process. 2. The connections between neurons, called synaptic weights or simple weights, are used to store knowledge. [23] An important advantage of artificial neural networks in relation to other algorithmic processes, is the ability to learn through experience.

In the field of artificial neural networks in artistic production, the recent work of the artist and researcher Mike Tyka is notable. One of the most recent series of works by the artist is called *Portraits of Fantastic People* and concerns the training of neural systems in the composition of human faces that never existed. The series of works has been screened at the important New Media Art Festival, “Ars Electronica” in 2017 and most recently in February 2021, at the online exhibition “Uno, Nessuno, Centomila”. To achieve photorealistic oil-canvas-like portraits, thousands of photos of people were uploaded from Flickr, which were then imported into a program called the Generative Adversarial Network (GAN). On his website, Tyka describes his approach as follows:

GANs work by using two neural networks that play an adversarial game: one (the “Generator”) tries to generate increasingly convincing output, while a second (the “Discriminator”) tries to learn to distinguish real photos from the artificially generated ones. At first, both networks are poor at their respective tasks. But as the Discriminator network starts to learn to predict fake from real, it keeps the Generator on its toes, pushing it to generate harder and more convincing examples. In order to keep up, the Generator gets better and better, and the Discriminator correspondingly has to improve its response. With time, the images generated become increasingly realistic, as both adversaries try to outwit each other. [24]

Tyka’s general practice in creating visual arts is related to his desire to push art towards more interesting expressions that artists have not yet invented. [25] At first glance, the artist’s Generative Competitive Networks are understood as a closed system of machines, a dialogue between two nonhuman agents. However, the way the two GANs work with one trying to fool the other allows the future replacement of one of the two with a human. Also, in a broader reading of how this work communicates with the human factor, it is useful to emphasize that the inputs that trigger the GANs interaction are images of people with which the artist feeds the program. The dialogue of artificial and natural in this case, concerns the training of recognition of human patterns by the networks. Such a reading of Taika networks introduces a kind of assemblage that has less to do with the collaboration of physical and non-physical entities in art production than with the way a closed system perceives and classifies the human through processes that escape control of its developer. [26]

Swarm intelligence, introduced by Gerardo Beni and Jing Wang in 1989, deals with the collective behavior of undistributed, self-organizing artificial or physical systems. [27] Some examples of collective behavior and intelligence in nature are found in the organized movement and cooperation of a flock of birds, an ant colony or a herd of animals. Artificial systems inspired by swarm intelligence are various robotic systems that use innovative algorithmic methods that are governed by a collective form of self-organization. Ant colonies present one instance where the study of the insects’ collective behavior relies on the optimization of algorithms.

An example of the use of such algorithmic methods in the art production process is the project of Lionel Moura. The system that Moura built is called Robot Art and was presented at the exhibition *A Machine for Creating* and in the catalogue entitled *Artistes & Robots* at the Grand Palais in Paris in 2018. Moura, created and programmed small robots (artbots) which move on a large piece of paper, leaving colored lines on their way and eventually creating an abstract composition. These systems have a satisfactory understanding of the environment in which they operate and are equipped with a small “brain”, which is based on algorithms governed by simple rules. [28] The works that artbots go through as they traverse the white surface are not pre-designed and so the end result is due to both some form of randomness in terms of the initial conditions of their movement and the interaction between them on the paper.

The artist calls his robots “neural swarms” because he uses ant colony optimization algorithms to program and train them. As he explains in an interview [29] his source of inspiration was the communication of ants through the release of pheromones, which ultimately determines the communication between them and therefore cooperation. The artist replaced the chemical with paint, in order to ensure that the color secretion on the paper would remain random. [30] As Moura explains, “The finalization of the work is determined by a kind of negative feedback, i.e., when the robots stop reacting as a certain destiny colour is achieved”. [31]

Generative art is important because, as Moura mentions in the Symbiotic Art Manifesto, it paves the way for the symbiotic dialogue between humans and machines, in an effort to achieve common artistic goals. [32] In this context, it might be fair to infer that artificial creativity is not explored in order to remove or replace the human creativity. Rather, it is often seen by the artist as a new path towards exploring new manifestations of art. According to Peace and Colton: “Humans and machines have different strengths, and instead of trying to squeeze machines into a way of thinking that is human, we should aim to develop computer systems that make the most of their power”. [33]

Ontology of the Algorithms of Generative Art

*In short, I teach robots how to paint,
but afterward, it is not my doing
— Lionel Moura*

As the above examples demonstrate, in the process of creating works, generative art systems take decisions based on algorithmic rules set by the creator through programming. In some cases, the artists/programmer may claim that the system represents his own artistic idea and in others that the system creates new original expressions. Artists/programmers make use of a variety of systems such as chemical, biological, mechanical, robotic, artificial neural network systems and swarm intelligence systems. In light of the aforementioned works of art, we see the emergence of some possible definitions of the artistic trend under investigation. Following the definition given by Philip Galanter, “Generative art refers to any art practice where the artist uses a system, such as a set of natural language rules, a computer program, a machine, or other procedural invention, which is set into motion with some degree of autonomy contributing to or resulting in a completed work of art”. [34] Galander’s choice to state that the artistic act of systems involves only a degree of autonomy is crucial.

Aside from Moura, who emphatically argues that artistic systems are autonomous, researchers in the emerging field of artificial creativity remain cautious about the degree of autonomy they attribute to such systems. For example, Boden, defines this trend as follows: “art is produced by leaving a computer program to run by itself, with minimal or zero interference from a human being”. [35]

There are clearly realistic objections in accepting the autonomous artistic performativity of a generative systems and of the algorithms that constitute it. It is often argued that the strict rules that govern algorithmic systems are incapable of manifesting the creative or flexible behavior that humans possess. [36] As the philosopher Georges Canguilhem wrote in 1947 in *Machine and Organization*:

...in the case of the machine there is a strict adherence to rational, economical rules. The whole is rigorously the sum of its parts. The final effect depends on the ordering of the causes. What is more, a machine functions within narrowly defined limits, and these limits become all the more rigid with the practice of standardization. [37]

However, what is usually missing from the discussion on the nature of algorithms is an understanding of their *new* ontology. As Robin Hill notes, “Neither the articulation of an algorithm nor the dynamic process constitutes the algorithm itself”. [38] By definition, algorithms “are supposed to be strictly rational concerns, marrying the certainties of mathematics with the objectivity of technology”. [39] Contrary to this view, the functioning rigidity we have attributed to machines so far could be mitigated, in light of some different and potentially creative features of the new algorithms. Such essential attributes will be discussed from an ontological stance as a possible way for the re-evaluation of the creativity of artificial art production systems. Such an attempt is challenging because, on the one hand there is a plethora of algorithmic systems currently used in generative art with many differences between the way they function; on the other hand, artists/programmers often avoid thorough descriptions of how their systems operate in order to exclude the possibility of copying them and thus, to ensure the originality of their results. [40]

To begin with, “an algorithm is any well-defined computational procedure that takes some value, or a set of values, as input and produces some value, or a set of values, as output. An algorithm is thus a sequence of computational steps that transform the input into the output”. [41] The encoding process mainly composes a series of algorithms in a splicer, meaning that the program “undergoes a series of translations: high-level computer language is compiled into executable code, which is then converted by an assembler into binary code”. [42] This process is known as programming and is defined at an early stage by the synthesis of a pseudocode, which is then converted into source code. The program consists of the coded computing mechanism, which affects the data, resulting in either their transformation or the production of new data. Thus, the program coincides with the implementation of the algorithm using programming commands and functions.

The combination of the coded algorithms with the necessary structures in an inseparable module forms the basis of each program, and therefore the starting point of each application. The set of programming instructions that are repeated in cycles until a certain condition is satisfied is called a loop. A computer program proceeds from beginning to end by performing a series of loops. In other words, programming is a kind of narrative. It is a narrative that addresses a machine, dictating to it what to do and how to

react to another specific narrative, which comes from the user.

At first glance, the autonomy of the system seems to be mitigated due to the need to interact with the human agent, who in part determines the operation of the system through programming. Nevertheless, although this interaction is essential for the organization of system algorithms in order to perform a work of art, the algorithm remains an autonomous entity. This autonomy lies in the way in which the algorithm separates itself and operates independently of its inputs. Therefore, the autonomy of an algorithmic system is not related to whether it can work without human intervention, but to its ability to exist independently of the data on which it operates or the program that encodes it.

The autonomy of algorithms is also related to their adaptability, their ability to recognize structural features of reality, locating patterns in the data space and adapting their functions accordingly. Through the action-feedback relationship of the system with the external environment, some adaptation processes take place. These processes concern the effort of the system to maintain its internal coherence and therefore to balance the external influences. The ability of the system to adapt to repetitive stimuli, which it receives from an external actor, leads to the possibility of alternating its reaction with each new interaction.

Consequently, the goal of an algorithm and therefore a system is predetermined, but it can change quantitatively depending on the environment in which it acts and the external stimuli it receives. For example, as mentioned in the case of *The Painting Fool* above, an algorithm that processes visitor actions or changing elements of the environment (i.e., number of people in a room, daily news) when integrated in a work of art it is possible to create, at any time, different versions of this work. In this context “code is not purely abstract and mathematical; it has significant social, political, and aesthetic dimensions” [43] often correlated with the environment in which the code itself operates.

In essence, the adaptability of the autonomous system is synonymous with its ability to resist any kind of external manipulation that attempts to change its internal coherence. Thus, the interaction of the system with the user and the environment in which it operates, seems to consolidate its autonomous action rather than prevent it. The adaptability of the system is important because, it both secures its autonomous action and it is directly connected to the creative process. As Cohen puts it, describing the characteristics of AARON: “the machine’s feedback system as a whole will need to possess a comparable adaptiveness to permit of the fluently changing pattern of decision-making which characterizes the practice of art”. [44]

As Kitchin points out, the algorithm is inherently performative in the sense that it can contribute to the implementation of many alternative scenarios. [45] As he notes: “As well as being heterogeneous and embedded, algorithms are rarely fixed in form and their work in practice unfolds in multifarious ways. As such, algorithms need to be recognised as being ontogenetic, performative and contingent: that is, they are never fixed in nature, but are emergent and constantly unfolding”. [46] As part of the assemblage of a code and then of a program, a system algorithm can produce in each execution either the same version of a project or different versions of it. Its potential lies precisely in the ontogenetic dimension which characterizes algorithmic systems. [47] In some cases, algorithms and their code incarnations are refined, redesigned, extended, and corrected by repeating through different versions. [48]

Aside of the performative nature, the algorithmic assemblage is important for two more reasons: firstly, because the repetition of different versions through the assemblage of a variety of algorithms prevent the results of the code from being perfectly defined and hence, they often fall out of the artist's/programmer's control. In some cases, the code has been programmed to evolve, rewrite its algorithms as it observes, experiments, and learns independently of its creators. [49] For this reason, the originality that governs the artistic creation of systems, although fed in them through programming, is not predictable or controlled by the programmers. [50] For example, as Tyka asserts in an interview about how artificial neural networks operate in art: "In many ways the challenge to understand the innards of an artificial neural network and explain its decisions or classifications remains unsolved and is an area of active research". [51]

At the same time, the performative actions of an algorithm are neither intentional nor explicit, but remain open to error - with the transition from one state to another not always being deterministic. The non-causal dimension of algorithms is not identified with the randomness that governs stochastic algorithms but rather with their complexity. Johanna Drucker, referring to a more general description of the executive nature of algorithmic behavior, notes: "Algorithms are instructions for processes, for performances, whose outcomes may usually be predictable, but of course, are as open to error and random uncertainties in their execution as they are to uncertain outcomes in their use at the higher level of their operation and use". [52]

The repetitive nature of algorithms is linked to a second property, the ability to inductive reasoning. The algorithm modifies its actions each time it is executed. Having said this, in every new execution of itself, the algorithm operates in a different way avoiding to repeat the same mistake, thus ensuring its internal coherence. The ability of the algorithm to achieve the same result or to correct or improve a previous result is identified with the recall of appropriate past experiences from its memory, a process which depends heavily on closed internal loops. As McCulloch argued in 1952, referring to the Turing machine's feedback capability, what is important and allows the machine to develop the capacity for inductive reasoning and real-world learning is the ability to receive the input of a new execution, the output data of its previously performed executions. According to McCulloch:

"It is a beauty of the Turing machine to be open to contingent facts from an external agent conceived as able, like the machine itself, to print symbols on its tape. These marks which the machine and the world may make and erase, serve both as signals for operations and for operands, sometimes subserving both functions simultaneously". [53]

Conclusions

*If a lion could speak,
we could not understand him
— Ludwig Wittgenstein*

In the prospect of the existence of fully autonomous, non-human systems of art production in the following years, this paper attempts to question the explanation of artificial creativity through anthropocentric analysis. As Moura notes: "Art produced by autonomous robots cannot be seen as a mere tool or device for human pre-determined aesthetic purpose, although it may constitute a singular aesthetic

experience. The unnamed characteristic of such a kind of art must be translated in the definitive overcoming of the anthropocentric prejudice that still dominates Western thought. In short, a true robotic art must be the matter of robots themselves". [54] In this context, the first part of the work sheds light on examples of collaboration between human and artificial entities in the creation of art. Observing the nature of the interaction of artists/programmers with nonhuman systems of art production, leads to a fruitful and less discriminatory understanding of the living and the non-living creative agents as two ontological partners who converse, jointly aiming for new artistic explorations.

The second part provides definitions for generative art along with a different reading of the ontology of algorithms. It then investigates whether the rigidity that characterizes algorithms is mitigated by highlighting the lesser-known aspects of their behavior. The analysis contends that overcoming the limitations of a creative artificial system, occurs from within the system itself and is intertwined with the very structure of the algorithms that constitute them. Lastly, from a methodological stance this analysis underscores the necessity of a theoretical framework which will allow a fresh understanding of the way nonhuman agents create art. I consider such an understanding as crucial for generative art to move away from a technophobic frontier and integrate with the ongoing evolution of art history.

The main problem in the future acceptance of a creative system as an artist *per se* lies in the fact that throughout the spectrum of historical narratives of art, the creative process has been identified with human nature itself. The human species has so far progressed with an almost undisputed confidence against the machine, believing that it possessed some features that no algorithmic system would be able to emulate: Imagination and creativity, an *ipso facto* human "code" that no programmer could "break". [55] [56] However, the transition of art production to the digital realm and the wider convergence of the fields of art and machine learning, raises concerns about the way we perceive the creativity not only of the machine but also of human beings. The shift that generative art brings to the traditional scene of artistic production is understood as the formation and emergence of a new *otherness*. The acceptance of *other* agents to be creative, requires awareness and self-knowledge of our own creativity, a quality that we think of as a *conditio humana*, defining us as human beings, but which still remains essentially unknown to us.

Living Biotechnical Lives: Noise, Parasites, and Relational Practices

Abstract

Life in the era of biotechnology opens up opportunities but also brings challenges related to our values and questions on how we want to see coexistence on our planet inhabited by many species. The parasite is our case study and an interesting concept that we inherit from biology, but which is also addressed in humanism and philosophy. As humans, we commonly understand a parasite as a negative concept that suggests that someone or something benefits at our expense. However, French philosopher Michel Serres has thought differently about the parasite. According to him, the parasite is based on relations between different entities and that there is often noise in these relationships. Michel Serres refers to biologist Henri Atlan, who has argued that noise forces the system to reorganize in a way that incorporates noise as a part of the complex system. The idea of noise included as a part of the system is quite far from today's thought-processes with the development of bio/technology that typically aims at noiseless, error-free and aesthetically attractive results.

Therefore, although parasites are often associated with terms such as inhospitable, undesirable and disgusting, and they are seen to be located outside of art and technology, in this paper we argue that the concept of parasitical is tightly intertwined into our contemporary biotechnical lives. The article relates the parasitic thinking by Michel Serres to an artistic mediation of the biological parasite, a tick.

Keywords

Parasite, Serres, biology, technology, noise, ticks, relations, biotechnology, science, evolution.

Introduction

Scholar and ecofeminist Vandana Shiva proposes in a published interview that the reductionist approach, typically present in the sciences, symbolizes violence in the level of the mind. This violence begins in the way we are brought up and learn how to think about the world. According to Shiva “the connection between reduction and science, its violence, the technology that it shapes, and a profit center of capitalist structure of limitless resource exploitation is all connected because when you declare that nature is dead, then you exploit her”. [1] This in mind, it is definitely interesting to investigate what we commonly regard as the darker aspects of biology, such as parasites - organisms that we consider unpleasant, and which might be harmful for our health. Similar darkness can also be seen in our practices with biotechnology on manipulating diverse organisms’ faculties, abilities, and their evolutionary trajectories.

However, this article is not specifically a critique of technoscience nor its development, but in what follows, we will conduct practice-based readings of Michel Serres’ text *The Parasite* (1982) in an attempt to formulate a non-reductionist position which include reflections on noisy evolution, parasites and practices relating to the biotechnological lives we are leading. [2]

Parasites

Stephen Crocker reminds us that the term parasite in French refers to three very different things, which however share the common principle of interference. [3] Thus, parasite may refer to a biological organism that lives off a host; a social organism who feeds on the charity of others

without giving anything in return; and static/white noise in a communication circuit.

One of the major humanities perspectives on the concept of parasite is written by the French philosopher Michel Serres. In his text *The Parasite* Serres proposes that the parasite is key to evolution and our relation to our surrounding world. The parasite, Serres argues, can lead us to an image of our world in which relations are enabling further mutation and *parasitism*.

“We parasite each other and live amidst parasites. Which is more or less a way of saying that they constitute our environment.” [4]

The parasite leads us to relations otherwise invisible or inaudible to us. In other words, the parasite according to Michel Serres reveals a relation to relations.

Figure 2. Ticks in the Tick Terrarium 2020. ©Laura Beloff

Biological Parasites

An example of a biological parasite, a tick, is a focus of an artistic research project by Laura Beloff (conducted

partwise in collaboration with Kira O’Reilly under the title #tickact). The biological, social and communicative circuits raise questions about the parasitical relations in humans’ evolutionary trajectory, biological organisms, technology and art. In this article, the tick is used as a case study from biology (and as well as it is the focus of the mentioned art project) representing a world of transforming relations.

Tick is an arachnid and a member of arthropod group together with spiders and mites. Today, we encounter increasing amounts of ticks in our environment; in the natural environment, but also in the borders of urban parks. Tick is becoming one of the frequent parasitic guests in our lives.

Ticks are considered as *vectors* in environmental sciences – this means that ticks carry pathogens, bacteria and viruses, which they transfer from one host to another. Some of these pathogens can cause serious diseases in humans, such as the Lyme disease that is a result of a transfer of the *Borrelia burgdorferi* bacteria to humans. This transforms a tick into a feared and unwanted visitor in our lives. But one can also see that as a vector, a tick creates horizontal connections, or relations, between the different hosts that the tick utilizes for its necessary blood meal. The blood meal is what we humans can offer for the tick, but commonly it is an involuntary act from us. In our minds the parasite is a feared concept that references that someone or something would benefit at the cost of us, which does not easily fit with the individualistic mindset we have been brought up with.

Noise

Interestingly, Michel Serres perceives the parasite and parasitic relation through the concept of noise. Serres’ reevaluation of *parasitic* noise builds on a basic principle of information theory. In Claude Shannon’s pioneering work in which he laid the foundation of information theory, he was researching an efficient way of encoding information and how to deal with the problem of noise. Shannon understood noise as elements of the signal that are not part of the actual message being transmitted [5] [6]. In Shannon’s work noise is recognized as a necessary consequence of transmission. Michel Serres compares noise to parasitism by proposing the following - “Theorem: noise gives rise to a new system, an order that is more complex than the simple chain. The parasite interrupts it, is vaccinated, becomes immune.” [7] Noise becomes as an integral part of the system.

When noise appears in every-day media such as static in a radio transmission, the presence of the medium is registered in what would, seemingly, otherwise be a clear transmission. As Crocker explains, Claude Shannon recognized that whether or not a certain effect is considered noise depends on one’s position in the listening chain. Noise is interference only from the sender’s point of view. From

the point of view of the receiver it may be considered a part of the information packet that is transmitted along a channel. [8]

According to Michel Serres, noise does not indicate a fault, a mistake, or an information-gap; rather, it indicates a surplus of information. To continue further considering the development and impact of technology; Marshall McLuhan famously argued, “The medium is the message”, which means that the user becomes the content of the message. [9] Also, in the early 1970’s art historian Jack Burnham pointed out about technology and artists’ role within the changing milieu: “With increasing aggressiveness, one of the artist’s functions, I believe, is to specify how technology uses us.” [10] More recently, scholar Benjamin Bratton has pointed out about proto-sentience and surfaces in urban environments. He writes how technology and clothing form a type of artificial skin for us, but also the city’s’ surfaces have begun sensing the environment. According to him – “the city also wears us.” [11] We have become an essential part of the system. It becomes clear that a medium/milieu affects, or acts upon, the signal. The active intention to transmit a signal requires that we open ourselves to the passive reception of the medium in which it can occur.

Relational Practices

Serres transposes the parasite to something which should be understood as a critique of common knowledge and especially of the self-understanding of sciences (including the humanities and the arts). This means that technology is already there as part of the relationality of practices. Technology may in fact not be the transcendental link to the framing of human culture as Heidegger, McLuhan, and Kittler have proposed since, according to Serres, there is no such intentional congruence between technology and culture. There is no intentional relationality between technology and humans, but there is a relationality of practices, causes and effects from what is done, while and after it is done.

Michel Serres introduces the principle of the productive force. He follows the French biologist Henri Atlan in arguing that noise in a system should not be seen as a positive force that does something. Rather, Atlan argues, noise prompts a system to reorganize in a more complex form that incorporates the disturbance. [13] [14] Here we really find the heart of Serres’ theory of the parasite.

“In each case, the parasite interferes in, and ultimately upsets, some existing set of relations and pattern of movement. It compels us either to expel it, or to readjust our internal workings so that we can accommodate the needs of the parasite. Noise, in other words, is to communication what a virus is to an organism, or a scapegoat is to a community. It is not simply an

obstacle, but rather a productive force around the exclusion of which the system is organized.” [12]

Figure 3. Tick Terrarium 2020; a wearable bioweapon. ©Laura Beloff

The parasite acts on existing communication, be it biological, informational or social. It instates itself in the circuit between a point of transmission and reception. The parasite does not act directly either on the sender or the receiver. It acts on the relation that joins, for example, an enzyme and the protein it breaks down or a tick performing the relation between different hosts by being the vector for trespassing bacteria or virus. Serres defines quite precisely that the parasite always acts on relations. He writes that while atoms lead us to ontology, the parasite leads us to relations. [15]

The property of the parasite of joining diverse entities enables new constellations and human thought processes, which are based on the relational practices, which inherently include noise as a component of it.

Figure 4. Tick Garden experiment 2021; artificial habitat for ticks. ©Laura Beloff

Noisy relations

The formed network of diverse relations and general interests in the contemporary feared parasite, a tick, form the backdrop for the work *Tick Terrarium 2020* by Beloff. The artefact, the *Tick Terrarium 2020*, is a wearable device for humans, which is made of several glass vessels. Inside the glass vessels are habitats made for living ticks with grass, moss and natural rubbish. This device resembles a suicide bomber's vest by its shape, but instead of carrying explosives the wearer is carrying fragile glass vessels with parasites living inside them. The work directly references through its shape and wearability the biotechnology research and development on ticks that was conducted in the U.S. between 1950's-70's with an aim of using ticks as

bioweapons - which is well described in the popular science book by Kris Newby. [16]

Serres sees the parasite as a key to evolution and similar understanding is also advocated by evolutionary biologists. Scientist Tuomas Avelo writes about human evolution and inherited parasites: "Whilst there was plenty of plant-based food in Africa throughout the year, in the harsher conditions in Europe, they [Neanderthals] only hunted meat on which to live during the winter. Meat, in turn, predisposes more to parasites, and therefore Neanderthals probably had a more effective immune defense than our own ancestors. [...] By moving to the Neanderthalian habitat and consuming the same diet, modern humans also inherited the Neanderthals' parasites. Neanderthals became extinct, but still their genes helped modern humans to adapt to the new environment in the most intimate of ways. [...] We have inherited from Neanderthals not only their parasites, but also their immune genes. While these genes were beneficial to modern humans as they spread around the world, now that there are no longer so many parasites in our environment, they have become harmful" [17]. By stating this Avelo defines that we (humans) would not have evolved to what we are today if there would not have been parasites and parasitic relations on the way. In a sense one can think of parasites as a kind of noise in the system that challenges and potentially reorganizes our minds and bodies - as well as forces us to cope with old and new relations and unexpected noise in them.

The notion of the performativity of facts is useful in approaching the artistic activity with Ticks. Those practices are in fact comparable to *experiments* carried out by practitioners who, according to Isabelle Stengers, raise the question of how to 'struggle against the role assigned to their practice?' She continues by connecting experimental practices to an existential struggle against the growing exposure of practitioners to a destructive pattern of a dominating neo rationalist umbrella-culture cancelling out any noisy images (and thereby the identity of the experimental practitioner as well) generated by experimental practices:

"Under the guise of the (capitalist) "knowledge economy", what is happening is no longer only the intoxication but the destruction of the social fabric which empowers researchers to think and feel, imagine and object. Soon those practices will indeed confirm the critical diagnosis that there was never anything special about them, that they were reducible to power interests. How to connect with those scientists who complain about their increasing subjection?" [18]

One can claim that many experimental art practitioners working with technology and biology create new kinds of

noisy images, which are in a way parasitical of the conventional scientific understanding of *nature* and humans perceiving it.

Artist Paul Vanouse's work *Labor* (2019), can be seen as conducting *experiments* with the hidden biotechnological lifeforms existing in our bodies and perforating through our skin when we sweat. Vanouse shows that microbes vastly outnumber the human cells in and on the human body concluding that: "Our microbiota is integral to who and what we are and complicates any simplistic sense of self. Likewise, the smell of the perspiring body is not just a human scent, unless we are willing to redefine what we mean by human." [19]

The dominating rational scientific culture seems to shy away from the parasite outside its micro-biological 'habitat', and from everything *noisy* when concerning the idea and borders of what is human, and what is not. Similarly, one can critically ask what are the criteria we base our choices on when we e.g., modify organisms or decide which non-humans are accepted and which are not? Parasites would presumably belong to the latter group. The criteria-in-use appear to be influenced by the prevailing technoscientific perspectives and the expected use value for humans. The made decisions, their embedded values and connected aesthetics are also trickling down visibly to art practices. For example, one could say that in digital and biotechnological arts certain types of aesthetics are dominating, which typically one could describe as aiming for clean, smooth and perfection. This is an obvious influence of technological development and biotechnological practices, which drive for better, more efficient systems and idealize continuous progress often with expected profit. It seems that the mainstream technological mediation (as well as development e.g. in synthetic biology) favors a perfect version of the world editing out the bad, the ugly and the unpleasant, such as parasites, noise and errors.

In the case of the tick-project and the work *Tick Terrarium 2020*, as well as the work *Tick Garden experiment*, the opposite is true; these parasites are brought to our vicinity to critically challenge the limits of our anthropocentric worldview and affection towards the non-humans. It is hard to deny that ticks would not evoke, on some level, feelings of hatred and disgust in us. But how can we go further from this beyond the desire for the perfect and control over life?

Vandana Shiva says about (reductionist) science that "it assumes that only things that can be measured exist. You cannot measure a relationship; a relationship can only be experienced." [20]

Biotechnical lives and noisy evolution

We began by stating that this article is not a critique of technoscience: rather, it is an attempt to establish a different relational understanding of practices in art and science. Through a practice-based reading of Michel Serres' text *The Parasite* we have investigated the noisy evolution, parasites and practices relating to what now appears to be a struggle against 'ourselves' and the social, as well as scientific, norms we so keenly construct. Increasingly, scientific culture and practitioners on diverse fields have been subjected to growing expectations of cancelling out noise and the parasitical. These are the darker sides of the biotechnological lives we are leading - and which we need to be questioning.

In this paper we are underlining the importance of Michel Serres' ideas about the parasite as the key player in the noisy evolution of the invisible relational practices that structure the way we live our biotechnical lives.

Authors' Biographies

Laura Beloff (PhD) is an internationally acclaimed artist and a researcher in the cross section of art, technology and science. The research is in a form of installations, wearable artifacts, and experiments with scientific methods that deal with the merger of the technological and biological matter. The research engages with human enhancement, biosemiotics, AI, AL, robotics affiliated with art, humans, natural environment and society. She is Associate Professor and Head of Doctoral Education in the Department of Art & Media at Aalto University, Finland.

Morten Søndergaard (PhD) is an internationally acclaimed curator and researcher in the histories, theories and cultures of transdisciplinary practices merging technology, media, art and societal trajectories. From the master thesis on the method of Michel Serres in-between poetry, art and science (1995) to the Phd on unheard avant-gardes in Denmark (Show-bix and the Danish media poet Per Højholt) (2007) the line of inquiry draws the analysis of transdisciplinary practices into epistemological questionings regarding the complexities of human and non-human relations, as well as a general study of the overarching question regarding experiencing and evidencing posthumanity. He is Associate Professor and Academic Director of the Erasmus Media Art Cultures Master Program at Aalborg University, Denmark.

Abstract

This article stems from ethnographic fieldwork I carried out in 2019 on the virtual platforms where vaporwave, an Internet countercultural phenomenon between a musical genre and a meme, is developed. In this text I show how copyright laws and technologies operating in the context of vaporwave's creation traverse and affect its creative forms and processes. Based on this case study of vernacular Internet creativity, I encourage an approach to digital countercultural or folkloric movements by putting into dialogue their symbolic dimension and the sociological, technological and legal bases on which they develop.

Keywords

Digital Culture, Creativity, Post-Internet, Copyright, Electronic Music, Memes, Internet Culture.

Introduction

Vaporwave is a digital aesthetic between a musical genre and a meme. It has developed entirely on the Internet since 2010 and its ambivalent nostalgic and ironic position, underground and pop, has given rise to numerous reflections and drifts. This aesthetic takes up and transforms the futuristic visions of the 70s, 80s and 90s, the popularisation of new technologies, the corporate culture of globalisation, the big shopping malls and techno-optimism from a critical nostalgia. Often described as music for abandoned malls, it performs an aesthetic of the disenchantment of 90s techno-utopianism, an ironic renewal of futures that were imagined but never arrived.

Theorists and critics such as Adam Harper, Mark Fisher or Simon Reynolds, among others, have laid the foundations to understand this digital countercultural movement, from *hauntology*, *retromania* or *accelerationism*. [1] [2] [3] Vaporwave has generally been understood as a counterculture that criticises and embraces capitalism, reclaiming corporate and commercial culture.

Numerous reviews and analyses of vaporwave in specialised magazines, books and scientific publications have linked it to *hauntological* electronic music. [4] [5] [6] [7] [8] This concept popularised by Mark Fisher derives from Derrida's *hauntologie*, "described as the way in which everything that exists does so on the basis of a series of absences that precede it and envelop it, while at the same time giving it consistency and intelligibility" and is used to describe a type of electronic music that deals with nostalgia, memory and the absence of a future. [9] Ambiguous and ghostly music linked to the crisis of capitalist society and postmodern distrust in the future that we can find in artists such as The Caretaker, William Basinsky, Philip Jeck or Burial.

At the same time, Adam Harper, in his article "Comment: Vaporwave and the pop-art of the virtual plaza" formulates a widely extended way of understanding vaporwave. The music critic describes vaporwave as an ambiguous critique of capitalism, a critique that is at the same time a recapitulation and an admiration. Vaporwave is understood as an art form linked to accelerationism.

Accelerationism is the notion that the dissolution of civilisation wrought by capitalism should not and cannot be resisted, but rather must be pushed faster and further towards the insanity and anarchically fluid violence that is its ultimate conclusion, either because this is liberating, because it causes a revolution, or because destruction is the only logical answer. [10]

Thus the samples of pop songs and television commercials are read as a critique of capitalism "from the inside", showing its paradoxes and participating in them until they collapse. Vaporwave would represent a strange and ambivalent critical celebration of capitalist consumerism. At the same time, vaporwave speaks about itself and its position within that capitalist machinery, configuring itself

as a metatextual discourse.

vaporwave can be heard as ambivalently dramatizing the decline of contemporary society as if accelerating it. It is a certain take on "the way things are." Floating somewhere between satire, nostalgia and envy, it bathes in capitalist luxury and gloss, huffing the fumes of advertising, and through the prevalence of signifiers of the early internet suggests a fond yet alienated self-image of the very virtual world it finds itself occupying-kitsch, well-meaning, but inhuman, aimed at someone else, too sublime. Its medium and its message indistinguishable, vaporwave is the online underground looking in the historical mirror. [11]

This microgenre has been the subject of great hermeneutics made from music criticism and cultural studies. In this article, however, we show how an ethnographic approach to this post-digital aesthetic is useful in revealing the creative and social processes that construct vaporwave. By focusing on vernacular Internet creativity, [12] [13] we will be able to analyse this countercultural movement without the hermeneutic violence that many researchers exert on our objects of study, whether in painstaking formal analyses or in grand sociological assessments. In this short article I will show concretely how the copyright laws and technologies that traverse the Internet articulate and dialogue with the creative processes of vaporwave.

Vernacular creativity

Within vaporwave we find multiple visual and musical expressions. The latter are mainly based on the appropriation (and in some cases production) of *muzak* or elevator music. This kind of lounge jazz, mood music, easy listening or background music is appropriated and compiled in albums under strange names, sometimes unaltered and other times mixed with ambient sound, teleoperator voices, echo or reverb, generating an ambiguous sensation of artificial calm or comfortable restlessness. Likewise, within vaporwave we can find musical productions based on sampling and remixing pop music from the 70s and 80s, very often slowing them down, making endless loops or creating chaotic mash-ups. Many of these mash-ups and remixes often use audio from antique commercials or TV shows, sampling slogans, background music and catchy melodies. However, what might be the main formal characteristic of vaporwave is the slowing down of popular songs from the 70s, 80s and 90s to turn them into strange, *unheimlich*, familiar and distorted artefacts. Many vaporwave productions are based on modifying a well-known song by drastically reducing

its beats per minute (bpm) and pitch (making it lower) and adding echo and reverb effects. This modification creates a feeling of something broken, of a memory damaged by the passage of time, of strange nostalgia or of an opiate high.

4 cover-arts of vaporwave albums. From left to right and from top to bottom: Floral Shoppe by Macintosh Plus, Chuck Person's EccoJams Vol. 1 by Chuck Person's, B L I Z Z A R D 9 6 by B L I Z Z A R D 9 6 and SANDRA WAVE by 猫 ∩ Corp.

But vaporwave, the genre, the meme, the aesthetic or the movement is not exclusively composed of musical productions, cover-arts, collages and screensavers, but encompasses all aspects of online mediation. It is a paradigmatic example to understand the idea of "vernacular creativity" on the Internet. This concept encompasses those creative practices that arise from highly particular and non-elitist ("ordinary" or "popular") social contexts and communicative conventions. [14] These creative practices, not necessarily linked to a commodification or exhibition, adopt multiple forms beyond those that we can understand within the idea of cultural goods such as books, videos, songs, visual creations, etc. All the practices of online mediation are susceptible to being traversed (and in fact, they are) by this vernacular creativity, from comments or likes to the creation of profiles, file names, tags, hyperlinks, typographic sources or the very platforms through which they are distributed.

In the digital ecosystem of vaporwave, these forms of creativity cross all these aspects mainly with ironic, joking or absurd dyes. The names of the songs and producers are incomprehensible pieces of text that mix numbers with bad

translations from Japanese, such as “MACINTOSH PLUS - FLORAL SHOPPE - 02 リサブランク420 - 現代のコンピュータ” or “2814 - 新しい日の誕生/Birth of a New Day”. These artist or song names are usually written with a space after each letter, something that has now become a sign inextricably linked to vaporwave, to the point that many refer to the genre as "A E S T H E T I C S" instead of vaporwave. This way of writing can also be found in forums, chats, social networks and comments as an implicit way of referring to vaporwave.

Screenshot from <https://mexicanwave.bandcamp.com/>

Instagram, Bandcamp, Tumblr or Soundcloud tags, designed to categorise productions and mostly used to gain visibility, are also another avenue for creativity within vaporwave. Within vaporwave productions, sub-genres such as *pizzawave*, *italianwave*, *brzl wave*, *vaporlevante*, *cutrewave*, *jesusgilwave*, *perreowave* or *favela de vapor* are constantly created without commercial or archivist intention. Genres and categories are constantly invented without seeking to be consolidated or known. This creativity shapes the ways of being on the Internet, whatever forms of expression one has access to, playing with jokes and disorientation.

At the level of production, we cannot separate creations such as songs or collages from other dimensions such as the creation of profiles or tags. As popular culture, in the online underground where vaporwave develops, musical practices make sense in the multimedia context in which they unfold.

Digital folklore and copyright technologies

An ethnographic approach that attends to the social space of production, and understands context, productions and mediations as an indivisible whole, allows us to find the articulations between the different forms of creativity and the technological and social media that generate and host

them. Thus, we can rescue the concept of folklore but not to invent a tradition or imagine an "ordinary people", but to unite context and form in a notion. By understanding vaporwave as part of *digital folklore* [15] [16] we can analyse how the dynamics of the Internet and the characteristics of the digital platforms from which vaporwave is developed intervene in the creation of the genre and in the creativity that is experienced.

From this point of view, I will show how copyright laws and technologies that affect the circulation of cultural products on the Internet traverse and affect the forms that vaporwave productions and creative processes take.

The role of the "content filters" of social networks and platforms such as Youtube, technologies that detect copyright violations of certain content to remove them, have a key place in the generation of countercultural digital currents and aesthetics such as *vaporwave*. In the pirate circuits of the Internet, these technologies have been subverted with 'hacks' such as 'mirroring' images (turning them upside down), modifying file names or altering the sound (modifying the *pitch* or *tempo* of audios or songs).

Wang, creator of the algorithm used by *Shazam*, an app that identifies songs by audio, explains how this technology works. [17] Broadly speaking, each audio file is associated with its "*fingerprint*" (*audio fingerprinting*), composed of data on the sound frequencies of the song, its position on a timeline and the relationship between them. Thus, through these song data, the algorithm is able to quickly identify sounds with their fingerprint, that is, with the specific song in the database. Storing not only the frequencies and their position on the timeline, but also the relationships between them, achieved fast and reliable accuracy. But the devil is in the detail. A simple hack can bypass this detection technology to circumvent copyright-based restrictions. If the algorithm takes into account the temporal relationships between the different frequencies, you just need to modify these relationships so that it can't work. This is the main feature of vaporwave, lowering the *pitch* and slowing down the *tempo* of existing songs to turn them into strange creations somewhere between the familiar and the bizarre. On the other hand, the way of writing used to name songs, producers or simply to talk about vaporwave (automatic translations into Japanese and placing a space between each letter) are related to a hack used by many Internet users to circumvent complaints of copyright infringement. In addition to these automatic detections by platforms like YouTube, the "Google Alerts" tool is widely used to find unauthorised use of songs. This tool communicates an "alert" to an account every time certain words enter its indexing field. Thus, a production company can track verbatim when one of its songs is used. The hack is clear.

Changing the text (for example, by adding a space between characters) can circumvent this technology.

These characteristics of the songs produce a disturbing effect, listening to songs that you recognize in an altered, broken version; a nostalgic sensation, configuring a distorted memory; an ambivalent critique, turning mass culture songs into *unmarketable* sound pieces; and a suspicion of ironic joking by publishing songs under incomprehensible titles in Japanese, created simply by slightly modifying a well-known song. This nostalgic critique and disturbing joke has been analysed by numerous music theorists and critics, but few relate this symbolic world to its more material aspects.

Beyond this link to hacking practices, the exploration of muzak and easy-listening music also suggests a connection to the Internet archive and copyright laws. The idea of 'stock', derived from photos that can be found in image banks such as *shutterstock* or stock audio and royalty-free music, is recurrent and takes on diverse meanings in the *milieu* of memes and digital folklore. These images and songs are used in many memes and works of digital folklore, as well as other aspects of 'stock' such as watermarking, to refer to the *normie*, the familiar/unsettling, the standardised, the capitalist and so on. From the well-known meme named 'Hide the pain Harold', referring to the use of photos of the Hungarian stock photo model András Arató, to the Instagram account @listillas, dedicated to making memes combining stock models with *normie* phrases, or the use of watermarking in certain ironic designs, the 'stock' has become part of the Internet.

Photograph/Meme of Harold found in the web *Know your meme*. [18]

Meme uploaded by @Listillas in her Instagram account.

These watermarked (a copyright technology that prevents illegal use of the images) stock photographs is equivalent to vaporwave's use of elevator music and "royalty-free" music. The ironic exploration into these free music archives, full of boring and cold music, is a creative practice that takes the copyright restrictions on music and acts on them, subverting or exploiting them. These songs are taken from the archive, appropriated and recontextualised on other music sharing platforms such as Bandcamp, Soundcloud or Youtube, or in forums and chats under incomprehensible names that suggest orientalism and complexity.

As we saw in the previous section, the creative acts involved in these forms of creation cross many forms of digital mediation and, in turn, are traversed by the technical and legal contexts in which they are developed. These creative forms are built on the immense archive of the Internet, playing with the meanings associated with the different platforms, the forms of presentation, selection, curatorship and the combination of elements from copying, plagiarism, falsification or appropriation.

As a conclusion

It is necessary to look at the material, technical and legal conditions of the musical space of the Internet in order to analyse its interrelation with the symbols and meanings associated with vaporwave. Understanding the critical and ironic character of vaporwave linked to the existence of the Internet in relation to the technical-legal restrictions of copyright laws allows us to broaden our gaze in the analysis of the cultural phenomena of digital folklore. By focusing on the relationship of vaporwave to hacking and stock platforms, I do not mean to argue that this aesthetic has a practical character nor that it is a direct cause of the application of hacks to bypass copyright technologies.

Likewise, I do not mean to prioritise this material dimension over the symbolic one. Ideas and debates about late capitalism, accelerationist logics or commercialization are an intrinsic part of vaporwave and constitute it as a genre. My intention in showing this concrete example is to encourage the understanding of countercultural movements by putting in dialogue their symbolic dimension and the sociological, technological and legal bases in which they develop.

Many analyses of vaporwave made by musical and cultural critics are guided by a logocentric approach, focusing on the philosophical basis of the productions or their deep meaning for our contemporaneity, leaving aside the creative forms and processes. With this small case I want to give rise to an understanding of a creativity that is experienced in a context, following Ingold's proposal. [19] To deal with the articulation, symbiosis or inseparability of creative processes with the material bases on (and with which) they are developed (in this case the Internet, but also computers, content filters, databases and archives, jpg files, timeline visualisation in audio editing software etc.). Rather than focusing on the philosophical reasons of creations or their deeper meanings, I prefer to look at their conditions of possibility, thinking about a kind of everyday creativity that links creators, materials and mediations.

The creative processes in vaporwave take place on the Internet, with computers, files, filters, algorithms, forums, networks of collaborations etc. and show how these technologies are not exclusively tools for transposing or constructing ideas. In vaporwave, as in all folkloric and artistic expressions, the creative and design work is constructed between the producer and the *machine*, that is, the material and social technologies, forcing us to change our way of understanding and valuing creativity, to leave aside the centrality of innovation and originality and to include copying, archival selection, recontextualization, falsification or plagiarism as creative forms.

Abstract

The Information Age has brought up new contexts and challenges to the way we produce and consume digital content — from personal digital devices to digital billboards in urban spaces. The latter are usually characterized by a high amount of visual stimuli, demanding a considerable amount of attention of the passers-by.

Crossing visual attention studies with computational design we develop a set of interactive prototypes to assess the digital capacity to capture individuals' attention and distract them from a main task.

As part of an ongoing research that aims to develop a system that is able to adapt its visual composition and create its own communication strategy according to its audience and environment, in this paper we focus on the development of computational artifacts to create stimulus-driven distractions. We analyze how these concepts and cross-knowledge may affect the attention of the audience towards these unexpected targets. The preliminary results suggest a set of promising stimuli that can be applied in the design of visual communication objects for this specific purpose. They also establish a basis for further research regarding other visual stimuli and open possibilities for explorations on the application of this visual communication strategy in more complex environments.

Keywords

Visual attention, computational design, context-aware systems, adaptive systems

Introduction

Urban spaces are rich in environmental stimuli [4], often comprehending visual stimuli. These can be found in several sources: from traffic signs, to advertisement boards, to animals, cars, etc, all these demand the attention of the passers-by. This high amount of stimuli represents a challenge when creating visual communication objects that should address the public's attention in these environments. However, when combined with the presence of digital screens, it can turn into an opportunity to explore new resources for the creation of visual strategies and address the contemporary context of urban spaces.

Since attention is a limited resource, each person has to be selective when deciding which targets to focus on. This selection involves attend to determined stimuli while rejecting others. [6] To address this issue, “a deeper understanding of

human attention skills is important.” [1]. As a result, we focus on the study of digital graphic objects towards effective visual communication strategies on visually competitive environments and therefore challenge the public's attention.

In our research we have identified two important approaches. The first, concerns the public's visual attention, i.e., understand how the brain processes visual stimuli and chooses where to focus its attention as much as creating visual stimuli that activates these brain functions. The second, concerns the public's engagement towards a graphical object, i.e., create visual strategies to maintain the public's interest in the object and to guide its eye gaze towards specific elements of the visual composition. In this paper, we draw a set of prototypes and experiments to explore the first.

We cross findings areas such as Cognition and Computational Design to support our research and the development of prototypes that explore the dynamic triggering of a selected set of visual stimuli in a visual composition. On the one side, the findings regarding Visual Stimuli guided the collection of promising visual stimuli to use, either individually or in combination, in the situation we are addressing — contexts where the audience is goal-oriented to other tasks and does not intend to consciously drive attention to graphic communication objects. On the other side, the knowledge of Computational Design allows not only the creation of motion-based graphic compositions but also the development of dynamic and adaptive systems, which application can be particularly interesting in less predictive and evolving environments such as urban public spaces.

In the present research we demonstrate the potential of this approach in addressing the issue raised. Through preliminary results we assign levels of efficiency to a collection of visual stimuli. Additionally, we propose a set of solutions for address the less efficient approaches while identifying new needs that shall be further tested. In sum, we aim to establish a research basis for the development of dynamic systems and consequent generation of graphic stimuli in visually competitive environments.

Visual Attention

To understand how we can address the competition for the individual's visual attention it is important that we first understand how the brain works regarding the reception of visual stimuli. We can do that through the study of Visual Atten-

tion, which “describes a set of mechanisms that limit some processing to a subset of incoming stimuli.” [8] These mechanisms are important because attention is a limited resource [6]. When exposed to a diversity of stimuli, there is a process of filter and selection where some are considered relevant while others are filtered out. After that we distribute our attention resources among the selected activities, either in the center or in the periphery of our attention [1]. This process of filtering and resource distribution “allows us to be aware of what’s going on around us without specifically attending to it” [1].

One common way to explain how our attention works, namely spatial attention, is the Spotlight metaphor, that explains that visual attention acts like “a flashlight that illuminates a region of interest, which allows for increased sensitivity and a more precise encoding of information from this spatial location.” [22] Our spotlight can be guided by our intentions and goals. This goal-driven attention is highly influenced by the perceiver’s goals, motivations and context [1][5][7]. That’s why humans are better at directing attention to targets when they have preliminary information about their features [7]. For example, it is easier to find your friend in a crowded scene when you know he is tall and wearing an orange shirt. This top-down process allows us to focus our attention in performing intended activities.

But how can we drive attention to targets that are not intended by the public? For instance, we can draw an individual’s non-voluntary attention towards a particular object, this is, without its prior desire [13] by using stimulus-driven attention. For example, when searching for a black shirt in a wardrobe full of dark clothing, your attention spotlight can be involuntary diverted if you unexpectedly encounter a bright pink shirt. The bright color was the stimulus responsible for the attention shift and not a conscious intention to find it. This type of processing, called Bottom-up, can be defined as “sensory analysis that begins at the entry-level—with what our senses can detect” [3]. It is “data driven” [3], “takes place in real time” [3], and is driven by “external stimulus event that automatically draws attention to a particular location” [8]. These stimuli are characterised by their saliency from the environment. Highly stimuli such as a car alarm, “a sudden flash of light” [1] or a bright pink shirt in a mostly dark wardrobe, can be easily attended.

In the process of selecting the set of stimuli to address in this paper, we focused on our main goal of capturing the passers-by’s attention in an urban space, which can be focused on performing tasks unrelated to the graphic digital objects we are addressing. Considering that the individuals may not be physically facing these objects, we refined our selection to stimuli to which peripheral vision is more sensitive. Among those stimuli we selected ones that create saliency based on motion and luminance.

Our peripheral vision is motion and light-sensitive which allows objects’ detection even in less favourable lighting conditions [2][20]. Changes in more complex environments can be easier detected if they contain luminance or motion cues, otherwise change blindness can occur and even dramatic changes can go unnoticed [19]. Considering these we developed our experiments applying combinations of the fol-

lowing stimuli: unexpected changes [21], abrupt onset motion [16][17], looming motion [23][10], abrupt and rapid light changes (blinking) and gradual light changes.

Context-aware Systems

In complex, dynamic and unpredictable environments such as urban public spaces it becomes a challenge to design visual communication for a specific target audience or environment conditions. Motion-based graphics may help to capture attention, but may be ignored if the visual stimuli are triggered in determined combinations of environment characteristics. To address this issue, we propose the use context-aware systems. These systems “have some awareness of the tasks users are performing and some understanding of the knowledge background of individual users as well as their location in the world” [9] and can generate outputs adapted to that knowledge.

We can find applications of adaptive systems in areas such as web-development, recommendation systems, ambient intelligence, etc. All adapt their outputs to external inputs from the environment and understanding of the user’s needs in a more or less intrusive way. A recommendation system, which may “recommend an item to a user based upon a description of the item and a profile of the user’s interests” [18] can retrieve, for example, custom advertising in order to attract attention and ultimately generate monetary profit. On the other hand, Ambient Intelligence and Intelligent Environments, in general, “are capable of recognizing and proactively responding to the presence of different individuals in a seamless, unobtrusive and invisible way.” [15].

In this paper we based our knowledge regarding these systems and use computational design and computer vision to detect human presence and adapt our visual output and stimuli behaviour to the the participants’ presence and displacement. By adapting to these characteristics in real time we aim to reinforce the participants’ awareness towards the digital graphic object and enhance the participants’ engagement and experience.

Prototype Development

In this section we describe the process of the prototype’s development. Based on the knowledge acquired in previous sections, we hereby detail the following: (i) experiment main goals, (ii) stimuli selection, (iii) prototypes development, (iv) and user tests.

Description

Based on the study described above we developed a series of prototypes to explore the application of several combinations of our selected stimuli in dynamic and interactive visual compositions. The main goal of this experiment was to understand and observe its efficiency in creating stimulus driven distractions to the participants’ attention to whom was asked to perform a specific task. The prototypes were developed in the software Processing [11], using the the OpenCV [14] library for background subtraction and face detection.

We based our stimuli selection in the knowledge that: abrupt onset — the beginning of movement — can highly

Figure 1: Prototype One

enhance the detection of a target [16][17]; looming motion — dynamic increase in the object size — makes them behaviourally urgent objects, which contribute to its capacity to attract attention. [23][10]; unexpected and abrupt changes captures attention [21][7]; luminance changes has “shown to capture as strongly as an abrupt onset” [10]; and finally that contrast is one of “the most general saliency factor” [22].

The prototypes were motion based and used computer vision to trigger the stimulus whenever motion and a participant was detected. This aspect was implemented to enhance unexpectedness but also to create a direct relation to the participant by reacting to its presence.

Prototypes Implementation

We will now describe each prototype and the stimuli computational expression. It is important to point out that the stimuli in every prototype is triggered by the detection of the participant. Once it stops detecting the participant the stimuli is cancelled and the visual composition returns to the original shape.

Prototype One (Fig.1)

Visual description: shape similar to the human eye (eyeball and iris);

Stimulus: onset motion;

Behavior when activated: the iris moves in the y axis towards the participants’ positions.

Prototype Two (Fig.2)

Visual description: similar to Prototype One. The difference was the use of abstract shapes to represent the eyeball and iris. This was developed to test if there was a difference in the result when showing a human-like eye form compared to showing an abstract eye form.

Stimulus: same as Prototype One

Behavior when activated: same as Prototype One

Prototype Three (Fig.3)

Visual description: grid of squares equally distributed over the width and height of the screen

Stimulus description: abrupt onset and looming motion;

Figure 2: Prototype Two

Figure 3: Prototype Three — Original form (left) and motion activated form (right)

Behavior: when activated, a previous selected square pops-up by increasing its size; a series of squares with incremental sizes are drawn between the original square and final one; this new shape moves towards the participants’ position.

Prototype Four (Fig.4)

Visual description: grid of rectangles equally distributed over the width and height of the screen

Stimulus description: onset and looming motion;

Behavior when activated: the rectangles increase shape proportionally to their distance regarding the participant’s position. The result is a circle-shaped blur that follows the participant in continuous motion.

Prototype Five (Fig.5)

Visual description: grid of circles equally distributed over the width and height of the screen

Stimulus description: gradual change in luminance contrast;

Behavior when activated: circle’s color gradually turned brighter as the participant approximated the screen.

Figure 4: Prototype Four — Original form (left) and motion activated form (right)

Figure 5: Prototype Five — Original form (left) and motion activated form (right)

Figure 6: Prototype Six — Original form (left) and motion activated form (right)

Prototype Six (Fig.6)

Visual description: grid of circles equally distributed over the width and height of the screen

Stimulus description: abrupt onset and change in luminance contrast;

Behavior when activated: circle's color gradually turned brighter as the participant approximated the screen.

Experiment Setup

The experiment took place in a room with diverse objects related to a photography studio. There was a white table in the middle of the room with a screen that would display the visual distractions. To test the experiment capability to attract the participant's attention through peripheral vision, the screen was placed in a 90° position in relation to the participant, and in the middle of the path between the participant's initial and final position — the target's location (Fig.7 and Fig.8). The person conducting the experiment was present inside the room and visible to the participant. This presence in combination with the studio photography objects served as complementary visual distractions to replicate a competitive visual environment.

Participants

The experiment was conducted with the individual participation of eleven voluntaries physically present in the experiment room. None of them had prior knowledge of the nature or goal of the experiment. The same task was given to all participants: step to one side of the room and walk a path towards the opposite wall, where a sheet of paper with a small text was placed (Fig.8). After the task was completed, the participants were informed about the scope of the experiment and were asked to describe their experience and perception of the distractor.

Figure 7: Scheme of the experiment room setup: (A) Participant's original position (B) Sheet of paper with text — Task (C) Screen displaying the prototypes — Distraction

Figure 8: Scheme of the experiment room setup

Results and Discussion

In this subsection we report and discuss the results of the experiments and propose further developments for the investigation. We perform a qualitative analysis of the experiments as the results were registered through observation and the participants' feedback noted.

While performing the requested task, one of the participants clearly moved the head towards the screen once the stimulus from Prototype Six was triggered; six participants reported that they saw the stimuli through their peripheral vision but continued focused in performing the task — this happened with stimuli from Prototype One, Two, Four, Five and Six; three of the participants concluded the task and reported that they could not perceive the existence or the activation of the stimulus — this happened with stimuli from Prototype Three.

Participant's oral feedback allowed to conclude that although most participants did not turn their heads towards the distractor, they have reportedly seen it. They also explained that they had to make a great effort not to turn their head towards the screen, in order to focus on the completion of the task — this was more evident in Prototypes Four, Five and Six. In addition, the text on the paper sheet was in a small body text which made the participants allocate a high amount of attention on that object and on the preoccupation of performing the task correctly. Regarding Prototype One, although the "eye" element is effective in capturing human attention we can argue its lack of efficiency due to the low capacity of the peripheral vision to perceive shape. Regarding the Prototype Three, which did not cause any level of distraction, there was a feedback from the third participant that identified a slight delay in the stimuli activation which may have contributed for its inefficiency. Finally, we also identified that complex visual compositions were less effective than the more minimal ones.

Although "salient items have an intrinsic ability to attract attention (...) the visual system can inhibit these items" [12] depending on the task attentional demand and on the observer's state. The high amount of attention allocated in the task of reading a text inhibited the distractor in different levels, which revealed to be an interesting output from the experiment. This situation is in line with visual attention studies that argue that reading is a controlled task, which requires a conscious control and a high amount attentional resources. This kind of controlled processes makes it harder to perform other task simultaneously or to notice high relevant information [1]. Also, the distance of the paper sheet — where the participants fixated their attention — to the screen, made it harder for the individuals to detect change in the visual composition displayed in the screen [20].

The overall conclusions of this experiment revealed a high distraction efficiency of abrupt onset and change in luminance contrast (Prototype Six), even when competing with a high attention demanding task, such as reading a small size text. A good distraction efficiency of onset and looming motion (Prototype Four) and gradual change in luminance contrast (Prototype Five). A medium distraction efficiency of onset motion combined with eye-like shape (Prototype One). And finally a low distraction efficiency of abrupt onset and loom-

ing motion. Possible reasons for some of these results are suggested in the previous paragraph.

Future Work

The preliminary results and analysis of the developed experiments allowed us to identify a set of important steps for the ongoing research and future improvements. First and foremost, we propose to test alternative explorations of the stimuli identified as less efficient. Then, considering the feedback obtained for the user tests we also intend to analyse the selected stimuli distraction efficiency when applied to visual compositions with different levels of complexity or when applied to competitive tasks with different levels of attention demand. Secondly, we aim to further explore the stimuli identified — either in this paper or in future iterations — as more efficient, and their application in the visual elements of graphic communication objects with an intended and defined message. Afterwards, we will test the computational capacity to read and interpret inputs from more complex environments — e.g., more participants at a time and higher number of environmental stimuli — and test the most appropriate stimuli for these situations. Once we achieve satisfying results in future developments, this is the effective capture of the participants' attention, we will drive our efforts to a study focused on feature-based saliency for maintaining the public's attention and exploration of the public's engagement with the content of the digital graphic object.

Conclusion

In this paper we described public urban spaces as complex environments with a high amount of environmental stimuli and goal-driven tasks. We identified the challenge of creating digital graphic objects that may stand-out from the remaining visual stimuli while addressing to a constantly changing environment. We proposed an approach for this issue by crossing the knowledge from visual attention and computational design in the creation of dynamic and adaptive motion-based graphical objects that trigger selected visual stimuli when detecting a human presence. With these objects we intended to create a distraction from an individual's goal driven task. We developed a series of prototypes and experiments to test their efficiency with a group of participants. The results allowed to identify the most and the less efficient approaches, some issues to be further explored, and established a basis for the next iterations of these adaptive motion-based and stimulus-driven strategies in visual communication objects.

Authors Biographies

Bruna Sousa is a creative technologist fuelled by curiosity. Aiming the creation of effective and affective visual communication, her work combines fields such as psychology and neurosciences with graphic and interactive design. She has a Bachelor and Master degree in Design and Multimedia from the University of Coimbra. Currently is a computational designer and researcher at the Computational Design and Visualization Lab, is enrolled in the PhD in Contemporary Arts of the University of Coimbra, and is also a teaching assistant on the Undergraduate and Master degree courses in Design and Multimedia at the University of Coimbra. Her research interests are related to computational art and design. She also explores different approaches in typography, graphic and motion design, being them interactive, participatory or adaptive.

Ana Rodrigues is a Computational Designer. Aside from being currently enrolled in the PhD Program of Information Science and Technology at the University of Coimbra she does research at the Computational Design and Visualization Lab., CISUC. Additionally, she teaches as an Invited Assistant at the same institution. She is particularly interested in exploring computational bridges that may emerge from crossing the domains of Visual Communication, Music, Cognitive Sciences, and Media Design. Other interests of hers include Computational Creativity and Artificial Intelligence.

Nuno Coelho (Univ Coimbra, CEIS20, DEI) is an Oporto based communication designer; a professor of Department of Informatics Engineering (DEI) of the University of Coimbra, where he teaches on the undergraduate and master degree courses in Design and Multimedia; and an Integrated Researcher at the Centre for Interdisciplinary Studies (CEIS20) of the University of Coimbra. He holds a Ph.D. in Contemporary Art from the University of Coimbra, a master in Design and Graphic Production from the University of Barcelona, and a degree in Communication Design and Graphic Art from the University of Oporto. As a design researcher, he is interested in history, material culture, digital humanities, and visual semiotics and representation. He has developed self-initiated projects in the intersection between design and art, raising questions, in its vast majority, about social and political issues. He has curated and coordinated design exhibitions and talks. He has two books published. www.nunocoelho.net

Penousal Machado is the coordinator of the Cognitive and Media Systems group and the scientific director of the Computational Design and Visualization Lab. of the Centre for Informatics and Systems of the University of Coimbra. His research interests include Artificial Intelligence, Evolutionary Computation, Computational Creativity, Computational Art and Design. He is also the recipient of scientific awards, including the prestigious EvoStar Award for Outstanding Contribution to Evolutionary Computation in Europe and the award for Excellence and Merit in Artificial Intelligence granted by the Portuguese Association for Artificial Intelligence. His work was featured in the Leonardo journal, Wired, and included in the “Talk to me” exhibition of the Museum of Modern Art, NY (MoMA).

Ecopornography in Digital Arts

stenslie@gmail.com / cerpina.zane@gmail.com

Abstract

This paper investigates the presence and use of ecopornography in digital arts. Here, “ecopornography” or “ecoporn” is defined as the representation of nature intended to stimulate the viewer into a heightened state of arousal and excitement similar to that when exposed to pornography. There has been an exponential growth in ecopornographic content in contemporary society and culture due to the massive use of digital media and technologies. Ecoporn is now more common, accessible, and persuasive on both personal and societal levels than conventional porn.

This paper calls for an in-depth analysis of nature-related content across digital media and media arts. How can digital arts be more critical in exploring and exposing the effect of ecoporn on society? When does ecoporn’s hyperaestheticization of nature lead to an anaesthetic loss of sensation? A new taxonomy of ecoporn can help us reflect on these questions. Five major subcategories are proposed: a) *Nature Pure*, b) *Nature Rough*, c) *Nature Hurt*, d) *Nature Saved*, and e) *Nature Fake*. Finally, the paper introduces the “Ecoporn Personality Test” – a digital tool that allows users to explore their ecopornographic preferences and tendencies.

Keywords

Ecoporn, ecopornography, digital arts, hyperreality, hyperaestheticization, anaestheticization, contemporary digital society, hypernature.

Introduction

Our encounter with nature can be as passionate as it is cognitive (Rolston, 1979). Within the digital arts, it can also tip into the hyperreal, where layers of media create new associations and experiences that contribute to heightened perceptions and emotions that might be far from the “real nature” outside your door. Such hypostatic, exaggerated, and even fantastical experiences of nature can be defined as ecoporn. Ecoporn is here, therefore, understood as the representation of nature intended to stimulate the viewer into a heightened state of arousal. The intended use can be explicit or naively implicit as in the many examples where new filters such as in Instagram apparently “improve” or deliberately beautify images of nature. Ecoporn’s heightening of arousal might be both cognitive and corporeal. Its intensity is comparable to the

boost in emotional states that is also found in pornography, but ecoporn is not necessarily or explicitly sexual.

Why compare the representation of nature to pornography? In a world increasingly worried about global warming and the onset of ecological catastrophes, we are progressively influenced and sensitized by digital representations of nature. How real are these impressions? And what effect do they have on us? Do they contribute to real-world interventions – or lead us into passivity through media overload?

Hashtag #nature is now one of the most used tags on Instagram with more than 525 million posts and counting (Newberry, 2021). From social media selfies with wild animals to 360° videos of pristine landscapes, and AR filters improving the looks of everything *natural*, contemporary society is oversaturated with more and *better* content about nature than ever. Digital technologies and social media have made ecoporn not just exciting, but its massive presence has also normalized its hyperreal imagery to a point where we hardly recognize it.

Nature has always been an important part of human survival and wellbeing. It is only natural that imagery of nature persuades attention and evokes a strong emotional response. In that sense, overly heightened human desire for nature can be compared to natural addiction, just like the urge for overeating, pathological gambling, or compulsive sexual behavior (Nestler, 2005). This addiction to nature is sensible as it is rooted in our existential dependency on it. Reading and knowing the looks and signs of nature can mean the difference between life and death. Less so in the world of digital aesthetics.

Mediated through electronic media, nature is often objectified, decontextualized, simulated, and presented as a commodity in similar ways to pornography, therefore, such focus on nature can be deemed ecopornographic (D’Amico, 2013, p.149).

In our age of global warming and ecological catastrophes, ecoporn has become a new, legal billion-dollar exploitation industry that is more common, accessible, and potentially even further away from reality than conventional porn. Traditional understanding about presentations of our lived environment is that they will always be one step away from the real thing. Entering the hyperreal dimensions of digital arts we enter a zone where the digital and virtual world becomes the real thing itself, a multidimensional, layered experience with a more

complex, possibly deeper meaning than “real reality”. The reality outside the box still exists, but the actual, perceived meaning is reborn and found inside the new hyperconstruct (Flisfeder, 2017). Immersed in the digitally hyperreal, how does a possibly skewed, misinterpreted, misconceived, or even idealized and adorably exaggerated perception of our environment affect our actions? Given the urgency of the Anthropocene, there is an imperative need to recognize how different representations of nature arise and affect the relationship to nature and the capacity of imagining and building better futures.

How do digital artworks displaying different forms of ecoporn affect the audience’s perception of nature? Can digital art and experimental media projects expose the contemporary society saturated with ecoporn? Or are nature-themed media art just another way to multiply ecopornographic content and simply arouse hypernature-addicted viewers? Hypernature is here understood as a made-up, potentially “better” version of nature that never existed (Next Nature Network, n.d.).

Hyperaestheticization of nature in digital arts

From representations of nature in its supposedly pristine form to exploring emerging global environmental crises, artists use digital technologies to create their own representation of nature and natural processes on the Earth.

Incorporating hyperreal references to nature in digital arts has created many amazing, inspiring, and jaw-dropping pieces. Nature set into the toolbox of digital technologies has also led to an extreme aestheticization of it. Such hyperaestheticization of nature into hypernature is at the core of ecoporn.

The use of nature as a powerful representation and signifier is not unique to the digital arts. Nature has been an artistic focus and element since the Lascaux cave paintings. In the late eighteenth and early nineteenth century, the open-air painting was en-vogue, powerful, and highly popular. Today they might seem like a quaint comparison to, for example, multi-sensory, immersive environments, but not only can traditional paintings be considered a predecessor of modern media, but also in their own time such imagery evoked strong feelings and excitement. Digitally transformed and re-represented they continue to do so in virtual, online galleries such as “True to Nature Virtual Tour” by The National Gallery of Art, USA (2020).

Digital representations of nature are frequently encountered in the digital arts. They are used as the main element in immersive environments, live image filters in social media such as AR makeup (Alpha, 2022), 360 videos, interactive sound environments (Jana Winderen, 2021) and not to forget as digital backdrops. In fact, the probably most viewed image in the world is “Bliss” by Charles O’Rear. Portraying the blue sky above a green and fertile landscape it was used by Microsoft as the default background for its Windows XP operating system (Wikipedia, 2021).

The aesthetic use of nature as iconography in digital arts reportedly has a strong impact on the users. In the “Osmose” installation by Char Davis (1995) users were

immersed in an interactive, virtual-reality environment modeled as a semi-transparent, glowing forest with an archetypal cosmic tree at the center. Users have reported profound after-effects (Davies, 2015). One user purportedly even said, “now I can die”.

Such examples demonstrate how digital art can reconfigure nature. One of the hyperreal aspects of “Osmose” is its representation of a more saturated, possibly even better experience of nature. It is definitively more immersive, intense, and encompassing than an average walk in a real forest. If Char Davis did not intend to create ecoporn, the installation has been a huge inspiration and a predecessor to many digital artworks that did. The immersive “We live in an Ocean of Air” (2019) installation by Marshmallow Laser Feast is one such artwork where: “...as the visual splendour kicks in, and you explore the space, there are gasps of wonder and peals of laughter as visitors explore the possibilities of the artwork. As the world around you begins to fade away at the end of an all-too-brief spell, there is a genuine feeling of loss.” (Jacobson, 2021).

Installations such as the “Osmose” and “We live in an Ocean of Air” harness their users with the power of digital technology that spurs them to imagine the world in other ways. Giving the audience such a radical autonomy far away from physical nature lets them both experience and question what is really real. Simultaneously their experience of loss is also indicative of their wish for a different nature. Or likely, as a consequence of hyperaestheticization, the continuous leveling up of excitement leads to an exhausted state of indifference. Nothing matters anymore and possibly results in a state of anaestheticization leading to an anaesthetic loss of sensation (Welsch, 1997). What was virtually and briefly beautiful is suddenly replaced with the grey weather outside. Will these sudden changes be met with increased engagement? Or a state of disinterest and disengagement? The emancipatory potential of ecoporn has been discussed in many ways.

Redefining Ecoporn

The first definition of ecoporn was introduced by Deep Ecologist Jerry Mander in 1972 in an article titled “EcoPornography: One Year and Nearly one Billion Dollars Later Advertising Owns Ecology” (Măntescu, 2016, p.6). Mander’s interest was to display the inherent power and dangers of corporal “greenwashing”. With a background in advertising, he acknowledged how companies were often misusing nature and ecology to build a more positive and environment-concerned public image (Măntescu, 2016, p.6).

Since the 1970’s researchers and ecocriticism writers have adopted and tried to expand his definition to address the persuasive uses of nature imagery. These contributions have largely remained within the realm of idealized representation of nature.

Several writers, including José Knighton, have criticized ecoporn as using the same production techniques as in pornography, to appeal, seduce and evoke desire

(Măntescu, 2016, p.8; Welling, 2009). Their main concern has been the heavy mediation and distortion of reality through the human viewpoint.

Bart H. Welling similarly analyses the contemporary visual discourse of “idealized and anthropomorphized views of landscapes and non-human animals” (Welling, 2009). However, he also accounts for “hard-core” obsession with explicit sexual and brutal content of wildlife such as mating and violent killing amongst non-human species (Welling, 2009). Further, Welling also recognizes the emerging dualism in ecoporn. For example, the contrasts of representation of nature as dystopia/utopia and destroyer/savior (Welling, 2009).

While the recent studies expand the notion of ecoporn in useful directions, the discussion remains too narrow and short-sighted, neglecting the vast variety and enormous amount of digitized, filtered, and altered nature representations that are mainstream today. A new taxonomy of ecoporn might be helpful in navigating its rocky waters.

A Taxonomy of Ecoporn

The stories and content about nature in digital media and media arts vary greatly. With the onset of the new geological age of the Anthropocene, heightened attention is now paid to Earth’s ecosystem being severely impacted by humans. Much like Jana Winderen’s field recordings, Jacob Kirkegaard traveled to Greenland in 2016 to record “pure nature” sound for his digital artwork “MELT”. The artwork resounds the recorded “different stages of ice melting, moving from violent sounds of ice caps grinding against each other to trickling sequences and flows of water” (Kirkegaard, 2016).

There is also an emerging trend of viewing nature entirely from the augmented viewpoint of machine learning technology. Anna Ridler’s tulips created by an AI algorithm in the work “Tulips from Mosaic Virus” (2018) evoke awe, without existing in the real world.

How does Kirkegaard’s representation of nature differ from that of Ridler’s? Both artworks can evoke strong emotional feedback. Yet the audience’s response to them in relation to nature is likely to vary, and the level of arousal might be different to each individual. How to discuss the potential emotional arousal and impact when digital artworks thematizing nature vary so notably?

Ecoporn serves as a filter to a nature that reveals itself as a cultural construct that is constantly molded, reshaped, and interpreted. To navigate and understand this complexity we introduce five different ecoporn subcategories seen most often: a) *Nature Pure*, b) *Nature Rough*, c) *Nature Hurt*, d) *Nature Saved*, and e) *Nature Fake*.

Nature Pure

Nature Pure represents the romantic, idyllic non-human world untouched by humans. In this category, there is no place for explicit content or even naturally occurring violence. In the age of the Anthropocene *Nature Pure* is the ultimate Disney fantasy. Digital media and in particular

new filter technologies have contributed to a diversity of *naturally*-looking views of nature. As in the case of “Bliss” by Charles O’Rear, a few iconic images are given the power to define the appearance of nature globally and universally.

Emerging projection technologies are used to extend the romantic view of nature conceived in traditional arts. Since 2008, the popularity of immersive 360° projections and VR experiences created based on the work of such painters as Van Gogh and Claude Monet (Exhibitionhub, 2022) have taken over art museums across the world (Cascone, 2021). Here viewers get immersed in 3D, 360 surround projections of idyllic landscapes representing the perfect perceived harmony in the environment. How does this influence the viewer’s relationship to nature when leaving the white cube?

If digitally created nature is not immersive enough, another approach is to use technologies to extend reality itself. What if the romantic, distant image of nature comes alive – breathing, moving, talking? Media artists use sensors, amplifiers, and various outputs to turn the often silent and still impressions of nature into more lively forms.

For example, artist Joakim Blattman’s installation series “Treverk” (“Woodwork”) (2015-) uses surface transducers attached to the trunks of trees, allowing the sound of the artwork to be affected by the electrical conductivity changes in the logs in real-time (Blattman, 2019).

Through curated experiences, including geo-located sound walks, media artists rush to reveal the invisible agency of non-humans. Can mixed-media experiences augmenting the romantic notion of nature change the way actions are taken towards non-human entities? Are people becoming more compassionate and caring towards the natural, analog world by seeing and hearing technologically amplified signals of nature?

Nature Rough

From raging forest fires to the flooded rivers ripping human habitats apart, the *Nature Rough* easily hooks on the viewers as the ultimate apocalypse. On October 14th in 2021, during the writing of this article, 5,497 people were watching a live Youtube stream of the La Palma volcano eruption, in the Canary Islands (afarTV, 2021). Natural disasters and explicit imagery of natural pecking order in the animal and plant world makes for an exciting, popcorn-ready ecoporn.

The ongoing environmental crises have become a major topic in the contemporary media and media art world. What happens to the audience when the power of unforgiving nature is posed and projected through media art?

In the work “Waterlicht” (2015), Studio Roosegaarde created an immersive virtual flood, showing how high the water level could reach in Amsterdam due to climate change (Roosegaarde, 2022). While visually submerging the audience way under the surface of an imagined rise in future water level, the impressive laser show is more than satisfying to the eye. Has the thought of future catastrophes ever been so aesthetically pleasing and stimulating as today?

What if the main output of such hyperaesthetized ecoporn images of rough and powerful nature is to turn the audience emotionally on? Instead of causing the intended reflective changes in behavior as the answer to potential threats to human existence?

Nature Hurt

With the onset of the Anthropocene – the new geological age also known as *The Age of Man*, there is increased attention worldwide to humans’ negative impact on nature and natural processes. This has accelerated the representation of *Nature Hurt* where nature is shown as the suffering entity directly harmed by humans.

The most iconic ecoporn of the 21st century is that of *Nature Hurt*. From plastic-filled seabird corpses and deforestation of the Amazon rainforest to hardcore snuff movies by PETA (PETA, 2012), it is hard to avoid the ecoporn that is supposed to make you feel guilty for troubles in nature.

Media art is often both interdisciplinary and critical of contemporary issues. Media artists are finding ever new ways to expose the pain and suffering that the viewer—as representative of the human species—should reflect on.

An example of *Nature Hurt* is the earlier mentioned sound installation “MELT” by Jacob Kirkegaard. The artist immerses the audience into the painful sounds of melting ice as a result of human-induced climate change.

Nature Saved

Paradoxically, in other cases, humans perceive and represent themselves as the major saviors of nature and wildlife. From selfies of saving animals to sharing and participating in donation campaigns for a good nature cause, social media and the internet are saturated with mixed media content of *Nature Saved*. Such ecoporn can literally even be porn. For example, Pornhub’s creative campaign “Dirtiest Porn Ever” (2019) is an adult film featuring workers picking plastic waste while a couple has sexual intercourse. In exchange for views, Pornhub donated for the cause of cleaner beaches in the world.

Such explicitly ecopornographic content is less common in media arts. However, artists gladly investigate intricate and speculative ways humans could undo or fix their damage to nature.

Artist Rihards Vitols in the project “Woodpecker” (2016) explores if the introduction of artificial birds could contribute to the natural balance of the forest. Commenting on the possible extinction of the woodpecker, he made artificial wood-pecking objects that mechanically pecked on trees (Vitols, 2016). The pecking vibration is supposed to keep the tree-hungry insects at bay.

How are the viewer’s real-life actions affected when seeing the many potential nature-saving scenarios in media

art? Does such ecoporn evoke action or soothe the viewer with the promise of better solutions over the horizon?

Nature Fake

Digital technologies offer endless possibilities to envision the concept of nature. What might look like *Nature Pure* at first glance, can also turn out to be *Nature Fake* and entirely made up by code. One example is the mentioned Anna Ridler’s “Tulips from Mosaic Virus” (2018) that is an algorithmic transformation of tulips according to the price of Bitcoin (Ridler, 2018).

The above discussed categories and examples give an insight into the different ecopornographic subcategories present in digital media and media arts. How do they affect or mirror our personalities?

Ecoporn Personality Test

There might be no way to avoid ecoporn in contemporary digital society. However, a heightened personal awareness of it could potentially improve our relationship with nature. Could a digital tool focused on self-reflection contribute to making better constructive decisions and lead to a real-life impact in the age of ecological catastrophes?

To explore the five subcategories of ecoporn and their different appeal to individuals, we are developing an experimental digital platform. The “Ecoporn Personality Test” will allow users to explore their ecopornographic preferences and tendencies.

Through a series of questions and related visual material, the test aims to analyze how different ecoporn subcategories arouse each user (Figure 1).

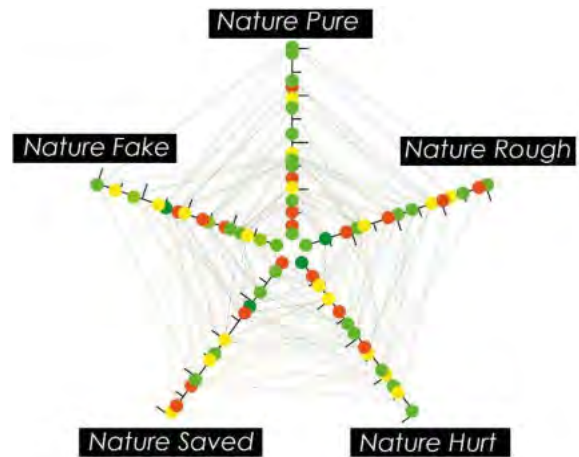

Figure 1. The five ecoporn subcategories in the “Ecoporn Personality Test”.

The first prototype is an online personality test. The platform uses common ecopornographic imagery circulating the internet and social media (Figure 2).

The “Ecoporn Personality Test” will be further developed as user inputs are collected.

Figure 2. The first version of the “Ecoporn Personality Test”.

Outlook onto Ecoporn Future Trends

The “Ecoporn Personality Test” is created as a tool for individual self-reflection. While it exposes the viewer to a large quantity of ecoporn, the project vividly frames the users’ preferences in the process. The massive exposure is intended to be a visible disclosure of their blindness towards ecoporn imagery.

The open question that the “Ecoporn Personality Test” still has not answered is if such an approach can be used to raise awareness of how one is hooked on ecoporn? How can digital arts instead of expanding the already existing volume of ecoporn be more critical in exploring and exposing its effect on society? This is an area in need of future exploration and the focus of the next development phase of the project.

Summary

Contemporary society is exposed to an ever-increasing amount of ecoporn. Ecopornographic content is everywhere from social media to digital arts. Digital technologies have accelerated its spread and creative impact.

Not only are many people unaware of their exposure to ecoporn, but they also seek it and create it themselves. Ecoporn constructs an artificial image of nature and—similar to pornography—connects its viewers to an idealized, hyperaestheticized version of nature.

By introducing five subcategories of ecopornography this paper calls for an in-depth analysis of nature-related content across digital media and media arts.

The examples discussed throughout this paper show the vast diversity of how nature is presented in media artworks. The paper further questions how to recognize and evaluate the potential emotional effects and responses to different subcategories of ecoporn.

The proposed online platform “Ecoporn Personality Test” is created as a self-reflective tool that allows users to reveal their ecopornographic preferences. The platform

gathers user responses to various ecoporn subcategories and playfully speculates on their potential effects. This experiment investigates how the field of media arts can address its involvement in the production and distribution of ecoporn. When is it good? And when is it anaestheticizing us?

Authors Biographies

Stahl Stenslie (NO) artist, curator and researcher, specializing in experimental art, embodied experiences and disruptive technologies. His research and practice focus on the art of the recently possible – such as panhaptic communication, somatic sound and holophonic soundspaces; disruptive design for emerging technologies. He has been exhibiting and lecturing at major international events (ISEA, DEAF, Ars Electronica, SIGGRAPH) and moderated symposiums like Ars Electronica (Next Sex), ArcArt and Oslo Lux. As a publisher he is the editor of EE – Experimental Emerging Art magazine (eejournal.no), he has written numerous scientific articles and co-founded The Journal of Somaesthetics (somaesthetics.aau.dk). His PhD on Touch and Technologies (virtualtouch.wordpress.com) Former professor in new media at The Academy of Media Arts, Cologne; The Oslo National Academy of The Arts; Aalborg University (DK). Currently head of R&D at Arts for Young Audiences Norway (kulturtanken.no)

Zane Cerpina [LV/NO] is an interdisciplinary female author, curator, artist, and designer. Cerpina lives in Oslo and currently works as project manager/curator at TEKS (Trondheim Electronic Arts Centre) and editor at EE: Experimental Emerging Art Journal. From 2015 – 2019 she worked as creative manager at PNEK (Production Network for Electronic Art, Norway).

Cerpina is the author of the *The Anthropocene Cookbook: Recipes and Opportunities for Future Catastrophes*, co-written with Stahl Stenslie and forthcoming at MIT Press, October 2022. Her extensive body of works also include curating and producing *Meta.Morf 2022: Ecophilia*; *FAEN (Female Artistic Experiments Norway)*; *The Dangerous Futures Conference 2018*; *Oslo Flaneur Festival 2016*, and *The Anthropocene*

Kitchen event series (2016-). Cerpina has initiated and been part of several important archival and research projects such as The Norwegian Media Art Library and is one of the editors for the *Book of Electronic Arts Norway*.

Probing Food and Power with Robotized Spoonfuls of Edible Paste

David Szanto, Simon Laroche

University of Ottawa, Concordia University, Canada

dszanto@uottawa.ca, simon.laroche@concordia.ca

Abstract

Food, technology, and humans are entangled in a set of complex relationships that both produce and resist systems of power. The specifics of these dynamics often remain hidden, whether in agrosience, cuisine, mobile apps, or other mediated contexts. In this paper, we present a reflexive analysis of *Orchestrer la perte / Perpetual Demotion*, a food-and-robotic art installation that demonstrates how putting food matter ‘where it doesn’t belong’ can reveal what often remains obscured in our bodies, digital realms, and other relational spaces. Conceived around the theme of domination and nurturing, OLP/PD features a feeding robot that delivers spoonfuls of edible paste to humans’ mouths, using facial-tracking technology. The work probes issues of mutual enslavement, deskilling, the loss of privacy, and the fear-risk-trust within eating. At a broader scale, OLP/PD also troubles food and safety policies, probes culinary authenticity and heritage, and heightens tensions relative to eating and bodily penetration. Drawing on our experiences, we show how digital-material art can illuminate a variety of ways in which dominance and power arise. We propose that this can help surface different and more equitable forms of interaction, whether among food, technology, and humans, or in the more abstract realms of power, culture, and ‘mattering.’

Keywords

Food, technology, robotics, power, nurture, domination, interactivity, performance.

Introduction

Food, technology, and humans are entangled in a set of complex relationships that both produce and resist systems of power. Since the industrialization of food production, this has become ever more evident, yet the entanglements date back to the first time a stick or a stone was used to extend a human being’s reach into the world. At the same time as letting us dig, poke, kill, cut, and cook, our physical tools have blurred the boundaries between what is human and what is technological, what is self and eater, and what is other and eaten.

Today, our hunting and gathering, foraging and culturing, husbandry and horticultural activities often take place in collaboration with digital technologies both visible and hidden. This includes the ways in which we exploit food apps on our

smartphones, the inventory management software of distributors and retailers, and the ever-growing ‘revolutions’ of digital and precision agriculture (Bronson & Knezevic 2016; Lupton 2018; Tian 2017). Numerous forms of non-human agency are now deeply integrated with the ways in which we grow, process, transport, sell, buy, prepare, eat, and even digest our food. In some cases, this web of practices is also dotted with sensing devices—data-capture mechanisms that are in service to both individual well-being and corporate control. Food data is big business, and its use is not agnostic (Carolan 2018; Laurier Centre 2021).

Some food scholars have begun to look at the risks, benefits, and perversions of the blending of food and digital technology. This work suggests that, without critique and pushback, much of the benefit of digitization will be reaped within large-scale agriculture, corporate expansion, and the transnationalization of taste and culture (Barrett & Rose 2020; Klerkx et al. 2019). As in many spaces that are shaped by technocracy, smaller players in the world of food may be becoming disadvantaged in ways that will only become apparent over time.

In parallel to this emerging area of critical scholarship, and as an exploration of certain themes that we (Simon and David) have been exploring some time, we present here a reflexive analysis of *Orchestrer la perte / Perpetual Demotion* (OLP/PD), a food-and-robotic art installation first exhibited in Montreal in 2014. (See Figure 1.)

Figure 1: OLP/PD feeding a human in four moments

While not exhaustive, these reflections are intended to surface insights and/or reinforce theorizations about food and power, particularly those related to materiality. Since 2014, our ‘feeding robot’ has been installed at six other events; a seventh installation would have taken place in March 2020 had it not been for the COVID pandemic. In each case, we witnessed our glossy-messy amalgam of material components become a lively and unpredictable social performance. Polished aluminum, brownish-orange edible pastes, a wooden IKEA kitchen table, hexagonal agar-agar gels, electronic circuits, 200 metal spoons, and a human ‘slave’ comprised (most of) the material parts. Taste and disgust, museum regulations, anxiety and enthusiasm, the concepts of art and design, Max/MSP coding, food safety training, human bias, and historically loaded language comprised (some of) the social elements.

Together, these components and the ways in which they performed together produced a series of occasions in which to observe what happens when we put food matter ‘where it doesn’t belong’. Many things that remain obscured in our societies, bodies, digital realms, and other relational spaces became evident, just as other questions about art and materiality remained hidden. With this text, we aim to unpack and reflect on some of those occasions, drawing out the material-social implications of food, technologic, and human relations.

Genesis of a Robot-Feeding Installation

We first met in 2012, introduced by a mutual friend and fellow artist-researcher, to develop an exhibition and colloquium around the themes of food and technological hacking. Although the larger project did not ultimately come about, a smaller iteration comprising three food-tech installations was eventually presented at the Musée d’art contemporain de Montréal (MACM) during the 2014 International Digital Art Biennial (BIAN), itself a part of arts organization Elektra Montréal’s programming. We had therefore been talking about and exploring themes related to our overlapping areas of research-creation—robotics/digital arts and food design/gastronomy—for some time. Notably, both of us shared a common interest in ‘looking under the hood’ of our fields of exploration in order to question and/or invert some of the norms they both present. Through the development of a robotic performance, we wanted to create an opportunity that “simultaneously reinstates the status of automata as counterparts to ‘humans’ and invites biological bodies to reassess their place in a world” (Dimitrova 2017, 162).

We were both interested in themes related to power and destabilization when it comes to human relationships with food and technology. More specifically, we wondered about the ways in which humans are both in control of and controlled by those tools/edibles we take for granted in the day-to-day. We found ourselves speaking the same language about our ostensibly different subjects, eventually realizing how similar many of our questions were. Does buying in to so-called convenience, access, simplification, and information exchange empower humans? Is a smartphone a

helper, a spy, a prosthesis? Do supermarkets and recipe boxes free humans from domestic labour or enslave us to systems that slurp up our preferences so as to sell us more product and deskill us yet further? Are we dominated by food and technology, nurtured by them, or both?

Eventually, this last theme became central to our ongoing discussions: domination and nurturing are implicit in the relationships that humans have with food and digital technology, and yet this simultaneity is not always so perceivable in the day-to-day. As we developed the concept further, we realized that the food-technology relationship is also one of domination and nurturing, and that part of this dynamic relates to microbial life forms—yet another player in the cycles of control that humans imagine themselves to be in charge of. We decided to therefore build a feeding robot, one that would deliver spoonfuls of partially fermented, partially deadened edible paste to human mouths, all using facial-tracking technology. We would use language (the duo-lingual title of the piece and the word *slave*) to destabilize discursive standards. We would install it in a space that is conventionally used for hands-off artworks. We would display the other systems of domination and nurturing that such an installation depends on—an apparatus of humans and refrigerators and food-safety guidelines and scheduling rosters. We would then step back and watch what happened.

And things did happen. Because the world of food art is relatively new, particularly in more-conventional spaces such as galleries and museums, we found ourselves bumping up against procedural norms with each iteration of the robotic installation. Some of these frictions were more predictable, such as questions of whether a waiver would need to be signed by gallery-goers before they opened their mouths. Others related to artistic specificity, as when one curator asked us to change the word *slave* to assistant, or when another told us she’d prefer that the mini-fridge that held the food supply be hidden behind a curtain. On one notable occasion, David found himself on a wind-swept Montreal street having a cell-phone conversation with the Maricopa County (Arizona) food-safety manager, who simply couldn’t understand why we weren’t going to have the robot food made in advance by a licensed caterer.

In each of these situations, the material-discursive entanglements that comprise food kept interfering with the conceptual-processual expectations of digital art. In what follows, we first consider the tensions between material objects and spectacular processes. We then probe moments from our experiences in mounting the piece at seven different art festivals, contexts that show how digital-material art can illuminate forms of dominance and power. Over a longer timeframe, we believe that these learnings can help surface different and more equitable forms of interaction, whether among food, technology, and humans, or in the more abstract realms of power, culture, and ‘mattering.’

Material Objects, Spectacular Processes

One way to conceive performance/art installations that involve interactive and digital technology is through the

design of its functional capabilities. That is, rather than initially concerning ourselves with the visual aesthetics, we first chose to address the behavioural cues of the piece—its “communication aesthetics” (Forest 1984). This meant devising a context in which humans come into contact with a synthesized agent, whether food, human, or material accessories. What might eventually happen among these elements would then be determined (in part) by the ‘open script’ that we would write. This script included the computer coding in the machine, which would enable it to act and react, as well as the instructions given to the slave. But it would also—in fact, mostly—be determined by the physical properties of the material elements we mobilized, as well as the unwritten ‘social scripts’ that tend to guide human behaviour in contexts like art festivals.

The result of this scripting was that the robot was able to ‘see’ visitors, grab spoons, and move here and there. As it slowly brought a spoonful of edible paste towards a visitor’s face, the human would (usually) open their mouth and adopt a submissive posture, ready to be nurtured and/or cede control. Further, because it is taller than most humans, the robot’s physical presence carried an additional quality of domination. The eventual rapport created was thus reminiscent of a parent or a caretaker feeding their child or charge. For us, the symbolic meaning of the experience derived from the interaction between those bodies and their physical-spatial properties, rather than being strictly attached to the conceptual meaning that the installation represents. To read about and imagine being fed by a machine is one thing, but the actual blend of awkwardness, loss of control, and subjugation brought on by performing the act is what gave the work its substantiality (see Boisclair 2019).

The food design followed a similar process. We had a very clear idea about what it would not be, that is, easily recognizable in either form or taste. We wanted the edible pastes to exist as matter infused with potentiality, distanced (as much as possible) from objective gastronomic referents. At the same time, their ‘recipes’ were as scripted as the materiality of the rest of the piece. Culinary histories of the places we visited were considered, particularly histories involving domination and power, such as fermentation techniques, the colonial shaping of Québec, the experience of Italian immigrants in Belgium, and the omnipresence of potatoes in Polish cuisine. So too were the ingredients themselves critical: agar-agar, invoking bacterial culturing; sugar and glucose, touching on slavery and industrialization; mustard seed and powdered ‘wasabi’, generating mild oral and ventral discomfort. In this way, the pastes were both material agent as well as abstract art, acting on bodies and minds simultaneously. They elicited reactions in the eyes, nose, and the mouth through its sensorial properties, while also adding to less site-specific feelings of uneasiness and renunciation.

Established in these ways for each installation, the robot was set in place and activated. We knew it was a multi-material object that would activate many forms of both spectacle and embodiment, but we had no sense of the range of performances that would unfurl, nor that they would be so

different in each context. We now understand it as both material and spectacular object, a set of processes involving matter and discourse, and a thing that is embedded in larger agencies beyond our own. While this is a much-explored theme in art and performance studies (Bourriaud 2002; Kirshenblatt-Gimblett 2012; Spielman 2013), as well as such fields as science and technology studies (STS) and new materialism (Bennett 2009; Law and Singleton 2000; Miller 2005), it was reinforced in ways that continue to bear reflection.

Stories of Materiality

Orchestrer la perte / Perpetual Demotion is an interactive art installation, a feeding machine, and an aesthetic and communicative object. For both of us in our respective practices, however, it is the narratives surrounding its exhibition that have become most interesting. These stories are now fully entwined with polished aluminum and circuit boards and cooking notes, and form an ever-widening envelope of ‘art’ around our formal structure. Embedded in this package are a series of questions that trigger our understanding of the ways that OLP/PD operates as a probe into the materiality of food and technology.

Where Is the Art?

This question first arose in 2014, when OLP/PD was part of the Hedonistika/BIAN/Elektra exhibition at the MACM in Montreal. Upon arriving at the loading dock of the museum, David was met by an administrator with a form to be filled out, identifying all materials comprising the food components of the art piece. Photographs were to be taken of the fridge, packing crate, tools, and other pieces of the apparatus. (Simon, having arrived separately, also went through this process with the table and robot.) Upon our departure, additional photographs would be taken and the original form consulted, in order to ensure that what came in was also what went out.

For standard museum installations, this makes sense—quite reasonably, the MACM would want to be sure that visiting artists weren’t popping a Riopelle or Kandinsky into their packing crates before exiting the building. But for the food—the three edible pastes labelled *lab whiz*, *plum vs. apricot*, and *cheesecake factorial*—were photographs necessary? As David expressed to the administrator, these elements of the artwork would be coming into the museum in chilled plastic containers, but they would be going out in the bellies of the visitors (or down the pipes of the museum’s bathrooms). This meant that making comprehensive documentation of what left the museum would be more than challenging, but it also raised the question, once again, of where art ‘resides’. For OLP/PD, the art is distributed across the material elements of the installation, the bodies of the MACM visitors, and the performance enacted between them. But as David and the administrator engaged in their own envelope of pre-vernissage performance, we also came to understand that the art of the work had implicated

bureaucracies and paperwork, not to mention plumbing systems both architectural and digestive.

Another happy discovery of the multi-sited (and multimedia) project came in the form of notes and comments and drawings that our slaves captured on the task list and roster sheets we had provided them. Intended as a bit of pseudo-bureaucracy attached to the slave's role, the paper and pen eventually became tools of distraction and even resistance. Following the installation at the MACM, as well as several other locations (notably in Wrocław, Poland), we found that the slaves had been exchanging messages, doodling, critiquing visitors, and amusing themselves otherwise with the task list sheets. (See Figure 2.) These informal representations of the tedium of being an OLP/PD slave were documentation of a performance we never anticipated triggering. Invisible to the gallery goers, as well as to us, the artists, the repurposed papers became an icon of the performative nature of the robot, not to mention a powerful symbol of how art-world laborers are often even more enslaved than we normatively imagine.

Figure 2: The slaves' task list sheets at the MACM installations

Is it Art...?

...or is this robot a great new way to feed people with disabilities, freeing up support staff from spooning three meals a day into the mouths of those in their care? That our critical artwork was sometimes viewed as a prototype for an applied piece of technology shows less about its own material presence and more about the other material things that certain contexts implicated. The question at first may seem out of left field: Why would an eight-foot-tall Delta robot—a

model used for industrial, pick-and-place operations on manufacturing production lines—have been our choice for a care-home design? On reflection, however, we realized that it was not the robot 'itself' that gave rise to the question, but rather its integration within other material ecologies.

We first heard it at the 2015 Maker Faire in Ottawa, Ontario, an aggregation of hackers, tech innovators, and artists who came together to experiment with robots and other digital technologies. We had been invited, through media-art contacts of Simon, to present OLP/PD during the run of the event. Some of the Faire's attendees are solution-oriented, some are more exploratory. Nonetheless, because of the nature of the gathering—largely angled towards practicality and action—it was a context in which hearing this question was not surprising. Robot-as-spectacle, robot-as-critique, robot-as-probe: these were not the ways that OLP/PD would have been standardly perceived by the Maker Faire participants. Robot-as-solution, robot-as-worker, robot-as-prototype: much more so.

At a broader scale, it is also unsurprising that a feeding robot would be thought of in practical terms. Robotic labour is increasingly supplanting that of humans, and even in pre-COVID times, there was growing consciousness around care-home labour shortages, as well as the dreariness of many aspects of such work, feeding included. To free up humans from this slow and not always pleasant activity could well be seen as the goal of OLP/PD. The link between industrial robots and ours was also present in the Delta design, and that material connection likely reinforced the 'incorrect' perception of our intent. In parallel, we also realized that the materiality of the food that was being served up—an easy-to-swallow, semi-solid, not-very-identifiable paste—had served as a prompt for the question. The edibles that the robot pushed at people were much like the puréed and mashed foods that are often provided in care homes. We eventually learned to accept and even invite such inquiries, rather than resist them as contrary or simplistic.

Is it Food?

"This tastes like my grandmother's fishy pâté!" said one visitor at the MACM exhibition, just as another (an artist familiar with David's work) said, "I'm not eating any more of your weird shit." The pale orange paste we had coyly named *lab whiz* was made from three naturally fermented and cultured ingredients (labneh, sourdough rye bread, and *nuróc măm*), along with those ingredients' industrially stabilized analogs (Cheez Whiz, Wonderbread, and Lea & Perrins Worcestershire sauce). David called it a "battle royale" between the power of microbes and the power of pasteurization, and imagined it playing out in the stomachs of gallery goers. For him, it was an experiment in conceptual food art. It was comestible—we all ate it, some with pleasure, others with doubt, but none (to our knowledge) with digestive distress. It was comparable to familiar foods (salmon mousse, processed cheese spread), and it needed refrigeration to maintain texture and palatability. Simultaneously, it was also distressing and unrecognizable to some (*fishy pâté*,

weird shit), and a few who tasted and tried to swallow eventually had to spit it out.

Somewhere between our *lab whiz* going into one of the robot's spoons and being expectorated into a visitor's hand, the paste may have ceased to be food. But had it been food before that? Certainly it had existed as such in its lifetime—as a set of ingredients bought at a grocery store, combined and processed in a kitchen, sealed into plastic-wrapped cylinders and kept 'safe' in a fridge at an appropriate 3–4°C. But when it went into the cake-decorator syringes and from there was pumped into metal spoons by the slave, then laid out on hexagonal agar-agar pads on an IKEA table anchored to a shiny robot, did it remain in a state of foodishness? What about even earlier, when we conferred about the effect we wanted it to produce in visitors' bellies, or the symbolic meaning we were aiming at—dominations of technologies, nurturing matter for humans, spaces of microbial control? Did our use of the materiality of food, when taken out of the cooking/eating/digesting context, turn it into not-food? Probably not fully, but the tensions between *pâté* and paste remained.

How Stable Is this Art?

Immaterial concepts and discursive ideas can traverse long trajectories through time without too much erosion or damage. But art that is made with things that move, sense, and ferment can be more fragile. As we packed and unpacked the robot, blended ingredients in somewhat unsanitized spaces, and kept pushing back on curators' demands, elements of OLP/PD began to fail. Moreover, in Mons, Belgium, when we placed the robot in the care of some less artistically engaged slaves (festival volunteers), pieces of it actually broke, and we're not entirely sure that the food safety procedures were followed.

This is one of the problems of giving body to concepts, and of asking less committed bodies to maintain already tenuous concepts: they tend to eventually come apart. Because of the fragility of matter (edible, technologic, human), we became aware that our rather conceptual work was decaying through use. Repairs and retraining (of both the robot and the slaves) had to take place between and before each exhibition. Every time we evaded food poisoning (real or imagined), we felt like we had gotten away with something, postponing judgment day to the next iteration. We ourselves felt somewhat fragile each time we were asked to mount the piece: did our psyches really want to go through the effort and risk? Did we have it in us to argue for the visibility of the mini-fridge, to precision drill the robot's mounting hole, to train up on new safety regulations, or to find clean kitchen areas to prep pastes and wash 200 metal spoons? Each time, the answer was yes, but each time it came out of our mouths more hesitantly. Our own material (and social) resiliencies were eroding, much like the robot itself.

Now, having had a hiatus due to a global pandemic, we look back at the artwork as a relative—and temporal—stabilization of different technological, food, and human matters. Like all performance processes, OLP/PD is constantly being made, unmade, and remade—a set of homeostatic

relationships between it, its contexts of exposure, its creators, and its audiences.

How Stable Is this Concept?

Even as we state that concepts travel better through time than matter, we have come to realize that the concept of the robot is powerfully linked to material realities over which we have little control. (This in itself is amusingly in keeping with the core theme of the piece.)

In 2018 in Lyon, France, for example—a self-proclaimed European capital of gastronomy—our choice of ingredients for one of the pastes brought concerns from parents about whether it would be "safe" for their offspring to eat. Made with a combination of fresh bread crumbs, panko, cultured butter, margarine, smoked paprika and liquid smoke, the *feu fumée* became a point of friction with some festival organizers and visitors. *But what about the children?* one concerned parent asked. *What if they burn their mouths? What if it's too strong for them?* This sentiment foreshadowed a similar moment in 2019, when David was in a classroom in Squamish, British Columbia, teaching about food and performance and using OLP/PD as an illustration. Again, pushback (this time from a student not facing the robot's glistening visage) came about consent and permission, and whether it was fair and equitable to serve food to people who hadn't adequately been informed of its ingredients. Another student raised the issue of allergies and intolerances, and whether our 'hidden' recipes were creating contexts of exclusion. Both of these moments displayed, once again, the ways in which food art now intersects with the trigger warnings and pre-admission disclaimers that have begun to haunt other forms of art and performance. Just as paintings and sculptures, music and dance implicate sensorial absorption, food brings affective, emotional, and physical impacts.

A perhaps more useful insight relates to the ways in which the matter of food art differs from that of more conventional forms, such as sculpture, ceramics, or painting. That is, because much food art relies on using normative media in non-normative ways, it often aligns with contemporary, avant-garde practices that eschew the beautiful (*l'idée du beau*) and the agreeable, and instead presents itself as a radical, sensory experiment. Our pastes were not aimed at producing pleasure, at least not in a conventional, gustatory sense. They were, instead, conveyors of experience, devices we used to challenge expectations regarding the ingestion of matter. The minimal intensity of *feu fumée*—slightly spicy, fatted bread, extruded onto a magnetized teaspoon in a darkened, spotlighted corner of a contemporary art space—showed how material edibility transects many norms of eating and art. (See Figure 3.)

Similarly, in the lead-up to the ill-fated Emerge 2020 festival in Mesa, Arizona, our use of *slave* in the promotional documentation became a point of contention. The organizers understood our intention, and even appreciated it, but felt that the impacts of American slavery (particularly in the then-Trumpean era of highly fraught race relations) created a context in which this term would act too powerfully. We acquiesced, changing the wording to "attendant" in the

advance materials, while nonetheless agreeing that we could utter the word *slave* on-site. This would allow visitors, and the slaves themselves, to engage in a conversation about the impact of the term, while keeping the un-contextualized website text a little less fraught. Because Emerge was cancelled a few days before we were to travel, we never got to test our deployment of the word in the United States. As awareness of historic enslavement practices in Canada grows (of both Black and Indigenous people), we will continue to remain attentive to the fragility of our discursive choices.

Figure 3: Material elements of the ‘food’ in Lyon, France.

Reflection, Conclusion

OLP/PD probes issues of mutual enslavement, deskilling, the loss of privacy, the permeation of intimacy and the fear-risk-trust complex within eating. At a broader scale, it also troubles food and safety policies, probes culinary authenticity and heritage, and heightens tensions relative to eating, bodily penetration, and the presentation of self. That it is at once a spectacular object and a material process means that identifying its ‘true nature’ is moot. Like other food performances and digital creations, the robot exists as a whole, yet one that is only entire when implanted in a context and interacted with by others. This is where its value lies, we believe. Through integration into the socio-material world, it also intervenes and produces effects. Through analysis of these effects, we (the artists, the critics, the gallery goers, the other witnesses) can discern the subtle and not-so-subtle power relations around us, leading to questions about where and how domination is established.

Our role as artists was to prepare ingredients, to assign potentiality to bodies both artifactual and organic (as well as

some that were in between), and to loosely establish a set of scripts. In order for effects to be projected and for affect to travel among the various bodies, we then set a table and invited visitors to assemble around it. By establishing and engaging with these contexts and environments, we and those that the robot fed entered into a lived experience that was both materially familiar and socially strange. The resulting semblance—an abstraction of power dynamics among food, technology, and humans—produced novel affects that we hope will lead to ongoing reflection about other modes of existence, ones that might hint at new recipes for the re-creation of human/non-human relations.

Acknowledgements

Research, development, and installation of OLP/PD has been funded over the years by numerous agencies and arts organizations, including: ArtEngine, Canada Council for the Arts, Elektra/BIAN, Fonds de recherche du Québec, Fundacja WRO, Groupe Molior, OFFTA, Productions Recto-Verso, and the Social Sciences and Humanities Research Council of Canada. The Hedonistika Montreal exhibition project was a joint initiative of Monochrom and Jane Tingley.

Abstract

In order to investigate the possibilities of co-creation between performer and interactive virtual system, we have developed a scenic installation composed of two parts: the virtual environment and the interaction interface. We offer an analysis of our creative experience from the point of view of the artist researchers in the field of real-time generative synthetic image. Our results show that the creation depends on how the performer perceives the virtual system as well as how he perceives its influence on this system. The creative potential of the system depends on the mechanisms generated and implemented by the artist in a metacreation context and his interpretation of the interaction data. Our perspectives point towards the conception of a *scenography-character*.

Keywords

Metacreation, performance, interactive digital art, artificial life, scenography, scenography-character, interfaces

Introduction

Artistic context

The process that produces artistic experiences or artifacts is no longer a secret enclosed in the artist's studio, but a system of creation set in motion by the artist and continued when confronted with the materiality of collective participation, of the spaces of exhibition or of everyday urban spaces. [1], [2]

The digital arts have been developed thanks to the advent and popularization of technological tools. They emerge as a transdisciplinary approach between design, computer science, complexity sciences, biology, and artificial life. The creative processes have become technological. [3]

In the context of participatory works, the viewer becomes an actor in the work and potentially a performer, who can even interact remotely. [4] The type of interaction is no longer responsive but can be adaptive, conversational, and creative, between machines and participants. [5]

The literature gives examples that an evolving virtual ecosystem can be creative or that this type of self-organizing system can demonstrate an emerging potential allowing it to improvise with a performer. [6], [7] Some developer-artists seize the computational capabilities of the graphics card in

an alternative way to create complex systems and use artificial life algorithms, giving rise to emerging behaviors and impressive endogenous interaction phenomena. [8], [9]

Other developer-artists create or hack interfaces using electronic sensors or mobile devices to establish a tangible, intimate and active relationship within the technological social context and connected networks. [10] Through such interfaces, artists seek an adaptive and dialogic, conversational engagement between the participant and the virtual system, in order to investigate possible relationships with the machine and to express the uncertainty of existence through the uncertainty in the work of art.

For Whitelaw, the conception of a generative, evolving, interactive system is one of the characteristics of an artwork that can be described as autonomous. He refers to this method of creating digital works by the term *metacreation*. [11] Such a system contains parameters of appearance and behavior which can be modified according to the interaction with the external environment to the virtual, what Bret calls the sources of exogenous interaction that complements the endogenous interactions which occur between the components of the virtual system. [12] This dynamic diverges from the initial instructions given by the artist-developer and may result in unpredictable behavior occurring during the processes. It is regarding this meta creative process that we will assess the creative potential of the virtual part of our scenographic proposal.

Project *Co-évolution, Co-cr ation et Improvisation Homme-Machine* (CECCI-H2M)

The research-creation process described in this article is part of the *Co-évolution, Co-cr ation et Improvisation Homme-Machine* project, led by Chu-Yin Chen: that investigates ways of sustainable behavioral coevolution with emerging human-machine co-creation. The project proposal merges two research-creation approaches through practice. That of the artist-researcher Silvia C rcu, who studies the choreographic interactions between performers and robots. And that of Isadora Teles, which aims to establish a dynamic of improvised co-evolution between performer and evolving virtual system. This article traces and analyzes the experiments carried out by the two researchers during two

artistic studio residencies, from the point of view of the artist developing the virtual system and its interfaces with the scene.

During their experiments, the artist-researchers compared their artistic proposals to find convergences and clarify their intentions and ideas. The common goal was the conception of a co-created performance on stage between the performer, an HRP-4 humanoid robot and an interactive evolving virtual ecosystem. It was also a question of characterizing what the possibilities of co-creation between the performer and two types of artificial entities would be, when those artificial entities are either embodied or not embodied on stage.

The project also aimed to question the design of autonomous and evolving creative tools for performance with the intention of staging an improvisation for the performer and his alter-ego taking the form of an evolving virtual ecosystem. Our hypothesis to establish a dynamic of creative collaboration was that the development of an autonomous and evolving ecosystem would be embodied and therefore would assume a physical form on stage, being able to influence the performer's gestures (**Fig. 1**).

Experimentations

Experimental Plan

The experimental plan to set up a creative and improvised interaction between performer and artificial entities consist of:

- Developing, separately, three prototypes of "species" for the virtual ecosystem as well as their mode of intra-species interactions.
- Developing three interface prototypes for interacting with elements on stage and embodying the same virtual system in the form of objects that can be manipulated, played, and penetrated by the gestures of the performer.
- To study the possible co-creative and adaptive interaction relationships between each "species" of the virtual system and the performer.

The aim of the proposal was to use metaphors of emotional states to imagine the shape and behavior of the different species that would inhabit the virtual world. The technical goal was to find ways of expressing and giving the sensation that, by their form and by their behavior, each species is possessed by or acts according to one of the emotions mentioned. Once the shapes and corresponding behaviors were clarified, the next step was to create and test the algorithms that could correspond to such sensitive expressions.

Creating a graphical simulation of a complex system must consider the technical challenge of animating and making many autonomous elements interact. This requires considerable computing power, which increases exponentially with the number of individuals. Therefore, the development of the virtual universe was carried out using mainly the technique of image synthesis by shaders.

The shaders enable the programming of the graphics card to generate images by calculations performed in parallel. [13] We have experimented with fragment shaders and then with compute shaders. Compute shaders allow us to get complex image and behavioral animation qualities which are difficult to achieve by other techniques, because they exploit the computing power optimized by the graphics card.

An important reason in the choice of technical tool was the existence of examples of simulation of common biological phenomena with the subjects treated by artificial life using such technique.

Compute shaders are used for scientific simulation as well as for bioinformatics and simulation of complex dynamical systems. [14] However, such references in the artistic field are rare and steps of taming and technical adaptation are required.

Virtual environment

Particle system with fragment shaders

The first prototype was designed to express the "dream" or the state of reverie. To do this, we have conceived a type of behavior which shows wandering flight, expresses a lightness in the movements and would be contrasted with another species which would represent "fear". This behavior leads us to think of the imaginary flight of fairies, a dance of birds or leaves heaving in the wind.

To set up this system of "imaginary fairies", we started by programming a particle system using fragment shaders, within the touchdesigner software. Fragment shaders make it possible to deal with many dynamic pixel data, but there can be no interaction between them, nor exchange of information.

The components of the particle system have basic properties of physical simulation, such as mass, velocity, and lifetime. They are influenced by forces external to the system, which can attract and guide them. An interesting aspect of the behavior of this particle system is that, if we

increase the particles' scale and the force of attraction, the collective behavior becomes an organic mass concentrated on a flow of force. This shape, green on a red background, is reminiscent of a pulsating organ (**Fig. 2**).

Figure 2. Recurring shapes during our experiments. Organ-like mass of fragment shader particles are depicted in green. ©Isadora Teles de Castro e Costa, 2021

This particle system behavior was not inspired by cell behavior, but it has emergent collective properties vastly used to model dynamic natural phenomena. [15] In our case it behaved like a pulsating organism or animal organ thanks to specific behavioral parameters explored through the process of improvisational interactional and “tweaking” on stage.

The void in the background of the virtual environment suggested an organ in preservation in a jar, isolated, but still “alive” (**Fig. 2**). The sensation of a living organ was due to the unstable movement of the system and therefore of the emerging collective form. This instability of the shape was caused by the data obtained from the capture of the performer by the Kinect, which controlled parameters inherent to the particles such as their maximum speed, their mass, and the constants of attraction towards the attractors. This phenomenon of data instability was the positive cause of the pulsating impression of the particle system organic form.

Particle system with compute shaders

Our second experiment was the modeling of a particle system whose position information was calculated by a compute shader. The change in technique was aimed at establishing an endogenous interaction among the particles and with the virtual environment. For studio residences, the particles could not be perceived among themselves.

The difference between compute shaders and other types of shaders (vertex, geometry, and fragment shaders) is that they do not fit into the render pipeline. The compute and the fragment shader have similarities, but they were designed for different purposes.

The compute shader allows us to use the GPU to perform calculations that are not necessarily related to 3D or image processing. This is the so-called GPGPU technology for General-Purpose computing on Graphics Processing Units.

In our case, we used it to calculate the position and velocity of a particle system guided by a mathematical function that generates organic flow, which can be used to simulate fluids.

We were inspired by the systems of particles moving in a Curl Noise. The technique is often used for dynamic non-autonomous systems such as fluid simulation or the displacement of the sand. In our case, we used it as a wind force to guide the particle movement. The wave variations and their organicity helped us get a prototype of the aimed behavior : an impression of a self-organized multi-agent system [14], [16] (**Fig. 3**)

Figure 3. Choreographic exploration in interaction with compute shader particles. The performer modified the parameters of a curl noise function. The noise guided the movement of the particles. ©Isadora Teles de Castro e Costa, 2021

We tested the interaction between the performer’s motion capture data and the second prototype of the “Dream” species. Two joints of the performer were linked to two behavior parameters of the particle system. The elbow position controlled the direction of the Curl noise that guided the movement of the system, and the knee position influenced the direction of the noise and the friction, that is, the damping of particle velocity.

These interaction links allowed an interesting synchronization between the movement of the particles and the performer’s gestures. This occurred because we were able to identify a notion of rhythm in the intervention in the friction of the particles and the fact that the movement of the arms influenced their direction, giving the impression of a dance master to the performer.

Cellular automata with compute shaders

The second species that would integrate the virtual ecosystem represents “fear”. Our main issue was to find a way to create a type of virtual agent that leaves patterns and traces on a surface by its growth or by its displacement to represent fear as something that spreads out on surfaces and that leaves traces. Traces of infectious and unhealthy appearance, and whose appearance is reminiscent of mold.

We were inspired by the modeling of the behavior of *Physarum polycephalum*, a single-cell organism that can exhibit the formation of complex and emerging growth

patterns. [17] The first step in modeling such behavior was first to set up a cellular automaton system to establish the basis of an optimized algorithm for endogenous perception and interaction between virtual individuals. This method is suggested by Arsiliath in his *Psychobiotik* workshop¹ where the goal is to build a complex system of autonomous agents with compute shaders. Two variations of the cellular automata were tested. One based on the concept of cyclic cellular automata and the second based on Langton's Edge of Chaos article. [18], [19]

The peculiarity of the cellular automata algorithm is that, depending on the combination of parameters of interaction behavior with neighboring cells, it can generate a large amount of different emerging patterns in a complex way and therefore difficult to predict by the artist. One would have to manually test a wide variety of different rule combinations to visualize the possibilities and choose a specific type of behavior corresponding to an intention, in our case, the internal emotional state of the performer.

The plethora of pattern possibilities emerging from several interacting entities is one of the issues studied by genetic algorithms (exploration of "landscapes" or "landscapes" of possibilities), especially when they are used as an aesthetic evaluation technique in interactive generative processes. [20] However, during the interactive experience, the performer explored this landscape of possibilities through his gestures, in a negotiation between the intention of his movement and the projected pattern that formed in response to the behavior generated by automata's evolutionary rules, conditioned by the position of the joints (elbow and knees) of the performer (Fig. 4).

Figure 4. Choreographic exploration in interaction with compute shader cellular automata. The performer's movements modified the parameters of the systems' behavioral rules ©Isadora Teles de Castro e Costa, 2021

Conclusions about the virtual environment

The development of a particle system through fragment shaders was a stage of learning and appropriation of the technique. The system was used during the experimentation

with the performer and opened aesthetic perspectives for further development of autonomous agents.

Once the technique for calculating particle behavior with the fragment shader had been entered, the use of texture buffers and separately rendered geometry instances allowed us to switch to the compute shaders to perform the calculation of virtual environment elements behavior.

The cellular automata algorithm was used as an intermediate step in the appropriation of the technique of building a base algorithm optimized for the creation of endogenous interactions. However, in view of the interesting patterns that emerge dynamically according to the exploratory exogenous interaction modifying endogenous interaction rules, this algorithm will be used as a component of the virtual ecosystem.

This will require an assessment of the expressive and poetic function of the patterns and an assessment of the interaction in the context of the artistic intention to express the internal state of the performer. The discussion is ongoing, but it should be noted the possible addition of a new kind of emotion to the virtual ecosystem following the experiments in the studio.

In the case of the prototype which aims to represent the state of "dreaming", the intermediate stage of development has also instigated thoughts. The particles produced with the fragment shader showed us the plastic potential of such a technique for building systems. We may use distinct levels of autonomy in qualifying different types of virtual individuals. However, a physical simulation operation without collision limitations and a degree of autonomy, can also prove to be a rich source of raw material for the creation of geometric shapes and masses in interaction with the performer. The variation in autonomy levels among the types of virtual elements was important to have a more malleable species, such as a kind of digital clay or a raw material that could be turned, like a vase on a potter's wheel. For the potter, although clay is not an autonomous or living material, it nevertheless presents physical properties and possibilities of plastic derivation rich in creative potential when it is modeled and glazed.

Likewise, the potential for plasticity of the particles' behavior, that were attracted and recalled by the symbolic representation of the performer in virtual space, made us question the condition of the autonomy of a virtual material conducive to creation. How exactly is a virtual simulation of clay matter, for example, more or less fruitful to co-creation than the simulation of a collective of ants or cells, when manipulated or influenced by a performer?

<https://twitter.com/arsiliath> (accessed Oct. 22, 2021).

Interaction interface

Tested hypothesis

First, we designed an electronic collar that captured the acceleration data of the perforator and transformed it into a rhythm of luminosity by means of two strips of LEDs.

Nonetheless, the interaction with the collar was not perceptible by the performer and this fragile structure did not adapt well to the performer's movements (**Fig. 5**). Given the priority of connecting his gestures to the virtual system, we conducted interaction tests by capturing movement with the camera of a Kinect. This allowed us to have fruitful interactions and gave us some leads about the links that the gestures could have with the virtual system. The interaction with the Kinect provided us clues on the plastic potential of virtual forms and their ability for enjoyment by the performer (**Fig. 5**).

Figure 5. Two moments of experimentation with the Kinect (left) and with the electrical-interactive necklace (right) ©Isadora Teles de Castro e Costa, 2021

Despite interesting interaction experiments with the Kinect, we wanted to keep the possibility of allowing the performer and director to improvise with sensitive interfaces. To explore the creative possibilities of the incarnation of the virtual on stage, the creation of sensitive stage objects that can be manipulated and played was important as a hypothesis to allow us to have a margin of movement in terms of layout in the stage and on the performer's body (**Fig. 6**).

Figure 6. Two different sketches representing how we imagined the interactive interfaces being manipulated by the performer ©Isadora Teles de Castro e Costa, 2021

Prototype 3: Communication between connected mobile devices and virtual system

To test our hypothesis of a modular, fragmented, and sensitive scenography, we needed connected devices allowing reliable communication and resistance to the movements and gestures of the performer. We therefore considered devices linked to mobile technologies as a hypothesis to solve this problem.

We have tested the portable device interaction hypothesis during the second studio residency (**Fig. 7**). During our experiments, the performer had to hold the devices limiting his movements. For the on-screen drawing interaction, the performer had to look at the screen of the portable smartphone. We do not yet know if this constraint of movement limitation is an interesting creative path, but, although this limitation seems unconstructive to the dancer, it reflects quite faithfully our daily use of portable devices.

Figure 7. Experiments of choreographic interactions with fragment shader particle system through the manipulation of a tablet. ©Isadora Teles de Castro e Costa, 2021

Conclusions about interface interaction

The use of this portable device by the dancer on stage led to the following observations:

On the one hand, the public or anyone connected to the web server could act as an attractor to the behavior of the virtual environment, partially controlling it from their smartphone. This is part of a process of active participation of the spectator in the performance. On the other hand, we could use multiple cell phones, which are more easily accessible to create connected objects or costumes. The function or the appearance of these smartphones would thus eventually be "recycled".

In our co-creation context, the exploration of the creative possibilities and the potential gestures that these portable devices allow remain to be deepened during a next residency together with an evaluation of the theoretical issues that their use gives rise to. For example, if we fix them on parts of the performer's body, what type of movement can the sensors of the portables acquire and make usable by the virtual system? The interaction by their sensor motivates an original use of cellphones or would daily gestures persist?

Results

For Whitelaw, metacreation as an artistic technique is theorized as a creator method itself, because the artist creates a creative process: "Familiar tropes of endless novelty and metacreation reappear; often the works are somehow autonomous; once made, they make themselves". [11] This creativity is developed in a different timeframe than the one we planned to study. Prior to the establishment of a co-creation between the virtual system and the performer, there is a co-creation stage between the artist-developer and his generative system that must be considered. In order to be able to characterize the emerging aesthetic phenomena that result from the functioning of the virtual system in interaction, the creation of a vocabulary specific to the generative system and to the performance.

The ability to describe a moment of creation and adaptation between the performer, the artist-developer and the generative system turned out to be necessary in our case study.

Although we have developed several types of virtual systems, they took on new meanings and those new issues arose during the studio experience. Prior to the establishment of a potentially autonomous and emerging system, the question of the perception of virtual autonomy by the performer as well as the physical characteristics and conditions of communication by the interface are important aspects that must be tested in situ. These are variables that can promote or jeopardize performance, and therefore, co-creation.

The hypothesis of creating an interface began with the idea of having a means of exchanging data between the stage and the virtual environment. Its appearance and operation have been designed to respond to artistic intentions and to the metaphor of the representation of emotions. Very early on during our experiments in the studio, we realized that their presence on stage fell within a broader framework than that of communication with the virtual ecosystem. We were confronted with the staging intentions and with the construction of the meaning of performance in general (in contrast with the sense of the virtual in isolation). The projected virtual environment and the interface became the scenography of the performance and therefore had to be considered together with the means of perception of the scene by the performer.

We developed some of the interfaces during the studio experience and tested them in the initial phase. This experience allowed us to direct our expectations and assumptions based on the materiality of the stage and the performer's body; the creation was therefore more applied and more suited to the desired artistic situation. The constructive or ineffective constraints of movement, induced by interfaces, were identified from interaction observations made in the studio. They allowed us to consider the performer's movement in a precise way

according to emerging hypotheses about the interface and embodiment of the virtual on the stage.

Through conversations and an interview with the performer, we noticed that the perception of co-creation (expressed by the performer as a perception of the autonomy of the virtual during interactions with autonomous entities) was more present when the interaction was simpler, clearer, and more responsive by the performer. This impression might be explained by the stage layout which was not very ergonomic or not very consistent with the idea of an exploratory and improvised creation with the virtual system. Indeed, the image of the virtual ecosystem was projected on a screen located behind the dancer and by which he was implicitly attracted. This generated a form of confusion or conflict of attention linked to the sharing of focus between the bodily creation of the moment and the follow-up of the exploratory interaction with the virtual. For the performer, the dynamic lived between that of being a spectator of an interactive installation and that of a dancer who focuses on his presence and his expressive gesture on stage.

This shared attention between the real and virtual environments turned out to be unconstructive and therefore uncreative. This observation made us consider the possibility of spatializing the projection on the stage, by means of a projection on the fabric of the performer's costume (**Fig 8**).

Figure 8. Experimentations with the projection of particle simulations over white and translucent fabric ported by the performer ©Isadora Teles de Castro e Costa, 2021

The first impressions of this ongoing test are already promising. They outline a path towards the resolution of the problematic of the interaction by the perception of the scenography. This scenography attracts the performer's commitment to the co-creation. The problematic of the perception of the scenography by the performer lead to the hypothesis of creating a scenography-character incorporated into the scene as a staged element. Such a hypothesis is as important a condition for co-creation as the construction of an autonomous evolving virtual ecosystem. Moreover, if the virtual system is not perceived as autonomous or if it is not perceived at all, how can it be in creative dialogue with the performer?

Discussion

Our experimentation in the studio gave us clues to understand the conditions conducive to co-creation in three key aspects of the scenic environment conception: the scenography (how the performer and the audience perceive the virtual), the interface (how the virtual perceives the "real") and the programming of the virtual system (creation of the behavior of virtual entities and of its endogenous and exogenous interaction modalities).

In view of the prototype state of species and interfaces, at several times the artist developer intervened to calibrate the interactions, test new relationships between the collected data and the parameters to improve the configurations of the virtual system. The presence of the artist-developer as an operator or mediator in the relationship between the performer and the generative system was studied within the INREV team and represents a concept and a model in its own right, within the dynamic of co-creation between the participant and the interactive device. [21], [22] The sensitivity and perception of the mediator enter as a variable in the evolution of performance.

The concept of performance co-created between mediator, performer and generative system gives us indications on how to incorporate a virtual system on the stage. Can or should this type of hybrid scenography have a mediator? Can he participate in the performance while being on stage? The operator's mediation on the perception of the performer's data by the virtual system could be used in the design of an evaluation function (fitness function) aiming to characterize the adaptability of the virtual system and its species as part of the implementation of an evolutionary step by genetic algorithm.

The studio development experience allowed us to consider the performer's expectations and needs and helped us build an emotional bridge between him and the virtual system. An added step in the interaction experience plan was the familiarization with the functioning of the system, during which the artist-developer explained to the performer how the system worked, how it was developed, what were his inspirations and what were the links that united the simulations or algorithms of artificial life described in many publications and the digital art systems created on these principles. After this introduction, the performer was able to forge subjective links with the virtual and led the interactions based on his new knowledge.

The learning and exploration phase have been shortened and new clues for co-creation have emerged, which Edmonds calls the adaptation and dialogue phase. [5]

A need of the performer was to perceive his influence on the rhythm of the particles. She felt that this influence existed at times and waned at others. The moments when she rediscovered this interaction became moments of creative awakening, driving new gestures. This need expressed by the performer motivated the start of the creation of a common vocabulary, mentioned in the **Results** section of

this article, which served as a bridge between the programming of the virtual environment behavior and the scenic vocabulary of dance. This need manifested by experience suggested the idea of introducing parameters into the behavior of virtual entities that could be identified as the "rhythm" of the virtual by the performer. How to identify dance phenomena in the language of virtual autonomy simulations to make the interaction clearer and more constructive with a view to co-creation? Other concepts from the vocabularies of the modeling of complex systems and of performance were exchanged such as: autonomy, incarnation, form, flow, among others, for which links will be built and discussed during the next studio experiments.

At the end of the first residency, we presented an excerpt from our experiments and received constructive feedback from the *Centre des Arts d'Enghien-les-Bains* and INREV teams. As spectators, they problematized the surface of the projection as well as the way in which we staged this projection. During a team discussion, we realized that this problem was also perceived by the performer and could thus be formalized from the angle of the perception of the virtual environment by the performer: how a specialized and fragmented scenography in space, not only at the level of the interfaces, but also at the level of the projections, can it contribute to a better perception of the scene and therefore encourage a dialogic / adaptive improvisation on the part of the performer?

This feedback was considered for the second round of studio experiments, when we tested projections on fabric in space and on the performer's costume. The new environmental specialization tests have been promising and are in line with our goal of building co-creation conditions.

Conclusion and Perspectives

The goal of designing a scalable virtual ecosystem quickly shifted to creating the virtual environment and building some form of onstage incarnation to support the performer's adaptive engagement. Our new research-creation hypothesis is to develop the evolving virtual environment so that its incarnation on stage allows spatialized perception and interactions with the performer. If we want the scenography to be played, touched, and manipulated by the performer, but also to be autonomous, acting and reacting to the stage environment, that supposes that it becomes an actor on stage. We call this conformation a scenography-character.

The dialogue will be established not only by the attention that the performer pays to the virtual environment projected on a screen or on himself, but also because in inhabiting the stage, the virtual induces constraints but also the suggested possibilities, which are as many attempts to confront these two elements.

The expression of emotions was initially implemented by following a process of metaphoric and analogical description of emotional sensation, and by transcribing it

through virtual movement from the point of view of the artist-developer. But these descriptions were changed during the studio experience thanks to observations and exchanges of ideas with the performer in an improvised situation. In this case, the expression of emotions by the entities is co-created at the level of the initial programming of the behavior of the virtual entities, within the limits of the emotion-behavior metaphor set up by the artist-developer. The scenography intends to express the alter-ego of the performer during an evolutionary transformation; its implementation will be our next work step.

The studio experience also caused the adaptation of goals and methods development of the virtual system and of the interaction interfaces, considering the limitations of the initial proposals through the materiality of the experience, the expressive needs and intentions of the performer / director and discovering the weak points and new potentials of the creation when it is put in a situation.

The characteristics of the hybrid scenography described in the article make us think of the possibility of interpreting the design of the scenography in a way integrated with the conception of the staging, by improvisation and by experimentation in the studio, in the form of a *scenography-character*.

THE MULTICULTURAL AND TRANSDISCIPLINARY CONSTRUCTION OF ANTI-CONSUMERIST CRITICAL THOUGHTS – THE MULTISENSORY DIVERSITY OF THE ARTISTIC INSTALLATION SERIES “THE WISHING TREE” (2012 – 2019)

Paulo Cesar Teles

University of Campinas - UNICAMP
Campinas, SP - Brazil
pteles@unicamp.br

Abstract

“The Wishing Tree” is a sort of multimedia sensorial installations made in artistic workshops that have proposed anti-consumerism thought and practice by a mix of recycling assemblage, handcraft, visual art, interactive music and technological artistic experiences. They are initially aimed at art educators and elementary and high school students and promote, from the integration of different means of expression, the integration between the visual arts, the audiovisual and digital/sensorial systems. This article evidences some aspects of these procedural art series, such as critical protagonism, agency, pro-activism and other ethical and cognitive additions in the courses of these international workshops-installations held between 2012 and 2019.

Keywords

Education Through Art, Art and Technology, Transdisciplinary Arts, Multiculturalism, Sensory Aesthetics.

Introduction

The pathological consumerism that plagues humanity today has been one of the main vectors of destruction of nature and civilization itself in the Anthropocene era (ISSMEMER & LÉNA, 2018), [1]. Reflecting and debating on this theme is necessary in all public and private instances, especially in the educational sphere.

From our background in the fields of communication technologies and Technological Art, we decided to provoke and reflect the above concern through the possibility of interactive and participatory integration between the arts, science and technology, in order to awaken, together with people involved, a critical anti-consumerist conscience through transdisciplinary artistic productions. Thus, we developed and carried out a series of multidisciplinary workshops that addressed, in their own ways, the artistic, technological and media fields, initially in elementary and intermediate schools, bringing together elements of recycling, drawings, sculptures, handicrafts, video,

animation, interactive music and interactive sensory mapping with approximation digital interfaces.

The foundations established for such achievements were based on an artistic and critical reinterpretation of the "Tanabata": a piece of traditional Japanese folklore constituted in a "tree" with written and hanging powers to fulfill wishes. However, the "trees" built in these workshops were derived from object waste and discarded industrialized product packaging. This leads to a reflection on realizing that such construction takes place from "realized desires" and, with this, a critical provocation to consumption practices led by desires and impulses (by necessity or will).

Twelve “trees” were built through workshops in schools, cultural centers, villages and indigenous villages in nine different countries, between March 2012 and July 2019. They took place in schools in Brazil (Campinas and Chapada dos Guimarães), Portugal (Guimarães), Germany (Kehl), Greece (Thessaloniki), New Zealand (Auckland), Nigeria (Osogbo), Nepal (Sikles), Namibia (Walvis Bay) and India (Annaikatti and Kochi). Some of these works were even exhibited at later art museums and cultural events.

We know how much visceral relationships, which nowadays tend to be established between art, science and technology, provide us with opportunities to explore unusual relationships between individuals and artificial structures of expression. As with all other areas of human knowledge, the evolving dynamics of this symbiosis have constantly led us to rethink procedural bases in the fields of technological art and emerging media.

Although, initially aligned with perspectives that take into account the fluidity of the constant material and behavioral transformation (JENSEN, 2001) [2] caused by the resulting informational actions-reactions between the work, the performer and the audience as well, in each place where they were carried out, provoked distinct and unique experiences and spontaneous actions as the final result, within the scope of human-machine interactions, from their diverse cultural, art-educational, motor and affective contexts. In this way, as the experiences took place, new concerns were attached to the ongoing investigations, caused by occurrences of a multi and transcultural nature (SANTOS, 2013) [3]. This has led

us to constant bibliographical, conceptual and conjunctural reviews, constantly promoting epistemological revisions and additions to this set of actions and resulting works, as well as their impacts on different and diverse audiences.

This manuscript brings the set of actions, results, past and former reflections that gave rise to and that derived from these local and transcontinental experiences. The dorsal thematic construction of these events starts this work, externalizing the diagnostic (JAGODZINSKI, 2020) [4] and tactical (FREIRE, 1970; BARBOSA, 1989) [5] [6] approaches, regarding the argumentative structure that anchors the development of these works. The productions and subsequent exhibitions of these works are discussed here from ontological and procedural conjunctions in their interactive and participatory aspects in all stages of their realization. The resulting expressions and concerns are finally debated in the light of a critical though changing "supra-relational" aesthetic, anchored in "ecosystem" (GIANNETTI, 2006; TELES, 2009; VEIGA, 2018) [7] [8] [9], multiversal and rhizomatic arguments (GUATTARI, 1992) [10].

Symptomatological radiography: the construction of an anti-consumer critical thinking through Art

"As art and media teachers, we have no choice but become symptomologists of our current crisis that penetrates so deeply how we live in the environment that we are modifying". this way, art-educator Jan Jagodzinski (2020, p. 266) defines the role of one who, at the same time, produces, teaches and researches in the field of Art, based on experiences, acquired knowledge and, mainly, an expressive diagnosis of situations and conditions experienced.

Even before the European aesthetic ruptures at the end of the 19th century and beginning of the 20th century (HAUSER, 1953 [11]; LITTLE, 2004 [12]), artists, in general, already sought to illustrate the materiality of their surroundings and formatted in his imagination, although he also sought subjectivities of an emotional nature and states of mind. Greek and Roman sculptures, as well as practically most of European art from the Renaissance to pre-impressionism, evidence this search as well as, with the acceptance and consecration of increasingly abstract arts from that *avant garde* period onwards, the supra-material diagnosis expressed has become more evident.

Among critical and affective apprehensions and consonances, the art educator also uses to encourage his students to become protagonists in order to provide, through expressiveness, not only their "soul state", but also to build, individually and/or collectively, their own knowledge. The symptomatology proposed by Jagodzinski acquires power and robustness when it is experienced in a dialogical and critical way, such as that already observed by Paulo Freire

(1970), for which "the dialogical man, who is critical, knows that, if the power to do, to create, to transform is a power of men, it also knows that they can, in a concrete situation, alienated, have this power harmed." (FREIRE, 1970, p. 46)

We will be critics, true, if we live the fullness of praxis. That is, if our action involves a critical reflection that, by organizing thinking more and more, leads us to overcome a strictly naive knowledge of reality. (Idem, p. 73).

Ana Mae Barbosa (1989), art-educator and former student of Freire, also provides subsidies for this supra-conjunctural look in the construction of critical knowledge through an artistic perspective. She argues that "despite being a product of fantasy and imagination, Art is not separate from the economy, politics and social patterns that operate in society. Ideas, emotions, languages differ from time to time and from place to place and not there is an uninfluenced and isolated view." (BARBOSA, 1989, p. 178)

We build History from each work of art examined by the children, establishing connections and relationships between other works of art and other cultural manifestations. (Idem)

More than a vector of consolidation of our Anthropocene era (ISSMEMER & LÉNA, 2018), consumerism, as an individual and collective social practice, became the main source of the system that produces and regulates our livelihood and performance in our world. At the same time that it produces everything we consume, it is, in fact, an inevitable destructive drain on matter, energy, information, as well as a producer of unprecedented waste and pollution. Its mainspring is the constant change that occurs in the forms, features and validations of products, whose terms and obsolescence have been predetermined in increasingly compressed time intervals. Stimulated by affective seductions, repetitions, viral media and machinic customization, consumers become hostages of this mantric spiral that prevents them from reflecting on effective alternatives that lead to a less destructive socio-environmental harmony than we currently experience.

The challenge posed here to this question originated from the encouragement expressed by the US-based Indian art educator, Dr. Mousumi De, to this author, in the sense of integrating artistic-technological productions to art education. This theme erupted in a dialogue between us in which she reported a work she did with teacher, artist and curator Roberta Altman with children from New York and New Delhi, based on the folklore of the "Tree of Desires" (Tanabata). In them, children expressed their desires through drawings and collages with recyclable material.

When designing this work, we decided to design a workshop that, initially, should reach Art teachers and

elementary school students (elemental, junior and secondary school), preferably aged between 09 and 14 years. They would be encouraged to express their desires through drawings, paintings, writings and video testimonials. Also, a three-dimensional sculpture in the shape of a tree should be built from used and discarded objects and packaging, with the knowledge that they are building a tree with fulfilled and consumed desires.

Interactive art + participatory art: ontological and procedural conjunctions

The touchless interactive aesthetic has since 2005 permeated our concerns about using the gestural actions of people in the empty state as part of a multimedia artwork. In our PhD thesis (TELES, 2009) we took this issue to a more robust understanding regarding the cultural and temporal diversification of interactive processes and interactional actions, anchored by theorists from different eras and scientific, philosophical and artistic currents. From Heraclitus' processualism to Giannetti's endo-aesthetics and the Guattaryan rhizome, passing through Hegelian dialectics, Einsteinian relativity and several other comparative references between ontological and systemic currents of thought.

Likewise, our experience in teaching in the fields of media studies led us to promote courses aimed at the audiovisual training of elementary and high school teachers in municipal and state public schools, from educative constructivist perspectives anchored in Paulo Freire, Ana Mae Tavares, Mario Kaplun, Jesus Martin-Barbero, Ismar Soares, among others (TELES and DE, 2017) [13]. In this way, the established challenge that emerged from that dialogue with De, came to merge this set of actions and epistemological baggage, developed that occurred in parallel throughout the first decade of the 21st century.

Touchless interactive works from lab to world: development, experimentation and mixed-media collectivization in art-educational workshops.

The search for the development of a touch-free sensory interface started in 2005 with the beginning of research into electronic and digital components that would transform the signals for capturing body movements into algorithms capable of producing and manipulating sounds, images and others machinic animations.

During this period, technologies that would promote DIY practice made it possible to actively connect a rich set of possibilities for action and sensory communication of the most diverse. Low-cost controllers such as the "Arduino" brand and derivatives, as well as nano computers such as the "Raspberry Pie" brand and the like, have opened the door to the imagination of garages, electronic and digital artists.

Presence, proximity, touch, heat, sound, color, mechanical pressure, speed sensors, among others, have become outstanding channels of artistic interactivity whose resulting works have become popular in the most diverse museums, events and cultural centers.

In addition to the Hegelian dialogical subjectivity (HEGEL, 2002) [14], the audience became a mechanical and bodily part in the "completion of the work" (MURRAY, 1997 [15]; WILSON, 2002 [16]; SHAW and WEIBEL, 2003 [17]; PAUL, 2003 [18]; HANSEN 2003 e 2006 [19] [20]; among others). Triggering and transformations of sounds, lights and images without touching or touching anything were for us a procedural consecration and a break with the cyborgism of material connection.

Figure 1. Sensory original structure scheme (XXXXXXXX,XXXX) ©Author's Copyright.

The option to establish the linear sensory capture of distance and approximation as a procedural basis for the triggering of interactive expressions in the works, from then onwards, was due to the possibility of "slicing" the total distance captured by the component for the execution of multiple commands algorithms and also the possibility of using several of these sensors in the same controller.

Figure 2. Photo montage: latest proximity sensorial interface controller, developed by Juliano Prado (left), the interactive installation "Pontos G – Um auto sem Natal", exibida no Museu da Imagem e do Som, Campinas, 2015 (center) and the interactive installation (in progress) "Antigenous 2.021 – current Resistances" (right)

The scripting of events to be triggered and transformed took the linearity of narrative time and replaced it with

spatiality. Thus, for those people used to script linear pieces, it would be as if minutes and seconds were transformed into centimeters.

Since then, the artistic pieces produced since then under this interfacial structure have not only become fundamental objects in our research, but also, on the other hand, got expressive results of fragments of one view of the world and of the moment, as well as of the interactive process framework itself.

Interactive and participatory processes as a “meta-endo-aesthetics” way.

The workshops that result in the interactive installations "The Wishing Tree" feature a pre-established plan between the author, the welcoming institution and the participants. A reference agenda with the proposed events is presented in advance to the future participants and then adapted before or during the event, according to the characteristics of the place, the participants and the total time available.

Figure 3. Photo montage: scholars building assemblage 3D sculpture from rubbish at Annapurna Secondary School in Annaikatti, Nepal, 2017 (left), the same job at Kingdom Kids School, in Osogbo, Nigeria, 2016 (center) and drawing their wishes at Agrupamento Escolar 2/3 João Meira, in Guimarães, Portugal, 2012.

In general, the list of activities for this workshop consists of:

- Initial lecturing to the participants: presentation of the project, debate about the theme and discussion of the work plan;
- Collection and recycling: non-organic objects are collected, cleaned and selected to be used in the sculpture - it is at this point that the previous usefulness of the object or packaging is observed, as well as the "leftover" which, when thrown back in the trash, they already do so by reflecting on the volume of consumption observed - in some places, especially in the indigenous villages of Silkes (Nepal, 2017) and Aldeia Milagrosa Pataxó Hahahae (Brazil, 2018) organic materials (tree branches and pieces) and local clay too were used;
- The construction of the sculpture: on the first day of the event (in certain places even before the event) a certain local tree is chosen by the participants to inspire the construction of the sculpture - the planning and

construction process, in which the separated garbage is transformed into a sculpture artistic is performed jointly by the author and the participants;

- Drawings and writing: students between the ages of nine and fourteen are invited to draw and/or write their wishes;
- Video interviews: a group among them selected by the responsible teacher reports their wishes on video recording - photos of their faces are taken for the final composition;
- Digital animation: some of the drawings produced are selected, digitized and animated - the rest are displayed along with the installation on the days of the exhibitions;
- Recording of interactive music tracks: musicians are invited to record a song to compose the installation under construction - with a laptop, a smartphone and a pair of headphones, participants record the theme composed or chosen together and then separately - the individual material is "recomposed" in the final composition of the work;
- Diagramming and editing of interactive reactions: through the "Isadora" software, images, sounds and animations are diagrammed and distributed on the display screen and their triggering are mapped in the linear space of the sensors (the number of approximation sensors has varied from one to three according to the size of the displayed place and the number of attendees at the event).

During the exhibition, participants and guests were encouraged to approach the sensors attached to the trunk or branches of the sculpture. Such movements made the animated images, the photos of the interviewed participants' faces, the interviews and the soundtrack (with the addition of each instrument or participant voice as they approached) to appear and become audible. those who participated in the construction, whether in assembly, drawings, sculpture or music, began to have an unusual contact with a strange and familiar work at the same time because of their co-authorship.

Figure 4. Photo montage: video collecting of wishes testimonials at Tulla Realschulle, Kehl, Germany, 2014 (left), recording of the interactive music's track at Vidya Vanan School, at Annaikatti India, 2019 (center), and digital editing process at !Nara Primary School in Walvis Bay, Namibia, 2018.

In turn, the mixed media interagency of waste from industrial products consumed with manuals and touch-free digital technology highlighted the pedagogical potential of expanding creative and multidisciplinary perspectives. The idea is not to teach a technique or a practical artistic craft, but, through the application of different techniques and skills already developed in each of the people involved, to build an expressive work that promotes at the same time unusual experiences in the field of art, and also to promote critical reflections on consumption, ethics and collectivity through the interactional and interactive environments established during the making and display of the artwork.

Figure 5. Photo montage: Assemblages tree sculptures at School of Oreokastro, Tessalonik, Greece, 2014, and at Thermoizina Siqueira Primary School, at Chapada dos Guimarães, Brazil, 2015.

Multicultural Impacts - Multiversal Results

Almost all installations resulting from these experiences were exhibited in the places where they were produced.

These are the cases of those that occurred at the Sesi Santos Dumont School, in Campinas, Brazil; at Agrupamento Escolar João Meira 2/3, in Guimarães, Portugal; at Tulla Realschulle, in Kehl, Germany, at the Secondary School of Oreokastro, in Thessalonik, Greece; at Somerville Secondary School, Auckland, New Zealand, at Shree Annapurna Secondary School, in Sikles, Nepal, at Aldeia Milagrosa Pataxo Hahahae, in Pau Brasil - Bahia, at !Nara Primary School, in Walvis Bay, Namibia, and at the Indian schools of Vidya Vanam, in Anaikatti, Tamil Nadu, and Tattwa Center of Learning, in Cochi, Kerala. The exhibition venue of the installation made at the Thermoizina Siqueira School, in Chapada dos Guimarães occurred in a local restaurant. In Osogbo, Nigeria, because the tree production was made in two secondary schools - Kingdom Kids and Excellent School - the grand finale took place in a city hotel capable of accommodating students, teachers and guests from both schools.

Some of these installations were later re-displayed in other locations, cities and countries. The installation produced in Nigeria crossed the Atlantic Ocean towards Brazil with the artists Olaniyi Sunday and Babalola Mahmood, who also brought some of their works painted in oil on canvas, and was exhibited in the lobby of the Mário de Andrade Library, in the city of São Paulo and at the

Museu da Cidade and Museu da Imagem e do Som, in the city of Campinas.

The installation, which was carried out with the Pataxó Hãhãhãe indigenous people - through an artistic residency promoted by the project "Indigenous Electronic Art" (AEI) led by the NGO Thydewa - was also exhibited at the Pankararu-Paraguassu Indigenous School, in the city of Pau-Brasil and at the Museum of Modern Art in the city of Salvador (Figure 4). It also became one of the reference works of the award that obtained the "Honorable Mention" in the "Start Prize 2019" awarded to the AEI by "The European Commission honoring Innovation in Technology, Industry and Society stimulated by the Arts" (CIBERARTS, 2019) [21].

The Brazilian curator and researcher Alessandra Simões (2019), who visited the exhibitions of the project "Indigenous Electronic Art", analyzes "The Hãhãhãe Wishing Tree" from the perspective of aesthetic results based on common shares between contemporary and ancestral poetics. She understands that they "cannot be understood as opposing expressions, but practices and knowledge that interrelate in unstable and syncretic spaces, whose ultimate goal is the junction of "art-life"" (SIMÕES, 2019) [22]. The installation was considered by her as "a true relational web".

The "tree sculpture" was made from the recycling of garbage found in the village, with digital proximity sensors and interactive audiovisual expressions based on the movement of people around. (...) the "ritual dimension" was unveiled with artists who incorporated ritualism in their work, such as the Tree of Wishes Hãhãhãe, whose parts were composed by collecting waste in the village, desirous of being transformed into art from a ritual of collective choices. (Idem)

Figure 6. The Hahahae Wishing tree at Museu de Arte Moderna, Salvador, Brazil, 2018.

The!Nara Primary School installation workshop, in Walvis Bay, Namibia, was also exhibited at the InSEA

International Seminar 2018¹, which took place in that same city the week following the event. I invited some students and the key-teacher, among those who participated in the workshop, to present this job together with me to an audience of artists and art educators from more than twenty countries. Event guests were also encouraged to interact with the wishes expressed by those children.

Altogether, among participants, staff and audience, more than two thousand people have already visited and interacted with these works on five continents (we still do not hold workshops of this series in North America). Some of those installations were re-displayed in art schools and museums. These were the cases of the workshops that took place in Osogbo, Nigeria, and in Aldeia Milagrosa, Brazil.

Some of the events received around eight hundred people, as in Osogbo and Auckland (in this school we held several daily exhibitions over three days, serving an average of sixty students each), while those with the least participants and visitors occurred in Chapada dos Guimarães and Sikles, with approximately forty people in each of them.

In addition, other installations were produced by us from the materials collected in those previous workshops and from the first "tree" produced, donated (back) by the Sesi Santos Dumont School and kept until today. The concatenation of these materials produced "world tour" versions of this work, which were exhibited at the University of São Paulo (ABCiber 2017)² and at the gallery of the cultural space "Casa do Lago". In these cases, we realized that they played the role of "interactive multimedia documentary". In those exhibitions, a set of photographs and a video documentation were added in order to provide the audiences (without any previous connection with the work) of information about the procedures and results emerged from those related experiences.

Figure 7. Photo montage: "The Wishing Tree World Tour" 2012 – 2019 exhibition at Casa do Lago, 2019.

1 The InSEA SEMINAR was hosted by the Society for Arts Education in Namibia (SAEN) at Walvis Bay, Namibia in October 29 to November 02, 2018.

Universal consciousness, spontaneous interactive polysemy and the constitution of a rhizomatic ecosystem multiverse

A brief analysis is needed here regarding the diversity of those who interacted with these experiences in relation to the impacts caused to them. For a more accurate understanding, we must distinguish those who acted in the construction of the installations from those who acted in the form of an agency audience (MURRAY, 1997), despite the fact that, in the exhibitions at the venues, the people were the same.

In this case, even though the productions have taken place in a vastly different way in the social, cultural, pedagogical and technological spheres, the concerns generated around garbage pollution were quite similar. The transformation of waste into an interactive multimedia work had a "universal" impact on the workshop participants by giving them a solid sense of belonging and attachment to that whose composition derives from the connection of the expressions of their aspirations with the metaphor expression of "once fulfilled desires" contained in the rubbish.

Actually, we never expected that the workshops would promote an immediate anti-consumerist conversion among the participants, but rather provide them with a dynamic opportunity for the issue to be reflected in a critical and creative way. Our awareness of space-time-cultural differences is in line with the reflections of Appadurai (1996) [21] regarding the reception and implementation of "external" paradigms and the care that this demands from all involved ones.

With regard to consumption, long-term change is not everywhere equally rapid, although it seems increasingly foolish to contrast static with changing societies. The question seems to be the pace and intensity of change, as well as the alacrity with which it is invited. (APPARDURAI, 1996, P. 71)

Anyway, in almost all the exhibitions that took place where the externalization of desires on the screen and on the posters was produced, they caused a lot of commotion among those present. At the Somerville School in Auckland, all students and many guests were also able to draw their wishes on posters, which resulted in the display of over twelve hundred wishes pasted on the walls of the venue. Several of them moved schoolmates, some teachers and relatives to tears.

2 The X ABCiber National Symposium took place in December 14 – 16, 2017 at Universidade of São Paulo in Sao Paulo, Brasil.

Figure 8. Photo montage: shot from the commotion of the audience with the wishes displayed on the wall at the Somerville Secondary School, 2015.

Other event to be pointed occurred at the indigenous Brazilian school Caramuru-Paraquassu during the “Árvore dos Desejos Hãhãhãe exhibition. Due to there was just one sensor attached on the assemblage sculpture, the participants have organized a collective circular walking around that piece in order to provide that all the audiovisual expression available can be triggered by everyone. It brought to light how collective actions made coordinately, even the singular ones, can bring access results to all (Fig. 9).

Figure 9. Collective circular walking around the Tree. Pau Brazil, Brazil, 2018.

On the other hand, in some of the experiences, unusual interactive strategies surfaced spontaneously from some of the participants. Students from Campinas invented a game of "hunting" the images of certain colleagues, which appeared and disappeared by approaching the sensors and entered ecstasy when they managed to fix the image on a particular face. The same "face hunting" took place with participants from Sikles and Walvis Bay. Due to the small size of the venue, image projections took place on their clothes and faces.

Thus, the spontaneous "gamification" created in the three cases was one of the people "finding" in the space mapped by the sensors, whose filling would lead to the appearance of a certain face. In the last two cases, one person stood in front of the projector to get the image of the installation projected on his clothes, while another positioned himself in front of the sensors, in order to "set" the proper face image and another one took shots the person, whose own face was being projected on their clothes, with his smartphone.

As for the external exhibitions, we can also discriminate the set of different audiences found in the events into: workshop participants, guests, and casual visitors (onlookers, art fans, scholars). Within the scope of the fortuitous audience, it is worth mentioning the occurrence observed in the Exhibition of the Nigerian Wishing Tree at the Mário de Andrade Library. A group of visitors, one by one, began to interact with the sculpture, entering and leaving the sensory zones abruptly, activating the sound and images projected to the rhythm of the music made available in the installation (playing in a loop) whose volume increased and decreased in accordance with their positions.

We can also observe that each experience carried out and shared in each of these collectives formed, in fact, a small "universe" with ontological and procedural elements that very much refers to the communicational scheme of Jakobson (apud COELHO, 1980) [24], Teles (2009) or even to Veiga's "ecosystemic view" (2018) that propose, each in its own context, symbiosis between beings, machines, actions and information systems. However, when we look at the set of all these small "systems", we realize how much their connections reveal a frankly rhizomatic "multiverse" (GUATTARY, 1992) when we realize that the connections between them are not limited only to the form of the project used in all of them, but it also covers the lessons learned in each one of them that were, in some way, used in the following ones.

Figure 10. Photo montage. Sesi Santos Dumont School's students interacting in the space for an specific image exhibition in Campinas, Brazil, 2012 (left), interactive image is projected on student's shirt at !Nara Primary School, Walvis Bay, Namibia, 2019 (center), Mário de Andrade Library Hall's visitors making a rhythmical interaction with the installation in São Paulo, Brazil, 2016.

Conclusion

Although garage technology is nowadays quite popular, especially in developed countries (Germany, Portugal, Greece and New Zealand), the "sensory magic" of making sounds and images appear and disappear only with the movement of the body without touch, it proved to be as "innovative" to the participants as in those countries with more restricted access to it (the cases of Brazil, Nigeria, Nepal, Namibia and India). In turn, although the experience of artistically recycling waste, focusing on desired and

fulfilled desires, induces waste to be more observed by people, we know that the absence of a continuous praxis tends to dissolve, in a short time, concepts and awareness constructed mainly by critical biases.

In any case, this trajectory used by experimental technological art for an effective educational application through critical, militant and expressive biases through it - also highlighted for us how different skills, competences, technological resources and cultural bases - can coexist and generate unique and common expressive universes among all parties involved. The participant people commotion occurred the Auckland's school, as well as the collective interactive process established in the Pau Brazil school as well, brought us some of how the critical thought can be triggered by technological, multimedia and handcraft in a single artistic experience.

Therefore, more than a multidisciplinary militancy and "mixed media", this series of artistic, pedagogical and sociocultural experiences was (and is) to show present, critics, artists and scholars in related and related areas a possible way of acting in an artistic and pedagogical way while at the same time inspiring other themes lacking in action, training and expansion of knowledge, as well as transformative artistic expression.

Acknowledgments

We would like to thank all the teachers, artists, students, partners and cultural and educational institutions that made possible, facilitated and voluntarily contributed to the realization of all these experiences.

The University Of British Columbia

Kelowna, Canada

miles.thorogood@ubc.ca, maria.correia@ubc.ca, aleksandra.dulic@ubc.ca

Abstract

Waterways Past, Present and Future is an informative interactive media exhibition aimed at increasing awareness of the fragile relationship between people and water in the Okanagan Valley and catalyzing sustainable water practices among residents. The exhibition draws on the power of multi-channel sound and video media immerse, provoke, destabilize, transform and move participants to act responsibly and sustainability. We describe the system design toward a networked multi-channel audio visual system capable of generating sequences of environmental recordings and interview footage over an arbitrary number of modules in an installation.

Keywords

Environmental Science Communication, Indigenous Methodologies, Recombinatory Media, Immersive Installation, Multi-Agent Systems

Introduction

The Waterways exhibition represents a four-year collaborative undertaking between the University of British Columbia Okanagan (UBCO), Elders and Knowledge Keepers of the Syilx Okanagan community, Kelowna Museums Society, Okanagan Basin Water Board, and the Okanagan Collaborative Conservation Program. Waterways was led by Dr. Aleksandra Dulic, Principal Investigator, and Coinvestigators Drs Jeanette Armstrong, John Wagner, Lael Parrott and Miles Thorogood from UBCO with other essential partners, including the Eno'owkin Centre whose input was vital in ensuring a rich cross-cultural Indigenous perspective on water. The exhibit features Syilx Indigenous-led best practices in water management and ecological resilience, including the return of the salmon to the Okanagan waterways and flood bank restoration along Shingle Creek and Okanagan River. These restoration initiatives demonstrate how Traditional Ecological Knowledge is applied along with Western science and show how Indigenous institutions have worked effectively with provincial and federal government agencies to co-manage and co-lead these restoration efforts. To communicate these stories, we recorded audio and video documentation of the environmental and cultural detail of the Okanagan landscape, soundscape, and community events, along with interviews toward designing an immersive installation.

The installation comprises two main spaces:

- The outer panels of the exhibit highlight Indigenous Syilx teachings and wisdom related to human-water relations and the value of water (Figure 1.). Visitors will also find screens of virtual worlds of the Kelowna landscape pre-colonialism. These screens are interactive and depict the diversity of life in the Okanagan, including plant, animal and insect species indigenous to the region. Visitors can experience the virtual world through touch-screen interfaces and explore what Okanagan landscapes and waterways looked like before development.
- The inner walls of the panels (Figure 2.) comprise five video screens where visitors experience recordings of the Okanagan landscape (b-roll footage). The recordings in b-roll sections impress the beauty and sensitivity of a diverse range of environments throughout the Okanagan region (see figure 3.). Accompanying a-roll includes stories of knowledge keepers from the Syilx indigenous community (Okanagan, and Colville Confederated Tribe) and Western science trained experts discuss the meaning of water, innovations in water ecosystems management and sustainability, new co-management arrangements for caring for our water and ecosystems, and lessons from these practices for the future.

A-roll interview clips discuss the following themes:

- **The value of water**, with a focus on what we can learn from Syilx Indigenous values that equate water with life, and consider water the most important natural asset.
- **Traditional Ecological Knowledge (TEK)**, with a focus on what this knowledge-practice-belief system comprises, its contemporary significance for understanding how ecosystems work, and how TEK and Western science can complement one another in dealing with the critical environmental and natural resources issues we face today.
- **The successful return of Sockeye salmon** to the Okanagan waterways after the canalization and damming of the Okanagan River and its tributaries and the near disappearance of Sockeye. This 20+ year endeavor was spearheaded by Syilx leaders and involved a co-management arrangement with the Okanagan Nation Alliance and provincial and federal authorities.

Figure 1: Design of the rear side of the Waterways modules.

Figure 2: Design of the front side of the Waterways modules.

- **Adaptive co-management** of environment and natural resources, a power-sharing arrangement between governments and local resource actors and stewards, that brings structured learning by doing and adaptation to environmental and natural resource practices.
- **The Columbia River Basin** of which the Okanagan is a part, including the status of the all-important Columbia Basin Water treaty currently being re-negotiated between Canada and the US and stories of change and destruction of water and land habitats from elders who have lived through the changes.
- **The restoration of habitats in the Okanagan**, including cottonwoods and riparian systems, the Yellow-Breasted Chat at the ECOMMUNITY Place on Shingle Creek in Penticton.
- **Injustice and racism** endured and experienced by the Syilx Indigenous community in their efforts to restore their traditional lands and water, and the demonstration of the resilience of the Syilx nation in the face of this mistreatment and injustice.

Related Work

For the past four years (2017-2021), the authors have documented the environment landscape and community voices from the Okanagan region in Canada with the vision of creating a multimedia installation named Waterways [4]. During this time, we developed media to express the place and voices through multi-channel visual music performance Aeon [10], and the multi-channel video and audio installation Journey of a Pod [3]. While travelling through Sydney, Australia,

in 2019, we were inspired by the installation *Sydney Elders: Continuing Aboriginal Stories* [6] at the New South Wales State Library that used screens installed in objects distributed around the gallery to display a synchronized montage of the urban and natural landscape, integrated with interview stories with Australian Aboriginal elders.

In designing the Waterways visual and sonic experience, we aim to create a multi-channel audio and video display of the local environments and voices in the Okanagan. A sound design complements the visual display by modulating location recordings of background sound, such as water from the creek, and foreground sounds, including bird sounds of the region. Interview footage fades into the scene to highlight the speaker, then fades back out to the landscape footage with the speakers' voice remaining. The aesthetic choice of the Waterways exhibit design is loosely based on Jim Bizzochi's [1] concept of Ambient Video, which he describes as privileging the use of nature sequences, slow motion, gradual transitions that are "pleasant, visually interesting and capable of supporting occasional close viewing. It should change, but not too quickly, and the details of any particular change should not be critical over a limited time frame".

Pan [8] demonstrates how immersive installations create illusions of time and space by applying multi-sensory display methods to envelop visitors in the experience. Pan calls attention to managing the physical space by using nonlinear thematic frameworks and dynamic displays and identifying multi-sensory stimulation as immersive exhibitions' critical attribute. Otondo demonstrates an example of such an installation, and Rabello-Mestre [7], who use a procedure of mounting field recordings over a multi-channel sound installa-

Figure 4: Screenshot of Waterways exhibit floor plan

tal elements. The picture plane is divided vertically between these two alternatives. This compositional and spatial framework has been at the core of Chinese landscape paintings.

The three distance concepts help us understand the process of positioning objects with each other and composing space itself with multiple and dynamic points of view. The deliberate representation of multiple points of view in the scroll painting allows for an abstract impression of the space, similar to music. It allows viewers to engage in rhythmic elements, such as points, lines, planes, sequences, and harmonies. Lines do not function as guiding elements that direct our attention from a particular point of view centred on the meaning of the work. The actual substance of the painting is in the sensation of multiple voices of counterpoints through linear melodies within the work. The journey through the painting is achieved by shifting the points of view and synchronizing pictorial elements within each sequence. The observer must participate in the experiential synchronization and linking of the different elements, sequences, contexts and content in time. This is a dominant method of conveying information within scroll painting [9].

System Design

The combinatorial use of media creates a continuous variation for viewers to experience the space of concepts the media represents. We designed the Waterways system to facilitate the composition and display of stochastic video and audio sequences from discrete media segments over a distributed network of modules. Each module includes a computer, an LCD screen, and two-channel audio embedded in a constructed display - with one speaker at the front of the box and another on the rear side to spatialize sound in installation contexts (Figure 6.).

The Waterways system can manage an arbitrary number of modules, with each video and audio channel addressed independently. A system management computer is assigned the role of the conductor that serves file requests to the modules that take on the role of players in the audio-video orchestra. A local WIFI network provides the infrastructure for communication between the conductor and players.

The conductor keeps a list of active players to orchestrate

and addresses these over Open Sound Control (OSC) by sending names of audio and video files sequenced from a generative software program. Modules can be added and taken away from the orchestra, which, in turn, the conductor adapts to the new network topology. Each module, plus the conductor, is then only tethered by a power cable to operate as a plug-and-play system.

At its core, the Waterways system includes a database of video and audio clips indexed by tags representing a particular concept. The system chooses a topic from the database, plays a sequence of a-roll clips, and selects accompanying b-roll footage and audio recordings to disperse across the screens and speakers in the system. The system conductor analyzes the database and, at run-time, moves between concepts based on a specified interval to remain within a concept and a list of transition probabilities to go to the next concept.

A remote player program receives commands from the conductor to play video and audio assets. When a video approaches its duration, the player requests another video from the conductor, who serves up the request based upon the current concept being explored. The player then crossfades the audio or video files to create a smooth progression. Accompanying audio tracks sequenced by the conductor include background sounds to engender the ambiance and foreground sounds to gain the listeners' attention.

Database

The composition approach taken by the Waterways system is building a database. The artist creates video clips of a-roll and b-roll footage and places these in a folder named with the concept. Audio files accompanying the b-roll footage are placed in a sub-folder named audio, with subsequent sub-folders for foreground and background sound. Additional concepts are added to the media space by repeating this process of populating folders. Populating named folders affords the artist a familiar means of managing and grouping media files.

After the database is populated, a Python script analyzes the directory structure and generates an index of the video files with the corresponding concept determined by the directory name. Similarly, an index of the audio files is produced that indexes the name, the concept, and if the sound is background or foreground. In addition, the script generates a $n \times n$ transition probability matrix of the concept names with weights for switching system-level exploration of the conceptual space at run-time. The script also generates a matrix for the weighted selection of accompanying b-roll footage given a concept; if the artist modifies the database, simply re-running the script updates the index.

Conductor

We designed the conductor program to generate sequences of audio and video file recommendations from the database. The Conductor references the matrix of a-roll transition probabilities to navigate the relationships between semantic concepts represented in the database of video clips. Starting from a random concept, the Conductor selects a parameterized number of shuffled a-roll clips from the video list, tagged with the concept and weighted by the number of times played, preferring clips selected the least.

Figure 5: Example of a system generated b-roll video composition.

Figure 6: Waterways system diagram

The Conductor then selects a b-roll section based on the weights supplied in the probability matrix. When requested, the b-roll video and audio files are scrambled and served sequentially to the players. When all recommendations from the list are served, the Conductor will either scramble the list again or reference the table to select a new b-roll collection. Concurrently, the Conductor pushes foreground sounds requests for the concepts to modules in a stochastic fashion - constrained by specifying the minimum and maximum time an interval to trigger the push again.

To manage this, a timer initializes when a new section begins, and the Conductor starts serving up b-roll clips to the players when requested. The Conductor sequences the a-roll clips based on the duration since the completion of the last a-roll. When the timer duration reaches its end, the Conductor then serves an a-roll clip to the next requesting player. The player notifies the Conductor when the clip finishes, the timer then resets, and the following a-roll clip lines up for serving at the next interval.

After all a-roll clips are served from the section and complete playing, the Conductor goes into a refrain section of sequencing only b-roll footage and audio for a set amount of time. After that time, the Conductor refers to the transition matrix to switch into a new section.

In a nutshell, the Waterways Conductor behaviour is summarized as:

- At system initialization, send a ping to log active players.
- * Choose an a-roll concept from the transition probability table.
- Choose a b-roll concept based on the a-roll concept selection.
- Select n a-roll clips from the video list for the concept.
- Select and shuffle all b-roll clips from the video list for the concept.

- Select and shuffle background sounds from the audio list for the concept.
- Select and shuffle foreground sounds from the audio list for the concept.
- Start a-roll timer.
- Push new b-roll and background audio request to all players.
- Serve b-roll media when requested from a player.
- Serve a-roll media when timer interval triggers.
- Reset a-roll time when Player notifies completion of last a-roll.
- Switch to refrain after a-roll list is exhausted.
- Repeat from *.

Player

A Waterways Player is responsible for making requests to the Conductor for new media to display and receive section change commands. Developed in OpenFrameworks, the software contains three video planes. A Player uses the first two planes for cross-fading b-roll video clips, while the third plane manages transitions of interview footage. On start-up, the program sends a ping over OSC notifying the Conductor that it is available to join the orchestra. If there is no response from the Conductor, the ping is resent at 1-minute intervals until notification from the Conductor that it is registered to perform.

A summary of the program behaviour is as follows:

- Send a ping at regular intervals to alert the conductor it has joined the orchestra.
- Receives video and audio file requests to play.
- When b-roll video is coming to completion, send a request for next video.
- after receiving new b-roll video request, cross-fade into the new clip.
- If conductor serves an a-roll request, fade a-roll in on top of b-roll.
- After a duration, the a-roll video is faded out to b-roll with audio from a-roll remaining.
- Alert the conductor when a-roll is complete.

System Management

Database

When working across multiple networked computers, there is the challenge of updating each machine's video and audio

Figure 7: Waterways installation view.

database. Copying the database to a hard drive and replacing the directory on each machine is one cumbersome solution - especially when there are many machines and repeated changes over a brief time. We use the rsync command-line utility to address this challenge for transferring and synchronizing files across networked computers. When the artist is ready to synchronize the database to all the machines, they run a script with the rsync utility that points from the local database to the directory to synchronize on each machine. To circumvent the need to enter the password for each machine when synchronizing the database through SSH, we generate and install public/private keys on the local and remote machines.

Installation Control

To make it straightforward for the gallery staff to turn on and off the installation, we developed an Android App to control the system using Processing with Android mode enabled. The App interface displays buttons for switching the system on and off and levels to attenuate the loudness of the audio space. The App communicates with the conductor machine by sending OSC commands for these particular operations. A program on the conductor machine receives these commands and forwards the volume level request to the conductor that tweaks the player level at each of the modules. The on/off commands are handled by executing scripts on the conductor machine that tells the player machines to open the player program and power up the LCD or close the player program and power down the display. The power-up and down of the displays were managed using the Samsung Smart Things API as this was the available functionality. In the future, we recommend using display devices enabled with LAN control over a direct Ethernet connection.

Remote Management

A risk assessment for the relatively complex public art installation of Waterways included accounting for unexpected fluctuations in the system's stability. We deemed it unsustainable to maintain the installation on-site with the anticipation of touring across Canada. As such, we deployed a remote management software to allow observation and debugging of the system and update the programs and database.

Conclusion

Altogether, the Waterways system facilitates authoring and display of a multi-channel recombinatory audio/video installation that autonomously explores the space of concepts detailed in the media. The gradual, relational, and ever-changing transitions between and within concepts provide a gentle cognitive engagement for the viewer. Further, distributed over multiple screens and speakers, the sonic and visual modulation of environments and voices further immerses the viewer in the spatial and temporal movements of the media design.

The exhibition features Okanagan environments and insights of Elders and Knowledge Keepers of the Okanagan community, scientists and conservationists. Although out of the scope of this paper, there is also a highly realistic virtual world where visitors can explore what the Okanagan waterways were like before development via a touch-screen interface. Waterways explores the nature of our relationship with water - from the impact of development and climate change on the environment to the importance of Traditional Ecological Knowledge in ensuring all living things have clean water, now and in the future. In keeping with Syilx environmental ethics, the Okanagan Waterways Project reminds us that we all have a responsibility to work towards building and upholding the sustainability of water for healthy ecosystems and future generations.

Acknowledgments

Waterways is a collaborative undertaking between the University of British Columbia Okanagan, Elders and Knowledge Keepers of the syilx Okanagan community, Kelowna Museums Society, Okanagan Basin Water Board, and the Okanagan Collaborative Conservation Program.

Abstract

Reflecting on the challenges and potentials that Mixed Reality (MR) media present for the production of digital performance art, we present the concept of the Augmented Reality (AR) artwork *kin_*. The piece is opening the question on how to transfer a real live performative experience into AR, as well as the question of owning and maintaining agency within an artistic fabric. This is explored with a focus on the interaction of different types of agents, using artistic research at the intersection of art, dance and technology.

Keywords

performance art, believable avatars, augmented reality, digital art, agency

Introduction

How can performance art be transferred into a digital context? What happens when the audience meets performers in digital form? How can believable avatars be created and staged? How can agency be designed within a digital performance? There are many questions that unfold from the initial one, bringing into conversation the rich theoretical background of performance art on the one hand and the theory of digital media, especially MR, on the other.

Figure 1. Mobile Augmented Reality dance performance *kin_* © Jochen Müller

As an umbrella term coined in the 1970s to capture all art forms that escaped other categorizations [1], performance art might be the only art form that is being defined as the undefinable within the art. In her attempt to delineate its development throughout the 20th century and up until the end of 1970s, RoseLee Goldberg asserts that it is in the very nature of performance to “defy precise or easy definition beyond the simple declaration that it is live art by artists”, adding that any strict definition would actually “negate the possibility of performance itself”. [2]

With all due acknowledgment of this uneasy and flexible terrain, for the argumentation purposes of this paper we agree to the definition of performance art as “practice that involves a person or persons undertaking an action or actions within a particular time frame in a particular space (...)”, central to its execution being “the live presence of the artist and the real actions of his/her body to create and present an ephemeral art experience for an audience”. [3] The creation in the moment of performing has been crucial to performance art itself since its beginnings.

Liveness plays an important role in the experience of the piece for the viewer. As an art form that traditionally relies on its physical immediacy, bound to its mediums of body, time and space, performance art seems to be multiply challenged when coupled with MR, which blends the physical and digital world into a new form of interaction and co-existence. AR is defined as a particular form of MR that runs interactively and in real time. The digital content of an AR experience is registered in real space.

The mentioned live presence or real actions are challenged in this context or, more precisely, we are challenged to reconsider the meaning of performance art in the medium that possibly disintegrates its very foundations, molding it into a new digital form that is yet to be defined.

While our first question – *How can performance art be transferred into a digital context?* tackles the aspects of technological possibilities and practical choices, the second one – *What happens when the audience meets performers in digital form?* invites for a more philosophical discussion on the experience of human-avatar encounters within a digital medium and its meaning in performance creation. The question – *How can believable avatars be created and staged?* addresses the production process of suitable AR avatars for the performing arts. Finally, the piece itself tackles the question on – *How (...) agency (can) be designed within a digital performance.* We argue that with AR it might be possible to attempt liveness within a digitized dance piece without losing the artistic and bodily quality to technology.

The discussion on these questions and notions is being built upon the example of the interactive performative art piece *kin_* (2021), created by artist Charlotte Triebus and an interdisciplinary team of developers of MIREVI Lab at University of Applied Sciences Düsseldorf.

The work *kin_* was realized in 2020/2021 and premiered with Erholungshaus Leverkusen and Kunstverein Leverkusen at City C from August till October 2021.

Installation Description

The interactive dance performance *kin_* is a dance piece with one up to three moving avatars and audience, developed for AR and freely accessible to download from the AppStore. The performance runs as an app on a personal device. (Figure 1)

Figure 2. *kin_* setup at City C Leverkusen 2021, © Charlotte Triebus

AR merges a real life setting with digital content and enables its usage almost everywhere due to its markerless design. Aside from being independent of specific locations, this possibility offers other advantages for developing and experiencing digital artworks that are not site-specific, such as free choice of viewing time and company or lower travel expenses. Although technically playable on any location, *kin_* is designed with an intention of use in spacious museum environments or private surroundings that offer enough space to the dance and the audience experience.

To run the AR experience at its fullest potential, a bright, quiet, and empty space should be chosen and permissions to access microphone and camera need to be given. The use of headphones is highly recommended for appreciating the connected, multidirectional sound experience.

kin_ is divided up into three dramaturgical parts that give structure to the piece. At starting the application an introduction is given, leading through the process of requirements and recommendations such as the placing of the content. The first part of the piece invites the user to get to know three avatars, their space, functionality and behaviors, by introducing choreographic material and setting the scene to slowly immersing the user into an AR setting. The second part consists of a fast choreographed trio of all three avatars dancing on relations and postures. Meanwhile the avatars do not take notice of the user in the second part, they fuse into one avatar at the beginning of the third part and start following the user in an intrusive manner. During the piece, the avatar(s) move closer to the user: the last part is staged as an interactive, following close up, that adds another layer of reality decomposition by introducing distorted facial expressions of the avatar. The piece ends with the avatar closing its eyes to disappear.

In the design of MR scenarios, a distinction is made between global and local agency:

when global agency is assigned to a user, their decisions cause permanent changes to the entire piece, while assigned local agency gives the possibility to influence individual factors that do not affect the overall event. [4]

For the sake of the dramaturgy within the dance performance, local agency competences of different sizes were assigned to the spectator in order to achieve a balance, so that despite influence, the piece remains perceptible in its entirety.

Making use of their local agency competences it is possible for the user to directly influence the piece through own movement and interaction, as the avatar dancers respond to proximity and distance, direction and angle of movement. The interaction of the user with the avatars is designed to be „indirect“ – triggered either by moving, inclining or tilting the device physically towards or away from the avatar, causing a dodging behavior. Direct touch is not encouraged and does not trigger any interaction with the avatar, but offers access to the menu structure of the app.

Each of the three compositional parts begins with a set constellation of the avatars. During the evolution of each part, the avatar corresponds to each user interaction in real-time, using different patterns of reactions, depending on input, angle and intensity of the approach. After dodging, the avatar continues to follow the choreography at a restored, reasonable distance at the new chosen place in virtual space until the end of that part. Each subsequent part continues, after the dodged avatars have restored the needed constellation for that following part. As the piece evolves, the avatar actively follows the visitor and comes very close to the camera for the final scene.

All reactions by the avatars to intended and unintended interactions of the visitor manifest in a uniquely arranged, non-repeatable performance each time the piece is screened. This way, the resulting performances represent a temporally and spatially non-repeatable version of the digital dance piece *kin_* in the chosen exhibition space.

For the likewise interactive soundtrack as well as a reactive costume, the artist collaborated with a composer, as well as a digital makeup artist. Three layers of sound are offered: the stereo ambient composition, split for the three different parts, samples, bound to a certain radius of each avatar, and different sound elements for dodging movements. The sound composition is arranged in 360 degrees and adapts to the orientation of the user.

The costume design includes asymmetrical fins reacting with a secondary animation to movements of the corresponding bone that each fin is attached to. The secondary animations of the fins are designed to physically imitate movement in water. Lighting estimation is included in order to adapt the lighting of the virtual scene to the real environment.

For the setup of the installation in a museum, the piece includes three large-scale banners showing high-resolution texture parts of the avatars: eyeballs, facial skin, and the normal map of the scanned dancer's hands and feet. The banners serve as a physical representation and contextual enhancement of the piece. (Figure 2)

Related Work

AR avatars can be reflected on different, mutually related levels - artistic, design-oriented, user-centered, technical, targeting social or ethical implications. Mixed media performance artworks offer an approach for separating the screening of a dance event from its live production tied to a specific time and place. Moreover, artistic experiments with AR can be understood as explorations of interactivity through technological means.

MR applications that revolve around movement related arts can be differentiated according to their two or three-dimensionality. For example, the work *Whiteout* uses videos of performers for displaying several pre-produced performances in virtual reality. [5] In this case, the three dimensionalities of the experience is based only on the 3D surrounding of the VR medium in which the videos are embedded and the perceived effect of depth at a certain distance from the video. The piece *kin_* is an example of staging three-dimensional avatar dancers which are approachable from every angle.

The approach of a three-dimensional avatar is also the main topic of Julie Curtiss' work *Lune* featuring a nude body which is interactively turning away and hiding its face from the user. [6] A similar approach is used in *kin_* with the avatar's evasive behavior as the user is coming too close. *Lune* and *kin_* though differ in integrating the interaction: *Lunes* evasive body movement forms the movement itself, whereas in order to avoid a rupture of the choreography of *kin_* the dodging behavior had to be integrated seamlessly into the performative fabric, which was not to be disturbed by the interaction.

Martina Menegons work *It feels like home* also features nude avatars in a performative virtual sculpture to be accessed through a webpage. [7] Other than in *kin_* the avatars are to be moved by drag and drop, imitating certain gravitational settings.

The design of movement of the avatars within the work can be understood as a second layer for differentiation - unlike projects that use movement loops (such as the

artwork *Dance Trail* by Cie Gilles Jobin), [8] the choreography of the project presented in this paper is continuous.

The introduction of an interactive element is adding a third layer to the performance, as shown in the dancing AR Playmoji Stickers of *Google Pixel's Playground* which enables facial reactions of the avatars to the user in real time. [9] Whereas the interaction of the dancing AR character is limited to reactions to certain mimics, the interaction with *kin_* is designed to be a full body interaction in virtual space.

The design of avatars is also closely related to the discourse revolving around the uncanny valley effect, showing that the representation of human-like avatars above a certain degree of similarity or realism is perceived as creepy and the interaction with the avatar tends to be unpleasant. [10] An internal research project on efficient avatar production facilitated meeting the objectives of realistic avatar design in *kin_*. [11]

Following Photiadis et al., "user experience arises from the integration of perception, action, motivation and cognition in an inseparable meaningful ensemble". [12] Also Law et al. compare user experience to a dialogue with the user's world through action being determined before, during and after the interaction with the experienced object. [13] Using diverse communication channels has been shown to be crucial for presence and interaction attractiveness. [14] Since an enhanced feeling of presence for the user was determined to be crucial for the art experience of *kin_*, an emphasis was put on the animation of expression abilities of the 3D characters, such as facial expressions, a full-body animation and full animations down to the fingertips to support different layers of believable, realistic movement at every moment in the performance.

The *technical perspective* focuses on the efficient production of believable avatars. Tools like Epic MetaHuman Creator can efficiently produce high quality, believable avatars. [15] However, the design of a fully animated realistic avatar of the dancer herself was not realizable due to the restrictive presets provided by the software. There are several tools for creating virtual characters based on photos [16], hand-held video input [17] or 3D scans [18]. Many approaches also use AI-based methods to generate the avatar structures. Motion capture systems provide an efficient solution for extracting information related to a human skeleton, which is often exploited to animate virtual characters. When the character cannot be assimilated to an anthropometric shape, the task to map motion capture data onto the armature to be animated can be challenging. [16] In [19] the authors addressed the problem to estimate accurate and natural motion sequences and proposes "Video Inference for Body Pose and Shape Estimation" (VIBE), which makes use of an existing large-scale motion capture dataset together with unpaired, in-the-wild, 2D keypoint annotations. In *kin_* we created animations using a tool-set of motion capturing systems and manual fine-tuning for the recorded animations. As to *social and ethical implications* revolving around believable avatars we have developed a mediation format targeting this issue, described later in this paper.

Artistic Background

What about mechanically, digitally, or biologically reproduced replicants or clones? It may be that a film or a digitized performance art piece will be the same at each showing. But the context of every reception makes each instance different. Even though every “thing” is exactly the same, each event in which the “thing” participates is different. The uniqueness of an event does not depend on its materiality solely but also on its interactivity – and the interactivity is always in flux. If this is so with regard to film and digitized media, how much more so for live performance, where both production and reception vary from instance to instance. Or in daily life, where context cannot be perfectly controlled. Thus, ironically, performances resist that which produces them. [1]

kin_ is an explorative dance piece about both human corporeality and body-based art through and with digital technology. It is considering several philosophical and sociological discourses, among them the transfer of performativity into the digital, reality entanglements and the dichotomy of surveillance and intimacy.

In the piece, one up to three avatars perform in augmented space and can be approached, influenced and experienced through the user's personal handheld device. To perceive the piece *kin_* in its entirety, the viewer must actively move around the dancers and through the piece.

With the post-digital assumption that humans are so intertwined with surrounding technology that these parts are not separable anymore [20], a cyborg can be understood as a term for certain forms of relationships between body and technology in which the organic and the technical combine in a hybrid life form. [21] In Materialist and Gender Studies the concept of the cyborg stands for the negotiations of traditional dualisms – questioning the distinction between the analogue and the digital, the overcome dichotomy of culture and nature, the social and the technological, sex and gender, and with it the body itself. The cyborg is a material-semiotic creature, entangling the formerly opposed binary opposites. [22]

Following this argumentation, *kin_* can also be understood as a playful statement that abandons anthropocentrism and the dancing agents that serve as surrogates for human dancers, and instead, follows the idea of an own techno-organic hybrid lifeform, as dancing cyborg, transferring organic contemporary dance movement onto digital avatars by digitizing a real dancer.

As choreographic material the artist decided to explore the techno-organic aspect by developing tightly choreographed, geometrical body and trio constellations with organic movement qualities, alternating between machine-like and humanly distanced observing poses. As a contrast, system-inherent tracking poses served as input for the choreographic material, to allude to the communication process between human and machine (in this case: the tracking-system). Poses, constellations and forms refer to loops and repetition, alluding to digital reproduction, without actually being repeated. As the dance evolves the poses get slightly shifted and twisted – giving space to the reflection on approximations to an ideal to the piece.

Performance art is happening in the very moment of the creation by the agents themselves. [23] Stating that agency is no distinct human quality but can be assigned to other-than-humans, constellations or inanimate objects, [24] *kin_* appeals to the shift of agency between performer and recipient in moments of interaction. *kin_* is labeled as an interactive performance with up to three avatars and spectator, and according to the definition of agency as “a potential to act” [25], inviting the user to also take part as an agent in the piece. (see also: [26]) Object-ontological theories argue that the connection between multiple actors itself accounts for its own agency. Derived from this, the fusion of a digital being with analogue features leads, at least theoretically, to a new form of being for the performative arts with a possible agency.

Since *kin_* is experienced with a handheld device, the physicality of the device is creating an inevitable frame through which the piece is being observed. The surveillant aspects of the window for the scene puts the visitor into a surveilling position. (see also: [27])

Through the potential to act and to move around the avatar within AR, the possible engagement is staged as a moment of empowerment for the user, to influence the events of the piece with their own actions. (see also: [28])

The abbreviation *kin_* in the title is short for kinship. The underscore is suggested for languages with a generic masculine grammar (such as the German language) as a symbol for a gender-equitable spelling that leaves room for a variety of forms and expressions of gender, in this case including digital ones.

The title gives a clue as to how the piece can be read: In order to survive on earth, we need other forms of kinship, following Donna Haraway's train of thought, making kin, both with other humans and non-humans. [29] She argues for a non-anthropological view and questions often propagated human exceptionalism, that we can only survive by „co-becoming“ with other ontologies.

Holding up this argumentation, the title *kin_* refers to the respectful exploration of the relationships between human and other-than-human, from the body of the dancer, to the body of the avatar, to the body of the viewer, interweaving different types of agents and agencies (once again.)

Following this idea, it was decided that the design of the AR interaction should take into consideration that avatars can be understood either as other entities, or as a representation of humans, suggesting the audience to interact with the avatars as one would treat another human. Slater et al. refers to the Golden Rule of Reciprocity as a guideline on how to interact in Virtual Reality. [30] This thought lead to uncommon UI decisions for the piece *kin_* such as indirect interaction or an uncommon placing-procedure – at placing the content after starting the application, the avatars would appear outside the frame of view– in order for the avatars not to be touched – as touching without consent is considered disrespectful towards other entities (Figure 3).

Figure 3. Avatar and user in respectful distance © MIREVI

Technical Implementation

The technical implementation of the piece is developed as a mobile AR project available for iOS. The user can download a mobile app in the AppStore [31], which contains the piece including all media assets. For efficient scanning and detection of the environment and the placement of the avatar dancers, an appropriate context recognition is necessary to position the avatars correctly in the real environment and register the virtual elements in 3D space.

In addition to the classic RGB camera of the mobile device, *kin_* provides significantly improved detection for devices using LIDAR scanners (e.g. with an iPad Pro). The technical implementation is done using a suitable workflow with the following steps:

- advanced avatar modeling,
- facial expression design,
- interactive costume development,
- dance motion tracking, and
- AR framework integration.

The development of a believable avatar that is not located in the uncanny valley is particularly challenging because a copy of the human performer that is as close to reality as possible had to be created. While it is possible to produce a realistic copy for a high-end character for non-realtime display as a movie clip, there are currently no comparable options for interactive rendering in a 3D engine such as Unity3D. A workflow and tool chain was developed to create, edit, and deploy the female dancer model. [11] The steps follow a pipeline for designing believable avatars in the film domain and are then manually reworked for deployment as an interactive AR app.

The costumes are produced as textured 3D models and combined with the uncostumed avatars by partially binding the models directly to the skeletal structure. This makes it possible to realize the reactivity of the costume in the final AR app, e.g. the movement of the fins when the arm is moved.

The recording of suitable facial expressions of the digital dancers is particularly important for credibility. For this

Figure 4. TEDx video talk on Mixed Reality avatars © MIREVI

purpose, the professional face tracking system dynamixyz was used and all facial animations of the performer were recorded and processed for integration into the AR application. The choreographed motions were recorded as individual sequences with a hybrid tracking approach, using Optitrack and Perception Neuron systems to fuse the results. The integration of the 3D models, textures and animation files was done in Unity 3D, AR Foundation was used for AR functionalities.

Extensive tests for a comparison of Unreal and Unity3D showed clear advantages for Unity3D. Although the production of realistic 3D avatars is easier in the Unreal engine and the rendering is qualitatively better, tracking support and presentation quality in the AR space in Unity3D is more powerful and allows for expressive representations. Additional interaction modules were used to ensure the reactivity of the avatars. A collision detection in the first part of the choreography notices when the user approaches too close to the avatar and starts an evasive movement before continuing with the choreography. In the last part the avatar follows the user in relation to her movements.

Mediation

Although *kin_* is impregnated with several layers of meaning, there is no further explanation of the piece nor context within the performance. In order to expose these aspects and bring the peculiarities of MR avatar design and post-digital reality entanglement closer to a broader user group, the piece has been used as a reference point in an alternative mediation format on avatar design and ethics. Instead of a classical artist talk, which discusses the background of *kin_* or our development perspective on MR avatars, we developed a format of dialogues between art and technology where we debate on design, production, and use of MR avatars in the post-digital age by combining different levels of narratives.

We are technically able to produce MR avatars, which are difficult to distinguish from humans or can even be manipulated by one, as well as to manipulate or create human images with Deepfakes. Thus, the question continuously arises whether the perceived reality is real, virtual or a blend. We decided to use these intertwined realities not only as a topic for our discussion but its very narrative structure. Using the artistic work of *kin_* as a starting point, different aspects of MR avatars, e.g. user experience, critical distance, ethics and technical production are addressed and made conscious by a dedicated intervention (a medial break) in the representation. The format begins with a somewhat too euphoric presentation of *kin_* in which the protagonist emphasizes the credibility and fascination with MR avatars. At the first media break, one realizes that the presentation is only a video on a mobile device, which is being critically examined by two people. A conversation develops about challenges and opportunities in production and the need for an ethical imperative when interacting with avatars. In the next media break, avatar production is presented on a very technical level including a motion shot, which arrives at the start sequence as a ring closure in the last media break. A final media break is used after the credits to comment on the entire production of the clip from the point of view of the avatars involved.

The production was done as a video shoot using green screen technology and screencasts from the AR app *kin_*. The digital effects were added in post-production. During the broadcast of the format at TEDx Koenigsallee, [32] a live Q&A session was additionally streamed, in which the two protagonists answered questions and presented some technologies in the same digital studio featured in the production.

Conclusion

The interactive dance performance *kin_* shows a way to experience dance qualities with virtual means taking into consideration both artistic bodily as well as digital possibilities. It challenges the visitors to question expected formats of performances and proposes to take part in the piece. The research can thus offer a form of empowerment that participates in the discourse around the contemporary, performative body, both in times of social and travel restrictions and virtual art formats, as well as giving a hint with regard to the increasingly urgent ethical questions in dealing with virtual bodies.

Sparking Emotion in Mexican Electronic Art

Cynthia Villagomez Oviedo

Guanajuato University

Guanajuato, Gto. Mexico

cynthia.villagomez@gmail.com

Abstract

This paper deals with the methodological and cognitive processes involved in how innovative ideas evolve in the human mind. It also addresses the principles and foundations of creating new ideas and the different phases of creative processes: participation, tendency, incubation, intuition, evaluation, actualization, communication, and participation. Also significant are the reactive, interactive, and emotional facets of the participation phase of the creation process. Hence, these aspects are analyzed in order to produce an in-depth reflection on the elicitation of emotions during the production processes of electronic artworks. Finally, the paper examines a number of techniques and resources used to elicit emotions in electronic artworks.

Keywords

Electronic Art, Production Processes, Creation, Elicitation, Emotion, Innovation.

Introduction

In Mexico, Electronic Art is a branch of Contemporary Art and part of the global phenomenon called Art & Technology, in which artists may use both cutting-edge and obsolete technology. An essential characteristic of many works of Electronic Art is that they require the participation of the viewer.

Over the last three decades, Electronic Art in Mexico has produced fascinating artworks and renowned artists. Prior to this period, pioneers like Manuel Felguerez or Pedro Meyer had already explored the artistic possibilities of new technologies, Felguerez with his work *Aesthetic Machine* (1979) and Meyer with *I Photograph to Remember* (1990).

However, due to the lack of information on Mexican Electronic artworks and their emotional content, it is in the realm of public interaction with the artwork that this investigation identified its area of research. Additionally, according to modern psychology emotions to be behavioral and visible; they manifest. The question that emerged from these considerations was, is it possible for artists or art students to deliberately plan to elicit specific emotions in public?

Aim and Scope

Hypothetically, the answer to the foregoing question can be inferred: as a result of advances in modern psychology in the detection and development of emotions, it is possible to create a model to elicit emotions in electronic artworks. Consequently, this chapter involves the analysis of diverse Mexican electronic art developments related to emotions. However, the model does not predict viewers' emotional response. As Jonathan Frome says, the emotional response to any given work depends on a "variety of contexts of viewing the artwork, and the varied individual histories and cultural backgrounds [that] make this impossible. [There is an] enormous influence of historical and cultural factors in emotional response." (Frome, 2007, p.831).

Then there is the fact that emotional response relies on the term "emotion," which in itself is highly ambiguous, since there are multifarious ways to classify emotions. According to Frome (2007), Ekman's basic emotion types are joy, sadness, disgust, fear, anger, surprise, interest, and contempt. On the other hand, others, such as Ortory, Clore, and Collins classify emotions as either positive or negative, while for Damasio, emotions are "vast". (Frome, 2007, p.831). It should be said that emotions, in general, function to our benefit, even the negative ones. Regardless of whether these may sometimes lead us to perform nonpositive actions, emotion arises for our well-being. Although space precludes a deeper discussion, it is my belief that emotions respond to stimuli by means a phenomenological 'feeling' that is associated with them and is designed to promote an organism's well-being. (Frome, 2007, p.832). Finally, for cognitive psychology, emotions are a product of thought which create behaviors essential to an awareness of the diverse topics that some electronic artists pursue.

Public Participation in Mexican Electronic Art

The use of technology in the arts gives rise to new artforms before which the viewing public is no longer made up of viewers, but of participants, in such a way that may be completing or even creating the artwork. There are multiple ways or levels of participation in Electronic Art:

- a) Using particular devices such as VR lenses, tablets, joysticks, keyboards, microphones, apps, and cell-phones, among others, (see, for example, "Escrituras" by Gilberto Esparza; "Kauyumari, The Blue Deer" by Arnold Abadie; or the works in the series of "Relational Architecture" by Rafael Lozano-Hemmer).
- b) Performing body movements, facial gestures, or particular actions ("Multiple Vortex Tornado" by Ivan Abreu, "Body movies" or "Level of Confidence" by Rafael Lozano-Hemmer, among others by the same artist).
- c) Speaking in a certain way or through special devices ("Voice Array" or "Less than Three" by Rafael Lozano-Hemmer).
- d) Typing on a keyboard, (the Arcangel Constantini Net Art pieces "Anima" and "Unosunosunosceros").
- e) Wearing specially designed garments ("Wearable Soundscape" by Amor Muñoz).
- f) Interaction on social media ("Arma Sonora Telematica" by Leslie Garcia).
- g) Interaction with another being ("Pulsu(m) Plantae" by Leslie Garcia).
- h) Musical compositions ("Meridian" by Ivan Abreu).

As Fakhrhosseini and Myounghoon observe, the experience of physiological change leads to feelings, and it is reasonable to believe that the public can use bodily movements to evoke emotions. (2017, p.245).

Themes and Emotions in Mexican Electronic Artworks

It is necessary to say most Mexican electronic Art elicits emotions in part due to the subjects they tackle, such as those relating to Mexico's politics or environmental problems.

A) Politics. Historical truths, social expression, and racism, among others. Depending on the artist's observations, these works can raise concerns among viewers.

Artistic works like "Taxonomic-comparative study between the Castes of New Spain and those of Contemporary Mexico" (2010) by Erick Meyenberg, about a million-dollar government investment in sequencing the Mexican genome. From an artistic point of view, this initiative actually heightens the differences that already exist between Mexicans such as skin color, or their cultural, social, or economic levels, to name a few. According to the artist, the first impression of the viewers is amazement at the bright colors and the light of the rings floating around it; then some of them will read about what the work is about (Villagomez, 2014).

Another example of a political art piece is "Loud Voice" (2008) by Rafael Lozano-Hemmer, a commemoration of the 40th anniversary of the 1968 massacre of students in Mexico City's *Plaza de las Tres Culturas Tlatelolco*. (Lozano, 2008). Witnesses of that deadly night speak sadly into a megaphone about what they experienced that year while brightness of several searchlights alters automatically. Also, by tuning to a radio station, thousands of people could listen to the testimonials.

The same artist's "Border Tuner" (2019) also addresses this topic, consisting of powerful searchlights located on both sides of the Mexico-US border in such a way that a "bridge of light" can be seen crossing the sky. (Lozano, 2019). The piece requires visitors who can interact by speaking into microphones situated at six interactive stations on both sides of the US-Mexico border. Participants produce a wide range of different emotions ranging from joy to sadness and beyond due to this interaction between people in El Paso, Texas, and Juarez. This artwork questions President Trump's immigration policies and his intentions to build a wall between both countries during his administration.

I first knew this piece as *The 43 of Ayotzinapa*, but the actual title of this work by Rafael Lozano-Hemmer is "Level of Confidence" (2015). This artwork recalls the mass kidnapping of 43 students from the Ayotzinapa teachers' college in Iguala, Guerrero, in 2014. The artist explains that the project consists of a face recognition camera trained to look for the faces of the disappeared students. As you stand in front of the camera, the system uses algorithms to find which student's facial features look most like yours and gives a "level of confidence", expressed as a percentage, as to how accurate the match is. The biometric surveillance algorithms used (Eigen, Fisher, and LBPH), are familiar in the military and police forces, where they are used to look for suspicious individuals. In this project, they are instead used to search for victims. The piece will always fail to make a positive match, as the artist has based it on the assumption that the students were likely murdered and burnt in a massacre in which the local government the police, and drug cartels were all involved. Despite, the commemorative side of the project deals with the relentless search for the students and the superimposition of their images on the public's facial features. (Lozano, 2015). I saw this artwork at the Guanajuato University gallery during the 2019 *Cervantino Festival* before the global covid pandemic. Without a doubt, the evolving mix of emotion it engenders is sadness, anger, and resentment.

Other worthy members of this category are Arcangel Constantini's "Anima, 3:00 am" (2002) and "Unosunosunosceros" and "El auténtico chilango" (2000), "Displaced Emperors" (1997) by Rafael Lozano-Hemmer; "Escrituras" (2008) by Gilberto Esparza; and "Arma Sonora Telematica" (2013) by Astrovandalistas and Leslie Garcia, among others.

B) Environmentalism. Many Mexican electronic artists are deeply committed to the environment, and so pieces have emerged dealing with water pollution, trash, obsolete technology, devices that interact with whales or plants, and so on. Depending on what the artists have observed, these works can elicit astonishment, concern, and, in some people, awareness.

One example in this category is Leslie Garcia's "Pulsu(m) Plantae" (2014), a work that analyzes the way plants communicate through biological communication process that are invisible to humans. The piece consists of a "sound prosthesis" derived from biofeedback, a technique based on plants' physiological functions and the instruments used to collect

information about the plants (García, 2014). The prosthesis translates these data on sounds as if the plant had a voice, so that, if the public touches the plant, speak, or turn on a nearby light, they will obtain a sound in exchange. When they see the plants react to stimuli, people's reactions are generally surprise and increased awareness of other beings' lives.

"Nomad Plants" (2014) by Gilberto Esparza reflects on the environmental and social impact humans have through such things as the exploitation of natural resources, resistance to the energy transition, lack of awareness, in order to find better, more empathetic ways of interacting with nature. An artist's "words technology" has a vast potential to make significant transformations in order to achieve this goal. The "Nomad Plant" is a living organism made up of a robotic system, an organic plant species, and a set of microbial and photovoltaic fuel cells. It is about the union of different forms of intelligence so as to constitute a more robust species with the potential to restore damage to the environment on a small scale. This robot takes polluted water and processes it in its fuel cells through a colony of bacteria native to these waters, which feed by transforming nutrients into electricity to be stored by its energy harvesting system. In this biodegradation process, the water quality improves and provides the plant species that also produces electricity with its metabolism. This energy cycle concludes with the release of its byproduct, oxygen. Therefore, it is not only a species adapted to the modified environment, but it also restores the energy available to the earth (Esparza, 2013). The robot was put to work on the river Lerma in Salamanca, Mexico. People's curiosity was aroused, which provided the artist with an opportunity to speak with people about the possibility of technology restoring a polluted environment.

"Nanodrizas" (2009) by Arcangel Constantini is a series of 13 robots capable of detecting polluted water in rivers and lakes. They also provide solutions to local environmental problems through wireless communication. The "nanodrizas" collect and send data to a station and respond to the conditions with chemical interventions, consisting of releasing bacterial and enzymatic remedies and sounds.

Another piece falling into this category is "Auto-Photosynthetic Plants" (2013) by Gilberto Esparza, which uses microbial fuel cells to create sound and energy from polluted water samples collected from urban spaces. The artist creates a symphony using microscopic bacteria as an orchestra. (UQAM, 2017), thereby raising awareness of highly contaminated water in cities produced by human activity and the consequences for the environment. The piece involves plants that amazingly transform polluted water into energy that enables them to survive.

Leslie Garcia's "Spherical Memory" (2019) is an installation that releases odors and edible spheres from damp earth. The piece first synthesizes the smell of the dry soil after a rainy day; then, a bioprinter makes the aforementioned edible spheres out of this phenomenon using plant oils released from the earth. The artist says these spheres melt in your mouth, liberating the aroma that flows from the pharynx to the olfactory bulb. As a consequence, brain connections

strongly link to emotions and memory. Finally, the project has a collection of more than a thousand testimonies of people who share the memories evoked by this experience. (García, 2014).

Further works in this category include Ariel Guzik's works on plants and whales.

How to Spark Emotions Through Mexican Electronic Art

At this point, we can infer that Mexican electronic artists are able to elicit diverse emotions through their work. However, creating a model to produce an emotion may be useful to both beginners and artists experienced in experimenting with the possibilities of obtaining a specific range of emotions, positive or negative.

To create a model to elicit emotions in electronic artworks, we will review and connect with different approaches to appraising emotions in order to contribute to Mexican Electronic Art. In what follows here, I will develop some ideas about emotion elicitation methods based on the studies of diverse authors.

For Seyedeh Maryam Fakhrhosseini and Myounghoon Jeon (2017) of Michigan Technological University: *Imagination, Films, Sound, Music, Images, Reading passages, Writing passages, Embodiment, Virtual Reality, Feedback, Self-Referent-Statement, Social Interaction, Physiological Manipulations, Motivated Performance Tasks, Combined Techniques* are ways in which emotions are induced. Below is a discussion of some of these techniques that may be appropriate to the realm of Electronic Art.

The same authors consider *autobiographical recall* as one of the most powerful tools for invoking emotions. No doubt recalling emotions in groups brings about reflection and awareness. Consequently, past events in the back of our minds emerge and, by doing so, can heal some individuals (groups like *Alcoholic Anonymous* or *Adult Children of Alcoholics* use this principle too). In Rafael Lozano-Hemmer's "Loud Voice" (Voz Alta, 2008) residents of the Plaza de las Tres Culturas in Tlatelolco recall the massacre of student protesters in 1968, which took place where they live. The result is an intense and moving work made by viewers' memories and emotions [1].

Historically, art has consisted primarily of *images*. For Fakhrhosseini and Myounghoon (2017), in daily life, people seek out evocative imagery in magazines, on the internet, or in various forms of social media. Although images are unimodal visual stimuli, they are capable of expressing and evoking emotions (2017, p.242). The authors mention that researchers use images to induce emotions, and that one of the most commonly used tools is the *International Affective Picture System*, with more than 1000 systematized images. In Electronic Art, artists do use images but frequently in combination with movement, interaction, or projection in specific spaces. Rafael Lozano-Hemmer uses this technique masterfully in "Level of Confidence" (2015) by using black and white photos of the 43 students murdered by narco-traffickers, police, and the Ayotzinapa [2] army unit. A small

town with significant production of the poppies that the *narcos* use to make drugs. Nevertheless, the crime remains unsolved by the Mexican government. The photos the artist uses were the ones the students' school made public and are typical in Mexican schools: 2.5x3 cm, black and white, facing the camera, etc.

Another technique to elicit emotions that Fakhrhosseini and Myounghoon (2017) mention is *embodiment*. The concept is related to a theory by William James, who suggested that the experience of physiological changes leads to emotional feelings. (2017, p.245). In many electronic artworks, participants move, strike postures, make facial gestures, or speak. Examples of embodiment in Mexican Electronic Art can be subtle or very clear. One example is "Multiple Vortex Tornado" (2013) by Ivan Abreu, which encourages members of the public to leaf through books, which they are doing when the sound of a tornado is heard [3] and the public is then enveloped by a soundscape. Another example of embodiment is "Body Movies" (2001) by Rafael Lozano-Hemmer, which consists of interactive projections where thousands of photographic portraits taken on the streets of the cities presenting the project are displayed by robotically controlled projectors. The portraits appear inside the shadows of the people passing the installation, so that many of them began to move, or dance, stretched in front of the projectors [4], where they are able to see both themselves and the photos.

Fakhrhosseini and Myounghoon also cite Virtual Reality as a further technique for eliciting emotions, pointing out that, "it has been shown that a computer can replicate an environment, real or imagined, that allows the user to interact with it. With virtual realities, participants can artificially experience some situations just as interacting with real-world people, objects, scenes, and events." (2017, p.246). VR opens the possibility for artists and scientists of recreating real or imagined environments to open up a new world, the virtual one, which can seem as genuine as the real one. One example of a VR artwork is "Kauyumari, The Blue Deer" (2016) by Mexican artist Arnold Abadie. Abadie won the Eco Film Festival in 2013 and decided to make a VR version of his winning entry. The short film shows a Huichol god who guides his people on a pilgrimage through the desert in order for them to recognize the mysteries of existence and the balance of the planet.

Films combine images and sound; viewers can empathize or identify with characters. Through cinema, the public "lives" real-life emotional situations, making the use of films one of the most ecologically valid emotion invoking techniques. (Fakhrhosseini and Myounghoon, 2017, p. 236). However, there is another way to classify how emotions evolve in a given artwork. For Jonathan Frome, film, literature, in fact all narrative art can generate *narrative emotions*, which are the most commonly felt when engaging with works of art. (2007, p.832). Electronic Art goes beyond narrative. But pioneering artworks like CD ROM "I photograph to remember"[5] (1990) by Pedro Meyer do explore narrative. The piece is about the life and death of the artists' parents and a family album about the body, old age, and illness.

For Jonathan Frome, another emotional category is that of *artifact emotion*, which is generated by our response to work as an artifact or crafted art object. However, an artwork prompts every kind of emotional response. Artifact emotions relate to the artwork as an artwork; they come from how the artistic work represents its content. In other words, artifact emotions are emotions of aesthetic evaluation. As Frome (2007) says, we tend to think of Artifact emotions as artistic judgments or preferences. They do not have the same intensity as other types of emotions. But they are nonetheless emotions; aesthetic evaluations can cause frustration, amusement, surprise, and other emotions in much the same way that narrative can. (Frome, 2007, p.833). Examples are the colors, the textures, the forms, or the images in the artwork that provoke admiration.

The final category of emotion Frome identifies is *ecological emotions*, which are generated when a participant responds to a given stimulus. The author focuses on video games, but these emotions fit the sphere of Electronic Art as a response to any interactive installation. Frome says that "Whereas an artifact emotion responds to a videogame at the level of representation, an ecological emotion responds to what the videogame represents, and responds to it as if it were real." (2007, p.833).

The table below shows some of the inputs of emotion related to Electronic Art.

THEME	EMOTION ELICITATION METHOD	TYPE OF INTERACTION	ELECTRONIC ARTWORK
a) Politics b) Environmentalism	a) Embodiment / Ecological emotion b) Virtual Reality / Ecological emotion	Use of special devices, i.e., VR lenses, tablets, joysticks, keyboards, microphones, app, cellphones, etc.	a) "Escrituras" by Gilberto Esparza. b) "Kauyumari, The Blue Deer" by Arnold Abadie.
a) Environmentalism b) Politics c) Politics	a) Embodiment / Ecological emotion b) Embodiment / Ecological emotion c) Images / Ecological emotion	Body movements, facial gestures, or certain actions.	a) "Multiple Vortex Tornado" by Ivan Abreu. b) "Body movies" by R. Lozano-Hemmer. c) "Level of Confidence" by R. Lozano-Hemmer.
a) Soundscape b) Soundscape c) Politics	a) Embodiment / Ecological emotion b) Embodiment / Ecological emotion c) Autobiographical Recall / Narrative / Ecological emotion.	Speaking in a certain way or through special devices.	a) "Voice Array" by R. Lozano-Hemmer. b) "Less than Three", by R. Lozano-Hemmer. c) "Loud Voice", by R. Lozano-Hemmer.
a) Environmentalism b) Politics	a, b, c) Artifact emotion / Ecological emotion	Clicking on a keyboard.	a) Net Art: "Bakterias", by Arcangel Constantini. c) "Unos unos y unos ceros", by Arcangel Constantini.

Conclusions

The development of the knowledge on emotional content and its assessment is innovative in Mexican Electronic Arts. The influence of Mexican electronic artists could be extended through application of the theory and concepts of the behavioral sciences.

It would be possible for artists or art students to plan works based on the range of emotions they want to elicit. This is not to say that they do not already try, but it does mean that the result could be more accurate. In Mexican, Electronic Art it is necessary to develop methods for emotion evocation, because our environmental, economic, social, and political situation requires it; we as a society need more influential artists to bring about an ecological and political change. And our electronic artists had proved that they have an enormous interest in changing our social landscape for the better.

Even though emotions are vast and depend on historical and cultural factors, scientists have performed a significant amount of research related to emotions and behavior. In this chapter, our efforts have focused on linking this research with the sphere of Mexican Electronic Art. It should be noted that the connection between Electronic Art and the Behavioral Sciences is a new topic of study.

Electronic artworks offer different forms of interaction; the artists believe that it is the public that finishes off their work, and that each person gives every one a new ending. Interaction makes this possible by asking the public to use a particular device, move their bodies, speak in a low voice or shout loudly, click on a keyboard, wear special garments, write or publish on social media, etc. That is why Electronic Art offers an extraordinary medium for awakening new ways of thinking.

The design of the model to elicit emotions that was created was based on an analysis of existing methods of stimulating emotions and those electronic artworks that use a particular form to communicate their artistic statements. It also involves different examples of research that examine the subject through autobiographical recall, images, embodiment, Virtual Reality, films and narrative, artifact, and ecological emotions.

Finally, more research should be done in both spheres so as to develop, for example, a database able to detect the specific emotions generated by particular electronic artworks. The truth is worth the effort; we have invaluable resources of new information on the behavioral sciences waiting to be explored to the benefit of Mexican Electronic Art, and artists and society as a whole.

Acknowledgements

My thanks to the University of Guanajuato and Tirtha Prasad Mukhopadhyay Ph.D. for his guidance during the research process, as well as the artists who participated by providing information for this research.

Author Biography

Cynthia Villagomez is a professor and researcher at Guanajuato University, Mexico since August 2002, she is the author of seven books, several book chapters, and articles about Electronic Art, Creativity, and Design. From 2003 to 2021 she was the editor of the University of Guanajuato magazine *Interiorgrafico de la Division de Arquitectura, Arte y Diseño*. In addition, she has made several trips Spain in connection with the research she has been developing. She is a Graphic Designer, with a master's degree in Creativity for Design from the School of The National Institute of Fine Arts and a Ph.D. in Visual Arts and Intermedia from Polytechnic University of Valencia (UVP), Spain. Her Ph.D. thesis on Processes of Production in Mexican Digital Art received UVP's "Extraordinary Award for Doctoral Theses" in 2016. She is a former Member of The Mexican National Research System, Level II of Mexico's National Council for Science and Technology, CONACYT.

Supra-dimensional Cinema: VR Case Study *TesserIce*

Clea T. Waite, Ph.D.

Colorado, USA

cleawaite@gmail.com

Abstract

The combined three-dimensional, stereoscopic space and embodied navigability of virtual reality foster a supra-dimensional perceptive space. They provide an opportunity to experience a four-dimensional, shifting landscape and acoustic, cinematic environment from within the fourth dimension. VR is uniquely positioned to visualize hyper-space as a mathematical construct in which the participant can experience four dimensions.

TesserIce is a four-dimensional, VR mediascape that utilizes these features, allowing one to enter the 4D space-time of glacial ice. The mediascape constructs a tesseract as an embodied cine-poem – a hyperspace of spatialized meaning and navigable time, examining the effects of climate change on polar ice. Within a crystalline, cinematic tesseract, a four-dimensional architecture composed of different scales, forms, sounds, and speeds of ice enacts the meta-dimensions of our contemporary data-world in manifold perspectives. Participants propel themselves through the hyper dimensions of this tesseract, unfolding uncharted vistas, juxtapositions, and timeframes - the space-time of Earth's polar ice. The stark iconography of ice serves as a distinct access point into the overwhelming complexity of climate change and its ramifications, creating an embodied experience of the time, scale, causes, and effects of climate change.

Keywords

Cinema, Virtual Reality, Tesseract, Climate Change, Hyper-space, Fourth Dimension, Somatic Montage, Space-Time.

Introduction

Physical reality may be a hyper-volume of past and future matter extending along the limitless axis of time into a higher dimension of space, beyond our sensory perception. *This* present moment is a continually shifting, metamorphosing shadow of this hyper-solid as it passes through our three-dimensional space. Visible evidence of this space-time hypervolume is our perception of changing states of matter over time: rusting objects, geological strata, coral reefs, melting icecaps...

The Earth's cryosphere, the frozen poles, is a four-dimensional space-time container of atmospheric history. Ice cores drilled from glaciers in Greenland and Antarctica provide a physical timeline 800,000 years back into the history of Earth's climate. Glaciers encapsulate a hyperspace of environmental time.

A Brief History of Hyperspace

Reality as observed in common experience has three directions in it: up-down, side-to-side, and forward-

back. This world consists of three orthogonal dimensions, laid out along the construct known as the Cartesian coordinate system (x,y,z). The necessity for three dimensions of space can be traced back to Aristotle where there is already a notion of three-space, the same Euclidean space used by Rene Descartes and the great 17th-century physicist of classical mechanics Isaac Newton to represent the familiar three-dimensional, macroscopic world we are accustomed to from daily observation.

The dawn of the twentieth century was accompanied by invisible dimensions of space and a curved universe in which the familiar rules of geometry no-longer applied. Non-Euclidean geometry was discovered in the early 19th-century by Carl Friedrich Gauss and solidified in the 1870s, introducing a new notion of hyperbolic geometry accompanied by a variable, curved perspective. Late 19th-century, Western culture was furthermore fascinated with the concept of *n*-dimensional geometry, hyperspace, and the idea of a fourth dimension. The four-dimensional cube, the hypercube or tesseract, was introduced at this time.

The profound mathematical discovery of non-Euclidean geometry resonated with creative artists and intellectuals, influencing the arts, literature, and the cultural psyche, in particular, the avant-garde. The new ideas ushered in new conceptual approaches to the depiction of visible reality that rippled through the artworld, such as dispensing with the linear perspective of the Renaissance and, for a time, the visible altogether. Turn of the century scientific discoveries instigated a break with the classical logic of Euclidean/Newtonian space and time that resulted in a cultural embrace of relativistic ambiguity and indeterminacy. The lingering aesthetic constructs invented by the artistic movements that evolved from this shift share critical concerns with the supra-dimensional approach to immersive cinema discussed in this paper. We endeavor to conjure a post-Newtonian space-time by breaking with cinematic linearity, single-point perspective, and spatiotemporal continuity.

Visualizing the Tesseract

Two strands of interpreting the fourth dimension developed at the turn of the twentieth century. One defined the fourth dimension as an additional dimension of space perpendicular to our own three, unimaginable to us yet encompassing our three-dimensional scope as the cube encompasses the square. The other defined the fourth dimension as time, imagining space-time as a continuous, four-dimensional volume of past and future

spread along a linear time axis, all moments existing simultaneously. This present moment constitutes a continually shifting, three-dimensional slice of this hyper solid cast through our lower-dimensional space.

Figure 1. W.I. Stringham, *Hypercube sections from Regular Figures in n-Dimensional Space* (1880) [1].

Mathematician W.I. Stringham attempted the first drawings of supra-dimensional hyper-solid sections in 1880 by calculating perspective projections from four-space into three. His drawings are shaded shadows of shadows, two true dimensions of spatial information lost in rendering (Figure 1).

In 1903, the mathematician Esprit Jouffret described the method for projecting a geometric configuration of n -dimensions onto a space of $(n-1)$ dimensions, giving us the possibility of visualizing a four-dimensional object from the confines of our three-dimensions (Figure 2).

Architect and designer Claude Fayette Bragdon played a key role in popularizing the fourth dimension at the turn of the twentieth century. Bragdon was intrigued by the notion of a supra-dimensional object that is only perceivable as shadows cast into our familiar three-space, and then only partially. Bragdon proposed that our ability to perceive the fourth-dimension manifests as time. Time appears as changes of state to immobile objects as the four-dimensional space-time form moves progressively through the three-space sliver that is the object's present. Space is transposed into time.

It was Charles Howard Hinton who coined the term "tesseract" in 1904 to describe a four-dimensional cube or hypercube. In his endeavors to visualize hyper-solids, Hinton used color to represent an additional dimension of information in his illustrations of hyper-cubes.

Hinton, like Bragdon, placed great emphasis on the need for a time-based experience, on motion, as

requisite for comprehending an object of an $(n+1)$ dimensions from within the limitations of an n -dimensional space. The invention of cinema has made it possible to aid in the perception of space – the ability to see around the object – using time. Time-based, animated rotation of a two-dimensional projection of a three object overcomes the perceptual limitations of a single, two-dimensional view by portraying three dimensions of information, (x,y,t) . The rotation over time reveals faces hidden in the depth, or z -dimension.

Fig. 41. — Perspective cavalier des seize octaèdres fondamentaux.

Figure 2. Jouffret's octahedroid or hypercube (1903) [2].

In 1962, computer scientist Michael Noll at Bell Labs was able to realize the dream of a tesseract viewable in motion, creating the first stereoscopic computer animated film of a rotating hypercube (Figure 3). Noll had the computer plot out images of the intersections of the hyper-form in motion with three-space, projected onto two-dimensional coordinates.

Noll adds an additional pseudo-third dimension, using stereoscopy and the very real extra dimension of time to portray the four-dimensional object on the two-dimensional image plane of the screen. Noll's stereoscopic, time-based rendering can display four dimensions of information on the two-dimensional image plane. – three-space and time, (x,y,z,t) .

Visualizing four-dimensional structures from the confines of our three-dimensional space is a question that continually challenges mathematicians and artists. Most "solutions" have envisioned these structures from a distance, looking *at* them rather than experiencing

them from within. These visualizations are shadows of shadows – the two-dimensional screen renderings of the three-dimensional shadow projections of the four-dimensional object.

Figure 3. Successive, stereoscopic frames of a rotating tesseract from the film *Hypercube* (1962) - the first stereoscopic, 3D computer animation of a tesseract by A. Michael Noll, Bell Telephone Laboratories.[3]

The three-dimensional space and navigability of virtual reality presents an expanded information space uniquely positioned to visualize four dimensions. It allows an opportunity to mathematically construct a space in which the participant can experience the shifting space-time shadows of four-dimensional space from within the tesseract. The three-dimensional space and navigability of VR provide an opportunity to fully experience the shifting landscape and acoustic environment of four-dimensional polar ice from within.

4D Cinema

Contemporary Western culture exists in the meta-dimensions of a redefined world, full of strange data vistas that surround us in manifold, crystalline perspectives. Supra-dimensional composition, grounded in geometry, is an unfolding, enfolding, evolving continuum that affords an artistic expression of reality more closely aligned to the mechanics of the post-Newtonian universe as we currently understand it.

Cinema, because it is both a spatial and a time-based medium, has a unique capacity to assimilate new, evolving spatiotemporal relationships in the arts and sciences, and to structure narrative according to a non-

Classical notion of causality. The history of cinema has challenged the representation of the irreversible and unidirectional relationship between cause and effect, the calling card of classical, Newtonian physics, nearly since its inception.

Three-dimensional film space is a closed system. The passage through narrative space is strictly ocular, linear, and virtual. The four-dimensional film space described here is hyperspatial, relativistic, ambiguous, and non-deterministic. Within this space, perspective is a function of the viewer's point of view. Narrative, too, is dependent on the orientation of the viewer. The narrative axis is non-linear and non-causal. Sequential linearity is replaced by spatial simultaneity. Navigation through narrative space engages multiple aspects of physical perception and occupies a liminal space between the real and the virtual. Somatic montage¹ is a spatial narrative approach to immersive cinema constructed according to a non-classical notion of space-time.

Supra-dimensional Navigation: Somatic Montage

The notion of an object that is only perceivable in time, an object containing time within its own space, is what makes the tesseract so intriguing. The tesseract as perceived from three-space has an inherently cinematic nature.

The sentient viewer of immersive cinema navigates a somatic montage of different patterns of juxtapositions and associations within the cinematic space. The spectator moves freely amid a multiplex geography of audio-visual fragments, building interpretations and decoding the poetic cipher.

Motion is essential for comprehending a four-dimensional object from three-dimensional space. We use the notion of the cinematic tesseract to formally explore immersive cinema in hyperspace. We create a spatiotemporal flow structure that explodes the screen into an architectonic, immersive cinema. A hyper-mediascape is formed whose poly-perspectival space is deciphered by the somatic perambulations of the beholder, guided by the syntax of a somatic montage.

Visualizing and navigating immersive environments using somatic montage involves portraying reality as time and space faceted into simultaneous streams, distributed in the space. The spectator is placed in a supra-dimensional position relative to the geometry of the *mise-en-scène*, creating alternative spatio-narrative perspectives. No narrative hierarchy, no explicit viewing direction or pathway dominates the flow. The narrative of immersive cinema must be composed as an open

¹ The nomenclature “somatic montage” was first introduced by this author in “The Cine-poetics of Full-dome Cinema” [4].

work, a prepared field of possibilities for an unpredictable viewer.

Poetry and montage are manifestations of the same idiom of fragmentation, juxtaposition, and association. The poetic language of supra-dimensional cinema is an unfolding, enfolding, evolving continuum that affords an expression of reality more closely aligned to the mechanics of the universe as we currently understand it. With somatic montage, we aim to reinstate an explicit connection to a poetic space, an enfolding of embodiment and participation within the spatiotemporal experience of the cinematic.

TesserIce: The Poetics of Hyperspace

The geological provides a glimpse of deep-time as a supra-dimensional force – a four-dimensional perspective that subsumes both past and future and whose scope far exceeds human perception.

The *Ice-Time* [5] series is a document of our unique moment in glacial space-time. This series of works realizes hyper-dimensional, cinematic spaces that transform the audience's subjective perception of time. The works present non-human scales of time, in particular the time scales of glacial ice, as an experience of the temporal reality of climate change.

Figure 4. External VR view of *TesserIce* (2021), a crystalline, tesseract architecture, shown unfolded. © Clea T. Waite 2021.

TesserIce [6], part of the *Ice-Time* series, is a four-dimensional, virtual reality mediascape that allows one to enter the space-time of glacial ice. It is a hyper-documentary poem within a crystal tesseract, a 4D hypercube, revealing the space-time effects of climate change

on the ice as individual experience (Figure 5). *TesserIce* brings human perception into the space-time of glaciers, creating an immersive, embodied experience of the time, scale, causes, and effects of climate change on the ice.

In the artwork, the participant enters a crystalline tesseract architecture (Figure 4). Within this architecture, different scales, forms, speeds, and sounds of ice filmed in the cryosphere compose the space. The participant's movements propel them along the four spatial axes of this tesseract, (x,y,z,w), between different cube-rooms, unfolding uncharted vistas, juxtapositions, and timeframes that reveal the 4D space-time of Earth's polar ice.

Filmed during an expedition to Western Greenland in 2016, the images of *TesserIce* present hyper-realistic, magnified views of ice taken at all scales, from the microscopic to the planetary. Movements of ice in the film are perceived as the effect of time on matter. The scales of time expand and contract. Movement often occurs at speeds beyond human perception – until the timescale of the ice is transposed to meet the perceptual time frame of the viewer. Time then reverts, drawing the sensate viewer back into the perceptual time of ice. The body of the beholder is enfolding, collapsing its sensory distance to the ice.

In *TesserIce*, the viewer is free to walk through walls, floors, ceilings, and time within the four-dimensional space. The navigation is inspired by Robert A. Heinlein's "Crooked House," [7] a four-dimensional architecture that continually wraps back on itself, infinitely. Viewing back into the third dimension from the four-space of the tesseract, the head and the tail of an object are coextensive. Neither inside and outside, nor top and bottom as we know them are distinguishable, and linear perspective is fractured into crystalline, poly-perspectival facets or curved into a space of relativistic proximities. Within this cinematic space, the action is as pervasive as sound.

In any technological variant of immersive cinema, immersive sound plays an increasingly critical role as a key sensory component of defining space. The acoustic soundscape plays an essential role in the sensory environment of the *TesserIce* experience. For *TesserIce*, we have recreated a physical 9.1 surround-sound mix in the Unity VR environment, experimenting with how this immersive soundscape "behaves" in a four-dimensional, navigable space.

Conclusion

The *TesserIce* VR experience constructs the tesseract as an embodied cine-poem, a hyperspace of spatialized meaning and navigable time, enacting the strange data vistas that surround us in manifold perspectives – the meta-dimensions of our contemporary, disembodied

data-world. *TesserIce* constructs a tesseract of polar ice in time as an spatial poetics. The artwork examines our culture’s altering perceptions of space and time, the deep time of Earth’s environment, by using polar ice to

create a unique experience of climate change.

Author Biography

Clea T. Waite, Ph.D. is an intermedia artist, scholar, engineer, and experimental filmmaker whose artworks investigate the material poetics that emerge at the intersection of art, science, and technology. She creates immersive, cinematic works engaging embodied perception, dynamic composition, and sensual interfaces – as well as one inter-species collaboration with several hundred tropical spiders. Her themes examine climate change, astronomy, particle physics, history, feminism, and popular culture. Waite received her Ph.D. at the University of Southern California in interdisciplinary Media Arts + Practice, combining a background in physics and computer graphics from the MIT Media Lab with her current research in cinema, media art, and critical theory. She brings a unique blend of expertise to her projects from which cross-disciplinary synergies emerge.

Cultivating the possible: using design methodologies for artistic research

Carly Whitaker

Floating Reverie
Johannesburg, South Africa
whitaker.carly@gmail.com

Abstract

Artistic research and art residencies allow artists to cultivate the possible, to capture a contemporary moment and to look towards the future. This seems to be their prerogative and a requirement for reflecting critically on ‘the now’. The digital medium demands this. In order for a new possible way of working to be imagined – artists and researchers need to look outside of their own contexts, towards other ways of working to ensure sustainability, longevity and relevance.

The covid-19 pandemic demands that artists, curators and researchers re-imagine their practice for a technology orientated future. As digital product design or interaction design has progressed, so have the research methods which aid in the realisation of digital products and systems. This field of human computer interaction (HCI), leverages design thinking as an iterative, agile approach. This paper will present //2Weeks special edition, the TMRW residency programme and the Floating Reverie website as case studies indirectly and directly been inspired by this way of working applied to an artistic research practice, curatorial projects and collaborative working within the digital medium.

Through the use of different methodologies and approaches to artistic research and art residencies, within the context of the digital medium, a reinforced connection between arts and technology has the potential to occur.

Cultivating the possible

Introduction

Artistic research and art residencies have the potential to cultivate the possible, to capture a contemporary moment and to look towards the future. The past two years have brought with it the COVID-19 pandemic and have demanded that we, that artists, curators and researchers re-imagine their practice for a technology orientated future. Positioning artist research within a digital context seems inevitable. The digital medium demands that we rethink what creative practice is, that we re-think processes and research within a practical context. One of the possible new ways of working is to look to the medium itself to ensure sustainability, longevity and relevance.

The different research methods and pieces of documentation required for digital product design or interaction design have evolved as the complexity of contexts and products have increased which result in the realisation of digital products and systems. This field of human computer interaction (HCI), leverages design thinking as an iterative, agile approach – focusing on the user. This approach, which places people, the user of the product, at the centre of the research,

guides all actions, solutions and ideas back to this point isn’t a new approach.

This paper will start with exploring the different methods that can occur within this scope of research and project realisation – focusing on how they have manifested in different artistic and curatorial projects. These projects directly and indirectly have been influenced by this way of working within the digital medium. *Residencies as artistic research* explores how artistic residencies can leverage the online digital medium in different ways in order to cultivate unique artistic research through action research. This section focuses on location, or context, as a motivation for practice. This will be showcased using Floating Reverie’s //2Weeks special edition which was held in April 2020, The Mixed Reality Workshop’s (TMRW) proposed hybrid residency programme and the redesign of Floating Reveries website as case studies.

Residencies as artistic research

The residency exists as an artistic space for practice to develop and emerge as a result of a dedicated time, context and location. Residencies can often act as educational spaces, where learning and growth occur for artists as individuals and for a broader community within the space – within an online space this too is the case - challenge existing methods of education and artistic research.

Miriam La Rosa explores the history of a residencies and defines them from a Western perspective, a residency can be identified by components such as “studio space, opportunity to exhibit and living accommodation” (Rosa 2). The author suggests that the residency can be seen as a “crucial step in the career of artists and, more recently, also curators”, in addition it is an “opportunity for visibility” and in some cases a “status symbol... to raise their own public profile, improving their reputation and enriching their CV” (Rosa 2). Allowing a safe space for making along with “seclusion and isolation” seem to be crucial to the residency as defined in this context. This “seclusion and isolation”(Rosa 3) comes with great privilege and access to both funding and mobility. The residency is often framed as this utopian space where making and existing are all possible within the constraints of the space. La Rosa goes on to suggest that the defining characteristics of our contemporary moment for residencies, is the ability for them to extend both artists and curators networks and allow for collaboration (Rosa 4).

In ‘Transnational, Collaborative Artists in Residency Programmes’ the authors describe the residency actively, as intangible, existing through “a structure of times, discussion, thought, action and proclamation” (Dekker et al. 33). The following are identified as inherent characteristics; “time and space for artist(s) ... to research and develop a new work, a modest artist fee, production budget”, regular critiques with communities, “online documentation of project process, testing opportunities, [and] public presentation of research” (Dekker et al. 33). This adds nicely to the definition of a residency; however the context, format and

capacity to determine how many of these criteria can be applied and implemented. Often it is up to the organisation running the residency to determine the intention or aim of the residency programme and the subsequent objectives. What does stand out in their description and criteria is the requirements of communication, for feedback, critique and dialogue to occur around the practice of the artist or curator. Enabling this space to occur, this support within a studio or practice context is what seems to provide further focus and vision for specific residencies. Regular and focused sessions (formal or informal) as it “strengthens connections, opens unforeseen exchanges and builds confidence” in the artists with the organisation” (Dekker et al. 35). Another important criterion is the documentation of the process of both the organisation and the artist. This does speak to a more technical focus of a residency, maybe to something more structural that exists in the background; however, documentation of the practice and process is crucial when evaluating and assessing the outcomes of the residency and the validity of the space of organisation. This documentation can assist in “valuable reflection and evaluation” (Dekker et al. 36) of impact of the residency, the organisation and the outcomes of the practice. These “moments for discussion and reflection” (Dekker et al. 36) or “dialogical relationship between all the parties involved” (Rosa 5) could be in the form of “organised presentations, workshops and test sessions.. [or] ad hoc in response to the needs of the project” (Dekker et al. 36) can provide support and enable documentation to occur. Dekker et al. also refers to the residency life-cycle, specifically within a collaborative space (Dekker et al. 38).

Tatsuhiko Murata, co-director of Youkobo Art Space in Tokyo, Japan, in a report from 2012, describes three general categories or models of residencies; “the ‘academic model’ (facilitated as academic bases of artistic research and creative production), the ‘community art model’ (taking the form of a community art centre designed to contribute to local development) and the ‘event-based model’ (organized as part of international festivals/exhibitions etc.)” (Murata 2). He goes on to describe another category or model, one which operates “solely for the support of the autonomous activities of the artist in a new creative environment” and suggests the term for this model: ‘microresidencies’. This model was identified and discussed as La Rosa points out through many roundtable discussions, workshops and a proposed way of understanding this model was established and represented in the referenced report. Many of these findings were based on Youkobo’s own context. La Rosa describes the model, which she applies to Largo das Artes in Rio de Janeiro, Brazil too, as “flexible, translocal and [opting for an] artist driven approach, seem to look at the residency as an opportunity especially thought of for artists and afterwards curated” (Rosa 5). She states that this is preferred over the “prospect for a horizontal collaboration between artists and curators”. Acknowledging the power relations that exist between artist, curators and the space they occupy together and separately further adds to the complex understanding of where the artist practice emerges.

The question of physical location or space has also been a requirement and for many artists or curators is a necessity as is the mobility of the artists. This takes us back to the romanticised notion of a residency and an artistic practice. It is crucial to acknowledge that this is not the case for many artists, nor is it possible La Rosa acknowledges that a “residency used to be about going ‘somewhere else’, usually beyond one’s own country”, but now it “can take artists directly into their own environment, their own cities or towns” (Rosa 6). The artists or curators could “experience difference there, but the challenges come not from working far away but from being in totally different contexts, professionally, scientifically, politically” (Rosa 6).

La Rosa identifies a fifth model, the ‘secular residencies’ which she states “stretches the limits and borders of what

residencies have been traditionally recognised with, for a very long time; almost becoming a metaphorical point of encounter, rather than a place of individual learning” (Rosa 6). This leads her to analyse three components; networks, collaboration and studio space.

This method of generating knowledge, of reflecting on one’s own practice in a residency context, starts to resemble and draw parallels with HCD and action research. Action research is a research methodology which stems from Lewin’s initial process which consists of the steps ‘observe-reflect-plan-act-evaluate’ (1952). According to McNiff and Whitehead (2006), action research is “a form of enquiry that enables practitioners everywhere to investigate and evaluate their work” (7). The process followed in action research is reflective as described by Schön in his book “The Reflective Practitioner” (1983), he describes reflection-in-action for practitioners - “not only that we can think about doing but that we can think about doing something while doing it” (54). This act results in “constantly [modifying] ongoing practice in such a way that learning takes place” (Leitch and Day 180). This is an intrinsic part of where knowledge and insight is generated during action research for the practitioner and for the participants. Leitch and Day (2000) go on to explain that reflection-on-action is the “retrospective analysis of [the practitioner’s] performance in order to gain knowledge from experience” (180). This process is not too dissimilar to that of UCD or IXD.

//2Weeks special edition

Floating Reverie is a digital residency programme that was started in early 2014 by its curator Carly Whitaker. It consists of two components – an online residency programme which once a month for two weeks, where artists are invited to iterate a concept on a daily basis over the duration of the two weeks. Floating Reverie is an ongoing annual experiment. Each residency, and artist, brings a new dynamic to the process and each has added insight to the framework. The residency has naturally shifted towards a process-oriented, research residency as opposed to a conventional residency focused on the art object or an exhibition. Artists use varying methods during their residency, but ultimately an action research methodology emerges, which cultivates an iterative outcome over the duration of the residency. The artistic process is often removed from the final showing of a work. It can be treated as mystical, as being for the artist’s eyes alone. It is not often that the audience or viewer is involved, or necessary, in the process. The //2Weeks residency breaks with these conventions, enabling the artist to reveal their process, reveal their research.

The Post-Digital instance occurs at the end of the residency year when artists are invited back to respond to their residency and process. It acts as a space for the artist to perform a re-imagining and to re-engage with the residency. Artists are encouraged to interrogate their own experience of the residency, their process, research, and how they produced work, while maintaining the essence of the digital residency during //2Weeks. This enables artists to take their digital residency, re-locating it to a physical, ‘real’ space.

In early 2020 the world started to embark on a collective change and our entire understanding of existing in the world shifted as a result of the global pandemic. This change was collective yet brought with it nuanced individual changes on a micro and individual scale, many of which we are still in 2021, yet to be able to identify. Towards the end of March in 2020 South Africa embarked on an initial three week national lockdown and we entered a State of Emergency. This was then extended for an additional two weeks, which Floating Reverie decided to engage with.

The //2Weeks special edition of 2020 took place at the end of April deliberately coinciding with the initial first extension of the hard lockdown, Level 5 in South Africa. The idea

was inspired by conversations with the artist 1001_1001. Our current context and way of working online resonates with Floating Reverie as a framework for artistic practice. The special edition was an open invitation to all previous residency artists and an opportunity for them to re-imagine their past residency on a new or similar platform. It was still focussed on process, practice and research, positioned as an opportunity to develop an idea - no matter how incomplete or complete. Daily iterations and outputs. The poignancy of this moment has not been lost on these artists.

Post-Digital 2019/2020 special edition is a re-imagining of the //2Weeks online digital residencies that took place in 2019 and the *special edition* in 2020. It is a reflection, a re-imagining and re-engagement of an experience, process and practice, and an interrogation of the residency. This *Post-Digital* presents creative practice emerging from, and because, of two pivotal moments in our contemporary context – before and during the pandemic. The artists who participated in //2Weeks during 2019 are engaging with their practice from before the pandemic, reflecting and re-imagining now in the heart of the pandemic in 2021. The artists who participated in the //2Weeks special edition are engaging with their practice from the beginning of the pandemic, also reflecting and re-imagining now in the heart of the pandemic in 2021.

As part of the *Post-Digital 2019/2020 special edition* there is an online component which was developed using the Art Curator Grid tool which allows you to plot and map out content (Whitaker). Each artist and artwork has corresponding Artist Notes and Curatorial Notes which have been compiled from interviews which are also accessible from the Art Curator Grid. This information was compiled progressively as throughout the duration of the exhibition, so the audience or viewers or users, could interact with different components at different points in the exhibition. These notes and documentation of artworks have also been compiled into digital publications.

TMRW residency programme

"Our World to Come", is a residency programme and publication developed by The Mixed Reality Workshop (TMRW), a gallery in Johannesburg, which will be held from March 2022 – October 2022. This programme will create opportunities for artists to develop their creative practice both in a space and remotely (hybrid context), exhibiting their final collaborative creative outcomes in the gallery space. Ensuring that there are spaces for artists to practice

ing, to exhibit in and have their work be engaged with and establishing a discourse is crucial for a sustainable creative practice and to ensure that their skills are developed, financially they can sustain themselves. The proposed project exists in a physical space, in the gallery that TMRW occupies and the online space - enabling artists the flexibility to work both remotely and in a dedicated space. This is heavily influenced by new creative practices which have emerged as a result of the COVID-19 pandemic. This programme will facilitate a sustainable development of creative and digital technological practices in South Africa and beyond. It will cultivate and contribute to the discourse on a digital, technology based practice - amplified over the past two years due to COVID-19 pandemic - many more artists are turning to digital mediums to explore their artistic practice.

The residency program offers a chance for six artists to participate, through an open call, and collaborate in the TMRW space over six months, each residency lasting for 2 months. One month will act as a studio/practice space and One month for exhibiting/showcase the work produced during the residency. There will be Two artists per residency - one based in Johannesburg and one working remotely in the Global South - working collaboratively. This format is influenced by the consequences of the pandemic and allows artists to embrace their location and leverage the online digital medium. The process of making between the two artists in each residency will be documented and engaged critically - contributing to the publication. TMRW's mandate is to cultivate space for artists to grow and develop ideas in relationship technology which is why a residency programme is integral to the sustainability of the space. Artists would receive a stipend, enabling a sustainable practice and capacity for themselves in a business context. Through the use of technology artists will be able to reflect iteratively using a variation of action research.

COVID-19 has been devastating to practicing artists financially, and the industry has lost much of its financial support from funders due to funding being rerouted to more immediately demanding areas in CSR budgets and NGO or government grants. The demand is far higher than the availability of funding and support in the current fiscal climate, leaving artists vulnerable to exclusion from the cultural spaces to which they previously had access and relied on.

TMRW has similarly seen a deep impact on its artists, and its own ability to run at the same capacity considering the different lockdown levels has impacted TMRW's curatorial planning drastically. Formerly the gallery has been able to have major Virtual Reality exhibitions, and with COVID-19 we cannot have interactive exhibits that require many people to touch the technology to their hands, heads or faces. This has had a knock on effect on the practice of artists. The different components - space to practice, to exhibit, to learn for both the artists and galleries is crucial for creating a healthy ecosystem. TMRW is passionate about positioning the space, not just as a gallery, but as a space to learn and grow with.

"Our World To Come" asks artists to respond to these impacts on their world, lives, artistic practices, and audience reach, asking them to reimagine the use of technology in a world where we cannot share devices, and where we rely increasingly on the digital realm as the gallery outside of the physical white cube.

Figure 6: Diagram of the relationship between the art making process and hybrid contexts.

Redesigning an archive

The Floating Reverie website has the opportunity to be filled with complexity and nuances revealing and capturing the archive of residencies, Post-digital exhibitions and discourse that has been created and generated around the programme. The archive consists of digital artworks, process, images representing different artists and what Floating Reverie represents.

The website has acted as a preliminary, literal archive of the work that has been done by different artists, but has the potential to be far more than that. When briefing the redesign in, the following was requested:

- The website should articulate the connections between the different artists within a networked curatorial methodology and the different themes that each residency explores, and each residencies post-digital artwork.
- The challenge is in represented an iterative, performative residency which has occurred over the two weeks, after the residency has occurred. This documentation becomes an artefact within itself.
- There is a lot of discourse (curatorial notes and articles) written on Floating Reverie

Based off of this, an information architecture, user flows, wireframes and design guidelines were developed and are in development. This process of approaching the archive from a mapping perspective, leveraging the concept of networks through the functionality is crucial. Below are some pieces of documentation which will seek to challenge the archive, its representation and ultimately the process of capturing the residency, artistic research though a reflective and reflexive manner.

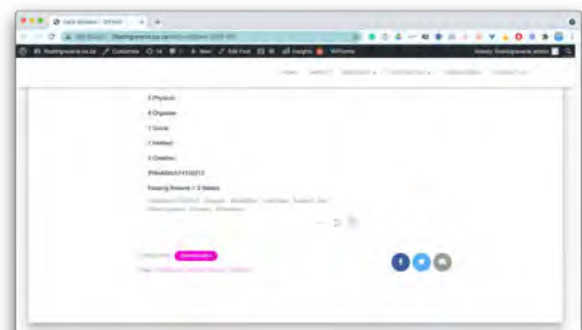

Figure 7: screenshot of previous Floating Reverie website.

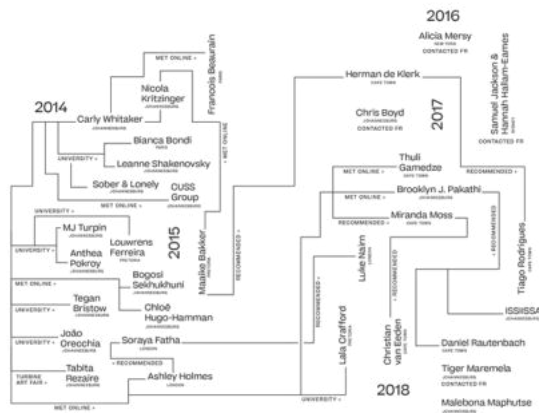

Figure 8: diagram of potential information architecture that will be used to guide the website structure.

Conclusion

Being aware of these research methodologies and experiences from art and design production and research context enables an artistic practice to emerge in a different way, through the consideration of technology.

Through the use of different methodologies and approaches to artistic research and art residencies, within the context of the digital medium, a reinforced connection between arts and technology has the potential to occur.

SHORT PAPERS

Extended Listening:

Towards non-humans interpretation of the sound environment through AI systems

Esteban Y. Agosin

DXARTS, University of Washington
Seattle, United States
estebanagosin@gmail.com

Abstract

Technology has allowed extended human capabilities, amplifying the sense of hearing toward the sonic perception of different physical layers of our environment, such as electromagnetic fields, ultrasonic/subsonic sounds, underwater sounds, long-distance sounds, animal spectrum, etc., generating as a consequence new symbols, new languages and new cultures.

In this sense, the main question in this paper is related to how can we transcend the current use of AI as a methodology to recreate or even create sounds, images, music, texts and move toward the development of models that could spawn a language created by machines.

Questions like that, provide the philosophical context to move forward to generate models that could lead the processing of sound towards complex and unpredictable results, allowing the development of methodologies to create non-human language involved in a technological ecosystem.

Keywords

Machine listening, Sound Art, Extended Listening, Non-human Language, Technological Ecosystem, Ontology of machines.

Introduction

In 1996, the artist Stelarc implanted in his forearm an ear made of human cartilage. This 'third' ear could connect through Bluetooth and transmit what it hears. In light of what technology will be able to do, what are the limits of the human body? How can we interpret the world from a sound perspective through technological listening devices? The human body is an interesting field of study in which technologies have had a significant influence. Technological advances in human history have allowed us to improve our life, providing solutions to medical problems, but also, technologies have allowed us to extend the human limits, giving a new context to reflect on the meaning of the body.

The relationship between the human and machine, in which technologies and devices act as an interface that extends our human abilities, allows for the amplification of the human perception, transforming, changing, and degrading the information from the environment. This could provide different and new interpretations or meanings of the world, and also creates new scenarios, symbols, and realities mediated by the technology itself.

Human Sound listening

New technologies provide new human physical characteristics, extending the natural capacities of our senses, allowing us to amplify the perception of the world.

Barry Truax states that the senses are our physiological mechanism to understand the information that surrounds us. It provides us with a system that allows us to perceive the threat and the characteristics of the environment, giving us resources to survive and build our thinking, ideas and concepts of the world. Despite these abilities, like all living things, human senses have their limitations with respect to their biological capabilities. Human vision, for example, has a specific range with respect to frequency, distance, and visual fields. The ear can hear a certain frequency range (between 20 cycles per second and 20,000 cycles per second), delimiting the possibility of listening to certain types of sound in certain distances and in some places, generating a long quantity of life, events, and situations out of our perception.

Furthermore, the human brain filters the data observed, smelled, or heard converting it into valuable information that depends on our interests, experiences, and circumstances. This generates a vision and perception of the world contingent upon our own biological and psychological limitations: "Whereby the senses employed are always already ideologically and aesthetically determined, bringing their own influence to perception, the perceptual object, and the perceptual subject". [1]

In this sense, the human ear has a physiological inability to block its function. Unlike the function of the eyes, where it is possible to stop seeing something by closing the eyelids, the ear, biologically, is always working. It is only possible to stop hearing if the brain decides to pay attention to something else. That means, listening is not automatic, potentially it is a conscious act to understand the world:

"In this sense listening is not a receptive mode but a method of exploration, a mode of 'walking' through the soundscape/the sound work. What I hear is discovered not received, and this discovery is generative a fantasy: always different and subjective and continually, presently now". [2]

In the mid-1960s, American artist Pauline Oliveros began to develop the concept of "deep listening." In essence, this idea refers to an attitude. To experience conscious listening is to act actively with the body, memories, and feelings; it is listening taking a position on how, and why to use the ear.

Pauline Oliveros (2003) states that the idea of "deep" refers to those things that are difficult or impossible to understand or something that has unknown and different parts. "To listen or listen deeply for me is to learn to expand the perception of sounds to include the entire space/time continuum of sound, finding the immensity and complexity as much as possible". [3] Oliveros states that the concept of listening requires an exploratory attitude towards the perception of sound in physical space. In this sense, listening is an active, unstable, untouchable, ephemeral,

and conscious sensory process toward approaching the world. It is confusing, filtered, and subjective; as Salomes Vogeling states, listening is a practice about doubt.

Extended body

As a consequence of that exploratory attitude, in the sound field, from science to contemporary art, different experiments and projects have crossed the idea about how to amplify the sense of hearing, resulting in the extension of acoustic listening practice, toward the development of technologies around sound listening devices. The purposes of this extension include reaching unreachable worlds, creating interfaces between the human and inaudible layers of sound environments, amplifying the limitations and abilities of the body, and incorporating new sound dimensions to understand the physical world that surrounds us.

One of the pioneer examples in developing sound listening technologies is Acoustic Mirrors. After the first World War, between 1915 and 1935, Great Britain created a military architectural structure based on a concrete, concave and parabolic design. Its shape allowed it to hear sounds at long distances and detect possible aircraft threats. During those years tens of acoustic location devices were developed for the passive detection of aircraft by picking up the noise of the engines. From devices such as horns that worked like ear prosthesis and body extension, to big concrete structures that gave both acoustic gain and directionality, increasing the observer's ability to localize the direction of a sound.

Extended listening

Thereafter, with the advent of electronic sound technologies, and the arrival of sound experimentation, this field moved from its scientific purpose to an artistic point of view, becoming one of the fields of study in the sound art aesthetic.

During the 1970s, German sound artist Christina Kubisch started to develop an interest in the sound of electromagnetic fields generated by human activity, and more specifically generated through the electronic devices around us. The performative experience of walks around the city was captured by sensitive wireless headphones, by which the acoustic qualities of aboveground and underground electromagnetic fields become amplified and audible. Since 2003, Christina Kubisch has been developing what she calls "Electrical Walks", all over the world. Searching each city for inaudible phenomena that human biology is incapable of perceiving, in order to reach to impossible layers of the physical world, amplifies not only the human abilities, but also amplifies the unknown places of the sound dimensions in the world, therefore expanding our perception of the world. In the words of Kubisch, "The perception of everyday reality changes when one listens to the electromagnetic fields; what is accustomed appears in a different context. Nothing looks the way it sounds. And nothing sounds the way it looks". [4]

Machine Ontology

Evaluating further the consequences of these devices in terms of human perception, meaning the flow of information: the environment, the human biology, the technology devices, and the human interpretation of the environment, and also understanding that the focus of discussion here is the relationship between human and machines, it is appropriate to ask what is the role of the machines and technology in that information flow: Is technology only a bridge between the world and humans? That question implies that machines or technology are only tools to achieve some purpose. However, observing how technology has changed everything around us, how it has evolved and is involved in probably all of the parts of

human life, it is possible to understand technology beyond its usefulness. In this sense, technology could be understood as a complex language; a culture that has its own codes, procedures, and meanings that converge with the environment. Therefore, it would be possible to state that technology is a complex system of interaction with the social system that generates new symbologies, objects, and codes of communication. Consequently, the relationship between humans and machines is not just morphological, it could be ontological as well. In this sense, the philosopher Guattari in his book *Chaomose*, reformulates the idea of machine extending it further the field technological, going beyond the signifier of the machines, and the limits that represent technological devices:

"Through these positions, we will attempt to discern various levels of ontological intensity and envisage machinism in its totality, in its technological, social, semiotic and axiological avatars. And this will involve a reconstruction of the concept of a machine that goes far beyond the technical machine. For each type of machine, we will pose a question, not about its vital autonomy - it's not an animal - but about its singular power of enunciation" [5]

In this sense, in the information flow mentioned above a bifurcation can appear: in one sense, the human interpretation mediated by technology, and in the other, an interpretation model mediated by the machine's own language, thus advancing to the hybridization: human/machine, and also toward an ontology of machines. In 1985, Donna Haraway presented the Cyborg manifesto, stating the concept of the cyborg as a refutation of the boundaries between humans and machines. This proposes a hybridization as a cybernetic organism that emerges from a given context, and social relationships. For Haraway the concept of cyborg goes further:

"The cyborg age is here and now, everywhere there's a car or a phone or a VCR. Being a cyborg isn't about how many bits of silicon you have under your skin, or how many prosthetics your body contains. It's about Donna Haraway going to her gym, looking at a shelf of carb-loading bodybuilders' foods, checking out the Nautilus machines, and realizing she's in a place that wouldn't exist without the idea of the body as a high-performance machine. It's about trainers. "Think about the technology of sports footwear," she says. "Before the Civil War, right and left feet weren't even differentiated in shoe manufacture. Now we have a shoe for every activity." [6]

The concept of the cyborg has generated a culture around the idea of the human machine, expanding the idea of the body, by using technology in our lives and using the body as material for experimentation. This transforms the body into something different from its nature, introducing the posthuman culture.

Machine Listening: towards Non-human languages

There have been years of the ongoing discussion about human hybridization by technologies, cyborgs, posthumans, and transhumanism. Considering this discussion and the current artificial intelligence research, it is possible to ask: could the technology go further and create its own existence beyond human beings? Is it possible to create systems that could give way to the ontology of machines mediated by A.I?

It is necessary to say that current A.I. is an ongoing technology that is much closer to an utopian philosophy than having real analogies between human intelligence and artificial ones. In this sense, Johana Zylinska states about the current AI generation that:

"The renewed interest in AI research has been accompanied by a change of tack: from what became known as Artificial General Intelligence, whose goal was

to replicate the human's mental functioning as such, to specialized, or 'narrow' AI, focused on performing particular tasks and solving singular problems. The new approach involves developing artificial neural networks, which at a rudimentary level imitate the way neurons in the brain work". [7]

This new direction transformed the utopia of thinking machines from speculative analogy with human complexity, into powerful computer skills that can resolve specific problems. This allowed for incredible advances in information processing, affording machines the skill of precise decision making, and performing certain and specific tasks based on the training of a large set of data. This new perspective is beyond the idea promised and speculated about historically, nevertheless AI technology is still a field that provides deep questions about the future of humanity and machines, giving the context to continue speculating on the question of what will come next.

In the sound field, different technological advances related to AI have happened in the last few years, generating both artistic, scientific, and commercial applications. Going back to the information flow mentioned above, it is especially relevant to mention the highly advanced sound recognition systems like speech to text, and also the new possibilities in sound recognition of more complex sounds, like every day and natural sounds, through signal processing and machine listening.

Machine listening is a branch of the AI field that amplifies the results of the advancements in speech recognition researched in the last 70 years. Therefore, if it is possible to process the voice and take linguist information, recognize words, gender, and even the speech emotion, is it also possible to recognize more complex sounds like music, or sounds from complex sounds environments? Izotope, for example, is a commercial tool for studio recording, that analyzes the audio signal and through machine learning techniques suggest custom presets that are tailored to the sound you're trying to achieve. Also, Andrew Owens of MIT, created an algorithm to insert sounds in silent videos. Through the image analysis and the training of thousands of movie scenes and sound effects, a neural network predicts which sound to synchronize with the image. Other advances in Machine Listening have allowed for the recognition and description of sound environments, which will determine if the ambient sound is an airport, stadium, library, park or coffee shop. There is also an algorithm that allows for the recognition of short sounds, like "sound objects" and also describing its characteristics.

These examples clearly provide extremely interesting tools to process audio signals and to gather valuable information that will allow machines to make decisions. but this model is still under the paradigm of usefulness and not under the question of how to get senses and deeper meanings from the information obtained.

From this perspective a question emerges, how can a machine listen to sounds and then process it to make an unexpected decision? That process may not be necessarily useful, but it could be challenging, confusing, provocative, or generate results in an imminent state. That means, in other words, it seems necessary to ask how this intelligent process can create art, but art pieces that are different from pieces that humans can create. It is necessary to find reasons to use this high technology in the art field, therefore, the artistic challenge is how to pass from the utilization of AI as a methodology that can recreate or even create art using known and human parameters, and move toward a model that can create an artistic language itself; a language potentially non-human.

AI from a critical perspective

The question fits about how this current powerful technology serves a complex purpose, and can also create systems in which machines observe and listen to the environment, not only makes decisions, although contradictory, can also create models where machines open

unpredictable paths. If this is the case, it is also taking an aesthetical position that is not human, creating devices and models that extend the listening towards autonomous "machinic" interpretations through AI systems.

In this sense, it seems necessary to have a critical position on AI and to observe this technology from a certain distance in order to explore conceptually at the same time that this technology is going forward. This attitude establishes a reflective context and opens a counterpoint to what the mainstream wants to state about what this technology is. Therefore, generating questions about: what really those results, predictions, and conjectures are? And How AI can provide a new way to create Art? But understanding this technology beyond being only a tool: How does AI provide an artistic language itself? Can this technology open up new or different aesthetics that could be named non-human aesthetics?

These questions and reflections, regarding the relationship between humans and machines, the interpretation of reality through listening, and as well as the question about how technological devices and AI create new contexts and scenarios, thrust the idea of the possibilities of experimental processes which could create complex interpretation models about the physical environment, that could give way to new symbols, senses, and meanings through sound experiences

The Ear and Imaginary Machinescapes

In the beginning of 2020, inspired from the philosopher Byung Chul-Han ideas related to how western and eastern countries were facing the pandemic, putting on the table concepts such as surveillance systems and individual freedom, I developed an artistic work called The Ear.

The ear is a listening, surveillance, and Artificial Intelligence project. It is a device that collects human voices, transcribes them into text, and with that information create new texts.

Figure 1. The Ear, University of Washington, Seattle, US

This Machine uses the collected texts as a data set, accumulating day by day more information from the environment where it is installed. The data set is trained constantly, creating AI texts based on the specific situation where this machine has been involved, transforming this piece also into a cultural apparatus. The AI texts generated are shown in small parabolic speakers using a computer voice, returning the data to the acoustic world. The experience with the piece shows how the human voice is transformed into a digital object and that can be analyzed, recorded, transformed, stored, and used, questioning the concept, sense and value of the information, privacy and freedom in our contemporary society, questioning also the relevance of the information collected in surveillance systems, and the ethical and political limits in this type of devices.

The aesthetic experience of The Ear emerges from the mistakes that this machine produces:

Speech to Text in real time makes several mistakes, transforming the coherence into a degraded text, transforming the data in absurd texts, and also bringing invented words. Furthermore, considering that the data set is based on the texts collected, the AI texts are even more absurd and therefore a weird kind of digital poetry

emerges, generating a listening experience based on AI experimental narrative created under the series of mistakes that this machine does, putting on evidence the imprecise and cracks of this kind of systems.

To further explore these interesting spaces of error that this kind of system leaves, In the beginning of 2022 I started a new project related to machine listening.

Figure 2. 3D Design, Imaginary Machinescapes device

Imaginary Machinescapes is a robotic intelligent listening device that senses and collects sounds from different sonic layers of the environment. Using the AudioSet Ontology (a large data set based on youtube videos with more than 2 million sounds and 527 labels) the system processes and classifies audio signals in order to recognize what kind of sounds the machine is listening to. This process will generate complex descriptions of the sound environment, allowing for interpretations yielding experimental sound narratives. This process also spawned new procedures that could generate more complex results; creating sound experiences through the exploration, expansion, and creation of linguistic models, and extending listening towards non-human interpretations through AI systems.

The system relocates sounds in a foreign landscape, recategorizes the information of the real time environment,

and plays sounds from other territories and ontologies, questioning the conflict of local and global, and also questioning the territorial identity in counterpoint with landscapes created by machines.

The sounds are displayed acoustically in a new natural territory, based on how the system understands the environment, thus reinterpreting the reality of the site, generating a machinic ecosystem produced by the dialog between the situational soundscape and the intelligent machine interpretation of the environment.

As in *The Ear*, the aesthetic of this system comes from the mistakes. In ideal conditions, machine listening can be very effective, recognizing and therefore categorizing the sound from the environment. But situating this system in a real environment, that means, several layers of sounds, and also a complex and diverse data, the system fails, bringing erroneous categorization. Also, considering that this system is using these categories in order to calls sound from an uncontrolled sound repository as freesound.org, both because the erroneous categories and also the juxtaposition of labels, the system open up unexpected results, creating a new soundscapes created by interpretation of the machine.

Taking both projects, one possible clue to going forward in the idea of non-human interpretation is asking where the holes, cracks, and gaps of this kind of system are. It seems like those spaces open up paths to the surprising, uncontrolled and unexpected, allowing us to ask about creativity and the sense of the use of AI in the art field. Under that perspective, perhaps, hacking, intervention and transformation through the navigation in the errors could be an aesthetic strategy that would allow us to re-appropriate, re-imagine and re-define the purposes and behaviors of the A.I systems in the art context.

Author Biography

He is a sound artist and electronic media artist. He has a degree in music from the University of Valparaíso, Chile and a Master in Electronic Arts from the National University of Tres de Febrero, Buenos Aires, Argentina. He is currently pursuing his doctorate at DXARTS, University of Washington, Seattle, United States (Digital Arts and Experimental media). His research has been orientated on the relationship between the human and machine, and how technologies and devices act as an interface that extends our human abilities, allowing the amplification of human perception, transforming, changing, or degrading the information that comes from the environment, providing new interpretations or meaning of the world. The last two years his work has been focused on machine learning, NLP, and machine listening applied to robotic and sound installations

Bridging traditional and digital crafts: Digital Dynamic Ornaments

Konstantina Angeletou

Designer, Artist
Vienna, Austria
angeletouk@pm.me

Abstract

This study draws parallels between the work of traditional craftsmen and the workflows of digital artists, and acknowledges both of them as cultural actuators and generators of ornamentation. Moreover, the elements of play and visual complexity are considered in the exploration of ornamental forms, as integral practices in both the analogue and digital realm. Play is a natural function, connecting intuition to actions, and specifically in the digital arts, it helps shape different notational systems bound to individual imagination. Visual complexity is explored as an ornamental quality that was forsaken in favor of minimalism and functional design, but nowadays is returning as an integral and desired quality in both traditional and digital ornamentation. It is, as well, a common feature of generative art, a field of digital art, which is interpreted as the augmented continuator of the intellectual and procedural heritage of traditional handcrafting.

Keywords

Play, Complexity, Ornamentation, Digital Art, Craftsmanship, Generative Art.

Introduction

“Culture arises in the form of play, it is played from the very beginning.” Johann Huizinga [1]

A first thing to consider is the relationship of the function of “play” to ornament. In particular, play has a close relationship to the traditional handcrafted ornament. Craftsmanship excellence often started from physical play and experimentation. The traditional handcrafted ornament was a result of workflows of repetition with the material, pushing the craftsman’s skills a bit further every time. This created an intense mind-hands connection similar to all skills that are “played”, such as music and sports.

The handcrafted object of beauty carried the individuality of the craftsman blended with his infused perception of society and reality.

“Its production involves some play, some waste, and above all a kind of communion. [...] As an object it represents and serves its culture; its daily handling is a

humble act of participation in that culture.” Malcolm McCullough [2]

The process is manifesting in a visceral, intuitive way; from his mind to his hands. Traditional craftsmen were admired for their skills; for each new intricate level of detail implied a lifetime of consistent practice on connecting the body to the mind.

The psychological action of play, which is based on intuition, led to the conceptual formation of symbolic worlds and notations, which were channelled in the traditional handcrafted ornament. So, the ornament was an expression of the culture, while play can be considered a cultural actuator. Personal and communal rituals, skills and operations are practiced and learnt through the fundamental action of play.

Figure 1. From play to traditional handcrafted ornament, to culture

The fall and comeback of the Ornament

Ornamentation was essential to experience culture; whether it was through the architectural ornamentation in churches and sacred spaces or intricate patterns on the clothing of priests in communal ceremonies. However, in the post-industrial revolution era, ornamentation was discarded.

“Revolutionary developments in the fields of industrialization, transportation, communication and production have led to heavy criticisms about social functionality being replaced by the figural-meaningless repetition of the visual-fanciful.” Hakan Sağlam [3]

A deep separation was introduced between objects that served functionally and those that did not. In this context,

ornamentation fell in the category of art which "...concentrates objects that have no other function than to be." [4]

Specifically, in architecture, "it is largely accepted that Modern architecture (1900-1968) abided by the call to eliminate ornament from architecture in lieu of augmenting the true spatial experience produced by architectural surface, form and space." [5]

"Eugene Emmanuel Viollet-Le-Duc [...] emphasises that architecture should tell the truth as an ethical and constructional obligation by saying that "the primary function of columns is to carry loads, and if they do not do that, they should not be placed on the facades of buildings like arabesque ornaments which are useless" [6]

"English architect George Aitchison has emphasised the point that in order to establish an architectural style of our own era, stylistic beauty should be taken into consideration more than ornament and he has expressed this though the following statement: that "pure, elegant and unornamented plain style should be applied everywhere from buildings to our tea-spoons." [7]

"The evolution of culture is synonymous with the removal of ornament from utilitarian objects." Adolf Loos [8]

The combination of such ideological inclinations with the new faster and cheaper building technologies of that era resulted in creating urban landscapes as we know them today; rectangularly organized, with utility-driven forms and minimal ornamentation.

"For Huizinga, the rigors of the Industrial Revolution caused adults to put away their toys; [...] He argued that, thereby, when utility rules, adults lose something essential in the capacity to think; they lose the free curiosity that occurs in the open, felt-fingering space of play." Richard Sennet [9]

With the rise of automation and mass production, the craftsmen were replaced. However, criticism arose and mass industrial reproduction was eventually accused of producing disposable form, devoid of personal or communal meaning.

"For it is not the material but the absence of the human labor, which makes the thing worthless ". Malcolm McCullough [10]

The absence of human touch implied a lack of the essential body-mind connection described in traditional craft excellency. This suspicion is wide spread till today, when handcrafted items are sold as rare and unique, while products of computation are replaceable and of less value. In the comeback of ornamentation in its digital form, creative computing has this reputation to overcome.

However, digital craft has capacities that can reshape the way in which human experience is channelled in creativity. Today, we could say that computation can approximate human thinking closely, particularly when it comes to abstraction. Computational abstraction can describe human conceptions of reality such as symbols, notations, information structures and processes. It can also describe natural pattern formations through algorithms.

"In much the same way as a recursive script may call itself, and perform a series of steps in a loop, until some condition is met, so can material systems." Santiago R. Perez [11]

The digital tools and interfaces go deep into the symbolic mind, by approximating the "abstractive power of human thinking" and expanding "our capacity to visualize abstract symbolic structures as physical images." Malcolm McCullough [12]

Not only this, but according to Mario Carpo, the mind-body connection can be restored; "...digital design and fabrication tools are creating a curiously high-tech analog of preindustrial artisanal practices." [13] Digital arts can be an intuitive medium, through which culture is abstracted and re-expressed. The automation is there but the human decision is there as well; It is important because computational systems are unaware of their context and "...have the unfortunate disadvantage of containing no information about when their contents are appropriate." [14]

Digital Dynamic Ornaments

Returning to the concept of play in traditional ornament, we can see that play can similarly create symbolic worlds through creative computing and digital notational systems, leading to our idea of a new digital ornament. However, traditionally ornaments were usually physical and static. Digital craftsmanship can manage not just inanimate but also animated forms. Animated forms can describe ornamental geometry that moves and digitally augments a space, potentially a minimally designed space. A digital dynamic ornament, or an ornamentation that is not based on physicality, that is dynamic and that serves the old purpose of cultural expression. Practices like projection mapping or video jamming or screens in public spaces are culturally meaningful, dynamic, interactive ornaments. Today a lot of these practices are often driven from advertising and it is important to connect to the bigger perspective of what they represent in the space and their cultural impact.

Figure 2. From play to digital dynamic ornament

Complexity in Generative Design and Traditional Crafts

After assessing the relationship of the social function of play to ornamentation, where ornamentation was redefined as something not necessarily physical or static, we will explore the role of visual complexity in this equation.

In particular we will examine visual complexity as a possible symptom of generativity. Generativity is the quality that characterizes generative design and art. Generative design is a method that is capable of producing limitless and unpredictable answers to a question, within specific constraints. And even though, the term generative design refers to digital practices, the concept of generativity stems from natural processes; nature could be seen as the absolute master of generating “unique designs”. No leaf is exactly the same as any other, yet they all fit in the constraints of the term “leaf”. However, creative computing is following closely.

Generative algorithms are saturated with the language of complexity theory, because “[...] it is integral to current understandings of the generation of pattern and structure in inorganic, organic and cultural dynamic systems.” [15] So, generative art can be seen as an effort to imitate nature, not just its form but its logic. This is very fitting to the long history of traditional ornamental culture. Upon a closer look, for example, ornaments in religious buildings always got inspiration from nature. So, traditional ornamental complexity was often derived from mimicking plants or natural geometrical patterns. Complexity was also obtained from exceptional craftsmanship and layered work. The human as a natural “generator” can produce complexity and endless answers for a single question, based on layers of personal skill, experience, physical constraints, luck.

Figure 3. Complexity in traditional handcrafted ornament

Complexity was put aside by utility-driven ideologies, as an unwanted feature. But it is not only a by-product of referencing nature; it can be a desirable aesthetic despite the various intellectual and artistic movements that supported a strict functional minimalism. There are a lot of references explaining how the right kind of complexity is more appealing to people than no complexity. Moreover, a lot of observant conclusions could be exported from the popularity of architectural masterpieces with complex geometries such as the Taj Mahal or St. Vitus Cathedral in Prague.

“Many studies have observed a relationship between visual complexity and affect (pleasantness). This relationship has been observed dating back to the early 1970s¹ and this idea has re-emerged more recently². Importantly, these studies suggest that more complex pictures are perceived as more pleasant than less complex pic-

tures, a hypothesis supported by earlier work where pleasantness and physiological arousal have been found to be higher for more complex abstract shapes³. At particularly high levels of complexity, pleasantness decreases, however, following an inverted-U shaped function⁴.” [16]

Generative design can be a continuator of intricate traditional ornamentation, filling the gaps that decades of minimal aesthetics left in the cities and objects of daily or ritualistic use.

In essence, generative systems in digital art provide new visual syntax for the communal experience, as “a natural extension of intellectual development that can be expressed in terms of our knowledge of notations.” [17] They are alike traditional craftsmanship in more ways; in the book “the Language of Ornament”, James Trilling [18] states that “ornament comes from ornament”. Historically, styles and ornament were catalogued, and these were used as the basis for generating most other new ornamented works. [19] Generative systems are also consuming cultural knowledge about, for example, Islamic or Chladni patterns and they are building on them. Throughout the process, the artist’s involvement is important and he is not outsourcing his intuition to a mechanistic process:

“ [...] (generative structures’) power will be realized through the complementary role of personal sensibility [...] Explorations of generative structure obtain power from hand, eye, and tools. They arise from personal knowledge, practice, and commitment of the sort found in traditional handcrafts, now applied to symbolic systems.” Malcolm McCullough [20]

Complexity and Play

Coming back to the concept of play, we can close the mental circle by establishing the relationship of complexity and play. Play in natural and social systems is basically an essential generative factor in creating complexity in nature.

“Evolutionary Biologist Brian Goodwin has introduced the role of play as an essential component of the “generative field” constituting complex adaptive systems. Complex patterns of behavior or play in animals, is compared with goal-directed behavior, which tends to have strong elements of repetition that give it a somewhat stereotyped, even mechanical, quality, play is extraordinarily fluid” [21]

In nature play accounts for generating unpredictability or complexity, and so it does in the formation of traditional handcrafted ornaments or digital dynamic ornaments.

“Play, or play-like behavior, is like a high-temperature or excited state, in which participants have reached a condition of highly unconstrained movement, a state like chaos. As they cool down again, order reemerges from this chaotic condition... One consequence of this repeti-

⁴ In the paper this is referenced as “Wundt curve,” Berlyne, 1970

tion is that out of the high symmetry of play, new patterns of order can emerge as the symmetries break again” Brian Goodwin. [22]

Conclusions

The notions of play in culture, handcraft and generative design expand to characterize digital practices on the whole.

“As all of us learn about this promising new domain, a chain of developments should be clear: play shapes learning; learning shapes the mind; mental structures shape software; and software data structures afford work and play.” Malcolm McCullough [23]

The idea together with the computational capacities can elevate the symbolic power of ornament in different dimensions; because now movement, sound or light can be “crafted” allowing for more intense manifestation of cultural experiences. Dynamic interactive ornamentation is taking the concept of creation-through-playing on a different level; now the receiver of the ornamentation is also a contributor. Vocal expression and dance were in the past natural ways for an audience to respond creatively in a cultural happening, but now the possibilities of interaction are endless.

This project is aspiring to contribute to the transmutation and resurgence of ornamentation in terms of workflow and associated values. The idea behind this study is to identify digital arts as a continuation of the cultural heritage of the past, and, in part, connect it to the architectural ornament. Ornamentation, an essential actuator in communal experiences, has now been redeemed of the accusations of the past and it is coming back augmented in a new digital reality. Generative design, digital notations, experimentation and complexity build on the tradition of the mimesis of natural inherent rules, iterations, symbols, intuition and play. The difference is that while not everyone could build the occasional cathedral, now anyone with a computer can start his way to altering virtual or even physical landscapes.

“Poiisis is in fact a play-function. It proceeds within the playground of the mind, in a world of its own, which the mind creates for it.” Johann Huizinga [24]

Acknowledgements

I would like to thank: Dr. Wassim Jabi for his supervision of my thesis during MSc Computational Methods in Architecture, where the initial framework of this study was developed, Dr. Robert Doe for his support regarding research methodologies, Dr. Katerina Chatzivasileiadi for her support in the development of this paper and Dr. Matthew Mosher for their advice for this submission.

Through her artistic project Ludik, she focuses on organic pattern generation using various motion capture techniques.

***eCO₂system*: exploring the environmental and social impact of the internet's materiality through a data-driven media art installation**

Caterina Antonopoulou

Department of Digital Arts and Cinema, University of Athens

Athens, Greece

cat-ant@dcarts.uoa.gr

Abstract

The internet's materiality often lacks attention in recent controversies surrounding the environmental footprint of physical versus online activity. The operation of the internet presupposes a physical infrastructure that consumes natural resources and generates pollution. The obfuscation of the materiality of the internet conceals power asymmetries produced by the uneven access to the control of the internet's material infrastructure.

This paper investigates the social and environmental impact of the internet's materiality through the data-driven, media art installation *eCO₂system*. The installation consists of an aquarium which is connected to the Internet of Things and contains a small-scale ecosystem of fish. The technologically augmented aquarium retrieves data from a social media platform and detects digital activity promoting climate change awareness. The living conditions of the ecosystem deteriorate according to the number of awareness-promoting posts, highlighting the divergence between digital actions and physical consequences.

A complex network of more-than-human agents is articulated around the aquarium, including things, animals, humans, technologies, cultural structures, and other material and immaterial entities. The dynamics of this network impel us to rethink technology as part of a symbiotic whole of heterogeneous agents and to adopt less technocratic and more ethic criteria to redesign, reprogram, (re)use and recycle technologies.

Keywords

internet's materiality, Internet of Things (IoT), media art installation, data-driven, social media platforms, climate change, ecosystem, more-than-human networks, opensource, DIY.

Introduction

The internet's materiality refers to the physical infrastructure required for the operation of the internet. This infrastructure is often overlooked by internet users who tend to

conceive the internet as a totally immaterial entity. The obfuscation of the internet's materiality obscures the social and environmental impact of the internet's operation and the asymmetric political relationships produced by the uneven access to the internet's material infrastructure.

The digital medium is largely perceived as immaterial [1, 2], namely as a "mere collection of 1s and 0s" in the void of immateriality. [2] However, this collection of digital bits cannot exist independently from the physical infrastructure (the physical memory of a material device) where it resides. Software cannot exist without a hardware which stores and executes it [3], or as Friedrich Kittler states: "There is no software." [4] Meanwhile, during the last decade, the number of objects connected to the Internet of Things (IoT) has exceeded the number of people on earth [5, 6]. Despite of a gradual "shift in the way engineers talk about the Internet" focusing on the physical aspect of interconnected devices [7], the internet is still largely conceived as immaterial.

Material infrastructures are systematically overlooked in order to obfuscate power relationships, hide them from perception and prevent potential will for change. The immaterial metaphors used to describe the internet -such as the terms Cloud and cyberspace- are deliberately misleading [3, 7, 8]. The Cloud is nothing more than "buildings with servers in them" [7]. This deliberate disorientation conceals the fact that infrastructures of power are material things [7] owned and controlled by human beings. By hiding the internet's physical infrastructure from view and access, users are excluded from open and wide participation to the control of such infrastructure. Additionally, the occultation of the internet's materiality contributes to the concealment of the vulnerability of data networks, which depend on material components -often precarious and exposed to extreme natural conditions-, such as the underwater internet cables. [7] This way, the seamless functioning of the internet, that users take for granted, can be limited or suspended due to physical disasters or due to deliberate actions by the authorities managing these components.

Additionally to the previously described social and political implications related to the control of the internet's

physical infrastructure, the operation of this computational equipment has a significant environmental footprint. Servers and other networked devices depend on fossil fuel power and their operation generate large quantities of CO₂ emissions. Indicatively, a cryptocurrency mining network was estimated to consume the same amount of electricity as an entire country of the size of Ireland. [9, 10] Especially social media platforms are among the most visited sites [11] significantly contributing to air pollution.

Apart from the operation of the internet's infrastructure, the processes of manufacturing, as well as the disposal of the devices that constitute this infrastructure further imperil the current precarious ecological balance. The manufacturing of electronic devices depends on the extraction of non-renewable natural resources, and unsustainable practices of transformation and distribution of the extracted minerals. [8] Moreover, the discarded parts of the infrastructure contribute to the accumulation of toxic electronic waste. The corporate strategy of planned obsolescence accelerates the substitution of electronic equipment even before it becomes dysfunctional, further increasing the production of e-waste. [12] Indicatively, approximately 250 million functioning devices are discarded each year in the United States. [12]

All phases of the lifecycle of internet's infrastructure and IoT devices -from birth to death- accelerate environmental deterioration, due to exhaustive and highly polluting mining processes, depletion of non-renewable reserves, extensive fossil fuel power consumption, vast emissions of air pollutants, and uncontrollable disposition of toxic electronic waste in dumps. The natural environment "bears the weight of media culture", from the manufacturing to the disposal of electronic material equipment. [13]

Related Works

Media artists address the aforementioned issues related to the social and environmental impact of the internet's materiality. Trevor Paglen, in his project *Deep Web Dive* (2016), photographs NSA-tapped undersea internet cables, while deep diving in the Atlantic Ocean. [14, 15] The photographs reveal the material infrastructure of the internet and the mechanisms of mass surveillance exercised on users' data travelling through the undersea cables. Paglen's work draws attention on the precarious nature of the internet and the limited access users have to the control of the internet's infrastructure which is owned by economic and political elites.

Inspired by *Deep Web Dive*, César Escudero Andaluz presents a dystopic future scenario, according to which the authorities that control the internet's infrastructure deprive users of internet access completely. In this scenario, he proposes the destruction of the internet's physical infrastructure and designs a device to achieve it. His artistic project *Free Universal Cut Kit for Internet Dissidence*

[*FUCK-ID*] (2017) consists of an autonomous device able to cut undersea internet cables. The digital files required to 3D print the device are available for free downloading through the artist's website. [16]

Joana Moll investigates the air pollution generated by the operation of internet servers. Her work *CO2GLE* (2014) is a net-based installation that displays in real-time the amount of CO₂ emissions per second generated due to the global visits to Coogole's search engine. [17] In her subsequent net-based piece *DEFOOOOOOOOOOOOOOOOOOOOOOOOOOREST* (2016), Moll visualizes the number of trees needed to absorb Coogole's CO₂ emissions, by dynamically depicting an equivalent number of tree icons on a website. [18] The artist conducts further research on the energy cost of online services and the free labor assumed by the internet's users, in her project *The Hidden Life of an Amazon User* (2019). The project aims to shedding light on business strategies adopted by companies, such as Amazon, which include "endless pages of indecipherable code, [...] activated by user labor". [19] According to the artist, "these strategies have a significant energy cost, part of which is involuntarily assumed by the user." [19]

Kate Crawford and Vladan Joler investigate the entire lifecycle of an AI device connected to the Internet of Things. In their project *Anatomy of an AI System* (2018), they create a map of the human labor, data and planetary resources consumed for the manufacturing, operation and disposal of the IoT device Amazon Echo. [20] This complex map reveals an extensive and dense network of interconnected entities including human agents, minerals, corporations, digital technologies, data, and other more-than-human entities.

The *Social Things* Trilogy and the *eCO₂system* Artwork

The artworks previously discussed explore the materiality of the internet infrastructure and of IoT devices, focusing on various issues related to the environmental footprint of their manufacturing, operation and disposal, as well as the hidden power relations related to the ownership and control of these devices and infrastructure.

eCO₂system (2019-2020) is an artwork that increases the visibility of the environmental impact of the internet's operation by directing its effects towards a real small-scale ecosystem of living organisms. More concretely, the *eCO₂system* installation consists of an aquarium containing a micro-scale ecosystem of fish (Figure 1). Parameters of the ecosystem change dynamically according to real-time data retrieved from the social media platform Twitter. Tweets tagged with the hashtag #stopClimateChange deteriorate the conditions of the ecosystem, by gradually decreasing the amount of water inside the aquarium. The artist's intention is to highlight the divergence between digital activity and its impact on the physical world.

Figure 1. The *eCO₂system* installation

eCO₂system is one of the three artworks of the *Social Things* trilogy. The trilogy consists of the media art installations: *inflated_ego*, *#freePrometheus* and *eCO₂system*. The three artworks critically reflect on the technological mediation of everyday life and highlight asymmetries of power and pathological behaviors related to the extensive use of social media. Each installation consists of a technologically augmented common object, connected to the IoT. The augmented objects dynamically change parameters of their functionality and appearance according to real-time data retrieved from wide-used social media platforms, such as Facebook and Twitter. The installation *inflated_ego* consists of an augmented balloon and addresses the narcissism of social media users and the rift between their digital and physical identities. The installation *#freePrometheus* consists of an augmented lamp and reflects on dataveillance by authorities and the phenomenon of digital listening. [21] Finally, the artwork *eCO₂system* consists of an augmented aquarium and reflects on the environmental impact of the materiality of the internet and the physical consequences of digital actions.

The creator of the *eCO₂system* used opensource software and hardware to technologically augment the aquarium. Through the embedded technologies the object acquired capabilities of sensing, actuating, data-processing and decision-making, as well as internet connectivity. The artist created a custom DIY electronic circuit, containing a peristaltic pump, a liquid level sensor, and an LCD screen. An Arduino microcontroller was used for triggering the peristaltic pump, receiving the input data from the liquid level sensor and controlling the LCD screen. The artist built the custom software with the Processing programming language and used the *simpletweet* and the *Arduino* libraries. The software runs on a Raspberry Pi 3+ board which is connected to the internet (Figure 2).

Through the embedded software the augmented aquarium establishes a connection to Twitter's API in order to

retrieve data from the social media platform. The connection requires user authentication according to the open-standard authorization protocol OAuth (Open Authentication). As soon as the connection is established, the algorithm starts querying the API periodically in order to detect new tweets tagged with the hashtag *#stopClimateChange*. Whenever a new tweet is posted, the software sends the information to the microcontroller. The microcontroller activates the peristaltic pump for a few seconds, which pumps a small amount of water from the aquarium to an auxiliary vessel. The LCD screen displays the username of the social media user that posted the most recent tweet.

The data received from the liquid level sensor guarantee that the volume of water will not decrease under a certain minimum level to ensure that the ecosystem will not be put in danger. If the liquid level sensor indicates low water level inside the aquarium the pumping process stops immediately, until the aquarium is refilled with water.

Figure 2. Schematic diagram of the *eCO₂system* installation

Thoughts and Reflections

The work *eCO₂system* increases the visibility of processes that usually remain invisible or hidden. Digital entities (tweets) acquire a physical dimension and are mapped to material entities (water) with physical qualities (volume). The consequences of digital activity have an immediate impact on a small-scale ecosystem, in real-time, before the eyes of the viewers, and thus they become easily observable and perceptible.

The unexpected and semi-automatic functionality of a familiar object (aquarium) draws attention to a dense network of interconnected entities that interact and produce this complex action. This network includes human entities (social media users, the artist, the audience, etc.), heterogeneous technologies (platforms, protocols, sensors, actuators, microcontrollers, servers, routers, and more), corporations (Twitter), laws and regulations (policy agreement to access Twitter's API, etc.), other cultural immaterial structures (language, ideologies, etc.), non-human living organisms (fish), physical objects (aquarium, vessel), other material entities (water) and more. A deeper analysis of each node of the network reveals further connections and inter-

Learning non-human. Can participatory practices change an institution?

FACT Liverpool

Liverpool, England

lucia.arias@fact.co.uk, neil.winterburn@fact.co.uk

Abstract

This paper shares learning from an artwork ‘Learning Nonhuman’ produced by a learning team working at FACT an art institution/production centre in Liverpool. [1] Artist Jack Tan worked with an intergenerational group of participants to develop a game that allows people to roleplay as nonhumans and propose policy changes on their behalf. The game was then played by FACT staff members, to inform the writing of a new environmental policy. In this paper, we are presenting our reflections on institutional learning coming from applying arts based learning experiences to the art organisation’s culture.

Keywords

Epistemological Pluralism, Pedagogy as Artistic Practice, Art and Design production centres, Cultivating the Possible.

Introduction

The learning project and artwork ‘Learning Nonhuman’ emerged through the design and application of an online game.

The game allowed people to play as nonhumans and to identify conflicts or issues that nonhumans experience and then to propose legal or policy changes. Within the framework of this project, we understood nonhumans as beings that we might share spaces with in our everyday lives, such as plants, insects, animals, birds and natural features, such as hills or streams. As Donna Haraway would say, our kin. [3] *“Those who have an enduring mutual, obligatory, non-optional, you-can’t just cast that away when it gets inconvenient, enduring relatedness that carries consequences.”*

Over 12 weeks, the Artist worked collaboratively with an intergenerational group of participants and the arts organisation’s learning team to create a prototype game. The game was tested by participants and also within the organisation as a governance tool for environmental planning and decision making.

The participants were a group of 3 adults over 60 and 3 young people between 11 and 14 yrs. During four months, they worked together with the artist, a game developer and had sessions with a trustee of a local residents committee and an Animal Computer Interaction Researcher. They worked together for a total of 12 sessions.

Thinking non-human

In his work, Jack Tan uses social relations and cultural norms as artistic material. They create performances, sculpture, video and participatory projects that highlight the rules — customs, rituals, habits and theories — that guide human behaviour. Tan was commissioned to produce this artwork in response to FACT’s ongoing annual theme, ‘The Living Planet’ a programme of exhibitions, artworks

and events presented online and in real life that explored our relationship with the natural world.

The Artist proposed a project to participants that promoted empathy with nonhumans and experimented with artistic ways to bring their voices and experiences into human policy and planning discussions. [2].

Their objective was to shift power and representation in decision making processes. They aimed to challenge the assumption that human beings are supposed to make all the decisions, based only on their particular experience. *“All I can do is to try and understand where I as a human end and where my fuzzy edges touch and intermingle with where the more-than-human begins.”* [5]

For this paper, we would like to focus on what FACT learned from this art commission.

Designing nonhumans of Liverpool

For three months during 2020, the group used different digital tools to transform a collaborative creative writing practice into an interactive gamified experience. Players that access this “game” would be rewarded for writing from the point of view of a non-human in their home city. The participants also designed a reward system based on how appealing the story was to convince humans to change human law or policy on their behalf.

This stage of the project culminated in participants playing a test version of the game. Their family and friends played as different nonhuman ‘folks’ (e.g. insects, plants, or birds). To win points, players left written ‘incident report markers’ detailing imagined injustices against nonhumans in locations on a digital map of the city. The grand finale of the game was played as a LARP (Live Action Roleplay) set in a fictional near-distant future in which Liverpool City Council recognised the rights of nonhumans as citizens. Participants performed as nonhumans in a meeting with the Liverpool City Council Committee for Nonhuman Relations. The committee was played by a senior manager, the CEO and a board member of FACT. Participants represented each folk’s cases in an attempt to convince the committee to make changes to council policy. The committee awarded the players points depending on how evocative their case was.

At that point, we thought that the next stage of the game would be for audiences across the city to play it and to invite actual Liverpool city councillors to play the role of judges in the live finale.

A taste of our own medicine

Was asking a few City Council representatives to be judges in a game tournament the best opportunity to test a decision-making model?

Was opening out an (early stage prototype) game to potentially 1000's of players to discuss environmental issues across the entire city the best focus for a second test?

This project was based on the Artist's parameters of "what if...?" What if we could see, hear, smell, touch, see and speak as nonhumans? What if we could find a way for that to impact how we think about the world around us? What if instead of predefining every outcome of the art project, we decided to cultivate the possible?

We decided then, to follow the learning [1], and take it to the most impactful place we could; we were going to apply the same process to our institution.

Like most other arts organisations in the country, ours was about to start writing a new environmental policy. It was in a conversation about policies and governance with the Artist, when we decided to approach our Senior Management. The Artist suggested "using the game" to start conversations about sustainability; and to turn the learning journey toward ourselves and explore how this might have an impact on our policies.

We invited colleagues to test a version of the game. They role played as nonhumans in and around FACT, writing incident reports addressed to the people responsible for new Environmental Policy. The reports described imagined injustices caused by FACT (from a non-human point of view) and made suggestions for changes to the new environmental policy.

The game was played over a week and culminated in a virtual town hall event online. The members of the staff writing the environmental policy performed as themselves in the role of judges, asking questions and awarding points. At the beginning of the event, the judges were introduced to the non-human players. It was explained that they were there to listen to and learn from non-human voices, to inform policy writing. Playing the game raised environmental issues in ways that we had never imagined before, including: pigeons in fear of becoming roadkill, trees complaining of being cleared to make space for public art and the water in pipes worried that they might leak away.

According to the Artist, the learning team and the senior manager who had performed as a judge at the virtual town hall, the main outcomes of playing the game had been:

1. how listening to colleagues speaking as nonhumans had helped them to look at the policy from lots of different angles.
2. how the institution could embed the practice of using role play to advocate for nonhumans in policy meetings.
3. how the organisation can represent its ongoing learning around environmental sustainability.

The Artist decided to present this process as the artwork: *"Rather than present just the participants' learning, I wanted the presentation to highlight the institution's learning of environmental and non-human issues itself as the artwork."*

Curatorially, the Artist thought representing the learning process in a conventionally 'finished' artwork would misrepresent the open ended, dialogical nature of the practice we had explored. *"For our project, I realised that learning about the nonhumans couldn't be confined to a time-limited project because learning and refining our relationship to nonhumans and to the environment has to be central if we are at all interested in understanding the*

climate crisis." [5] He worked with us to curate a selection of documentation, game prototypes and reflective writing to present as a digital assemblage on our institutional website.

The Duty of Care. What did this project bring to our practice?

For the past few years, we have been trying to articulate our experience of bringing participants into the production of artworks that are shared as part of our Artistic Programme.

The Duty of Care is a shared approach towards understanding our mutual responsibility to produce the best artwork, while providing the best learning experience for participants.

1. It sets the basic working principles. These principles evolve from different projects: it is influenced by educators and thinkers, but mainly from our learning from the artists' practices and ways of working with participants:

- Participants are experts that share their unique voice and experience.
- The role of the artist is to convey different strands of that knowledge and lead on the artistic vision.
- Participants are made aware of how and when the artwork is going to be criticised by values associated with aesthetic art experiences.

2. It builds on FACT's Safeguarding Policy. In our experience, safeguarding procedures, participant recruitment and workshop facilitation go hand by hand in a participatory project:

- Guidelines for both artists and stakeholders that explain expectations and responsibilities throughout collaborations.
- Risk assessments that respond to different social dynamics, technologies and spaces.

3. It helps to articulate FACT's Learning programme and the importance of the ethical responsibility in the curatorial work with artists. We invite artists to make an artwork which makes the journey of everyone involved evident to the viewer, without the need to watch yet another "documentation video".

4. It creates a space to advocate for the interest of the artist & participants, within the institution. As we work more closely with other teams, we learn how to bring curatorial thinking to learning activities. In the process, our colleagues become more sensitive to the nuance that participants and artists bring to learning projects.

We repeat the same assertions that generations of people in our shoes have made about what it takes to create high quality arts-based learning experiences; the time, quality and effort needed to make it happen, the care needed to represent the artwork in the same curatorial space as others in the program, without flattening the layers.

This curatorial dialogue has an impact on the overall artistic programme. Most of the projects we produce as part of the Learning Programme are presented in the gallery space or virtually on our website.

5. It is a space for reflection. The Duty of Care is developed from inside the practice while we are producing the learning program. We collaborate with external curators and researchers to help us reflect on what we do. This happens through a combination of informal chats, formal discussions and by writing documents together.

The most unexpected (for us, at least) conclusions from our Duty of Care has been that our work is as much about supporting institutional learning as it is about exploring participatory art practices. This project took this responsibility a little further. Is it possible for the institution to learn from the knowledge that artists and participants produce together?

When participatory art practice changes the institution

From conversations with the Artist, we realised how much this commission had brought the learning programme and team's practice to the centre of the artistic programme. Not by advocating for the representation of participants or by "fighting" for learning to have a place in the artistic programme. It did so by bringing the approach developed by the Artist and participants to the organisation's governance.

The work in the Learning programme was now in the spine of the institution, where power lies, where policies are written and applied. The participatory artistic practice designed a way to bring the different structural levels of the organisation together.

As the Artist explained: *"It's about how you create body memory in an institution. How an organisation embeds 'lifelong learning' is through its structure and policy. If the learning team leaves for example, and none of your knowledge is in the DNA of the organisation, it all disappears. The whole organisation has to be a learning, listening organisation and has body memory. I think that's the museum of the future."*

Learning team art commissions are easily absorbed by the art organisations when the outcome is curated as an art object and presented in exhibitions. In this project, the outcome is the whole process of producing knowledge. Because of this shift, our colleagues had the experience of testing the learning process and not just the final object.

On this occasion, our colleagues turned into participants themselves, they had a meaningful experience playing the game.

This is our Marketing Manager talking about their experience playing the game: *"Playing the game really made me think about the wider impact that our organisation has in the city. Thinking beyond our human audiences and focusing on the ecosystem in which we exist, the game pushes you to consider your personal and professional actions, whilst enabling important conversations through the powerful action of play."*

This is a huge flip in perspective towards learning in an arts organisation - not just benevolent giving to 'the community' but really finding out what we can learn from what the artist & participants create.

As the artist puts it: *"How do you design a museum as an organism that is constantly in conversation with its communities and its environment and remembers it? One of the key ways is to make boundaries between gallery and education, artwork and policy, contracts and creativity, board and staff, etc., more porous and to put this approach into policy and to practise that policy."*

What's left

This project shows how participatory art approaches and knowledge produced with participants can be replicated in

other contexts, including institutional decision making. Not every project has to work at this level, but it proves the potential for art to shift arts organisations and the system from within.

The potential long-term learning of institutions lies in its approaches, policies, procedures and governance. The Artist helped us to reflect on our role as a team in the organisation and on a practical level, they have worked with us to redesign our Artist contracts to better reflect our vision, objectives and ethics.

Since last April 2021, Jack Tan is the first artist to have a residency on the FACT Board of trustees. Throughout a year-long residency he will develop the work he started in this project, exploring themes of institutional trust and transparency.

Complex acquisitions: understanding the infrastructural properties of born-digital objects in museum collections

Gabi Arrigoni

Victoria & Albert Museum

London, UK

g.arrigoni@vam.ac.uk

Abstract

Whilst born-digital collections continue to be developed in several museums internationally, this paper contributes to debates as to how we conceptualise born-digital objects. Many complex artifacts of digital culture, in fact, elude the behavior of traditional collected objects. Here, we concentrate on three examples to illustrate different degrees to which born-digital museum acquisitions can be understood as infrastructures. By examining an immersive reality piece, a procedurally generated film, and a digital platform, this paper addresses hybridity, fluid relationships across the main and auxiliary parts of an acquisition, and the lack of clear boundaries to define what the collected object is. It concludes that developing deeper understandings of the infrastructural properties of born-digital museum acquisitions could support changes in institutional practice and thinking to better accommodate this emergent area of collecting.

Keywords

Born-digital collections; digital design; infrastructure; digital preservation; platforms; contemporary collecting.

Introduction

Our cultural and creative production is increasingly digital, based on digital tools, distributed through digital channels and frequently engages critically with the impact of digital technologies on society. For a few decades now, archive and museum professionals have explored and developed means to preserve digital files [1][2], digital time-based media, digital art, videogames, and architectural design records [3][4][5]. Some museums are also collecting complex born-digital objects such as immersive reality works, mobile applications, and social media [6][7]. Scholars and professionals are increasingly becoming aware of the challenges of collecting and preserving digital culture, some of which are associated with the way born-digital objects elude the traditional, self-contained objecthood typical of museum objects [8]. The field of videogame preservation, for instance, has shown how collecting institutions face the question of defining the boundaries of artifacts which come to life in online environments, incorporating user-generated content, and encompassing a range of components from source code, to hardware and controllers, from patches to packaging and marketing materials [9]. The documentation of user or visitor interactions also has an increasingly important role alongside the preservation of digital art [10][11][12], and it is already a typical feature of videogame heritage, where walkthroughs and gameplay videos constitute an invaluable testimony of games of the past [13]. The scholarship has also considered the significance of born-digital records of the creative process in the fields of architecture [14] and videogame production [15], especially valuable for pedagogic and research purposes.

This paper explores three case studies to emphasise how complex born-digital objects rely on multiple infrastructures

and present infrastructural properties which have an impact on the way they are accommodated within the collection. This concept refers to understandings of the digital infrastructure ‘as the computing and networking resources that allow multiple stakeholders to orchestrate their service and content needs’ [16]. Complex born-digital objects in fact, are frequently characterised by an expansion of their socio-technical and structural ecosystem, so that the organising logic of the museum acquisition reflects the layered architecture of digital technology.

This understanding will help to emphasise both the recurrence of multipart acquisitions and the way born-digital-objects are embedded in multiple infrastructures (comprising the internet, open standards, servers, datacentres and hardware devices). The concept of infrastructurality is proposed within the specific context of museum collections, to support curators and conservators in addressing the process of decontextualisation and recontextualisation of the object from its original online environment to the museum’s own infrastructure. More specifically, the three examples address the co-presence of physical and digital components (hybridity); the flexible relationships across main and collateral components, such as materials illustrating the making process; and the boundless, irreducible dimension of digital platforms.

The case studies

Our methodology is based on the investigation of three different types of born-digital objects two of which, at the time of writing, are in the process of being acquired by two UK-based institutions, whilst the third one is a speculative example. The analysis is based on conversations between the authors and the curators responsible for these acquisitions, combined with insights from a range of experts (curators, conservators, designers, museum professionals, archivists) invited to take part to three workshops looking at these objects under the perspective of collection management, preservation and access [17]. The interviews with the curators and the workshops focused on understanding challenges and examined the ways in which these acquisitions push institutional boundaries.

The first case study, *In the Eyes of the Animals* (henceforth *IEOTA*), is a virtual reality piece by Marshmallow Laser Feast (MLF), launched in 2015 and now part of a pilot acquisition scheme at the British Film Institute. The work enables users to experience a forest from the perspective of three animals (dragonfly, frog and owl), and is rendered by computer generated graphics based on footage captured with laser scan and 360 drone cameras. The work has been presented in different versions for different settings, outdoor and indoor, and the institution is exploring the acquisition of digital files comprehensively covering all these different iterations. MLF has also crafted bespoke ‘mossy’ headsets and vibrating backpacks synchronised with the sound design, to deliver an especially immersive and haptic experience. These have been used in some but not all of the versions.

The second object is *geist.xyz*, a procedurally generated digital film by design collective ZEITGUISSED. The Victoria and Albert Museum (V&A) has recently completed the acquisition of the film and a set of digital materials illustrating the creative process behind the piece, including a dedicated microsite; research & development clips in .mov, .gif and .png formats from the studio archive that depict the process through which procedural animation is made; the ‘Parametric Animated’ patterns pre-rendered, in .mov and .gif form; work in progress 3D data, which includes a series of alembics and .obj files of the virtual textiles represented in the film; and the soundtrack.

The third object is Instagram, which was identified by the research team as a speculative case study to explore the challenges an art and design museum would face in collecting the platform as a piece of interaction design. This meant addressing the social media not just as an aggregator of user-generated content and testimonies of the present, but more holistically including its architecture, modules and interactions.

Hybridity

Like many born-digital objects, IEOTA presents both entirely digital components (such as executable files, source code, software packages) and physical ones: in this case, the headset and backpack, that, with their own unique design differ from replaceable playback equipment. In the context of this short paper, we want to concentrate on one of the many challenges to collect and preserve this work, which pertains specifically to our proposed understanding of the object. This concerns the barriers to acquiring the hardware components alongside the digital ones, due to a combination of policy constraints and lack of resources in the institution (BFI). In fact, the BFI National Archive Collection Policy (2011) formally concentrates on the acquisition of moving image artefacts only, leaving out physical objects. As a consequence, the institution lacks suitable storage space, financial and staffing resources (such as skilled conservators) to effectively care for the hardware. The barriers to collecting the hardware threaten the integrity of the piece as they put this particular version and user experience at a higher risk of being lost. In fact, the particular version, and user-experience associated with using headset and pack is at a higher risk of loss. Additionally, the presence of multiple versions shows how the infrastructural dimension of IEOTA goes beyond hybridity, and poses the question of which version(s) should be prioritised or considered more suitable for preservation. Further, it challenges the BFI National Archive preservation strategy which is based on the application of standard procedures to a variety of analog and digital film formats. The novelty of interactive virtual reality technologies and the complexity of an acquisition comprising multiple versions and a considerable bundle of files, by contrast, demand the development of specific workflows, monitoring and preservation solutions.

Within its experimental framework, aimed at understanding needs and requirements for a type of object which has never been collected by the institution before, the BFI is not prepared to commit to its preservation in the fullest sense. Instead, IEOTA is becoming part of the BFI National Archive but not formally accessioned to the collection. This enables the institution to work outside normal policy constraints and concentrate on the bit storage of the digital files. Although this approach does not guarantee future public accessibility, it constitutes an initial step towards exploring more comprehensive preservation strategies, and might enable future conservators to bring the piece back to life, once it has become obsolete.

Process

When collecting the present, and especially the digital present, there is a limited window of time where a wealth of materials is available before they become unavailable. Born-digital records of the creative process, for instance, are subject to individual or industry-wise archival approaches that can be inconsistent, non-standardised, and rarely conceived as a step towards long-term preservation, but rather as a back-up strategy directed at ensuring short-term interventions on the project. Some museums, including the V&A, have a tradition of keeping evidence of the process, especially for research purposes and to inspire further creative work. At the V&A, in particular, there is an established practice of acquiring process-related items associated with design and architectural objects, and to keep them separately from the main object, in a collection called Designs.

The experimental attitude of ZEITGUISSED’s aesthetic practice, directed at pushing the boundaries of the technologies used for their creations (especially 3D software suites such as Cinema4D and Marvellous Designer), leads to a different understanding of the process material, which they describe in an interview as ‘smaller fragments of finished work’ [18]. In fact, *geist.xyz* depicts a range of inorganic textiles, floating in a space which subverts the rules of gravity and shows ZEITGUISSED’s mastery of digital software. The process-related items are part of an ecosystem of digital experiments in textiles that exist in a space of fantasy and speculation but that could potentially become real.

Figure 1 ZEITGUISSED, *geist.xyz* (2016). ©ZEITGUISSED and Victoria & Albert Museum

By recognising these materials as networked but independent items with their own inherent value, the curatorial section opted for an approach to managing the acquisition which breaks with the museum’s traditional separation between core and auxiliary objects. In fact, film and process materials are in this case kept together with no particular hierarchies established across the institution’s information system. This also reflects an awareness that the preservation strategy for *geist.xyz* will consider the same understanding of the acquisition as a complex ecology of parts.

The autonomy of the process is reflected by the way these items depend on their own production tools to remain accessible. Differently from the film, which presents itself as a standard output suitable for most players, the 3D data files in alembics format can only be accessed through the proprietary systems used to create them. Open-source alternatives are under investigation, but they are unlikely to represent the work as the author intended, because they will use different software libraries which will alter the original custom set-up used by the designers.

Boundlessness

Digital platforms [19][20] are distributed, shared, manifested through performances which are unique to each user, programmable with multiple features, evolving from one version to the other, and embedded into an extensive infrastructure of digital and physical systems. Social media platforms have been examined by digital preservationists and

museum professionals as a source of important testimonies of the present, and hence used as tools to gather resources for future historians [21][22]. However, no institution has yet embarked on the enterprise of collecting social media or other kinds of platforms (streaming services, e-commerce, search engines...) holistically as objects of interaction design with their own architecture, modules and interactions. The research team and the workshop participants identified a number of challenges to collecting Instagram, including its cloud-based (not downloadable) nature, the privacy and proprietary systems hiding its networked interactions, privacy and broadly legal issues associated with the presence of user generated content and specific terms of use.

Further, platforms like Instagram embody more strikingly than other objects the interstructurality that we are discussing in this paper. Asked to attempt to identify what a comprehensive acquisition of Instagram would entail, the participants' list included: the mobile app files for different operating systems and for different versions of the platform across time, the interface design, the source code, relevant databases, dedicated hardware, contextual items such as interviews, documentation of user-experience, social history content, curated captures of exemplary interactions and so forth. Participants felt that the decision-making process to identify priorities across such a heterogeneous set of items could be daunting, and that it might be determined by a combination of curatorial intention, institutional mission and scope, and pragmatic choices (what is desirable? what is effectively available?). Consequently, in the case of Instagram, the identification of what is the core object and what is collateral proves difficult and ultimately meaningless, showing how new understandings of the object are needed to guide practical approaches to collection management such as acquiring, accessioning and distributing within the institution's asset management system.

Shifting practices: between sustainability and future-proofing

The three case studies illustrate how born-digital acquisitions behave as infrastructures, demanding for careful processes of decontextualisation from the networked systems where they are embedded, reconfiguration of the relationship across the multiple items composing the object, and recontextualisation within the museum's own infrastructure.

The hybridity of many born-digital objects means that part of the object might fall outside collection policies and that institutions are not fully prepared to deal with the different needs of digital and physical components. The example of *IEOTA* shows that institutions used to caring for discrete objects need to reconsider both policies and practices to accommodate the infrastructurality of born-digital objects and their emergent characteristics.

The case of *geist.xyz*, signals a change in institutional practice motivated by the specific rationale of ZEITGUISSED's experimental approach. This results in reconfiguring traditional hierarchies between main and auxiliary objects, which are reflected in the way items are distributed across the museum management system. Within the limits of this short paper, there is no space to delve into the connections across the procedural nature of this strand of

digital artistic practice, the role of process, and the opportunities for collecting and safeguarding the making-process afforded by the circumstances of collecting contemporary objects. However, it is important to recognise that process and auxiliary items in general can acquire new relevance due to the uncertainties surrounding the long-term preservation of complex born-digital objects. Process and auxiliary items, in fact, can become integral to the public access and future understanding of the object.

Finally, the example of Instagram shows that for some objects there is no a-priori distinction between main and auxiliary items, and that the object can overlap with the infrastructure. The spillage of the collected object beyond its traditional boundaries and the presence of multiple items suitable for acquisition requires a thinking of collection management and preservation approaches. Further, it marks the existence of a potentially fruitful conflict between sustainability and futureproofing. On one side collecting multiple items can put a strain on an institution's limited resources; on the other side, the availability of a range of contextual and process-related materials, can ensure that curators and conservators will have more than one option in terms of preservation and display solution, and will be able to reconstruct or reinterpret the object, once obsolete, thanks to the rich documentation collected.

Conclusion

The aim of this paper was to broaden the ways through which to interrogate the notion of a collected object in the context of born-digital museum collections. This is informed by the idea of infrastructure, to respond both to the multiplicity of items that could be acquired, and the embeddedness of these objects into networked systems. Whilst we anticipate that this will help museums developing new approaches to care for these objects, we are conscious that more research is needed to refine this conceptualisation and examine its implications for institutional practice. What this paper does not do is also to problematise the notion of the infrastructure within the context of digital culture. For instance, there is a need to disentangle more thoroughly the infrastructurality of the collected object from the broader contemporary tendency to integrate services and social behaviours within digital infrastructures and platforms [23]. Nevertheless, the concrete examples discussed in this paper provide the first steps towards a reconceptualisation of born-digital objects that will benefit both scholarly reflection and professional practice.

Author Biography

Dr Gabi Arrigoni is a Visiting Fellow at the Victoria & Albert Museum, where she previously worked on the project 'Preserving and sharing born-digital and hybrid objects from and across the national collection'. Her research interests include the process of preserving and remembering the recent past and the heritage of digital culture. She has co-edited the volume *European Heritage, Dialogue and Digital Practice* for Routledge and a number of articles and book chapters and in the field of digital cultural heritage.

Online collaborative design with students for autobiographical VR stories about Covid-19

Sojung Bahng, Victoria McArthur

Media Production and Design, Carleton University (Ottawa, Canada)

sojung.bahng@carleton.ca, victoria.mcarthur@carleton.ca

Abstract

This research examines opportunities for using virtual reality (VR) as an autobiographical storytelling tool for students during the COVID-19 pandemic. Collaborating remotely with eight university undergraduate students in Canada, we created eight individual 3D nonfiction VR pieces that express the students' own pandemic experiences. Through a collaborative design process, our findings highlight how VR was used as a meaningful device for telling students' autobiographical stories about the COVID-19 pandemic: delivering the storyteller's own feelings, creating a sense of confinement and disconnection, showing environmental details, and expressing inner worlds.

Keywords

Autobiographical VR Storytelling, Virtual Reality, Immersive Journalism, VR nonfiction, Collaborative Design

Introduction and Background

Many artists and filmmakers have attempted to create VR works that provoke emotional engagement in nonfiction stories [1]. These attempts have predominantly focused on the notion of empathy; most exaggeratedly in the case of the empathy machine – a term first used by Chris Milk at the TED conference in 2015 [2]. Another example is an immersive journalism model created by Nonny de la Peña, which refers to news that is recreated virtually in 3D to allow viewers to experience events from the first-person perspective as though they are actually present [3].

Although many VR documentaries and immersive journalism pieces have been created to elicit empathy or identification with protagonists or people in real-world situations, it can be unclear whether the work actually delivered the protagonists' perspectives and emotions if the work is not created by or with the protagonists themselves. Although VR gives viewers the freedom to look around and interact with the environment [4], VR creators determine the position of virtual cameras and aspects of the environmental design or setup, which might reflect the creator's perspectives about the work more than it reflects the protagonists' actual perceptions of their lived experience.

Therefore, it is important for people to be able to use VR to create their own autobiographical stories and share their perspectives and experiences with others. However, there have been few attempts to create autobiographical VR stories, or those in which the creator relates their own lived experiences [5]. In this context, our research is to explore the democratization of VR storytelling and support storytellers of various skill levels in creating and representing their autobiographical stories in VR. We conducted a practice-based study to design autobiographical stories collaboratively with students who lack experience and skills in creating VR stories. We ran individual collaborative design [6] meetings with eight undergraduate students in Canada and created eight individual 3D-based VR short videos about their stories regarding their COVID-19 pandemic experiences.

Research shows that teachers who collaborate with their students empower them to enhance their self-determination, problem-solving, decision making, goal setting, self-knowledge and self-regulation [7]. Collaboration with students to make VR projects can be an effective pedagogical method that allows students to learn and explore VR storytelling more actively. Based on these perspectives, students were assigned the role of director and were supported by a member of the research team throughout the VR design process. Following their feedback, we translated their ideas into VR short films. This method allowed us to understand how they approach VR design as novices, how their mental model of VR evolves over time, as well as the challenges and opportunities they encounter when creating an autobiographical VR story.

This project also represented a unique opportunity to help our students create and share their own COVID-19 experiences, leveraging the storytelling affordances of VR. The COVID-19 pandemic has had significant impacts on mental health issues in North American university students, including increased levels of stress, anxiety, and depression [8]. Creating their autobiographical stories about the COVID-19 pandemic could allow people to indirectly experience undergraduate students' experiences of COVID-19 and the effects of isolation on their daily lives. The resultant works can serve as a historical archive that contains personal feelings and ideas related to the pandemic experiences of university students.

In summary, this research demonstrates how 3D VR can be used as a meaningful tool to create personal storytelling about the COVID-19 pandemic for students and provides insight into the democratization of VR autobiographical storytelling in practice, which could allow many people to create their own VR stories in collaboration with VR experts.

Collaborative Design Meetings

Student participants in this study had been previously enrolled in and completed an online course about immersive storytelling taught by the first author in the winter of 2021. Following the conclusion of the course, students were invited to participate in the study over the spring of 2021. A total of eight students from that cohort participated in this study. We refer to the student participants as S1-S8 throughout the following sections.

In the course, students were asked to create a rough prototype of a two- to four-minute VR autobiographical short film about their pandemic experience. The collaborative design meetings were conducted using the prototype they created for the course as a starting point for the study. Due to pandemic restrictions, both the course and the study had to be conducted online. As such, the students were not able to gain physical access to the VR lab and VR prototyping software. Instead, they only created their work in the course for 2D screens using a first-person controller in the Unity game engine that simulates VR experiences such as walking around the environment and looking around using a keyboard and mouse.

The student participants had no previous experience with 3D modelling, animation, interaction design or VR before taking the course. In the course, they learned how to import free 3D models into the Unity game engine and set up the environment. They did not learn 3D modelling but learned basic texturing techniques in Maya. Using the Unity timeline, they learned how to create a simple animation and insert spatial audio.

We conducted one-on-one design meetings via Zoom to translate students' final projects into the 360° video VR format while also helping them refine or change their projects' audiovisual aesthetics. Prior to the first meeting, students sent the Unity project folders that they had created for the final assignment to the lead researcher, and the researcher connected the VR headset (Oculus Quest 2) to their project. At the first design meeting, the lead researcher showed how their work could be viewed through the VR headset by demonstrating her usage of the VR headset in real-time.

Based on that demonstration, we discussed how to refine and develop each participant's final assignment for VR with them, specifically for a 360° video. Using their input, we helped them to transfer their projects to the 360° video format. We then worked collaboratively with students to complete technical and aesthetic refinements. Students were assigned the role of director, and the lead researcher assisted with VR design and technical implementation based on their direction and discussions. We collected their ideas, comments, and feedback on the collaborative design process in the first and second meetings.

Based on the results of the first and second design meetings, we exported their work as a 360° video using VR panorama software from the Unity asset store. We used a 360° video instead of other real-time VR formats because 360° video is most accessible to students. Students received a cardboard head-mounted displays (HMD) in the mail along with a \$30 Amazon gift card for remuneration. In the third meeting, they viewed their projects, discussed what they felt and thought when they experienced their work using the HMD, and reflected on the collaborative design process.

Design Outcomes

VR Projects

Based on our one-on-one collaborative design meetings, we created eight individual 3D 360° VR pieces featuring the students' autobiographical stories about their experiences during the COVID-19 pandemic. All eight students expressed their pandemic experiences in creatively different ways and provided the narration in their own voices. They represented how their daily lives during the pandemic became repetitive, lonely, inescapable, confined, or surreal. Audiovisual aesthetics in each of the projects are diverse and depend on students' expression, including realistic scenes, low-poly cartoony aesthetics and fantastic or surreal environment construction. Each work's running time is 2 to 5 minutes in length.

Greenhouse by S1 represents her yearning to connect to the world and the loneliness arising from her disconnection during the pandemic in a poetic way. In *Confusion & Life*, S2 describes his repetitive and lonely routine in his studio apartment as a Chinese international student. *Pandemic Dream* is based on S3's bizarre dreams during the pandemic, presenting various surreal moments and perspectives such as lucid dreamlike experiences. *Loop* by S4 portrays her isolated life during the pandemic through replication of her room to

allow the viewer to feel as if they are actually in her room. *COVID Confinement* demonstrates S5's pandemic experience as if he is in a prison cell; the door disappears, the ceiling descends, and the light becomes red. *The City of Dawn* by S6 represents the Wuhan lockdown. She believes the Wuhan lockdown might have directly influenced her life and many other people's lives. *Sinkhole* is based on S7's inner experience of the pandemic. He metaphorically expresses his status as a sick person in a motel room by using surreal and abstract aesthetics. *Solitary Confinement FT COVID-19 Pandemic* by P8 shows many different rooms that gradually become smaller to represent his sense of confinement and feelings of entrapment.

Collaborative Design Process

During the design meetings, we showed the students how to view their projects with a VR headset in real-time. Based on this demonstration, we discussed how we could refine and change their projects for VR design.

Aesthetic consistency: Most students constructed their environments using existing assets without changing the textures, so they did not consider aesthetic consistency. Therefore, some visual elements did not match. We discussed how we could help them with their project's visual aesthetics. For example, we discussed changing of colors, model shapes, textures and other elements to increase the project's aesthetic consistency. Collaborative design discussions during the sessions were used to finalize decisions about the students' desired aesthetic and how they would like it to be represented in VR. Based on this, we changed the visual aesthetics and showed the students these changes in the second meeting.

3D environment reconstruction: some students created environments without considering the perspectives afforded by VR, in which the environment can be seen by the viewer

from all directions. For example, one student designed an outdoor scene only for a 2D screen, so outside of a specific view, there was a lot of empty space. Based on the lead researcher's discussions with the student, we created the surrounding terrain by adding more buildings and a mountain. Due to technical limitations, one student only used a 2D texture to create land and grass. Following the student's direction, we created 3D terrain and grass to replace the flat 2D texture.

Visual details: we refined many small visual details based on the design meeting. For example, we created a reflection texture for a mirror image that looks like a real mirror, and we inserted video texture on a computer monitor to simulate the character playing a video game. We also added more objects to certain scenes, and we changed the light to intensify the atmosphere the students wanted to express.

Camera position and movement: We showed students how their work can be seen through a virtual camera setup in real-time and discussed the position and movement of the camera with them. When the students created their final assignment, they used the Unity FPS (First-Person Shooter) controller to simulate their first-person perspective VR experience. They could navigate in the environment they created using a keyboard and mouse to look around the virtual environment. However, for the 360° video format, the viewer is in a seated position, so they can only experience different 3D perspectives in the scene by changing the perspective of camera. We discussed with the students which camera positions and movements could deliver their stories most effectively. The camera movement was adjusted carefully due to the dangers causing motion sickness. Five students used slow camera movements to represent their movement in the environment, and two students used cut scenes rather than moving cameras to reduce the danger of motion sickness and intentionally show sudden changes and disorientation. Three students used an extremely low or high camera position to exaggerate the surreal components of the scene or to make the viewer feel overwhelmed.

Audio design: The most important part of the audio design was the students' voice narration. Taking the camera position and movement for the 360° VR format into account, the narrative structure of four projects needed to be changed. The students re-recorded the audio narration and sent it to us, and we combined the new audio narration with the new virtual camera. Furthermore, many students did not use audio elements effectively and did not consider features such as spatial audio. We discussed how spatial audio can be used impactfully based on camera position and movement. Based on this, students sent us more audio effects and we added sounds that came from specific directions in the virtual environment, such as a knocking sound behind a wall, the sound of a toilet flushing in the bathroom, and television sounds coming from the position of a television located in the 3D scene. We also discussed the impact of music in creating emotion or setting the mood in film.

Findings and Discussion

We collected and analyzed participants' responses to the collaborative VR design process and each individual VR piece that we created based on the design meetings. We recorded the online meetings using the record function in Zoom. The average length of each session is approximately 45 minutes, and the duration of the recorded videos totals approximately 20 hours. We collected students' ideas, comments, and feedback about VR design in the first and second meetings. In the final meeting, we conducted semi-structured interviews with the students and focused on their

responses to their experience viewing their individual revised VR pieces using the cardboard HMDs we sent to them. We transcribed all the recorded video sessions and then analyzed the data using an inductive thematic analysis following Braun and Clarke's six phase approach [9].

We found that VR allowed the students to deliver their feelings as the central characters or protagonists. All eight students said that they actually felt as though they were in their rooms or the environments they created and re-experienced the feelings they had felt during the pandemic. This may be not a surprising finding, as VR brings a sense of presence and the first-person point of view. However, this finding is important because our students felt as though their feelings were accurately represented in the resultant VR shorts through our collaborative process. There is always a risk that narrative elements that are important to the storyteller can be incorrectly re-imagined or omitted in the final project. In the context of this study, our method effectively sidestepped this issue, resulting in an effective representation of the students' own feelings and lived stories.

We also found that camera position and movement were important to allow viewers to experience the character's feelings. As storytellers, how to position and move the virtual camera is related to the identities and activities of the subject in the stories themselves. For example, if the camera is on the bed, the viewer may feel like they are on the bed. If the camera is positioned in front of the desk, the viewer could feel that they are sitting in front of the desk. When the camera moves forward, the viewer may feel that they are walking forward. The extreme camera angles, such as a very low angle, could also make people feel like they are small entities in the virtual world. If the camera position is very high, they may think that they can observe events as they unfold from a distance.

In traditional film and screen fields, camera angles and movements are considered very important factors when creating the moods of work and conveying the feelings of the story's characters [10]. However, in VR, the camera position and movements are considered less important because most research focuses on the sense of presence in the environment itself [1,3]. Although there is no frame in the virtual environment, the camera position and movement can be experienced more physically in VR, so the virtual camera should be carefully adjusted to tell a VR story. Especially in the context of autobiographical storytelling, the camera position can be directly related to the subject's perspectives and feelings in the stories.

We discovered that 3D VR can be used as a meaningful storytelling tool to create stories that accurately reflect our sense of confinement and disconnection during COVID-19. Seven of our participants used VR storytelling to express the sense of loneliness, isolation and disconnection encountered during the COVID-19 pandemic in different ways. This may suggest the students' experiences in dealing with their feelings of isolation during the pandemic are somewhat similar; however, this finding shows that VR can be used to deliver people's personal stories specifically related to feelings of helplessness, frustration, and isolation. Many people use VR to create a fantasy and escape from the real world, freely exploring other worlds; however, it is important to be aware that current VR technologies cannot deliver a complete, fully immersive experience due to the limitations of interactivity and immersive technology. There are always hardware and software constraints that limit our interactions in VR. Due to this, ironically, VR can be a powerful tool to explore stories that focus on the loss of movement or agency [11].

Conclusion

We found that the students perceived 3D VR as a way to effectively express their inner worlds and perspectives, such as feelings of being in a dreamlike state, subconscious desires or even fantasy elements. Five students mentioned that 3D VR was particularly helpful to express their personal pandemic experiences in more creative or surreal ways. Two participants intentionally used surreal aesthetics to express their inner worlds and perspectives. The findings may have been different if we had used 360° cameras rather than 3D VR. However, 3D VR can give storytellers more artistic freedom to create their story environments, adjusting the virtual camera position and movement in dramatic ways. This media affordance allows the creator to express their inner world and perspectives rather than mimicking the realistic environment and situations.

Furthermore, we also discovered that the disorienting features of VR bring many more surreal or unrealistic experiences than 2D-based traditional media. As viewers in VR experiences, we often feel as if we are in the virtual environment, but we cannot see our own bodies in VR, which can make the experience surreal, disorienting, dreamlike and imaginary. This can sometimes be an unintentional side-effect of the affordances of VR. However, sometimes this can be leveraged by VR storytellers as a powerful tool for conveying feelings associated with surrealism or a dreamlike state. Many VR creators try to use VR to represent reality accurately and mimic real-world situations as if people are in reality; however, VR can be used meaningfully to deliver subconscious, fantastic and dreamy worlds that cannot be easily expressed in the real world.

We found that the environmental detail in the virtual environment helped our student participants convey a personal story. All eight students were surprised by how well VR revealed many details of the virtual environments they had created, and how much these details added to a strong sense of presence and gave more information about the stories. The advantages of showing environmental details in VR storytelling do not simply mean providing a lot of visual information is best. Environmental details and objects can be used as main storytelling components because the viewer has the opportunity to look around and explore the environments to understand someone else's personal life during the pandemic. However, it has been noted that too much simultaneous spatial and temporal information can increase the mental effort required by the viewer [12]. Because the VR shows a lot of environmental detail, viewers can miss the temporal or important narrative-related information or other parts of the stories. Therefore, adding detail to the environment is not necessarily good; intentional deliveries of visual information using the environmental details will be the key to storytelling.

In addition, all student participants mentioned that the collaborative design process gave them opportunities to learn and explore complex VR design processes in depth. Although they could not work with VR technical implementations, they mentioned that discussion with a VR expert allowed them to become more aware of their ideas, defining them more clearly and finding design issues by themselves. Six students said that they could clearly understand what is possible and not possible using VR through communications, which also helps them understand the specificities and affordances of VR. Five students noted that what they had learned from collaborative design gave them decision making abilities with technical assistance, allowing them to express their opinions and ideas freely, while understanding technical limits and possibilities simultaneously.

This paper presented an online collaborative design approach for autobiographical VR storytelling by students during the COVID-19 pandemic. For practical examination, we created eight autobiographical VR pieces about COVID-19 collaborating with undergraduate university students. We conducted one-to-one online collaborative design meetings with eight students to explore how VR can be a useful and meaningful tool for creating stories about the COVID-19 pandemic. The discussions and interviews from the meetings revealed four elements—delivering the character's feelings, creating a sense of confinement and disconnection, showing environmental details, and expressing inner worlds—that were used by students as methods of autobiographical VR storytelling. This study highlights the democratization of VR as an autobiographical storytelling tool and the significance of online collaboration as a pedagogical method in VR storytelling during the pandemic.

Abstract

Video conferencing has become an essential part of everyday life for many people. However, traditional 2D video calls leave much to be desired. Eye-contact, multiple viewpoints, and 3D spatial awareness all make video conferencing much more immersive. We present TeleWindow: a frame with mountable volumetric cameras that attaches to a display for immersive 3D video conferencing. The full system consists of a 3D display and a frame with up to four volumetric cameras. Our system was flexible conceptually as well as physically. We intended our research to be “unfettered” rather than focus and directed, e.g., for anything directly entrepreneurial and commercial: “art as unsupervised research” [1]. In contrast to similar work, our focus was on making an accessible system for exploring immersive teleconferencing so cost of materials and required technical knowledge is kept to a minimum. We present a technical baseline for immersive, easily replicable 3D teleconferencing.

Introduction

If the COVID-19 pandemic has shown us anything, it’s the need for effective video communication tools in the

contemporary world. Remote telepresence systems provide benefits across many use cases, from education to healthcare to everyday conversation. However, traditional video conferencing still has many barriers to an immersive experience, including a lack of eye contact, a static viewpoint, and no three-dimensional spatial awareness. Aside from the highest-end solutions, current commercial systems are sufficient for communication, but fail to provide the immersive experience of a face-to-face conversation. Accurate 3D spatial representation may be necessary in industry and healthcare use-cases, and immersive communication makes a huge difference in educational and everyday instances.

Much work has already been done implementing software and hardware methods for real-time 3D teleconferencing. However, most of these systems require significant resources, technical experience, and equipment to function. To achieve widespread immersive teleconferencing, these systems must be accessible to individuals and organizations without access to cutting edge expensive technology.

While existing hardware and software for 3D remains prohibitively complex or expensive, much will rapidly become more accessible as computing systems continue to develop. Volumetric capture cameras and workflows are also becoming increasingly more ubiquitous as they can be found on a multitude of mid and high-end mobile devices.

As such, we focus on creating an easily replicable physical system to demonstrate the feasibility of widely available immersive video communication. We present a modular system built with commodity depth cameras that can be replicated and installed by an end-user on a home system. Our work establishes a baseline for easily replicable 3D teleconferencing implementations.

Motivation and Related Work

Thomas Sheridan identified three main operational components of virtual “presence:” accurate sensory information, the viewer’s ability to change their viewpoint, and their ability to manipulate objects remotely [2]. Since we focus on video communication, we do not consider remote manipulation a crucial function of our system and instead focus on the first two requirements identified by Sheridan. To tackle these problems, we require accurate, real-time capture and display of three-dimensional data with a dynamically updating rendering perspective.

Many systems have since been developed that meet some or all of these requirements for virtual telepresence, as described in “Immersive 3D Telepresence” [3]. An early effort from UNC reconstructed a 3D view using a “sea” of two-dimensional cameras [4]. Carnegie Mellon used a dome of 51 cameras to reconstruct a three-dimensional screen [5]. Schreer et al. presented a system concept for a real-time 3D teleconferencing system [6]. Finally, blue-c was perhaps the first actual implementation that represented real telepresence; it reconstructed two 3D scenes and shared the data between two systems [7].

With the advent of commercially available depth cameras, contemporary systems have been able to capture and display 3D scenes in real-time. UNC developed one such system using multiple Kinect cameras placed around a room [8]. Most recently, Google announced “Project Starline”, a massive and expensive system for 3D teleconferencing [9]. Other similar attempts have been made to also provide physical presence in a remote space, such as the Telehuman [10]. While these systems clearly demonstrate the possibility of remote telepresence systems, they rely on significant setup, including multiple cameras spread throughout the room, expensive equipment, and significant technical experience. Our system implements similar methods with out-of-the box technology and a simple frame around the display for a more flexible and modular system.

Most current depth cameras use a combination of point cloud data for depth representation and 2D video for texture information to achieve accurate 3D RGB video data. Many commercial systems are available for volumetric data capture, including the ZED stereo cameras, Kinect from Microsoft [11], and the RealSense cameras from Intel [12]. These cameras use some combination of infrared, RGB, and lidar data to generate 3D visual point clouds. We

settled on the RealSense camera for our system, as discussed in the System Description section.

To process volumetric data and register point clouds we turned to the Point Cloud Library [13]. PCL is a comprehensive C++ library for the intake and manipulation of point cloud data, and capable of interfacing with most current commercial depth cameras.

System Description

Figure 1. A CGI rendering of the frame around a display. The final system included four cameras.

Hardware

The physical implementation of our system consists of an eye-tracked stereo lenticular display from SeeFront 3D Technology with a simple frame built around the display to hold four Intel RealSense D415 volumetric capture cameras and attached lighting. The frame and cameras can be seen in Figure 1. We decided to use RealSense D415s as they proved to be a good balance of form factor, cost, performance, and accuracy; a good fit for our goals of accessibility, especially when compared to other popular depth cameras such as the Kinect. Four cameras were used in the initial build of our system with configurations available for simpler setups using fewer volumetric cameras. Lights were added to provide even illumination of the scene and increase depth camera accuracy. The physical system itself was designed to eliminate the need for required wearables such as headsets or tracking modules.

Capture Pipeline

The capture pipeline begins with a non-real-time point cloud registration sequence to roughly align the RealSense cameras using an ICP algorithm [14]. A quick and rough initial alignment is all that is needed after the volumetric cameras are locked into the frame. The multitude of cameras are used to overlay point clouds on top of each other to minimize typical occlusions on a human figure (i.e., beneath the chin or behind the arms) from lack of depth data. Point cloud data is culled so that depth data is constrained to the subject within the capture zone. In contrast, previous

work focused on room-sized teleconferencing and required cameras distributed around the room. For a one-to-one use case like ours, the view is restricted to the movement typical of a face-to-face conversation and does not require angles of view that extend past the frame. An example of the point cloud merge can be seen below in Figure 3.

Figure 2. An example of the merged point clouds. On the left, the different colors each represent a view from one of the cameras.

It's worth noting that much of the research with 3D video capture and display uses the Microsoft Kinect rather than RealSense cameras. We found that images and point clouds were generally more accurate with a Kinect, but multiple cameras caused interference between infrared screens used for depth-mapping, and their bulky nature made mounting difficult. The accuracy of RealSense cameras is more than sufficient to exhibit an accessible 3D teleconferencing setup, and has improved considerably since we acquired them for this project.

Rendering and Display

First, the RealSense cameras return RGB texture data and a grayscale depth map. Next, the point cloud is extracted from the depth map and colored with the RGB texture using RealSense software. The transformation matrix from the registration step is used to align the point clouds within virtual space. Eye-tracking data is received from the See-Front display's eye-tracker, which is used in an off-axis projection algorithm to present a head-tracked multiscopic view of the captured volume [15]. Eye tracking can also be performed on the RGB texture data with existing open-source computer vision software such as OpenCV.

Discussion and Future Work

The system itself runs in real-time with a resolution of 3840 x 2160 at 30 frames per second with all four cameras running. Point cloud registration can also be manually fine-tuned to more closely align point clouds given errors during ICP alignment. To save cost and avoid volumetric

streaming issues, we worked with a single standalone system, to explore both real-time properties (as a "Telemirror") and record/playback opportunities (as a "Telerecorder"). This allowed us to focus on issues of immersion rather than bandwidth.

Our results may be described as "noisy and inaccurate" yet "cinematic and authentic." We wanted to minimize the cartoonishness of smoothed, highly interpolated avatars in favor of a "raw" look. We often used Star Wars' Princess Leia hologram as exemplar: even though it was completely fictive and made for a sci-fi film, it consciously included vertical raster lines and noise spikes. This intentional representation of noise and unfiltered data minimizes any "uncanny valley" effect, and our test users appreciated this alternative-to-avatar approach.

Test users also recognized glasses-free 3D as a necessary component. There is a certain magic, sitting in front of a 2D display, when the eye tracker locks on the users' eyes and the image instantly becomes stereoscopic. It is a unique media experience.

Given a single system, we could only explore multiscopic, "multi-view" perspective via pre-recording. For example, a single volumetric frame can be grabbed which allows a user to look around their own face, something impossible to do with a mirror. We find a multiscopic perspective is a key feature for maintaining immersion in future TeleWindows.

Future work may involve exploring the middle ground between a "low-tech" solution, our solution presented with the TeleWindow system, and high-end teleconferencing setups like Google's Project Starline. General improvements can be made to our system such as refinement and streamlining of the current capture and rendering pipeline. Since the initial development, new cameras have become available, and volumetric capture technology has already become more accurate with cleaner captures. Implementation of real-time deep learning based rendering helpers may also minimize occlusions and clean up depth data for better representations of human beings. But our exploration also has a twist.

As summer 2020 approached, the COVID pandemic had engulfed the world. We were in our third year of TeleWindow exploration, with the bulk of our work taking place during the summer with recent Media Arts and Computer Science graduates. Our flexible, "unsupervised" approach gave us a well-informed view of both the big picture of immersive teleconferencing and the in-the-trenches experience of what works, what doesn't, challenges, and opportunities. We decided to spend summer 2020 applying what we learned to something focused and practical.

We focused on how we could help college students as millions went online for the first time. Students were the perfect subject for our research because a) they were regular users of teleconferencing software and b) we could safely assume that nearly all of them had a laptop and smartphone.

The result was a “cheap simple hack” of separating the speaker view from the presentation or seminar view by moving it to a smartphone above the laptop’s camera and screen [16]. It’s not where we expected to go. We began by considering predictable solutions like computational view interpolation, relighting, and more spatial sound. But once we tried our hack, it worked much better than we expected. We produced several hundred and freely distributed them around our campus. Other universities participated as well. We don’t think we would have discovered this solution without the “unfettered” “unsupervised” TeleWindow exploration behind us.

We anticipate moving forward in both directions: continued exploration of the original TeleWindow and further development of “cheap hacks,” along with various versions in between.

Figure 3. Our cheap simple hack for telepresence.

Conclusion

The system outlined here was designed as a jumping-off point to explore what was possible in the field of immersive teleconferencing given increasingly accessible tools and technology for volumetric capture and display. The system and variations can be easily replicated. Our “simple hack” was one variation, an extreme scaled-down version. An immersive middle ground could contain a 2D, but still head-tracked multiscopic version, using a single clip-on volumetric camera. Our own exploration into telepresence demonstrated the feasibility of a widespread, low-cost immersive teleconferencing experience.

As is often the case exploring emerging media, unanticipated results occur. While some are not so good (but always increase knowledge), others can be magical. We encourage further exploration of more such uncharted territories.

Acknowledgements

We gratefully acknowledge support from Clay Shirky, Xiaojing Zu, and Jeffrey Lehman for this project. Students and recent graduates who have worked with us include Ada Zhao, Barak Chamo, Danxiaomeng Ivy Huang, Deyin Mia Zhang, Diana Yaming Xu, Grace Huang, Jingtian Zong, Mateo Juvera Molina, Nathalia Lin, Runxin Bruce Luo, Tianyu Michael Zhang, Xincheng Huang, Xinran Azena Fan, Yufeng Mars Zhao, Yunru Casey Pan, Zhanghao Chen, and designers Ignazio Moresco and Paolo Salvagione. Thank you all!

Debunking the quantified self through artistic data portraits

Laia Blasco-Soplón, Pau Alsina, Enric Mor

Universitat Oberta de Catalunya
Barcelona, Spain

lblascos@uoc.edu, palsinag@uoc.edu, emor@uoc.edu

Abstract

Today the “quantified self” is a technical reality that structures datasets of all kinds of interfaces. These interfaces are created with the goal to establish, develop and transform the relationship with the self, the data and the society. In a “datified” world, data visualization challenges traditional representation systems by opening up a wide world of analytical and graphical opportunities. As user interfaces, data visualizations are artificial devices that carry cultural messages in a wide variety of forms and media. Additionally, data visualizations are never neutral mechanisms of data transmission since they affect the messages, providing a model of the world itself, a logical and ideological scheme. The fascination related with big data and the creation of increasingly sophisticated user interfaces pave the way for the proliferation of diverse mutations in the perception of the world and of ourselves. The false neutrality and transparency of quantitative representation of one's own self is built on the assumption of a closed and measurable self that perceives itself as an entity that can be calibrated, compared and evaluated using numerical parameters. In this context, our research is focused around the implications and mechanisms of the quantified self and its visualization and also about the role that artworks based on data can play.

Keywords

Quantified self, qualified self, artistic data visualization, big data, interface criticism

Introduction: data portraits, subjectivity and metaphor

Erik Kessels 2011 installation “24 HRs in photos” (Figure 1) is a sea of printed photographs uploaded to Flickr in a 24-hour period. Through that work, we realize the banalization of the image itself, the loss of value implied by its massification, the datification of a mountain of selfies, faces without faces and bodies without bodies that are lost in the vastness of big data.

Photography has been, and still is, a very powerful tool for representing the self. However, since the big data explosion, today the self is also represented by the data that comes from our digital trails.

Figure 1. 24 HRs in photos. © Gunnar Knechtel Photography, 2014

During the late 1990s, years before the term of the quantified self appeared in 2007, Donath [1], Xiong [2] and Viégas [3] began to build and discuss about data portraits [4]. A term applied to the first portraits with data that were created as artistic experiments to explore the possibility of portraying people from their data.

“Unlike photo-realistic portraits, which show physical features such as gender, age, or race; data portraits are abstract representations of users’ interaction history” [2].

Some of these early projects exploring the aesthetic qualities of data for representing people should be mentioned such as VisualWho [1], Chat Circles [3], PeopleGarden [2], Newsgroups Crowds and Authorlines [5], The Anthropomorphic Visualization [6], or Lexigraphs [7].

Lexigraphs [7] (Figure 3), for example, is an experimental tool that produces portraits from Twitter usage data. Each user is shown as a silhouette created from the words derived from their updates, the portrait that moves to the rhythm of their updates. This work tries to obtain graphics with an artistic value and, in turn, obtain patterns of personal representation in the results [4].

Data portraits are intended to make visible and convey to the naked eye aspects of the social interface and allow, at the same time, the user to explore a subjective, mutable and complex image. Each aspect of the visualization has a function and reference is made to the metaphor (abstract forms, a flower, a humanoid body or a bust, for example) as a key aspect for its functionality but also for its poetic evocation. The interesting thing about this proposal is not

it could be. Individuals are reclassified in terms of their associations and links with others, and then included or excluded based on the attributes of the data groups to which they belong. The knowledge generated is used to support predictive systems, calculate the future behaviors of an individual and act preventively.

Today, big data is a technical reality that structures data sets of all kinds but does so in an opaque and silent way, without revealing its mechanisms or strategies. In the data sets of the different companies are "quantified selves" that they want to attribute them as a true revelation of our pre-selected years. With Foucault [19] we can say that these data sets, rather than building new relationships with an essentialist self, directly produce a self in practice. The quantified self is a technology of the self that responds to a truth inscribed in self-care, in pure individual governance [19].

The qualities of a quantified self

But what qualities do these quantified selves have? Authors such as Davis [20] or Lupton [16], [21] begin to raise the most qualitative dimensions of the quantified self playing with the term qualified self [13]. This qualitative component is present from the beginning in the decisions about what to measure and how to do it. In turn, it is also present in subjective narratives and interpretations, mechanisms by which data is transformed into stories that self-trackers tell about themselves. They are the bits with which they give meaning to their atoms [20].

In turn, the quantified self is also becoming a qualified self by applying tracking methods to qualitative phenomena such as mood, emotion, happiness or productivity [17]. However, although it manages to measure emotions, feelings and bodily responses to a certain degree, it does not have access to the field of affections in the strict sense: the social, psycho-structural, or other factors that cause affective responses or interpersonal interactions. Worker tracking technologies, for example, can tell us which working conditions or interactions seem to cause a particular set of emotions or behaviors, not how or why. They claim that they show us what a body can do, but in reality they only show us what certain bodies have been seen they can do from a particular point of view. This is characteristic of a change from "truth" to empty functionalism, from deductive science to a coarse and inductive orientation of "this works" [22]. And so, the fallacy emerges based on the fact that the self can be quantified, that the identity and the self is something that can be measured, represented and perceived numerically. This simple assumption implies the idea that there is an objective self, an essence to be discovered that can be captured and reduced to quantitative data, in favor of a renewed extreme positivist illusion.

On the other hand, the intensely individualistic approach of quantifying the self is also noteworthy. When the notions of health, well-being and productivity are presented through data extracted from self-control, the social determinants of these attributes are hidden. Illness, emotional distress, lack of happiness or lack of productivity in the workplace are mainly represented as failures of self-control or individual efficiency and, therefore, require greater or more effective efforts, including perhaps greater intensity of automatic tracking regimes, to produce a "better self" [16]. Therefore, the quantified self approach can be considered as one of the

many heterogeneous strategies and discourses that position the neoliberal self as a responsible citizen, willing and able to take care of their own interest and well-being. Foucault's writings on the practices and technologies of the self in neoliberalism are pertinent to understand the quantified self as a particular way of governing the self [16]. The quantified self technologies introduce a micro and self-surveillance, with more psychological and emotional implications that affects power, body, knowledge and space dimensions. Some individuals do not make self-determined decisions but delegate the power to make decisions and to determine what is beneficial for them to the technologies. [23]

Also, repairing in what we are shown and how it does it, Moore & Robinson [22] point to the ontological premise of Cartesian dualism with the dominant mind over the body, where the data provided by a body without authority is interpreted by a rational mind that takes command and makes decisions about his subordinate body. Lupton [16] points to a vision of the body / self as an entity similar to a machine that provides inputs and outputs.

Of the representation and perception of the self

The era of data and quantification entail the development of new forms of data management and analytical techniques that are based on machine learning and new visualization modes. In a "datified" world and in the middle of the quantified self era, data visualization challenges traditional representation systems by opening up an immense world of analytical and graphic opportunities. These representations also affect the perceptions of the self, impacting one's feelings for oneself.

As we saw above, the data portraits, first artistic experiments on the representation of the self through the data we generate, put subjectivity and metaphor in the foreground. With the arrival of big data there is a naturalization and neutralization of an infallible and omnipotent data that erases the traces of subjectivity. The quantified self, governed under the capitalist and data market logic, hides the mechanisms and metaphors that produce the representations of a self that is supposed to exist and that the data is capable of revealing. It is an individual self, which can be measured in numerical terms and can be calibrated based on the same parameters as other selves. It compares and competes with the data of others or with their own, building a statistical self that controls itself and self-regulates. The self is perceived as a subordinate machine body that provides data to a mind that dominates and domesticates it.

Thus, in the face of the illusion and positivist impulse to capture the quantified self reduced to fully objective data and devoid of all subjectivity, it is possible to oppose the constructivist vision not only of the data and its visualizations but also of the same processes of subjectivation and of one's own self as a practice, that escapes all omniscient truth. Are we going to approve the given and hidden metaphors as the only true representations possible? Are we willing to limit our subjective perception to what the logic of quantification dictates? How can we question these logics? How can we break the hegemony of what is shown to us and gut what is hidden?

From the first artistic explorations of data visualization such as data portraits until today there have been many

more approaches from art to data. As we can see in the brief survey of projects in the field of artistic information visualization of Viegas and Wattenberg [24], artistic data visualization uses the same sophisticated visualizations techniques of academia or commercial, but in a very different style and for different purposes. Data oriented artworks expose a particular point of view and actively guide analytical reasoning and encourage a contextualized reading of their subject matter. What role can art play to highlight the subjective dimension behind any visualization

of data? Are we able to build new subjectivities and metaphors that give space to other, more complex, risky and more sensitive selves? How can it be claimed from there that data are always portraits? In this research we propose a review of the terms in which we relate to data visualizations. The data portrait concept is the starting point to rethink the subjective and ideological dimensions of data visualizations and the logics of quantified self and big data.

Authors Biographies

Laia Blasco-Soplón is the director of the Arts Degree at UOC (Open University of Catalonia) and professor of the Multimedia Degree and the Digital Design and Creation Degree at the same university. Her artistic and academic research focuses on the design, study and criticism of interactive visual tools for experimentation and learning.

Dr. **Pau Alsina** is associate professor of Art and Humanities studies at UOC (Open University of Catalonia) and of the Official Master's Degree in Digital Art Curation (ESDI). He is the director of *Artnodes*, an academic journal of artistic research linked to science and technology, since 2001. Currently he coordinates the UOC's Art, Science and Technology program, from where it develops, with eight other institutions, a research, training, production and dissemination hub in the city of Barcelona. He is the author of several books, chapters, and articles on the intersections between art, thought, science, and technology.

Dr. **Enric Mor** is associate professor at UOC (Open University of Catalonia) where he teaches human-computer interaction, human-centered design and creative coding. He is the director of the master's degree in Interaction Design and User Experience. His research is focused on technology-enhanced learning, human-computer interaction and design. Currently, he is researching across the fields of media art and interaction design.

Codex Endogenous: Designing Interactive Self Data Visualization Tool for Trauma Impacted Individuals

Alexa Ann Bonomo

University of California, Davis

Davis, California, USA

abonomo@ucdavis.edu

Abstract

The Quantified Self is best described by Gary Wolf as “self-knowledge through numbers.” William James’ theory of the consciousness of the self and the study of coping inspires drawings that retell personal narratives. *Codex Endogenous* is a project that reveals and visualizes the beauty and morphology of a “self” and its environment. Here, “codex” refers to a collection of pages stitched together, and “endogenous” is a term in cognitive neuroscience used to describe phenomena that is spontaneously generated from an individual’s internal state. Every day, quantifiable information about the self is produced and collected like pages in a book. Daily data drawing is a method of journaling with naturally emitted data from the self, creating an oracle into an individual’s brain body connection. This paper evaluates the characteristics of what daily data drawings are, methods of collecting data, and the possibilities of using data collection and visualization as a mindful-ness practice for people who are diagnosed with post-traumatic stress disorder.

Keywords

Data Visualization, Mental Health, Journaling, Therapy, Tools, Generative Art,

Introduction

There is simply too much information to keep track of the complex narrative that makes up your own self-hood. When you look in the mirror and see yourself, you can point out the physical appearance, but it is often a much harder task to recall accurate self knowledge. Self knowledge can be difficult to unravel and recall because of the complexity of themes within our psyche. There is not a mapped out visualization with a detailed legend for navigating, but rather a novel with sequences of interconnecting events that have themes and story lines [13]. A common symptom of Post-traumatic Stress Disorder is a sense of losing one’s body and mind connection. There is a part of the brain responsible for sensing the self called the “default state network” (DNS). It’s how we know we are alive. Patients with PTSD show a startling lack of activation in the self-sensing parts of the brain [10]. Neurofeedback is used as a treatment that uses visualization of the “electrical symphony” of a patient’s brain waves to cause emotional arousal and in return enhances the sense of identity [9]. In effort to build a similar mirroring effect, *Codex Endogenous* provides a reflection of the self each

day. Generated from naturally emitted data, daily entries have the ability to be recorded through a network of devices.

Codex Endogenous aims to construct a narrative about the self by examining drawings produced from devices that collect biometric, environmental, and self-reported information. A daily representation of data is translated into patterns that make up a visual language mapped on a canvas. A user may collect pages that adds to their own narrative, positively reinforcing identity and relation to one’s own environment.

The inspiration for this project came from the practice of meditational drawing. The process involves sketching a simple mark on the paper repetitively in a meditative state and watching the pattern build and grow into a larger complex form. Then the creation of a new pattern begins, builds complexity and exists against all the previous patterns on the page. With the ability to create graphics with creative coding and integrating devices that are best described as the *Internet of Bodies*, a term described by Giorgia Lupi as technology that captures and stores information about a person’s location, bodily functions, audio and visual perception and even self recorded information that would reflect an individual’s thoughts [4].

Background

This project is situated heavily in generative design as an art form. Imagery is created by constraints defined by the data that is streaming through a program. The art form originated in cybernetics and general systems theory in the late 1960’s. Roy Ascott coined the term “cybernetic vision”, referring to concepts drawn from computer science. Methods of computing to mathematically display graphics using algorithms derived from artificial intelligence or artificial life [1].

Codex Endogenous utilizes self-tracking, otherwise known as The Quantified Self. Dating back to the first cave paintings, humanity has been compelled to record themselves for thousands of years. When this complex human tendency to preserve themselves combines with the power of computation, the conversion of human bodies and minds into data flows are figuratively reassembled for the purpose of self-reflection and interaction [8]. The quantified self is defined by using “invisible technology” in order to collect data that reflects the daily lives of people, like a data double. Motivation to collect such data comes from a desire to change or improve.

According to Ksenia Fedorova, technologies that utilize

biosensing to gain an accurate “picture” of one’s mental and bodily state would help create balance with more “informed” behavior [2]. This project attempts a snapshot for a person to distinguish and identify their mental and bodily state, while grounding themselves in the environment. Data is taken from streams of data that is left by the self during the span of 24 hours. Later the data is recalled in a one-time journal-like task.

James divided the history of self into three parts – its constituents, the feelings and emotions they arouse, the actions to which they prompt. When we use sensors to automatically track ourselves, we are reminded that our ordinary behavior carries more obscure signals that can be used to inform our behavior [12]. The collection of the data for this work aims to seek information that makes up the empirical self. William James grouped all of the components of the empirical self into three subcategories: (1) the material self, (2) the social self, and (3) the spiritual self. In this work, items of data that include bio-metric, sleep, and environmental information can be classified as the material self as it pertains to the tangible objects, people or places that carry the designation *my* or *mine*. Data collected about who people interact with each day is classified as the social self. In effort to support the spiritual self, thought and emotional data through daily survey is collected.

The way in which personal narratives are recalled from memory inspired the modality, origin, and meaning of data that was used in developing drawings each day. The philosophy behind the method of data collection is heavily informed by the concept of “Data Humanism”, coined by Giorgia Lupi. The idea addresses the issue that as a result of the rise of Big Data, attempts at complex infographics become merely eye-candy and leave us with copious amounts of unreadable and cheap graphs and pie charts. In actuality, the conventional nature of these visualization lacks depth and exploration in possibilities of what *could* represent more meaningful data to the viewer [7].

Self Data Visualization and Trauma

Semiotic explorations within personal data have been used as a tool for simulating and representing the inner experiences of individuals using data trails [3], but there is an absence in work regarding tools for individuals who are prone to experience lack of self, such as patients diagnosed with Post Traumatic Stress Disorder. The combination of using self data as visual feedback integrated as an artistic representation is designed to act as an intervention to promote self-healing. *Codex Endogenous* was developed as a tool for an individual to acquire information to act as scaffolding to one’s own self-concept, a collection of beliefs and thoughts that make up an individual’s perception of the self. A negative self-concept is commonly reported amongst patients diagnosed with Post Traumatic Stress Disorder [6]. The page like structure of *Codex Endogenous* provides a narrative based experience similar to collecting pages in a journal. It is a procedure of data collection that is then translated into markings on a page through the means of generative art and data visualization. The form of the markings are completely determined

by variables that change based the data collected for graphical output onto a page. This means that the graphical form of the artistic daily data drawing is completely unique upon the self, metaphorically acting as a mirror and acting on an individual’s inner experience. For trauma-impacted individuals whose inner experience also includes the lack of sense of self [11], this intervention is designed to stand in as scaffolding that otherwise is hindered or disabled.

We can imagine a simple scenario for the use of daily data drawings. A person is diagnosed with PTSD and starts to receive outpatient care. Their treatment plan includes establishing care with a psychiatrist and regularly seeing a counselor for talk therapy. While they are receiving care on their own, they start to think about journaling as a form of self-care. *Codex Endogenous* provides them with a free form interface to draw out their own daily data trails which provides them with feedback about their self-information generated from factual data. Their idea of self is now more enhanced than purely what they would originally write in a journal.

Methods

The thought process behind the format and visual representation in this project is informed by an understanding of human memory. The term *implicit memory* refers to when a participant does not deliberately attempt to collect information from the past, yet memory is still expressed in the performance of a task (e.g. walking or playing a learned song on the piano). *Explicit memory* is exhibited when participants consciously and deliberately attempt to recollect information from the past, such as life events that are primarily sensory experiences (e.g. recounting a childhood memory of having dinner at their grandparents house) [5]. Self Knowledge requires both implicit and explicit memory to form a personal narrative. The following describes the ways in which data collection parallels memory and functions as the data that makes up the self to be used for daily data drawings.

Given this information, *Codex Endogenous* proposes that there is a connection between data as personal narrative from memory and the modality in which data from devices are collected. When translated into the visual output, the journal-like output for personal use is a form of Data Humanism. This is because visually representing self-data in respect of self psychology, such as the empirical self or what makes up a person’s self-concept and human memory, we can approach the design of a visualization with more meaning and thoughtfulness. Iterating on Lupi’s words – “We are ready to question the impersonality of a merely technical approach to data and to begin designing ways to connect numbers to what they really stand for: knowledge, behaviors, people [7].”, this work takes into consideration a humanistic approach with respect to the physical and mental experience of whom interacts with their self data.

A survey of data collection was conducted to deepen the understanding between the usage of a device and how the output of data is internalized. A myriad of devices was tested, such as a Fitbit tracker, web API’s, an eye tracker, cameras, and sensors to detect the external environment. The selection of data collection methods had to satisfy the following criteria:

Figure 1: Example of beginning, middle and end using a mouse-drag interaction to draw out patterns for a daily data drawing.

- There is a direct and strong connection oneself narrativeto the data that is output.
- A wearable device functions symbiotically with the self with minimal disruption during the day.
- There is a low sense of surveillance
- The data can be retrieved on the web via API.

The Fitbit tracker and Web API's fit the criteria the best. For information that requires a conscious recall, a screen-based visual interface that includes input for emotional, social, and thought data that is then collected and stored in a database. If you can imagine yourself living out each day, think about what information your body and mind "outputs". The chosen modalities of data collection were designed to carry out a composed way of getting self feedback to an individual. This includes heart rate or sleep patterns – the type of data that is retrieved automatically through the use of our devices. In a sense, they are an extension of ourselves when it comes to the data it is capable of generating. In this model, the data that is collected through automatic means like the Fitbit and data from Web API's is considered implicit. The data that is collected from the visual interface is considered explicit. The collection process combined with the content being self information is metaphorically represented as retrieving memory about the self.

In this project, the method of collection the implicit memory data is straightforward. This is because implementation is based on setting up the stream of data and making it available to be used when it comes time to create a daily drawing. This was done using JavaScript. On the other hand, it was a more involved design process to achieve an accessible and meaningful web interface that collects emotions, social information and thoughts.

Because of the lack of assessing a full range of emotional experiences in previous surveys to measure emotion, Harmon et al. developed a questionnaire to assess situationally

induced emotions that expand the range of mood states seen previously that assess only specific ranges of emotions such as anxiety, pride, and shame and guilt. The importance of a tool that assesses emotion comprehensively is because the same event occurring in two different individuals' life may evoke two different emotional states between the two. Another reason of importance is the possibility of an event evoking mixed emotions. The Discrete Emotions Questionnaire developed by Harmon et al. includes "basic by prominent emotion theories" that allows individuals to distinguish emotions and determine a level of which they are feeling them. The questionnaire declares eight different broader categories of discrete emotions: Anger, Disgust, Fear, Anxiety, Sadness, Desire, Happiness, and Relaxation. Amongst these larger categories, subcategories consisting of more specific emotions.

Codex Endogenous takes this list of emotions to be checked off each day. To be completed in a way that imposes less burden on the user, there is no scale like there is in the original questionnaire. While there is worth in denoting the intensity of emotions each day and reflecting it in a visualization can be achieved easily, the focus was on minimizing burden in completion of the form while maximizing the sense of being able to identify personal mood states, bring it forth to attention and opening the door for reflection. It is intended that every day the form would be completed. The submitted data goes to a database for later retrieval and visual encoding during the data drawing stage.

The social and thoughts form works the same way as emotion and is submitted to a database. The user recounts their day and notes memorable names of those who they interacted with during the day. The thoughts form prompts the user to describe their day in 3 simple words. This answer is used to title the drawing. The purpose of the minimalist nature of only writing 3 words is because it creates a task to pull the most important elements remembered from the day and in turn creates less cognitive load when going back into the

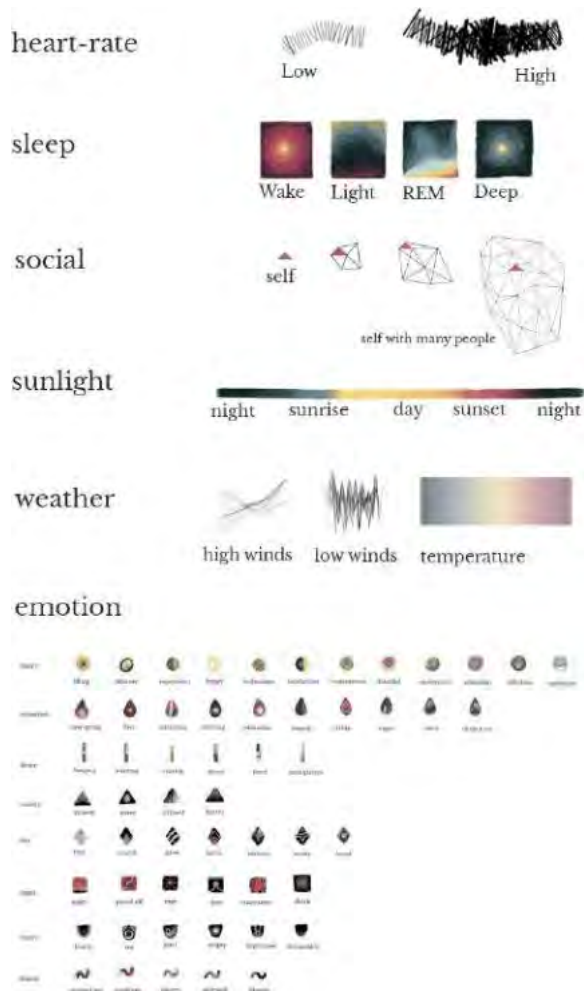

Figure 2: Legend to each pattern correlating to heart rate, sleep, social, environmental and emotional data ©Respect Copyright.

archive of daily drawings. This feature contradicts the conventional function of keeping a journal where meandering thoughts get written down.

Conclusion

Codex Endogenous seeks to provide groundwork for a procedure to concurrently collect personal data pertaining to aspects of the self. Two main processes make up the procedure: observation of self data trails, including biometric and environmental data produced by our network of devices and an intervention for collecting emotional, social, and thought data. The journal-like collection of daily data drawings aimsto provide an accessible and non invasive way for individualsto receive a *semblance* of neuro-feedback, as a complimentary tool to be combined with professional psychiatric treatment and counselling for PTSD patients.

Live Data in Live Performance

G. Isla Borrell

Paris 8 University
Paris, France
giborrell@gmail.com

Abstract

Real-time data feeds offer a new kind of liveness in the performing arts, and an opportunity for natural phenomena like wind, tides and air pollution to join in live performance as dynamic, unpredictable forces. By heightening the presence and agency of living systems, real-time data can contribute to a less anthropocentric portrayal of the world.

Keywords

Data art, liveness, digital performance, data theatre, Gaia

Live Data in Live Performance

We live in an age of unprecedented data accessibility and data malleability. Data is not only available, it is available in digital form; easily analysed, easily transmitted through networks, easily converted into visual and sonic displays. In the visual and performing arts, experiments in the 1960s used electronic systems to create interactions between different elements of a performance. Pioneers include Merce Cunningham and John Cage, who used proximity and light sensors to enable the positions of the dancers to influence the sound in their performance *Variations V* (1965). This kind of transformation - movement to sound, sound to image, input to output - is characteristic of art and performance made using data feeds. The following year saw a key event in the history of art-science collaboration: *9 Evenings: Theatre and Engineering*, a set of performances detailed by Clarisse Bardiou in “Un Exemple Fondateur De Collaboration Interdisciplinaire”, where she observes that “the transformation from one medium to another is a dimension explored by Robert Rauschenberg (the sound of tennis rackets controlling lights), Lucinda Childs (movement into sound, sound into image) and David Tudor (sound into lighting variations and image)”.¹ [1]

Nowadays, digital technologies facilitate the capture of various types of data, while Bluetooth and Wi-Fi enable us to transmit it rapidly and wirelessly, and a host of software

is available to transform it and present it in different forms. The rapidity of this process means that raw data can be converted into palatable visual, audio and text formats and presented to an audience almost at the same moment as it is produced. This is a kind of liveness, and as such it carries immense value for the performing arts.

Liveness

Liveness is a key concept in performance studies, and one that evolves. As Philip Auslander has observed, “[t]he default definition of live performance is that it is the kind of performance in which the performers and the audience are both physically and temporally co-present to one another. But over time, we have come to use the word “live” to describe performance situations that do not meet these basic conditions.” [2] Radio, recording technologies and the internet have challenged our cultural understanding of what a live experience is, so that we now listen to recordings of artists “live in concert”, live-stream events that take place elsewhere, and live-chat with friends and customer service chatbots online. This last example touches on the other aspect of liveness that is now called into question: the *alive-ness* of the participants.

In the performing arts, a coincidence in space and time between audience and performer is still often considered to carry a higher value than, for example, online performances where audience and performer inhabit separate spaces, or pre-recorded performances which audience members view later. Even in the case of performances that don’t conform to the ideal of spatial and temporal co-presence, an instinctive preference for liveness prevails. Theatre-makers and audiences alike favour real-time interactions between real and virtual worlds and between audience members, even when these interactions occur in the digital realm. In episode 43 of the performance studies podcast *On TAP*, Sarah Bay-Cheng² notes that engagement and enjoyment are enhanced by connecting to other audience members on Twitter while watching an online performance. [3]

¹ Translated by the author.

² Dean of the School of the Arts, Media, Performance and Design at York University.

The urge to maximise liveness is apparent in examples of text, music and image generators in performance. Theatre-makers frequently opt to run their algorithms during the performance so that generation occurs live, despite the risk of technical hiccups, even when the audience wouldn't be able to tell if it had taken place in advance. In 1997, Jean-Pierre Balpe created *Trois Mythologies et un Poète Aveugle*, a performance that relies on a text generator and a music generator. During the show, the two programmes produce the text and the score, which are then performed by human readers and musicians. [4] In the United States, Annie Dorsen's experiments with text-generating algorithms started with *Hello Hi There* (2010)³, shown in figure 1, where two chatbots generate a conversation from a database composed of several texts about human nature, creativity, language and power. [5] This piece for two computers also raises the question of whether or not a human performer is still an essential part of the evolving definition of live performance. She followed up with *A Piece of Work* (2013), a show in five acts, each of which applies a different algorithm to the text of *Hamlet*. In addition, the sound and lighting, also managed by algorithms, adapt according to the words chosen by the text generator. In all of these examples, the algorithms perform live – in real-time in the same room as the audience – and this liveness is treated as a selling point in promotion and descriptions of the performances.

Figure 1. Two computers on stage conducting a live algorithm-generated conversation, in Annie Dorsen's *Hello Hi There*. ©W. Silveri.

Data feeds

A data feed, or data stream, passes up-to-date data from a source to a user. It provides an evolving sequence that reflects real-time changes. This is pertinent where whatever is being measured is in a state of flux, and the user wishes to view the changes as they happen.

³ Further information about Dorsen's work is available on her website <https://anniedorsen.com/>

In theatre and dance, data feeds tend to be taken from within the performance itself. A common example is the use of wearable sensors to gather motion and biometric data from performers or spectators. This data is relayed to a server, converted into visual or sonic form, and incorporated into the performance. Examples include:

- *Boiling Mind* (2020), produced by a team at Keio University and Darmstadt Technical University. Audience members wore electrodermal and cardiac sensors. The data from the sensors was converted into data visualisations and also affected video, sound and lighting parameters. [6] See figure 2 below.
- *Noor: A Brain Opera* (2016), produced by Ellen Pearlman, used an electroencephalogram (EEG) headset to measure a performer's brain activity. The data was used to choose between banks of video and sound files, so that the projected images and soundscape corresponded to the emotional state of the performer. [7]

Figure 2. Infographics displayed behind the performers show each audience member's electrodermal and cardiac activity in *Boiling Mind*. ©Moe Sugawa

Examples from the visual arts, such as the work of Andrea Polli and David Bowen, demonstrate the artistic potential of live data feeds sourced in the natural world. Polli is a digital media artist and a professor at the University of New Mexico. She has been creating art installations based on sonorisation and visualisation of digital information since the 1990s. Her recent work centres on using lights to present ecological data.⁴

- Exhibited in cities across the United States and Europe, *Particle Falls* (2008-) is a large-scale projection installation displayed on the side of a building. A nephelometer measures the level of PM2.5 particles in the air every 15 seconds. This data is translated into bursts of colour in the projected image. [8]

⁴ For photographs and videos of Polli's work, visit her Flickr page <https://www.flickr.com/photos/andreapolli/>

- *Energy Flow* (2016-17) is a light installation on the Rachel Carson Bridge in Pittsburgh. It uses LEDs to show the energetic potential of the wind in real time.

David Bowen is a digital artist specialising in converting data into movement, primarily using data from natural systems connected to dynamic sculptures.⁵

- *Cloud Piano* (2014) videos the sky, processes the data and transmits it to a mechanical system that presses the keys of a piano, producing music that responds to the movement of the clouds.
- *tele-present water* (2011) is a sculpture that hangs in a gallery and moves in response to water currents in the Pacific Ocean, using real-time data from a data buoy.
- *tele-present wind* (2010), uses an accelerometric sensor attached to a dry plant stalk to capture its movements as it sways in the wind. The data is transmitted to mechanisms attached to a group of similar stalks inside the gallery, which reproduce the movement. See Figure 3.

Figure 3. *tele-present wind*. The stalks move in unison, replicating the movements of a stalk positioned outside in the wind, sometimes many miles away. ©David Bowen

Artworks created using data feeds drawn from nature offer us new insights and new ways of perceiving our world; as something in flux, as something alive, spontaneous and constantly evolving.

Gaia

Coinciding with rising alarm over the impact of human activity on our planet is rising interest in changing our understanding of the Earth and our place in it. Anthropologists and philosophers like Bruno Latour and Anna Louenhapt Tsing are exploring and espousing an ideology wherein we are part of a multispecies network of living things. In this network, all animals, plants and natural processes have their own kind of agency, and man is no longer the star player.

⁵ For more about David Bowen's work, visit his website <https://www.dwbowen.com/>

Gaia is the name suggested by environmentalists James Lovelock and Lynn Margulis and adopted by Bruno Latour to designate this conceptualisation of our ecosystem. *Gaia* in this context is "neither the Greek goddess, nor nature in the sense of landscape, nor the Earth as a planet, but a personification of this fully living system that evolves with us and confronts us."⁶ [9]

With their trilogy of conference-performances, *Théâtre de la Terre*,⁷ Frédérique Aït-Touati and Bruno Latour promote this more integrated, less anthropocentric understanding of the world. They liken this re-evaluation of our place in nature to the change that came about with the scientific revolution in the 17th century, when the belief that the Earth was at the centre of the universe was challenged by heliocentrism. [10]

Conclusion: Live data on stage

Experiments with live data on stage have demonstrated its potential, often using biometric data generated during the performance. This type of data reinforces the centrality of the human performer. However, as evidenced by the work of Andrea Polli and David Bowen, it is equally possible to use data feeds drawn from meteorology, oceanography, and other non-human sources. Using real-time data from such sources enables natural systems to engage in art and performance with a degree of unpredictability and agency. It enables *Gaia* to be present and active; discernibly alive. The use of this kind of data on stage could contribute to an ideological shift that situates humanity within a network of natural systems and living things.

Isla worked for several years in production design, props and set decoration for film and theatre before beginning postgraduate studies. Her thesis project, *Data Theatre, la mise en scène des données à l'ère numérique*, explores the creative potential of data on stage, particularly the use of live data feeds to generate image and sound.

‘Taman Tugu: Interference/Resistance’: Addressing Urban Rewilding with a Musical Augmented Reality Experience

Yoni Collier

Leeds Beckett University
Leeds, UK
y.collier@leedsbeckett.ac.uk

Abstract

‘Taman Tugu: Interference/Resistance’ is an immersive, interactive musical work that has been mapped onto the pathways of the Taman Tugu jungle park in Kuala Lumpur, Malaysia. Taman Tugu is an unusual place – a large rewilded space teeming with wildlife in the centre of a modern metropolis. ‘Taman Tugu: Interference/Resistance’ uses Audio Augmented Reality and placed sound to raise questions about the importance of urban green spaces in general and rewilded urban spaces in particular. This paper explains how the work asks these questions of its audience through the mapping of electronic sound over the unique geography of Taman Tugu.

Keywords

Placed sound, locative media, site specific art, rewilding, augmented reality, immersive music.

Taman Tugu

Taman Tugu is a jungle park in the centre of Kuala Lumpur, Malaysia. Opening in 2018, the 50 acre park lies on the site of a former city neighbourhood, some signs of which can still be seen in the concrete ruins that poke through the foliage. The park contains more than 4000 trees, including over 1000 categorised as ‘endangered’ or ‘critically endangered’ by the International Union for Conservation of Nature. More than 230 indigenous Malaysian rainforest tree species have been planted, many of these species being selected due to the wide range of fauna they will attract; the overall aim being to encourage biodiversity. [1]

Taman Tugu is an unusual place; a reclaimed green space teeming with wildlife in the middle of a modern metropolis. It provides an excellent example of how we can do much more than simply preserving existing urban green spaces, demonstrating that we can be proactive in the creation of rewilded areas in our urban centres. It therefore also

provides a suitable location for an artistic work that examines the importance of such spaces.

Taman Tugu: Interference/Resistance

Performed through a GPS-enabled Smartphone and headphones, ‘Taman Tugu: Interference/Resistance’ (henceforth referred to as ‘TTIR’) is an Augmented Reality (AR) musical work created in response to this unique location. The bulk of the music created for the project uses field recordings gathered in the park as its raw material. AR is often perceived to be in the visual domain; users can view digital content overlaid onto the real world by looking through a phone screen or Smartglasses. However, AR experiences can be created for the other senses as well; *Audio AR* (AAR) takes place when a real-world soundscape is overlaid with digital sound. [2]

GPS technology allows for the mapping of a composition over a landscape so that the music (or non-musical sound) is experienced within the context of a very specific geography. It is possible to achieve a fine alignment of sound with space that enables the structuring of a musical work around specific landmarks. Behrendt has termed this type of work *placed sound*: “Here, artists or designers curate the distribution of sounds in (outdoor) spaces, often – but not exclusively – by using GPS. The audience typically experiences these sounds via headphones and sometimes via mobile phone speakers or other mobile speakers. The audience does not contribute their own sounds or determine the location of sounds[...] but each member of the audience creates their own version or remix of a ‘placed sound’ piece, depending on their trajectory”. [3]

A placed sound work is tied to a specific location by definition, and this offers the artist an opportunity to tap into deeper layers of meaning associated with that location. Indeed, in their Brief Bibliography and Taxonomy of GPS-

Enabled Locative Media, Bleecker and Knowlton show the greatest interest in “experiences that take into account the geographic locale of interest, typically by elevating that geographic locale beyond its instrumentalised status as a ‘latitude longitude coordinated point on earth’ to the level of existential, inhabited, experienced and lived place”. [4] In creating a work that is closely linked to its performance location, numerous opportunities are opened up to the artist. It is possible to create an interplay between the real-world soundscape of the location and the recorded sounds played back through headphones or speakers. Furthermore, the recorded sounds can be related to the historical and/or cultural context of the location. It is also possible to very closely align real physical objects with virtual *sound objects*, creating *audio-visual congruence*; a concept that will be explored in more depth further on.

Pieces that are inseparable from their performance locations therefore allow for a deep layering of meaning, as well as for intriguing opportunities for creating audio-visual congruence. In ‘TTIR’, the audience hear a musical piece that has been mapped on to the environment while also experiencing the sounds of the surrounding ambiance in real time; a soundscape that has formed the basis for the musical composition itself.

In his writing on Kudsk Steensen’s AR work ‘The Deep Listener’, Obrist proposes that “digital world building can in fact entangle us with the natural world rather than separate us, training our attention on the details of how our actions create irreversible change to those environments and the biodiversity it plays host to – a necessity in light of our current environmental emergency.” [5]

‘TTIR’ layers a digital sound layer on to Taman Tugu in order to celebrate the park and its soundscape while exploring themes that resonate strongly within the Natures and Worlds track of the ISEA2022 conference. The work warns of the fragility of urban green spaces while also acting as a call to arms; the transformation of urban areas into places where nature is allowed to flourish is a small but immensely worthwhile step in the fight against climate change. This paper explores the methodology behind the creation of the work, explaining how the piece was conceived and structured to deliver its message.

It is hoped that the work will encourage new visitors to come to Taman Tugu, while offering regular visitors an opportunity to explore the park in a new way. The work premiered on September 4, 2019 as part of the international Soundwalk Sunday festival. The first public presentation of the piece occurred at a fully-booked event at the park on

December 1, 2019, and was covered on Malaysian national TV news channel Berita RTM.

Methodology

Field Recordings as Raw Materials for AR Music

‘TTIR’ is created largely from field recordings, both processed and unprocessed. In places these field recordings are augmented by synthesised tones that have been designed to sympathise with the timbre of the Taman Tugu soundscape. The recordings were gathered at various locations within the park over a period of several weeks in 2019.

The park has a rich soundscape; bird and monkey calls, the sounds of animals moving through the undergrowth, wind rustling the foliage, water dripping and running in small streams. In certain places the sounds of the city encroach too; motorbikes, trucks, construction work. However, the ever-present sound that underpins it all is a veritable roar of insect noise. It is the sound of insects therefore, that forms the base layer of the composition; recordings of this noise were manipulated in the studio to create drones that retain the shifting timbres of the jungle soundscape. The intention is that these drones appear to be embedded in the soundscape of the location, rising out of it and creating moments of interplay with the sounds of the real world. The drones are augmented by melodic parts played on instruments that were constructed using samples of bird and monkey calls, or other distinctive jungle sounds.

Delivering a Message Through Mapping

The recordings were mapped onto Taman Tugu as 22 overlapping audio zones using an app named Echoes. [6] Participants can download the Echoes app for free from the Apple App Store or Google Play Store and use it to stream ‘TTIR’. The audio zones are triggered by a participant’s phone GPS when the zone is entered, while the behaviour of the audio itself is dependent on various settings determined by the artist. The audio can start abruptly, or can fade in gradually as the participant approaches the centre of the zone. The audio can be looped until the participant leaves the zone, or can play once from start to finish before ending. ‘TTIR’ makes use of all of these audio behaviours.

In the weeks the artist spent exploring Taman Tugu gathering field recordings, it was noted that a striking feature of the park was the way in which the city of Kuala Lumpur felt entirely absent in certain places, while being extremely conspicuous in others. In the depths of the park, the foliage masks the city both visually and aurally, immersing the visitor in nature. In other places, a path can rise onto a ridge where the skyline of the city can clearly be seen, and the sounds of the city can plainly be heard.

These liminal zones – in which one finds oneself between nature and the city - became key areas in ‘TTIR’ and were mapped by the artist as can be seen in Figure 1 below. In the places where the sounds of the city infiltrate the park, this shift in the soundscape is exaggerated by the music. Digitally distorted layers of jungle soundscape and field recordings of urban sounds are layered into the music at these points; a jarring reminder that the city is not far away and could in certain circumstances swallow Taman Tugu once again.

Figure 1. Artist’s map, hand drawn in the jungle, showing the points on the Taman Tugu trails at which the city becomes visible.

These are moments of audio-visual congruence, and they are central to the success of the work for two reasons. [7] Firstly, they heighten the level of immersion experienced by the audience and secondly, they help to reinforce the themes explored by the work. In his introduction to AAR, ‘Sounding Out Aural Augmented Reality’, Green explains that one requirement of such experiences is that virtual and real objects are aligned in space. In addition, he suggests that “the contextual alignment of an augmentation with reality is of equal or greater importance than spatial alignment. For

contextual alignment, a conceptual link between the virtual and real realms is needed.” [8]

Reid & Fleuriot describe the physical-virtual collisions of audio-visual congruence as an example of *magic moments*; “those moments which are deemed to be both moving and memorable and thus are those that people really value.” They deemed these moments to be of such importance to ‘situated mediascapes’ that they identified a “need to design for coincidence; that is creating events which we know will happen synchronously in the real and virtual worlds.” [9] Hazzard holds that there “is strong consensus that music shapes and drives an audiences referential and emotional interpretation of imagery” while Stevens demonstrates the impact of music on the interpretation of images, explaining that “when watching images and hearing music the viewer will form mental associations between the two, bringing the connotations of the music to bear on their understanding of a scene.” [7] [10] ‘TTIR’ makes use of the inclination of audiences to forge links between what they are seeing and

Figure 2. The 22 overlapping audio zones as they were mapped to Taman Tugu in the Echoes app.

the music that they are hearing in order to encourage engagement with the themes the work seeks to address. The final mapping of audio to Taman Tugu in the Echoes app can be seen in Figure 2, above.

Participants in ‘TTIR’ do not have to walk a set route through the park. The audio zones are arranged in such a way that the park trails can be navigated in any way the walker wishes. The message of the work is unaffected by the trajectory of travel and relies only on the participant’s willingness to explore the park. The work was designed in this way in order to encourage an approach to place that was known as *Topos* to the Ancient Greeks. In his paper on the subject, Parmar defines *Topos* as being “less concerned with directed travel than peripatetic wanderings and the experiential nature of the journey.” [11] By dispensing with a map or prescribed route, it is hoped that ‘TTIR’ foregrounds the experiential nature of a walk through the jungle and its accompanying sights and sounds, while leaving room for the themes of the work to emerge gradually as the walk progresses.

In summary, ‘TTIR’ provides a physical alignment of real and virtual objects (when the city is visible, the soundscape reflects this) that is also a contextual alignment that drives the message of the work (this green space provides a fragile refuge from the city and this requires consideration).

Conclusion

Musical composition that is strongly rooted in a specific location can help us to a greater understanding of landscape and our relationship to it. [12] ‘TTIR’ is an AAR musical experience that acts as site-specific discourse; using Taman Tugu as a refraction point for a series of broader intersecting themes, it acts as a stark reminder of the climate crisis but also invites participants to reflect on the benefits of rewilding urban spaces.

Author Biography

Yoni Collier is currently working towards a practice-based PhD; an examination of how location-based recording, musical performance and production can be used as tools for examining artistic practice, landscape and history. Alongside a written thesis, Yoni is composing and producing immersive, interactive musical pieces that are laid over specific landscapes and ‘performed’ through location-aware Smartphone apps. Yoni holds a BA in Popular and World Musics from Leeds University and an MSc in Sound Design from Leeds Beckett University. Alongside his research, he continues to work as a freelance producer, composer and performer. His experience in composition for visual media includes work for dramatic film, corporate clients and video games. His music has featured on TV shows on ABC Family, ITV and Sky Sports, and he has scored films that have been exhibited at numerous international film festivals including the BFI London Film Festival and The ECU European Independent Film Festival.

RESILIENT TERRA

Patrizia Costantin

Aalto University
Helsinki, Finland.
patrizia.costantin@aalto.fi

Abstract

RESILIENT TERRA is a proposal for a collective curatorial research project looking for alliances. It aims at politicizing the notion of geoengineering by bringing together a variety of artistic practices and interdisciplinary approaches that explore geoengineering within and beyond the neoliberal context. Through a relational methodology, RESILIENT TERRA's objective is that of engaging the wider audience with concepts of geoengineering and climate justice, in order to create a space for socio-political debate that encourages transformation and speculative thinking on multiple 'larger' futures.

Keywords

Curatorial research, relationality, archipelagic thinking, intra-action, terraforming, geoengineering, new narratives, artistic research, art and technology, futures.

RESILIENT TERRA

This paper outlines the initial stages of RESILIENT TERRA, a curatorial research project that begins with explorations of the shift in meaning from terraforming to geoengineering within the global climate crisis and the "neoliberalization of the Anthropocene". [1] Benjamin Bratton defines terraforming as the process of transformation of an ecosystem of alien planets or moons into environments that are able to support Earth-like life. [2] However, he continues, the term has gained new connotations: it can now be associated with the technological interventions necessary to mitigate the effects of climate change in the Anthropocene. [3] RESILIENT TERRA aims to foster a discussion within and beyond academia and institutional contexts to engage various kinds of audiences into the current debate on geoengineering. McKenzie Wark argues that there is in fact an urgency to engage the wider public into this highly political discussion as the elites cannot be left to handle the "state of advanced metabolic rift" which themselves have caused. [4] This is a project proposal that aims to facilitate the coming together of different practices and forms of knowledge and that questions the apparent artificiality of AI and planetary technology-generated-data in order to speculate on alternative futures.

In this context, planetary scale is to be understood as the "big-world condition of co-existential nth dimensionality". [5] Patricia Reed's definition calls for relational modes of worldbuilding to move away from the neoliberal conditions which are the roots of the term's own existence. [6] In addition, the concept of contemporaneity – a "present constituted by the bringing together of a multitude of different temporalities on different scales" [7] – grounds the research at the intersect of temporalities against the linear histories of neoliberalism. It also fosters the articulation of critical thought as one of the means to escape the no-alternative scenarios precipitated by the current economic system, already well articulated by Mark Fisher in *Capitalist Realism: Is There No Alternative?* [8] The starting point of RESILIENT TERRA is to critically problematize visions of geoengineering ventures that may market the ecocide as a planetary investment opportunity, thus hindering the realization of alternative solutions which take into account climate justice.

How can the concept of geoengineering be questioned through a political lens that contrasts an understanding of the climate crisis as an opportunity for the accumulation of capital? Can we still conceive of ways in which planetary scale technology can be deployed to support practices of climate justice? These are some of the questions on which RESILIENT TERRA's methods have been built on. The methodology is inspired by Édouard Glissant's archipelagic thinking [9] and is built on the ideas of mondialité [10] and Karen Barad's intra-action [11]. These concepts support the relational nature of the project at multiple levels and allow RESILIENT TERRA to emphasize climate justice issues within a politicization of geoengineering practices. Archipelagic thinking allows me to envision a model for curatorial practice that enables the coexistence of fragments, agents and narratives through processes of "broken comprehension, ambivalent competence, unhinged knowledge". [12] This rogue knowledge connects to Glissant's proposition for a mondialité (or globality) that does not "homogenise culture but produces a difference from which new things can emerge." [13] The image of the archipelago outlined by Glissant visualizes a particular mode of exploring contemporaneity, one which encourages diversity and

multiplicity and that opposes global homogenizing and alienating practices. [14] The aim is to address each enquiry through curatorial, artistic and discursive methods that allow a diversity of viewpoints to come together and multiple perspectives to emerge.

The intertwined plurality of the agents involved in the curatorial project is articulated through the idea of intra-action. [15] In intra-action, responsibilities are distributed and human and non-human agents intra-act in a co-constitutive manner. [16] Incorporating this idea into the methodology allows me to think of the curatorial as evolving sets of relationships which have the ability to inspire the development of political ways of worldbuilding and strategies of resilience. Within these parameters it is also crucial to consider what Reed refers to as “situational insistence.” [17] This is an approach that preserves the particular in the context of the planetary, much like Glissant’s understanding of the local within mondialité. It is through a methodology built on practices of relationality and non-hierarchical configurations that RESILIENT TERRA aims to form an interdisciplinary think tank that encourages research, artistic explorations and knowledge production that focuses on what making geoengineering political means on a planetary scale as well as on a local and situational level.

RESILIENT TERRA looks to contribute to the urgent debate on viable and reliable responses to climate change effects with a relational and intersectional methodology that enables a discussion on geoengineered futures which includes what techno-positivist approaches tends to disregard: “social in/justice concerns.” [18] In recent years, the work of Holly Jean Buck and Benjamin Bratton has produced invaluable research. By exploring the dichotomy between connotations of geoengineering with ecomodernism and politics of inequality and the link between sustainable technology for climate justice, Buck speculates on how a geoengineered future may look, giving us an intervention on climate realism (or the eco-planetary crisis). [19] Planetaryity is also a key concept in the Terraforming research program at the Strelka Institute, which explores, among other themes, a comprehensive notion of terraforming (from urbanization to planetary design for life survival) as a tool for keeping our planet safe for Earth-like life. This planetary perspective, formulated with data collected by the stack of planetary technologies, [20] allows us to shift the anthropocentric focus of terraforming and open up the geoengineering project beyond human survival to other species.

Within this framework, RESILIENT TERRA fosters research on imaginative spaces and resilient narratives

linked with terraforming and geoengineering in the socio-political and environmental realms affected by the metabolic rift. One of the concerns that motivated this research emerged from the existence of initiatives such as the Breakthrough Institute. J.D. Demos criticizes Ecomodernism and references Michael Shellenberger and Ted Nordhaus’ essay *The Death of Environmentalism: Global Warming Politics in a Post-Environmental World* (2004). Demos explains how Shellenberger and Nordhaus, founders of the Breakthrough Institute, “sought to dispatch what they termed the “politics of limits” – the kind based in the regulatory environmentalism of the 1970s emphasizing Earth’s finite carrying capacity – and replace it with a “politics of possibility” dedicated to technologically-driven economic growth.” [21] He continues by highlighting the growing bond between Big Tech and Green Economics, which would turn geoengineering into a neoliberalist strategy for saving the planet. [22]

Inherited from Science Fiction literature is an idea of terraforming as “the utopian moment par excellence”. [23] It represents a process of transformation of an alien planet (often Mars) into an environment safe to inhabit for humans. Although, the immediate question that arises is: Utopia for whom? The connection between utopia and terraforming and by default geoengineering is one of the narratives that RESILIENT TERRA contests in order to make manifest in accessible ways the white supremacist, colonial and neoliberal biases intrinsic to the trope of terraforming. One of the challenges is to distance geoengineering from these traits and from Ecomodernism while investigating possibilities that may arise from reframing it within the context of climate justice. What can we learn from Afrofuturism’s space settlements that can help us reimagine a habitable future for all on our planet? Another question that arises here is if utopian speculations can help us experiment with imaginary and self-enclosed models for alternative futures that fight what China Miéville summarizes as the threat of lucroforming: “In neoliberalism, we see the quickening logic of “lucroforming”, a politico-geo-transformative agenda to make our entire planet ... the most fecund biome possible for capital.” [24] It is in this context that RESILIENT TERRA values personal utopian speculations but requires us to consider these intersectionally, as local agents on a planetary dialogue that values situational knowledge, histories and futures.

To avoid lucroforming and ecomodernism from becoming the new normal, artists, thinkers and practitioners from all fields are required to envision alternative futures. At her acceptance speech for the

National Book Foundation Medal for Distinguished Contribution to American Letters (2012), Ursula Le Guin called for artists to envision exactly these alternatives in order to avoid being stuck in this not at all promising present:

“Hard times are coming, when we’ll be wanting the voices of writers who can see alternatives to how we live now, can see through our fear-stricken society and its obsessive technologies to other ways of being, and even imagine real grounds for hope. We’ll need writers who can remember freedom — poets, visionaries — realists of a larger reality.” [25]

In real-life geoengineering projects, the presence of artists and creative thinkers is rare. Two examples come to mind: the Biosphere 2 experiment (1991-1993) and a NASA experiment in which a team of scientists, architects, urban planners and artists were employed to design speculative space habitats for millions of people (1975). The book *Space Settlements* (2019) by Fred Scharmen offers an account of this particular event. The Biosphere 2 project, recently popularized by the documentary *Spaceship Earth* (2020) directed by Matt Wolf, was a utopian experiment that attempted to replicate Earth’s atmosphere in an enclosed ecosystem should humans, due to ecological disaster, have to vacate the planet. The latter example is especially relevant due to Steve Bannon’s involvement and influence in turning 1993’s failed experiment into an opportunity to experiment on and with climate change effects on Earth.

RESILIENT TERRA’s investigation has begun with the work of artists, researchers, writers and collectives who have explored aspects of terraforming and geoengineering in their work through a variety of lenses and approaches. DESIGN EARTH (founded by Rania Ghosn and El Hadi Jazairy in 2010) is a research initiative working with design and architecture to reveal aspects of the eco-crisis. Their project *Cosmorama* (2018) speculates on planetary narratives in space and raises the ever-relevant questions of space sovereignty, terraforming practices and space pollution. In *Geostories: Another Architecture for the Environment* (2018) they present us with a “manifesto for environmental imagination” that through geographic fiction asks us to rethink our relations and understandings of planetary scale systems. [26] The more recent *The Planet After Geoengineering* (2021) is a multimedia speculative work which complexifies geoengineering as a form of management beyond the popular good vs evil dichotomy. The project, which was presented at the Venice Architecture Biennale 2021 also included Holly Jean Buck, Benjamin Bratton and Kathryn Yusoff as contributors. [27]

Kim Stanley Robinson’s science fiction novels allow us to imagine different future scenarios that are all very much embedded in the present. *Mars Trilogy* (Red Mars, Green Mars and Blue Mars, 1992-1996) is a key literary exploration of terraforming in climate fiction. The subject is the transformation of Mars into a habitable planet for human beings but, in classic sci-fi fashion, the author uses the terraforming trope as a means to reflect on the current status of Earth’s various infrastructures (organizational, economic, socio-political, ecological, etc.). [28]

Sun Ra and Parliament’s Afrofuturist space-age narratives contribute to the process of decolonization of the idea of geoengineering itself. Outer space represents a public and free space where speculations on better futures are still possible to imagine. Sun Ra’s work in the 70s (*Space is the Place*, 1974, for instance) frames outer space as a utopian possibility for people of color to escape Earth-bound racism, injustices and colonial histories of oppression. [29] Parliament’s *Mothership Connection* (1975) presents funk as a state of being, an attitude toward living holistically in the world; with George Clinton envisioning a futuristic space age in which the main protagonists are black people. [30]

Back on Earth, Superflux’s *Mitigation of Shock Singapore* (2020) speculates on the living conditions of an apartment in Singapore towards the end of the 21st century. The context is an ecosystem falling apart due to the effects of climate change. Human and non-human forms of co-operations in the post-Anthropocene era together with strategies of resistance and adaptation are the subject of a variety of works by Superflux, funded by Anab Jain and Jon Arderin in 2009, such as *Invitation for Hope* (2021) and *Refuge for Resurgence* (2021). [31]

Of interest are also two further initiatives. Geocinema: a project of artistic research exploring future cinema: a cinema in which the “big-data infrastructure combining information from thousands of sensors and satellites might be considered as a “lens” for planetary-scale drama and storytelling.” [32]; and Natasha Myers’ *How to grow livable worlds: Ten (not-so-easy) steps for life in the Planthropocene*, a 10-point manifesto for decolonizing the Anthropocene through a plant-centered approach. [33]

These are some of the works that, together with the key references appearing throughout the text, have inspired the formulation of RESILIENT TERRA as a speculative curatorial research project proposal. This is a project in its initial stages that needs alliances with interested researchers, artists and creative practitioners from different fields to take its best form in real life as a collaborative and

relational initiative aimed at politicizing the concept of geoeengineering beyond the framework of the neoliberal Anthropocene and within the context of climate justice.

Biography

Patrizia Costantin (PhD) is a lecturer and researcher in curating whose work investigates the curatorial as a site for knowledge production and political worldbuilding. She is particularly interested in exploring the role of curating as a relational practice for negotiating with reality, contemporaneity and the technological realm. Costantin holds a PhD in Curatorial Practice (Manchester Metropolitan University, 2019). Her thesis, *machines will watch us die: a curatorial study on the contemporaneity of digital decay* explored digital decay after the material turn in media studies through a postmedium approach. The project emphasized the multiple materialities and temporalities of digital technology and experimented with curatorial strategies with the aim of making visible digital decay and its contemporaneity within the context of a research exhibition. She is currently Head of Visual Cultures, Curating and Contemporary Art – ViCCA major – and Lecturer in Curating at the School of Arts, Design and Architecture at Aalto University.

FORM AND TIME / DECENTERING SITES OF ART STUDIO PEDAGOGY

Judith Doyle, Simone Jones, Elizabeth Lopez

OCAD University

Toronto, Ontario, Canada

jdoyle@ocadu.ca, sjones@ocadu.ca, emlopezgil@gmail.com

Abstract

From the art school's studio-based format, the authors situate *Form and Time* as a *Studio Presentation* course. Scheduled to launch on campus in Fall 2020, the course pivoted to fully remote. Thematic units of Space, Form and Time were explored in synchronous meetings and asynchronous video lectures and micro-workshops.

Studio Presentation courses can engage art students in dispersed, interdisciplinary research-creation networks, through strategies including a diversity of fabrication options, DIY and place-based knowledge and accessibility as approaches to meaning through making.

The authors ask: how can hands-on fabrication skills and health and safety instruction be incorporated into large format studio courses? When is face-to-face, hands-on learning crucial and for whom? How can virtual studios be used for community collaboration and exhibition opportunities, online and in-person?

Form and Time and its collaborators in WebXR foreshadow new modes of art school studio delivery that decenter and critically intersect with studio precedents suddenly disrupted by remote learning during COVID-19.

Keywords

course-based research, studio-based pedagogy, research-creation, art as research, WebXR

Background

Before Fall 2020, *Time-Based Media* and *Form and Structure* were required first-year studio courses at OCAD University in Toronto, introducing media and sculpture-installation practices. Classes met weekly in fabrication studios, computer labs or studio/seminar rooms, where safety, basic techniques, and studio critique were

introduced. These gateway courses fed into specialized programs that culminated in studio thesis work. This approach to teaching studio art foundations has gone largely unchanged since the late-twentieth century in the Faculty of Art at OCAD University (OCADU).

Fault lines in this model emerged before the COVID-19 disruption. Inequities of access are disproportionately experienced by racialized and international students, learners from northern communities and First Nations, the financially precarious and those who cannot or choose not to relocate to downtown Toronto. This includes students facing accessibility challenges of physical and mental health, and those encountering systemic discrimination within the art school. OCADU's 2017-2022 Academic Plan¹ frames accessibility alongside decolonization. Renewal of pedagogy and BIPOC cluster hires are amongst initiatives implemented by OCADU to support accessibility, sustainability, representation, inter-disciplinary, relational and place-based knowledge and practices, and decolonization including training in anti-racism. Curriculum is also being reconfigured to implement the Truth and Reconciliation Commission of Canada's Calls to Action², including educating teachers in how to integrate Indigenous knowledge and teaching methods in post-secondary classrooms. Finally, large-format cross-disciplinary courses including *Form and Time* are designed to offset the costs of small studio classes.

Remote Delivery During Pandemic

Cross-disciplinary and thematic, *Form and Time* was designed by Doyle, Jones and participating teaching faculty to combine delivery approaches: large scale auditorium faculty presentations alongside smaller faculty-led studio-seminars and micro-workshop makerspaces with

¹ (OCADU's) Academic Plan 2017-2022 devotes Priorities 6 and 7 to interdisciplinarity and changes in studio delivery and the teaching and learning environment, in the context of an institutional call to decolonization.

² The Truth and Reconciliation Commission of Canada's Calls to Action – Education and Reconciliation, 62.ii (TRC Calls to Action, 7)

technicians and teaching assistants. Students conduct weekly creative experiments from thematic units: Space, Form, and Time.

In Fall 2020, the new course pivoted to fully remote delivery for three consecutive semesters with enrolments of between 150 and 240 students each semester. The COVID-19 response called for quick improvisation, with the creation of a suite of instructional videos for weekly release, and a reworking of prompts for creative experiments that could be undertaken without access to campus.

Each week, an instructional video was released on Space, Form and Time subthemes. Students posted weekly experiments and comments to Discussion Boards, with bi-weekly synchronous online meetups on Teams. *Form and Time* launched online with the *Space: Site Specificity* module, acknowledging the worldwide emergency conditions of physical distancing, border closures, police brutality and anti-racist protest. Creative activities included walking, observation, documentation and experimentation.

Students produced creative experiments that referenced their specific sites (local, regional and international) including personal aspects of the disparate places they occupied.

Decolonizing Site, the week two module, included the option of an experimental Land Acknowledgement: Emilia Nahdee layered images of herself in Oakville Ontario, and Walpole Island Unceded Territory. Nahdee writes, “Indigenous culture, land and history is still alive, vibrant and dynamic. Those who choose to look closer will find details in the layers, but the constant in the image (and this land as well) is the experiences of the Anishinaabe Indigenous person. I intend through the blurred appearance and saturated layering of images for my audience to reflect, looking closer at their own communities and actively acknowledging the land and its first peoples”³. (Figure 1).

Basic techniques normally introduced on campus in the first-year shops, translated to experiments with non-traditional materials and processes that were available to students in situ and encouraged documentation of experimentation and process work, DIY techniques, and fabrication using everyday materials close to hand. Faculty and teaching assistants shared their diverse skills and practices, contributing to a growing library of video micro-workshops with specific technical instruction. Students were assessed on a rubric of criticality, ideation, experimentation, observation and thoroughness of the documentation. An atmosphere of collegiality, community and peer-to-peer learning and exchange of ideas emerged

and was critical to the success of the online studio learning environment.

Figure 1. Emilia Nahdee, *Land Acknowledgement*, digital compilation photograph, 2020. © Emilia Nahdee.

To highlight weekly student experiments, several student projects were featured in weekly Artist Spotlights on the course home pages, motivating students by example and encouraging risk-taking and experimentalism. Students shared their work in weekly, synchronous meetups and in-depth ‘Crit Club’ presentations that they could opt into. Faculty observed that these synchronous critique sessions were popular; although not all chose to share their work, many participated as observers, providing feedback, engaging with ideas and sharing their individual responses to the course themes. These discussions were intensely interdisciplinary, with students executing their ideas using a variety of media and approaches. Many students shared that they came from a traditional drawing background but were now interested in 3D and digital explorations in relation to their 2D practices. Building on these initiatives, Doyle and Jones identified a need in *Form and Time* to develop a more ambitious community exhibition space.

WebXR Exhibition and Critique Studio

At OCADU, WebXR experimentation began in the Unreal Club based in the Social Media and Collaboration Lab (SMACLab) led by Doyle, who used volumetric capture in her workshops conducted at the Athens School of Fine Arts in 2019 and at ISEA 2019 Gwanju: *Tangible, Embedded, and Embodied Interaction*.⁴ Dr. Graham Wakefield at the

³ Emilia Nahdee, “Artist Spotlight”, Form and Time Canvas Homepage, September 2020, cited October 12, 2021.

⁴ These workshops received support from the Ontario Arts Council in 2019.

Alice Lab at Toronto’s York University (York U) explored WebXR with his advanced students. The researchers at OCADU and York U secured funding to develop an open-source open-access WebXR Exhibition and Critique Studio for undergraduate and graduate students, focusing on project creation, curation and critique, supported by the Government of Ontario’s eCampus program.⁵ The project aimed to develop WebXR to support local and community-based pedagogy by developing accessible technology, using research-creation and course-based research methods.⁶ The collaborators included Dr. Graham Wakefield and his researchers including Nick Fox-Gieg, and Doyle, Jones, Elizabeth Lopez and Dr. Haru Ji at OCADU, who during Summer 2021 designed, prototyped and tested WebXR approaches. Prototype artworks were created by Joaquim (Juka) Almeida and Paulina Aviles to identify and stress-test WebXR features, and as inspiration for students. Participating remotely from Mexico as an undergraduate Intern, Aviles’ work engaged with museum practices of collection by creating volumetric collages from photogrammetric captures from the collection in a local cultural archive. Almeida, an OCADU graduate student, created an experimental fusion including archival Brazilian Cinema Novo film, performance, sound and mask in a VR space. He writes “...This mask represents a *Cangaceiro*, a folkloric Brazilian entity... captured through photogrammetry (and) stored as a point cloud. (Figure 2). The films (included in the WebXR gallery) were designed to offer a virtual reality experience, composed by layering personal diving footage from Brazilian seas with extracts from a 1937 anthropological documentary about the Cangaceiro movement...”⁷

Figure 2. Screenshot of WebXR, work by Joaquim Almeida, *Cangaceiro*. ©Joaquim Almeida.

⁵ WebXR Exhibition and Critique Studio, funded by the Government of Ontario and through eCampusOntario’s support of the Virtual Learning Strategy, 2021.

Collaborative Sites

Each course-based team created templates, resulting in three toolkits for exhibition and creation in WebXR. The *Form and Time* team at OCADU developed an A-Frame WebXR interface and user manual (Nick Alexander) with quick use entry-level programming templates (Tyson Moll). The Project Manager (Lopez) and Virtual Studio Manager (Ernesto Rodriguez) directly supported students in their creation of photogrammetry and its installation in WebXR, working with students in group synchronous sessions or over email and file sharing.

Design and prototyping by undergraduate and graduate students in the Creative Computation class based in the Alice Lab at York U led by Dr. Wakefield included course work on WebXR features for real-time collaboration and generative art, including design to best support distributed creative experimentation.

Dr. Ji piloted WebXR as part of OCADU’s Digital Futures Atelier 1, in the 'Endless Forms Most Beautiful' unit. For this project, Ji and her researchers developed a prototype framework for generative art. Students forked the template and edited it to add their own generative artworks. Tim Chou, a second year Digital Futures student wrote, “I want to use this space to display my process of this generative experiment. Each side of the wall shows a new and different result produced by manipulating or changing the fundamental rules”. Looking forward, OCADU faculty are investigating potential spaces where generative and pre-configured artworks and assets intersect and overlap.

Reflections and Observations

Launched in an emergency, *Form and Time* defamiliarizes and troubles dichotomies between studio delivery modes—online or in-person, synchronous versus asynchronous. Employing a multi-modal, flexible, responsive format, the course engages different modes of delivery and group sizes, embracing experimentation and interdisciplinary approaches to artmaking and research-creation. Building community for students in their first year of university is an important component of the course. Student participation in synchronous and asynchronous opportunities for information sharing and exchange of ideas fostered an inclusive environment that was dynamic, respectful and highly rewarding.

⁶ “...art with an activist impulse... offers speculative frames through which to *defamiliarize* and *reorganize* the local. (Loveless, 301)

⁷ Joaquim Almeida, Artist Statement, October 2021.

The authors observe that direct teacher-to-student feedback including marking poses challenges in large-format studios; individual feedback is time-consuming and not scalable. Student peer-feedback, including group work, is key to managing class size and motivating students. Studio Presentation is a form of blended delivery, combining online and in-person, and smaller and larger scale encounters. Optional sign-up activities—field trips, gallery visits and micro-workshops—provide in-person possibilities introducing first-year students to their peers, the campus and local art communities. Differing faculty expertise and preferences for teaching modes (online, partially remote) can combine and complement each other through shared online resources and scheduling innovations. Online resources, including WebXR, can facilitate collaboration with other courses, faculties, universities and community-based networks, developing an archive of open-source, open-access assets, including the studio WebXR platform alongside micro-workshops, video tutorials, student examples and creative computation toolkits.

As access to campus and fabrication studios reopen, we can seize the opportunity to reconfigure studio pathways for creative experimentation, materials handling and technical instruction. Importantly, online exhibition and display of student work can expand beyond the confines of the institution, to build relationships between communities (institutional and non-institutional), localities and student groups.

WebXR enables blended modes of studio art delivery. The authors explored generative art, photogrammetric capture, and creative, collaborative coding in this project. Cinematic capture from virtual environments for video installation also benefits from open-source access to WebXR. INTERPLACE—a video installation featuring screen captured moving images from WebXR of the *Form and Time Fall 2021* class—was exhibited at the Ada Slight Student Gallery and the Great Hall at OCADU in Winter 2022. The exhibition included multiscreen monitors, projection, surround-sound and live sonic art performance by Paul Geldart. The video installation merged online and physical places, featuring student photogrammetry produced in their home studios across dispersed localities during COVID-19. (Figure 3: detail, *Yellow Staircase* in WebXR)

INTERPLACE marked the occasion of return to in-person exhibition on campus following pandemic restrictions; it was a powerful encounter. This back-and-forth between WebXR and local in-person exhibition and performance is a fertile option for hybrid, online and blended teaching pedagogy. Expanded and mixed reality exhibitions, collaborations and events foster community-based engagement and extend the potential to decenter studio art pedagogy by supporting community-based networks.

Authors Biographies

Judith Doyle is an artist practicing in cinema and expanded reality. An Associate Professor at OCADU, they are Chair First-Year Art and co-direct the OCADU SMACLab.

Simone Jones is an artist whose works are shown internationally. They are a Professor at OCADU.

Elizabeth Lopez is an interdisciplinary artist and researcher whose works are shown in Canada and the US.

Memory's death... or the desire of immortality

Ricardo Dal Farra

Concordia University / CEIARTE-UNTREF
Montreal, Canada / Buenos Aires, Argentina
ricardo.dalfarra@concordia.ca

Abstract

Who tells history? We can find multiple versions about the electronic art history, most of them with subtle differences, but it has been unusual -until a few years ago- to find references pointing to countries out of a small group from Europe and North America. Several projects have been developed to change that situation. The Latin American Electroacoustic Music Collection, hosted by The Daniel Langlois Foundation for Art, Science and Technology, represents an example of the relevant role and the impact that the archival of electronic artworks and its public access can play in having another perspective about history.

Keywords

Archiving, electronic art preservation, electroacoustic music history, cultural decentralization, Latin America.

Introduction

The journey from the cultural memory and the ethical concerns to the practical strategies on preservation and the impact of disseminating knowledge generated by computer art has been navigating a sinuous road.

Memory's death could benefit some as much as the desire for immortality could block the way to innovation open naturally to new generations. Computer art memory has been partially dead, or perhaps deaf or blind or simply looking to the other side, maybe to avoid the perception that the so-called digital revolution has reached most of the known world and that history does not happen only in a few "central" countries. The desire of immortality and for being a cultural lighthouse as much as the guardian of the right values and the significant art should not take us all to mislead that intelligence and sensibility belongs to a few.

Who tells history? Who knows about it or who has the opportunity to do it? We can find multiple versions about the computer art history, most of them with subtle differences, but it has been unusual -until recently- to find references pointing to countries out of a small group from Europe and North America. Inequalities have always existed and if we want to see a change, probably we will need to work hard ourselves to produce new results. There are many lost and hidden stories about computer art that probably should be part of the official history and not just left aside. There have been people, ideas and concepts, artworks, discoveries and inventions, and we expect someone will take care of keeping the memory of all that for us but sometimes it simply doesn't happen and when we look around after a while, it seems that the history has not been the one we thought it was and we remember, but a different one that is being told by others.

Between the obsession for archiving everything and the difficulty and strong responsibility of deciding what to preserve, the opportunity to archive computer art makes us face a challenge involving from technical issues to political, social, cultural and economic aspects.

How many histories can be told about the same subject? To who their narrative is directed? I have heard some educated young people saying that "if something is not on the Internet, does not exist". Then, today the digital divide could be not linked to who has access to the web but to who dominates the inclusion of content or develop the strategies to keep our attention on certain places and not others. It looks like we are bombarded with cues guiding us to consider that the art conceived by some cultures are the only ones to be recognized as valid.

The Daniel Langlois Foundation for Art, Science and Technology [1] in Montreal has been a leading organization heavily focused on studying theoretical aspects related to preserving electronic and computer art and actually archiving it. A number of major projects have been developed or hosted there since the late 90s, including the Latin American Electroacoustic Music Collection [2], among many others.

Music & technology innovation in Latin America

The political and economic instability in most Latin American countries has been deeply affecting the life of its inhabitants for decades. Support for artistic activities has usually been postponed to solve urgent social problems. In spite of that, the development in the region of the electronic arts in general and the electroacoustic music in particular, is really astounding. To name but a few examples: Mauricio Kagel (Argentina, 1931 - Germany, 2008) composed eight electroacoustic studies in Argentina between 1950 and 1953, according to Hugh Davies' International Electronic Music Catalog published in 1968 [3]. Kagel was one the pioneer composers that were laying the foundations of a rich history of experimentation and creation in the region. Reginaldo Carvalho and Jorge Antunes in Brazil, León Schidlowsky and Juan Amenabar in Chile, Joaquín Orellana in Guatemala and Horacio Vaggione in Argentina are only some of the many names in the ocean of electroacoustic music creativity that has always been Latin America.

José Vicente Asuar composed between 1958 and 1959 in Chile his piece *Variaciones Espectrales* using only electronic sound sources. The Estudio de Fonología Musical was created in the University of Buenos Aires of Argentina by Francisco Kröpfl and Fausto Maranca at the end of 1958. During those same years and also in Argentina, César Franchisena was also experimenting with electronic sound sources at the National University of Córdoba radio station and composed *Numancia*, a ballet music on tape, in 1960. A landmark in the electronic music history of Latin America was the lab created in Buenos Aires during 1963 at the Centro Latinoamericano de Altos Estudios Musicales - CLAEM of the Instituto Torcuato Di Tella (the Electronic Music Laboratory was part of the Latin American Higher Studies Musical Center of the Torcuato Di Tella Institute). Peruvian composer César Bolaños created *Intensidad y Altura*, the first piece for tape produced at that lab, in 1964.

Figure 1. Latin American composers at CLAEM's Electronic Music Lab.

In Cuba, Juan Blanco composed *Música para danza* for tape in 1961 and *Texturas* for orchestra and tape between 1963 and 1964. Blanco composed around a hundred works using electroacoustic media, including music for mass public events and large venues, like the five-tracks 1968 tape piece *Ambientación Sonora*, played during 30 nights along La Rampa Avenue in Havana. Carlos Jiménez Mabarak composed in Mexico *El paraíso de los ahogados*, a piece on tape, in 1960.

Also in 1960, engineer Raúl Pavón built the prototype of a small electronic musical instrument featuring an oscillator with multiple waveform outputs, a white noise generator, a variety of filters, an envelope generator and a keyboard. Named *Omnifón* by Pavón, his creation was among the first voltage-controlled electronic sound synthesizers. Well before that, in the early 40s, the aforementioned composer Juan Blanco designed an innovative electronic instrument similar in concept to the Mellotron. His *Multiorgan* was based on 12 loops using magnetophonic wires. It predated the Mellotron -that is considered the predecessor of the digital sampler, the instrument that changed the way of doing music- by several years. Fernando von Reichenbach invented in Argentina the *Analog Graphic Converter* in the 60s (also known as: *Catalina*). It was used to transform graphic scores -from pencil drawings done on a paper roll- into electronic control signals adapted to work with analog sound equipment. José Vicente Asuar produced in Chile a hybrid analog-digital computer system in the mid 70s, exclusively devoted to create music.

Figure 2. The Analog Graphic Converter developed by Fernando von Reichenbach at CLAEM during the late 60s.

Reichenbach redesigned CLAEM's Electronic Music Lab and invented several devices, such as the keyboard-controlled polyphonic third/octave and octave filter and a touch-controlled patch-bay that helped composers to simplify some cumbersome processes in the studio. Today, Reichenbach's inventions are starting to be internationally recognized.

Latin American Electroacoustic Music Collection

Unavailability of musical recordings, bibliography and almost any basic reference to the electroacoustic music activities that were developed since the early 1950s in several Latin American countries was commonplace when I started to work on the field around the mid-1970s. That situation did not change much during several decades.

In various Latin American countries, universities, state organizations and major private foundations have taken initiatives to support art research and the use of new media already in the early 60s, but most have stopped before developing the resources to document their processes and preserve the results. Many early tape compositions, for example, have been lost or the master recordings damaged.

The Latin American Electroacoustic Music Collection, with over 1,700 digital recordings [4] of compositions by almost 400 composers, and accompanied by photographs, scores, interviews, a trilingual historical essay [5] and over 200,000 words in its database, represents an example of the relevant role that the archival of artworks and its public access can play in having another perspective about history. This is today a key resource in the field, being consulted extensively by people from around the world each month (e.g., researchers, composers, performers, musicologists, historians, artists and the general public) and helping to transform the usual perception of "ownership" that exists related to some countries with respect to the computer art history.

The archive it includes compositions for fixed media (tape, DAT, CD, HD or similar) as well as mixed works for acoustic instruments or voices and fixed media or live electronics/interactive systems. There are also some multimedia works in the database. In the case of pieces for fixed media and other sound sources (e.g., mixed works), full recordings as well as "tape only" parts (i.e., fixed media) are preserved and catalogued. The archive also includes audio and audiovisual recordings of interviews [6] to composers and technical innovators (e.g., Alberto Villalpando from Bolivia, Manuel Enriquez from Mexico, Alfredo del Mónaco from Venezuela) as well as photographs, videos and some scores (e.g., by Alcides Lanza from Argentina, Javier Alvarez from Mexico, Milton Estevez from Ecuador).

From a technical perspective, the archiving of audio material went through a myriad of problems: recovering from massive hard disk crashes, finding analog tape recorders with old track formats, re-digitizing material to correct severe DC offsets in brand-new equipment, computer operating systems and FireWire conflicts, etc. Defining how best to work with very noisy old recordings was another challenge (a few pieces were processed using an advanced de-noise system to moderate hiss, always preserving the original recording and following the composer's advice). The bulk of the process was done between 2003 and 2005 at the Langlois Foundation, working with three different computers and nine hard disks to manage the audio and visual files, the database and the large amount of info as well as the daily international communications.

Worth mentioning that while the recording quality of some music stored on old analog tape could have suffered through the years, digital technologies for recording storage were the ones presenting the most difficult challenges. For example, some DATs (Digital Audio Tapes) lost part of their recordings and only a loud digital noise was in place of the music. In those cases, the problem was not only a poor quality (e.g., because of hiss or the loss of high frequencies) but a complete lack of the recorded signal, without any possibility to recover the original materials.

There are 1,723 compositions preserved as digital audio -with CD quality- in the database. While all is available for listening to researchers who ask for an access code (to avoid copyright infringement) contacting the Langlois Foundation, 558 works from those are freely available and can be listened to by the general public online. The database has also over 200,000 words in information, and there are multiple ways to find the information in there. The digital audio recording of a composition can be found by its title, the name of the composer, the country linked to that composer, the year or decade when the work was composed, etc. In addition, there are two playlists to access and listen to the compositions: one sorted alphabetically by the last name of the composer [7], the other sorted chronologically, following the year the piece was composed [8]. Instrumentation, program notes, production studio, version, composer's bio and more have been also included for each work when the information was available. Part of that comes from two previous reports I wrote commissioned by UNESCO, between 2002 and 2003: *Historical Aspects of Electroacoustic Music in Latin America: From Pioneering to Present Days* [9] and *La música electroacústica en América Latina* [10]. They were published online and are available through the UNESCO's Digi-Arts knowledge portal. These texts include references to hundreds of composers who were born or pursued a portion of their professional careers in Latin America: 191 from Argentina; 14 from Bolivia; 90 from Brazil; 39 from Chile; 39 from Colombia; 5 from Costa Rica; 44 from Cuba; 3 from the Dominican Republic; 11 from Ecuador; 5 from El Salvador; 6 from Guatemala; 73 from Mexico; 3 from Panama; 4 from Paraguay; 15 from Peru; 12 from Puerto Rico; 27 from Uruguay; and 35 from Venezuela.

This is one of the most visited and consulted collections of the Daniel Langlois Foundation.

Final words

The Latin American Electroacoustic Music Collection has recovered and made visible (and listenable) the creative work of many electronic artists otherwise almost forgotten. It has defied the wish of immortality and the hegemony of the electronic art history narrative, breaking one of the memory's death roads and slowly shifting and widening the way the history of electroacoustic music is been understood.

Archiving and disseminating electronic and computer art history findings is crucial to comprehend the present and to build our future.

Abstract

The 21st century sees the rise of wildfires, which radically destabilize the anthropocentric paradigm that places the human at its centre, by manifesting what theorists like Bruno Latour term ‘terrestrial agency’. As a manifold process that encompasses Earth’s ecological systems, we have been co-evolving within these processes, harnessing them for our civilizational progress. Yet, our concomitant refusal to acknowledge nature as an independent agent in which we exist has exacerbated climate change, leading us into what scholar Rick McRae terms the ‘age of violent pyroconvection’ [10] – an age in which life on Earth will be shaped by wildfires and their complex dynamics. It amplifies the autonomous nature of terrestrial agency whose behavior defies human assumptions [8]. These evolving dynamics between the human and the planetary require new aesthetic contexts in which two autonomous yet interrelated agencies mutually transform and disrupt each other. Existing creative visualization paradigms have struggled to aesthetically engage this relationship, falling short of providing compelling sensorial points of engagement. The paper briefly analyzes exemplary artistic works and proposes a novel aesthetic framework premised on integrating immersive visualization systems and Artificial Intelligence (AI) programming. It experimentally explores this architecture in relation to the *iFire* research project currently in development at The University of New South Wales.

Introduction

As the world has warmed over the past two decades as a result of dynamic terrestrial and atmospheric processes, so have fires increased in their incidence and scale [4]. Examples are the ferocious wildfires that most recently tore through North America and Argentina in 2022, the Mediterranean, Northern America and Russia in 2021, and Australia in 2019 and 2020 [8]. Most wildfires are characterized by mega-scale, unprecedented speed, generation of their own weather systems and their unpredictable dynamics [9]. Over the past two decades, they have caused devastating loss of human lives, fauna, habitat and property, in turn further warming the planet [14]. As

climate systems change across the globe, we are entering an age scholar Rick McRae refers to as the ‘age of violent pyroconvection’, in which our lifeworlds will be predominantly shaped by fire, with more communities than ever affected by its manifold forces [10]. Theorists such as Manuel DeLanda, Bruno Latour and Michel Serres analyze such developments as expressions of a terrestrial system whose independent yet symbiotic agency is perpetually evolving in a non-linear way as it interacts with the human world [6]. Its forceful amplification requires us to comprehensively address our position within this planetary system, learning to adapt to forces that act according to their own logic [10]. Wildfires represent a concentrated manifestation of such destabilizing agency, giving rise to uncontrollable forces. Yet, engagement and resilience to their complex dynamics will be necessary to secure human habitation into the future.

Research into the complex interplay of the many variables that determine wildfire dynamics currently spans a vast range of disciplines, interweaving, for example, creative visualization, atmospheric sciences, mathematical modelling, geological studies and historical enquiry. The resultant multi-layered data adds to the knowledge base about wildfire activity in different parts of the world, revealing a complex interplay of factors that influence evolution and progression of fire fronts. These include, for example, fluctuating wind directions and strength, the degree of moisture as well as fuel type, terrain particularities and accessibility for firefighting resources on the flanks of megablazes. Studying these variables in the field allows creative and scientific researchers, along with fire personnel, to model wildfire events to gain insight into the forces at play and to embody possible future scenarios and their likely evolution.

The aesthetic capture and visualization of this interrelated information, however, is challenging. In sensorial ways, immediate access to wildfires is experientially hazardous due to severe temperatures that eliminate oxygen and melt matter within split seconds, as well as prohibiting detailed documentation via cameras or sensors. This means that despite its massive volume, the available data on fire activity is to some degree always incomplete and requires careful and reflected interpretation [2]. In terms of visualization, captured data formats and volumes pose hurdles to seamless assimilation, entrenching the gap that exists between scientific representation of fire variables (conventionally ren-

dered in schematic maps on the basis of multidimensional netCDF files) and their on-the-ground experience. Representing, communicating and gauging the complex nature and vast scale of wildfires is therefore difficult for expert and general audiences alike. Consequently, despite its increasingly central role to planetary ecologies, wildfires currently remain abstract to the human imagination, primarily represented visually through remotely captured imagery, graphic models, news feeds and secondary effects such as smoke and scorched flora and fauna. This constrains effective engagement with the terrestrial forces that are shaping our lifeworlds and hampers our preparedness. This is especially the case in an age in which personalized engagement with visual information has become the expected norm [5].

As wildfires change our life-worlds, interactive art provides an opportunity to engage with this autonomous yet symbiotic terrestrial agency by creating virtual environments that challenge our assumptions and help us shape our dynamic relationship with its ongoing evolution.

Engagement of the Terrestrial in Current Artistic Paradigms

Art has played a key role in shaping our experience and application of fire, providing a conduit for the exploration and development of human and terrestrial relations. A pivotal figure within Modern Art has been Joseph Mallord William Turner (1775-1851) who conceived fire as a dynamic thermodynamic process, dissolving all matter and representational forms through its fiery energy [1]. For Turner, fire presented as an all-encompassing phenomenon, fueled by the birth of the Carbon Age through the Industrial Revolution. Aesthetically, he explores a terrestrial agency that is leveraged in a feedback loop with the human and makes the unleashing of matter's thermodynamic potential the focus of representation [13]. These representations leap beyond the frame of the canvas, challenging its material underpinnings. At other times, they implode, demolishing conventional optical perspectives. Turner's painting *The Burning of the Houses of Parliament* (1834/35) shows London's center of political power ablaze, an uncontrollable agent in its own right, at war with the fabric of human society, generating a moment of radical uncertainty in which human agency is confronted with an entirely autonomous and alien planetary agent. The scene is captured from a distant perspective, allowing viewers to take in the scenario in its expansive breadth – with flames erasing the built structures, engulfing their surrounds and welding river, streets and sky into an indistinguishable whole whose blazing energy radiates outward and draws all focus into the fiery maelstrom at the image's center. Turner's 'pyrotechnical canvases' [12] shifted terrestrial agency centre stage. While laying the foundation for the modernist aesthetic that disintegrated figuration into an atmospheric flux, he simultaneously initiated an entirely new aesthetic cosmology that prioritized terrestrial agency and its disruptive turbulence [3]. His work changed the aesthetic paradigm by taking us inside the destabilizing dynamics of this agency, rather than picturing it from the outside.

More recently, contemporary art has made powerful ad-

vances in the depiction of fire-laden landscapes. Installations like David Claerbout's evocative *Wildfire (meditation on fire)* (2019/20) immerse viewers within an all-encompassing visual field. This computer-generated video projection reconstructs a fiery forest landscape across large-scale screens. Using slow-paced panning across images of a blazing fire ground, it reorganizes spatial perceptions of the firescape. Positioning viewers in a 3D-modelled landscape of a fictional wildfire, it enables deep contemplation of the spectacle through a reconstructed scenario, amplifying the concept of a fluid materiality despite its adherence to a hyper-realist representational approach. The friction between the rendering that embraces recomposition as aesthetic principle and the passive visual articulation of the firescape, constrains the terrestrial as a stable and mute object. Viewers here partake in an expanded experience of terrestrial energy through immersion within a space that sensorially invites contemplation of an optically mastered fire [7].

The meditative qualities that stem from the artwork's large scale and durational composition, contrast markedly with the frantic energy conveyed through on-the-ground visual documentations of wildfires, as for example evident in the award-winning work of Matthew Abbott for the Australian photographer collective Oculi. Captured at the flanks of megablazes such as the Currowan Fire near Lake Conjola (NSW), Abbott's iconic coverage of the 2019/20 Australian Black Summer documents firefighting efforts at close range. It provides affectively moving accounts of devastation through detail-rich compositions and stark contrasts that visually transport the viewer into the unfolding crisis. Terrestrial agency here is documented as a ferocious impact, made accessible to human contemplation as a visual spectacle. This aesthetics limits the terrestrial to being a static observational object, affirming the supremacy of the human gaze.

While the works of Turner foreshadowed an entirely new understanding of fire as a destabilizing actor, Claerbout and Abbott tend to depict fire as a dynamic event able to be mastered by the human gaze and its technologies. While imbuing fire with force, they render it passive and immobile rather than an unfolding and unanticipated force. As such, their capability to aesthetically express the non-linear autonomy and unpredictable agency of terrestrial phenomena is inherently constrained, capturing as they do a mute tableau of interacting forces whose combustion is frozen in time and space. The centrality of human agency remains the dominant framework through which the planetary lifeworld is conceived and experienced.

Proposal for Terrestrial Aesthetic Framework

Representing wildfire agency as more than an inverted imprint of our human gaze requires an aesthetic framework that can respect and embody its autonomy. It demands the modelling of kinetic and multidimensional terrestrial spatial processes, which cannot be understood by human cognition alone, requiring an AI system able to visualize the complex processes involved. This would integrate the speed and scale of AI in establishing patterns and predicting behaviors with the subtlety and adaptability of human situational understanding and decision making. It would provide autonomy to the

fiery landscapes, so they can follow their own logic and behave as independent agents. This would provide the means to embody compelling scenarios that enable viewers to sensorially engage with dynamic wildfire events. By enfolding and scaling a section of this fiery turbulence, such an aesthetic framework would enable researchers and users to imagine spaces where they can collectively experiment with this disruptive planetary agency.

Under the direction of Australian Research Council Laureate Fellow Dennis Del Favero, a research team at The University of New South Wales's iCinema Research Centre is currently collaborating with artists, AI and fire scientists, designers, programmers and social psychologists, firefighters and planners across a range of organizations. These include the Australian and New Zealand National Council for Fire and Emergency Services, Data61 of the Commonwealth Scientific and Industrial Research Organisation, San José State University's Wildfire Interdisciplinary Research Center, The University of Melbourne and the Spanish Pau Costa Foundation. The aim is to develop an immersive visualization environment capable of rendering complex wildfire dynamics in real time. Titled *iFire*, it uses a virtual setting consisting of an AI fire-laden landscape that evolves interactively with users and translates these interactions into changes to its appearance and behavior. The team has scripted a database architecture that automatically extracts netCDF file input from the fire modelling software *SPARK* and *WRF-SFIRE*, using field data from recent mega-blazes across the USA and Australia, translating these into dynamic scenarios simulated through the *Unity* game engine. This historical data will be used as a training ground for an Artificial Intelligence and Machine Learning Framework which will analyze patterns among documented fire variables, using these to model a library of wildfire behaviors from which an infinitude of new possible scenarios can be algorithmically sampled. These will be played out in a high-fidelity custom 3D environment, displayed across a range of networked immersive systems, from 360° cinemas, wall screens, head-mounted displays to laptops (Figure 1). The 360° 3D cinemas on their own will enable full-body and full-circumference interaction between multiple users and the intelligent fire-laden setting, where the setting interprets a user's corporeal and kinetic behavior and translates this into visual changes in its behavior. It will enable users and 3D setting to interact with one another by rendering users as avatars and the setting as a landscape. Motion tracking of user actions and the translation of AI decisions will create dynamic and responsive interactive scenarios which incorporate behavioral changes by the users and setting as they interact.

This architecture will provide the means to experimentally prototype a co-evolving and open-ended aesthetic between human agents (represented through the user) and a simulated terrestrial agency (articulated through the AI landscape). Co-evolution means that the two agencies are engaged in a reciprocal feedback loop, mutually transforming each other through intelligent and adaptive response to one another's input [11]. The intelligent fire landscape system will be programmed to generate unpredictable scenarios that confront the users with ever new developments, allowing users to en-

Figure 1: The *AVIE* 360-Degree Cinema ©iCinema Centre

gage with an unfolding wildfire that morphs under varying climatic conditions. The full-body immersion enabled by the *AVIE* cinema will allow for deep sensory immersion within the digitally reconstructed image field, leveraging the advantages of the fluid materialities afforded by the digital that can dynamically generate terrain in real time. Through animation and non-linear progression, in which both human and AI agencies act and respond according to their own goals — rather than through a simplistic immediate binary cause-and-effect structure — autonomy and co-evolution are engaged, enabling users to expand their situational awareness and decision-making capability. Just as human actions have accrued cumulative effects on terrestrial systems, for example, by burning fossil fuels, the *iFire* visualization system will incrementally reflect the impacts of a multitude of user interactions. As in the physical world, the AI visualization will do so in a non-linear way, executing actions according to their own logic and factoring in user response. By interactively exploring and transforming the dynamic range of possibilities involved, it will offer a new genre of collaborative human and machine co-creativity through which they will be able to compose a wide spectrum of previously unanticipated and mutating fire landscape encounters. In these encounters, both agencies are autonomously framed, engaged with the uncertain tension generated by their mutually indeterminate yet independent behavior.

Conclusion

By deploying immersive and intelligent technologies within a terrestrial aesthetic, the *iFire* project generates an opportunity to prototype an open-ended exchange between human, machine and terrestrial agencies. While building on advances in art to engage the non-linear aesthetic potential of pyro-

convective processes, it utilizes an advanced human-machine partnership as a way of exploring the larger terrestrial systems in which they are embedded. Its novelty resides in integrating scientific data and sensorially compelling experiences to enhance insight into and engagement with highly complex pyroconvective processes [7]. Imbuing the fiery topography with its own intelligence enables the experiential exploration of unforeseen pyroconvective impacts whose constantly evolving processes defy human-centered logic. *iFire* enables us to reimagine such extreme scenarios to prepare us for the Possibles to come.

Abstract

Over the past decades, the development of technological equipment and the arrival of the *Digital Era* have generated numerous artistic products that integrate technological devices and that have lesser durability than other traditional cultural objects, such as Media Art Installations. The field of Art Preservation, responsible for safeguarding the collective knowledge heritage artefacts contain, is facing new challenges, and the solution lies in applying innovative strategies all the way through the life of the artwork, starting in the acquisition stages. What should we as art conservators consider when performing feasibility analyses in the acquisition of technological artwork? This paper analyzes the fragility of this art-science intersection with the aim of establishing preservation strategies that ensure the viability of this type of artworks in an institutional environment.

Keywords

Media Art Installations; Obsolescence; Change; Preservation; Feasibility

Introduction

Media Art Installations are groups of elements -in this case, related to technological objects like computers, cathodic-ray TVs and such- that work together as one with the space they are displayed in and have the purpose of introducing spectators to a particular experience. The traditional idea of the one-of-a-kind object is expanded in this type of artworks [1] since they exist somewhere between performance and sculpture [2].

Regarding its preservation, we need to think about technology, which in this scenario is no longer a tool but a medium [3]. Therefore the devices may convey the intention of the artists and be an essential part of the artwork's materialization, which means that conservators will have to take care of their inherent fragility and obsolescence [4]; in other cases, these elements will be considered as consumable or replaceable [5]. On the other hand, we also need to take care of intangible aspects and figure out if the environment where we display the installation is adequate and how will we enable users to interact with it¹

The nature of these artworks, where some elements are fungible based on their relationship with the immaterial values of the installation, allows for a reflection on changeability and variability, a complex conceptual tool that can give conservators an interesting advantage in the race against time and heritage loss.

Change as value: possibilities against obsolescence

The conversation around change is commonplace in the discipline of art conservation, and therefore there are several theoretical positions on the subject.

Historically, we identify good change with *patina* [6] and bad change with decay; in the first scenario, the item acquires new values -usually related to the ideas of aura and historicity-; in the second one, the item loses originality, integrity and subsequently authenticity [7]. But what happens when change is a part of the artworks essence or can be applied to some of its elements?

In her 2017 book *Paik's Virtual Archive: Time, Change, and Materiality in Media Art*, Hannah Hölling shares a reflection on this topic. From her point of view, one we also share, multimedia installations have the potential to transform their appearance and constitution, depending on the space they are settled and the degree of spectator's participation. This change could even mean that the work of art is no longer what it was but has acquired a new ontological condition, as it happens, for example, with Nam June Paik's installation *Zen for Film* (1965), which is now a relic and a static artefact [8]; that is what she calls *changeability*. Additionally, we should also speak in these installations about *variability*, the degree of applicable change within a particular range that sets the artwork's identity and integrity outside of which the item is no longer the same. This type of change could then be considered valuable for the work of art if made inside a reasonable range of action rather than a risk [9].

To apply preservation strategies related to variability, every media art installation should, of course, be evaluated individually. In the last few decades, some ideas around art conservation have clearly shifted, we have overcome the relationship between matter and identity, and now the work's essential properties lie in the relation between material and immaterial elements and their link with conceptual values -such as artist's intention or social context representation- that should be defined and documented thoroughly and will be the basis of our practice [10]. As David Garetta states: *being able to understand a piece of information is meant that one can do something useful with it* [11].

Once we have a clear idea and score of these essential parameters, we can apply different strategies, ranging from the smallest degree of variability -with storage or data migration- to a medium degree -emulation of an old appearance made with new materials- and even a full re-interpretation and reconstruction of the work [12].

Possibilities seem endless, but where do we draw the limit, and perhaps most importantly, when do we have the ideal degree of knowledge to make an informed decision?

¹ It is to be noted that with interaction we don't always mean physical interaction, but a participatory observation; as the media artist Antoni Muntadas states: *perception requires involvement*.

Feasibility of Best Media Art Installations: the start of preservation

To ensure the survival of this type of heritage, documentation should be performed throughout the entire existence of the artwork, ideally starting in the ideation and production of the installation. This is why collaboration between artists and conservators has been advocated as a fundamental for good praxis [13], either through consulting in the development of the piece or via subsequent interviews [14]; however, this is not always possible.

The second-best scenario would then be the acquisition stage, which differs from one institution to another, although it would perhaps be beneficial to develop some standard procedures for media art installations [15]. In this phase, conservators must work collectively with other stakeholders, such as engineers, curators and even lawyers, in a multidisciplinary team since we are also dealing with an interdisciplinary item. They will have to reflect on the physicality of the installation, both software and hardware, in order to maintain its functionality [16]; provisions should be made for the need for technical equipment, physical and virtual storage space and others. It is also to be considered some other collateral aspects to the artwork, such as property rights or the overall cost of maintenance or auxiliary equipment for viewing and checking the state of preservation of the works

The feasibility of the work inside the institution will also rely on musealisation, the level of adaptation of a work of art to the demands and policies of the institution [17]. Before a media art installation enters the museum, stakeholders should set the limits on its variability, taking into consideration not only the decay of its technical elements and the safeguarding of its immaterial aspects but also the adequacy of the exhibition space and the access we will be able to provide. This information should be reviewed every time the installation is settled, strengthening our knowledge of the artwork and pointing out the possible interpretation errors; ideally, the process should be carried out by a stable team that is familiar with the artwork.

In this scenario, it may be possible to apply variability to the maximum degree, re-interpreting the installation; a commonly known example would be *TV Garden* (1974), by Nam June Paik, a single-channel video installation that consists of a number of TVs scattered in a space filled with plants. This work was exhibited in Paik's life numerous times; therefore, it has a clear corpus of instructions that set limits for its variability, it can be executed with a new set of plants and TV, always a minimum of thirty, and if it increases to forty or more, a second video channel may be added [18]; with the agreement of the artist, *TV Garden* has always been re-installed with CRT TVs, sometimes with emulation techniques by inserting flat screens in the CRT frames [19]. Another interesting example would be *Transmission Tower: Sentinel* (1992) by Dara Birnbaum, which underwent a more visible transformation as CRTs were replaced by flat screens, also with the artist's permission [Fig. 1 & 2]. Although they look like similar installations, both have been re-installed and have gone through a similar degree of variation; conceptually, both changes have had a different effect. In the first case, Paik's garden reflects on the naturalization of technology, which dies and is replaced like the plants that surround it in a never-ending cycle. Since technology surely develops continually and rapidly, conservators could -hypothetically speaking- substitute TVs with new elements of our technological second nature like mobile phones or tablets. Contrarily, Birnbaum's statement is a critique against TV broadcast as a mass media, a situation that no longer occurs in our society with the everydayness of the Internet. Even with the au-

thorization of the artist, media art conservators should be careful, and reflect on the consequences of variability in the future knowledge of the artwork, if it suffers too much change, we could be damaging its immaterial values, recasting the installation into a caricature of what it once was [20].

Fig. 1. ©The Arcillect, *Transmission Tower: Sentinel*, 1992, <https://twitter.com/archillect/status/1005469591701803008>.

Fig. 2. ©Marian Goodman Gallery, *Transmission Tower: Sentinel*, 1992, <https://www.mariangoodman.com/artists/32-dara-birnbaum/works/40252/>

A third scenario is also a common situation in the preservation and exhibition of media art installations: removing the artwork from storage without access to the artist's opinion and without documentation analyzing its variability; in this case, we should apply a historical perspective and limit changes to those that maintain the functionality of the work, unless we have a clear set of instructions with different directions.

Conclusions

As we reflect on the context and effect of Media Art Installations and accept its variability, we are also shifting the point of view from a so-called *freeze-frame* paradigm -that pursues to secure the object in an illusion of eternal steadiness- to an awareness of future possibilities and evolving identities [21].

The limits to this variability and changeability of the artwork should be decided as soon as possible, taking into consideration not only physical elements but also immaterial values. It will be impossible for the conservator to completely recognize the threats to the piece's future presentation or to comprehend which features of the piece may alter and to what extent, if he or she does not thoroughly comprehend its key attributes.

This is decisions should be taken in the present, especially in the acquisition process -when we are able to communicate with more ease with the artists and comprehend better their intentions- in order to ensure the feasibility of the installation in the institution, but also be reviewed every time the piece is settled if there are new possibilities to apply.

KÖDOS: multiple investigations through art, science, and technology

Abstract

The artistic poetics produced related to science and nature increased prominence as they incorporated political, technological, and social changes into their discourse aware of the environmental crises and their connection with the capitalist economic program. Hitherto, the union between artists and scientists has inspired works that, in general, incorporate new forms of organization between organic systems, technologies, and symbolic processes. Many contemporary artists conduct their projects through multispecies collaborations and work with a high potential for questioning and formulating non-hegemonic knowledges. This paper focuses on the recent KÖDOS experiments, a Brazilian art collective, which aims to investigate the visual poetics in relations with non-human organisms (living and non-living) and technologies to provide alternative and speculative models to inhabit the Earth. KÖDOS is composed by Claudio Filho and Fernanda Oliveira both members of ACTlab - laboratory for arts, science, and deviant technologies hosted at Universidade de Campinas (UNICAMP), Brazil.

Keywords

Anthropocene; Art; Science; Technology; Ecosystemic Intelligence.

Introduction

The New Climate Regime and the transformations that outcomes with the concept of Anthropocene had instigated several research in the arts, science, economy, and philosophy areas. The term broadly stands for analyses and practices, which question the boundaries between men, culture, and their own environment of centuries of European-centralized thinking. The Anthropocene easily assumes a broad scope with the potential to include multiple and complex postulations; However, assorted nomenclatures diverge to its main features: Anthropocene – from the fossil fuels industry [1]; Plantationocene – with the exponential commercialization of agro commodities [2]; Capitalocene – delimited by the capital era [3]; Cthulocene – as a process that integrate the humans and non-humans' dynamics [4], and so on. The Italian scholar Rosi Braidotti highlights the “post-Anthropocene” as a critical process about these various definitions. By including the prefix “post”, according to her, we are delimiting alliances with living beings, science, sociability, power dynamics and technologies [5]. In similar circumstances, Ulrich Beck points out in *Risk Society: towards a new modernity* the prefix “post” used as a key word of our times:

“It hints at a 'beyond' which it cannot name, and in the substantive elements that it names and negates it remains tied to the familiar. Past plus post - that is the basic recipe with which we confront a reality that is out of joint” [6].

Both uses can guide our perceptions about the Anthropocene: a political place that can only succeed through some no-holds-barred wrestling against the old theories and conventional ways of thinking, whose life has been artificially prolonged by the word 'post', and at the same time delimiting new forms of relationship with the Earth.

Taking the “post-Anthropocene” as a guideline, this paper proposes a discussion about some ideas that surround the human, non-human, other-human intelligences in the art field. The study of artworks allows us to imagine other possible relationships with the systems of nature, technology, and society nowadays. The aim is to articulate these notions with other non/other-European perspectives between pre and post Anthropocene intelligences that operates in the merge with Ancestral knowledge expressed by Amerindian thinkers as Davi Kopenawa, Ailton Krenak, Viveiros de Castro, and the new media technologies, which directs us to an operative way to understand the poetic processes that act in these intersections.

Art, Anthropocene, and Nature

Art and Nature are topics that remain a challenge until now. However, the discussion has one of your embryos in the 1980s with the Art Ecology movement, furthermore, with a global economic crisis, artists have been becoming aware of the seriousness of environmental problems and their connection with the economic program [7]. This broadens the political-environmental engagement artistic actions related to nature. Joseph Beuys, Agnes Denes, Hans Haacke, and Jackie Brookner were some of the many artists who have engaged works between art and nature, expressing the inability of many government policies to measure the consequences of climate change for the biosphere. Recently, the focus on the manipulation of Nature and living organisms through art can be conducted towards collaborative action between human, non-human, living, non-living organisms, and technological networks. Roy Ascott's enthusiasm for wet media is updated by contemporary artists from the second decade of the 21st century. Collaborations among artists, biologists and scientists allowed others to speculate senses of life systems organizations, biological, synthetic, and symbiotic processes manipulated in the most varied scales. Artists team up with researchers and computer scientists intending to expand the boundaries of the artistic object. Some works of art “directly relate the artist to other beings and techniques, which made symbiosis its product” [8]. We can observe

these relations between art, technology, science, and nature in the works of Guto Nóbrega, Paul Vanouse, Oron Catts and specially in CESAR&LOIS collective by Cesar Baio and Lucy HG Solomon. These, among other artists, conduct provocations with a high potential for questioning and formulating deviant knowledge.

Towards to ecosystemic intelligence.

The concepts briefly explored here intend to make a poetic and speculative provocation of other operating systems that support society, ecosystems, and the Earth. In this perspective, the formulation of "non-correlational thinking" by Whitehead is significant, which, through a review by Steven Shaviro on *Discognition* (2016) was defined as a proposal or sentence for the assembling of knowledge that is not intentionally constructed from the Anthropocene dialectic: Which remains "on knowledge" when we consider the world-without-us or the autonomous reality of beings outside of human thought? According to Shaviro, speculative models of thought are manners to understand and occupy the Anthropocene's Earth:

"Speculation – fictions and fabulations – about sentience. There is something oddly recursive about this, since sentience itself is arguably a matter of generating (or being able to generate) fictions and fabulations" [9].

By speculating the organizational arrangements of non-humans with technology, we can expand the possibilities of creating operational dynamics that help us to face the obstacles of the Anthropocene. In short, the use of the presented concepts leads us to advance towards the relationship between non-human organisms, such as fungi and bacteria, with the recent digital informational systems in the contemporary art.

To exemplify what is stated above, the collective CESAR&LOIS, composed by artist-researchers Cesar Baio (UNICAMP) and Lucy H.G. Solomon (California State University San Marcos) probes the evolution of humanity's relationship with nature by advancing intersections between the parallel networks of technological, biological and societal systems. By arranging alternative conceptual models for thinking across networks, reframing the artist's and potentially viewer's understanding of what motivates and shapes society, set off important triggers. In the context of computation scale the artists criticize the intellectual and economic production systems in the form of artistic poetics.

For them, ecosystem intelligence [10] is the awareness of performative image forms in relation with hybrid systems and artificial intelligence. The ecosystem intelligence inquires the centrality of the human being as a unique model for the Nature's organization. This involves properties and dynamics that sustain life in non-human organisms, a quote almost incomprehensible or insignificant in the capitalist way of making knowledge. Ecosystem intelligence is the union of pre and post-anthropogenic intelligence that when combined can result in innovative proposals aimed at the well-being of the world [10]. Ecosystem intelligence can explore collective dynamics in a world of emergencies through the arts, organisms, technologies and life sciences:

"(...) We acknowledge the importance of the balance of biomes and microbiomes, both within and outside our bodies, and the biological linkages which connect species and creates nested relationships among whole sets of species: ecosystemic connections. These connections, if replicated within technological systems, constitute an ecosystemic intelligence, an AI that engages with a broad planetary community and which operates according to broad principles of community well-being" [10]

Figure 1 - Degenerative Cultures ©CESAR&LOIS Copyright.

CESAR&LOIS potentially see in art the possibility of producing experiments that reflect the aforementioned characteristics. The work *Degenerative Cultures* [Figure 1] operates from a collaborative model between entities that were previously understood as disconnected from or opposing their conventional logic. The work is a biohybrid agent that blurs the lines between biological and artificial intelligences. In the composite microbiological and digital knowledge network, prehuman and posthuman intelligences work together to probe the centuries-old dichotomy between humanity and nature [11]. The collaborative union of these systems makes them operate under a new perspective, engaged with nature and problematizing the Anthropocene. With the collaboration of non-human organisms active in their projects, artists, researchers and scientists become strategic mediators to elaborate forms of knowledge that challenge the Anthropocene project.

“By advocating for ecosystemic artificial intelligences (EAI), we align ourselves with the movement to decolonize knowledge, a movement that can also inform and reshape society and technology, such as those social structures and embedded technologies that for the most part still adhere to the archaic principles of a dying world. In response to this movement and its underlying broadening perspectives, we ask: how do we move forward and away from centuries of progressive thinking, in anticipation of AIs that embrace new possibilities for connected thought?” [10]

KÖDOS

The investigative approach that Art, Science and Technology studies take is against most descriptive scientific accounts of nature. In addition, the Brazilian art collective KÖDOS acts at these intersections. Conceived by Claudio Filho and Fernanda Oliveira, both multimedia artists members of ACTlab - laboratory for arts, science, and deviant technologies, hosted at Universidade de Campinas (UNICAMP), Brazil – KÖDOS often draws conversations and collaborations with other artists, scientists and researchers.

For KÖDOS, the Art, Science and Technology highlights the complex and often contradictory paths of knowledge, valuing and living with a common interest in the different forms of life in collaborative relationships. Unexpected collaborations between non-human living organisms and technology can promote a model that guides us in readings between art, nature, science and technology in the face of new impasses of the environmental crisis, information and communication theories, and the de-colonial and multispecies studies. At this point, I ask: how can the artist make it work the questions concerning the Anthropocene with the technological environment of daily life?

Technological art refers to the technical tools that artists seek, use, and create to solve problems of different kinds. These tools progress over the decades, and this makes each period have a different meaning of the use of technology [12]. Thereby, is necessary to analyze works that use technological devices, such as computers and databases, given heed to their historical, geographic, and political context as part of the post-Anthropocene perspective. The use and manipulation of data have been a topic of wide discussion nowadays, as the increase of data with social networks that we continuously produce at each digital interaction through sharing, accessing websites, messages, posts, likes, research, etc.

Figure 2- Data-River, ©Kōdos
Copywrite.

In this scenario, the exploration of databases become a place for artistic exploration.

Technological devices participate as agents to give visibility to what is not visible, or difficult to see. The work *Data-river* [Figure 2] by KŌDOS proposes an environment that is built across multiple interactions. *Data-river* tries to unlimit the gesture imposed by technological mediations and its implications on the body as collective regime and in the processes of co-learning between humans and non-humans. The work seeks to re-signify human-data-landscape relations, intervening in the code of operation of digital images. What the artists propose was a resumption of attention to these invisible images operations. The method was to subvert the geolocation logics (real coordinates in physical space) of rivers' photographs presented in databases and include them as decentralization vectors on the programming of a digital image (virtual space code lines) through the software P5.js. The entire layer that makes up the images is understood by codes, and the results are abstract images in which the disruption of pixels programmed from the numerical data of geographic coordinates reveals their movement and disruption in the automatic processing logic of digital images. The work is presented in a format that highlights the hybridity of the image located on the boundaries between photography and landscape. The paradox of the presence

of technology in the environment is the information overload, based on the increased reach of technological products, which creates an illusion of democratic access related to the evolution of the acquisition of digital communication devices.

Conclusion

How does the artist act in the field of multispecies studies and what articulations does he provoke by involving non-human entities in his poetics, procedures, and discourses? The artworks briefly narrated here acts with the force of contestation and to reconfigure our thought of technologies, beings, and environment in the 'post-Anthropocene'. Therefore, contemporary artists articulate current notions of nature, Anthropocene, and multispecies studies, often integrating living organisms and technological systems, to update the production of previous decades through poetics and criticism based on multidisciplinary collaborations. The exploratory link between the activities of CESAR&LOIS and KŌDOS collectives are carried out through collaborative strength, manifestations that propose to fable multispecies landscapes together, which conflict with scales, disciplines, perceptions and affectations on Earth.

Polyphonic Materiality in Extended Reality

Kate Geck

RMIT University
Narrrm/Melbourne, Australia
kate.geck@rmit.edu.au

Abstract

Much human-computer interaction design (HCI) research on materiality investigates the ways in which computational qualities become embedded within physical materials, often under the banner of ‘the material turn’. With the development of extended reality (XR) and the emerging metaverse, how might we understand and articulate the qualities and agencies of digital materials as they overlay, embed and replace the physical world? This paper advocates for an ontology of digital materials to understand how they actualise in the world without being tangible, providing a way for XR designers and artists to critically work with them as part of an assemblage. It will introduce an idea of polyphonic materiality, drawing on Anna Lowenhaupt-Tsing’s concept of polyphonic assemblage. It will locate digital materiality within Giles Deleuze’s idea of the virtual and actual, and Karen Barad’s concept of agential realism. This provides a conceptual underpinning to the proposition of polyphonic materiality as a typology for doing XR design, where material properties emerge as various physical and digital processes coalesce or intersect.

Keywords

Extended Reality, Materiality, Polyphony, Assemblage.

Introduction

Contemporary computing is increasingly entwined with physical materials through the Internet of Things and smart materials. Much human-computer interaction design (HCI) research on materiality investigates the ways in which computational qualities become embedded within physical materials, often under the banner of ‘the material turn’. [1], [2], [3], [4] With the development of extended reality (XR) and the emerging metaverse, how might we understand and articulate the qualities and agencies of digital materials as they overlay, embed and replace the physical world? Our ongoing tangible experience with the physical world platforms a generally well-developed appreciation of the forces, affects and properties of physical things. The sensorial qualities of physical things

mingle with practical, cultural and aesthetic considerations. We attune to the supply chains of physical materials to understand how sustainable and ethical they are. Yet digital things foremost appear to us as mediated representations. Coupled with metaphors that tend toward the immaterial, it becomes difficult to position their affective capacities and qualities. So how might we begin to describe and discuss digital materiality in HCI design? Speculative films can do well to critically illustrate the atmospheric, lived experience of the digital materials in XR such as Keiichi Matsuda’s 2016 ‘Hyperreality’. [5] Such films help to visualise the nascent relations between digital and physical materials as experienced by humans. Science and Technology Studies provide precedents for materialising the intangible relations of people, actions and systems through Practice Theory and Actor Network Theory. Mikael Wiberg proposes interaction itself as a material, one which transcends categories of the digital and physical. [6] In these propositions, any materiality of the digital is folded into human-computer assemblages. It manifests *as* a relation; a critical concept, but one which does not specifically address what digital materiality itself may be within that relation. We have language to describe the social, the physical - even the atmospheric. Yet with the increasing incidence of mixed reality and immersive virtual environments, it seems timely to wonder specifically about the affective capacities and qualities of digital materials like 3D objects, images, posts, and videos as well as the interface elements, code and design patterns that present them. This paper advocates for an ontology of digital materials to understand how they actualise in the world without being tangible, providing a way for XR designers and artists to critically work with them as part of an assemblage. It will introduce an idea of polyphonic materiality, drawing on Lowenhaupt-Tsing’s concept of polyphonic assemblage. It will locate digital materiality within Deleuze’s idea of the virtual and actual, and Barad’s concept of agential realism. This provides a conceptual

underpinning to polyphonic materiality as a typology for doing XR design, where material properties emerge as various physical and digital processes coalesce or intersect.

Polyphonic materiality

Extended Reality (XR) encompasses a nascent suite of technologies and devices that enable augmented, mixed and virtual reality. Each of these extended realities intersects the digital and the physical in different ways. In this paper, digital materials are considered as the projected and presented media that manifest during an interaction with technology. A non-exhaustive list includes images, 3D objects, posts, videos and interface elements, and these naturally are connected to the design patterns and code that manifest them. As XR technologies continue to develop into physical space, working from a material perspective might assist to understand what atmospheres and effects may emerge when the digital entangles with the physical world as mixed reality, or immerses us within virtual worlds. Polyphony provides an interesting metaphor to both assemble and appraise this materiality. A musical term, it speaks to both the collective and the individual. Multiple rhythms, melodies or tones operate as independent voices that together produce a unity. Polyphony can suggest harmony, but it is different structurally and conceptually to a purely harmonic pattern. A homophonic harmony sees all of the voices in the collective operate in service of a single, key melody as in Figure 1. Polyphony lets multiple voices collect together as a single texture: maintaining their independence while still suggesting connection and interplay. You can listen to these voices separately or collectively, and importantly you can keep moving between these listenings. [7] Interaction design has spent much time in tune to what might be seen as a homophonic harmony, where the digital is forever in service to the ‘real’ or physical world. Yet with such an entangled or imbricated [8] play of digital and physical materials in contemporary culture, it no longer makes sense to separate the two [9] or to place one above or in service to the other.

Figure 1. Homophony and polyphony as 2 examples of Musical Textures (Kate Geck, 2021).

The material turn in interaction design has seen a greater attunement to the physical properties of interactive objects, as well as a greater understanding of the complex ecologies they exist in. Tending to physical materiality allows us to examine how sustainable a material may be in terms of its life cycle, its supply chains and the labour practices entangled with its production. Working from a position of materiality thus allows designers and artists to relationally position things, people, time, and space within an assemblage. Drawing the digital into this assemblage might further enable designers to understand the ecologies within which digital materials sit: we can think about the aesthetic and sustainable aspects of digital materials such as the atmospheres that emerge and the resources involved in their manifestation. Tsing conceives of assemblages as ‘open-ended gatherings’ noting that they ‘allow us to ask about communal effects without assuming them’. [10] She sketches the diffractive conceptual usages of assemblage, before offering polyphony as her divergence. Relevant to interaction design, her concept of assemblage is centred in a notion of encounter. ‘Ways of being are emergent effects of encounters’, gesturing to the net effects that may exceed the sum of parts within an assemblage and asking ‘how do gatherings sometimes become happenings?’. [11] Bennett further discusses the emergence of effects within an assemblage. Working through the lens of a ‘vibrant’ materiality enables her to flatten the hierarchy of actors, parts or things within the assemblage, advocating for its collective agency:

“Assemblages are not governed by any central head: no one materiality or type of material has sufficient competence to determine consistently the trajectory or impact of the group. The effects generated by an assemblage are, rather, emergent properties, emergent in that their ability to make something happen (...a blackout, a hurricane, a war) is distinct from the sum of the vital force of each materiality considered alone. Each member and protomember of the assemblage has a certain vital force, but there is an effectivity proper to the grouping as such: an agency of the assemblage”. [12]

XR can be seen as an assemblage where our encounters with digital and physical materials is polyphonic: we interact between physical objects and digital interfaces. Materiality itself in these encounters is polyphonic: the sensation of the screen or projection connecting with the form, colour and composition of the digital interface; the pattern of an endless scroll connects with the form factor of the phone in the hand and the compositional qualities of the digital materials on the screen. Polyphony provides a useful metaphor for thinking about our engagement with materialities in interactive experiences. Situating XR

design thinking within a polyphonic assemblage of materiality allows us to attend to different rhythms, tempos and voices, attuning to the conditions and effects of their manifestation without preferencing either the digital or physical.

Furthering an ontology of digital materiality to uncover agency of the intangible

Yet still, the materiality of the digital is difficult to grasp. It cannot be touched by human skin, and so, a binary emerges: the physical world is ‘real’ and here, while the digital is ‘not-real’ over there. We work within nebulous webs, nets, clouds, and ethers; while in everyday vernacular the virtual itself describes the almost. [13] These barely-there metaphors shape networked spaces in the periphery as shadows, making it hard to understand their material effects in the world. But, like shadows, network ethers are atmospheric; they obscure, cloak and cast affect on the bodies that entangle with them. Acknowledging the digital as a material with qualities and capacities could help to better understand its atmospheric effects on humans and non-humans alike; particularly in light of mounting evidence on the psycho-social effects of interface culture. In talking about materiality in HCI, Wiberg remarks that ‘despite growing interest in smart materials and increasing capacity to treat computers materially, we have yet to transform our thinking about the ontology of atoms and bits’. [14] Fundamentally, this concern applies to the nature of the digital, to understanding or even conceptualising its materiality in the face of its intangible nature. How then might we conceive an ontology of the digital to enable it to find an active position within the polyphonic assemblage?

First of all, dismantling the conflation between real/physical and not-real/digital is necessary. Arguably, this conflation occurs due to differences in tangibility of the physical and the digital. Because the digital has no ‘tangible matter’ its ontological status is greatly reduced. Deleuze’s concepts of the virtual and the actual are useful here, where despite their differences in tangibility both are conceived of as ‘real’. The virtual is as real as the actual, existing as a suite of intensities that manifest within all materialities. [15], [16] This concept removes tangibility from the condition of realness. Importantly, it provides a way to consider the materiality of the algorithm. An algorithm may represent many virtualities, and through its meeting with users and data, it actualises particular conditions, qualities and events. This idea connects with Karen Barad’s agential realism. Drawing on the slit experiment in quantum mechanics, where the appearance of matter changes depending on the way in which it is measured, agential realism posits that an apparatus

produces ‘cuts’ in reality as it intra-acts with particular materials [17]. Algorithmic material futures thus emerge when the agency of the algorithm actualizes particular realities [18]. In this way, Deleuze and Barad provide a conceptual underpinning to position digital materiality as an agential force that transcends tangibility.

Relations, encounters and atmospheres forming through the digital

We can suggest an ontology for the digital, agreeing that it is ‘real’ and in many cases, agential and we can situate it as material within an assemblage, conceiving that materiality itself is polyphonic and discursive. How then might we describe, categorise or address the qualities of materialities that are digital so that we can design with them? In this paper, digital materials refer to images, videos, posts, interface elements, code, and design patterns. This is an initial scope, and should be further interrogated through ethnographic investigation and the development of a taxonomy of digital materials. From this initial scope, digital materials can already be seen as always part of an assemblage. This is a critical way to conceptualise them: images/video/posts manifest through interfaces and code in their production, presentation and consumption. Therefore, digital materials emerge through design patterns, and these design patterns entangle directly with algorithms and data. Typically, these materials are located within an attention-extraction paradigm for doing design, creating design patterns that hook users in and use their data traces in exchange for profit. This is the paradigm on which the metaverse is being built. We can presume many digital materials will continue to exist in a highly relational way to the user, as part of a personal assemblage: images from people we know, people we follow or from things we have searched. A differential force emerges in the digital - these images are both parsed and produced in relation to ourselves. Particularly in the case of targeted ads, digital images appear because of traces of ourselves in data patterns and reinforce certain moments of previous interaction. The nature of encounter with these digital images is fundamentally different to the ways we would encounter equivalent moments or vignettes in the physical world. This is coupled with the infinite nature of their emergence and their capacity for real time modulation. Digital encounters can be stored, they can produce atmospheres that can be ongoingly modulated by information, and they can be highly relational, even targeted. The forces of emergence that produce digital materials are different to those that produce physical materials. As such, one way to draw out the qualities of digital materials might be with reference to attention, allowing us to understand how they are algorithmically attentive to us. Some qualities of digital materials might

include the way they are ‘targeted’. This might be with reference to the self: digital materials might offer ‘improvement’, ‘distraction’, ‘belonging’ or ‘difference’. Under this attentiveness, some qualities might reference ‘temporality’: ‘rhythm’, ‘duration’, ‘tempo’ with respect to the cadence of the digital manifestation and individual schedules. Digital materials could be considered through their formal material properties like transparency, saturation and blending. Their motion or animation could also factor in here. Digital materials have uniquely emergent properties such as generative forces of modulation as well as degrees of malleability/customisation. These are only speculative ideas, but offer opportunities for further investigation for HCI researchers, artists and designers to better understand what qualities might exist in digital materials that make them different to physical materials beyond tangibility, and help to identify and design with their affective force.

Conclusion

There are many calls at present to address the targeted algorithmic appearance of ads and news feeds. The

MEDIA ART AND FACE RECOGNITION: CRITICAL LINE OF WORKS

Paloma González Díaz

BAU, Centro Universitario de Artes y Diseño de Barcelona

Location, Barcelona (SPAIN)

Contact Emails: pgonzalezd@uoc.edu / paloma.gonzalez@bau.cat

Abstract

In recent years, Media Art practices related to facial recognition reflect present concerns about AI in general and facial biometrics in particular. The ambiguities, biases and lack of ethics present in the development and implementation of facial recognition techniques is present in pieces and essays by creators determined to reveal the lack of ethics and transparency of these mechanisms of classification and control. Artistic spaces and festivals are beginning to support and make these kinds of issues more widely visible.

At present, we distinguish three lines of critical work: those that attempt to "annul" the effects of technology, those that show how detection algorithms work, and a small group, more experimental and less fruitful so far, made up of works that propose to reinterpret the uses of technology more in line with social needs.

Media Art and face recognition: lines of work artistic practices

Facial recognition technologies (FRT) make it possible to verify the identity of individuals through the still or moving image of their face. Its popularisation in recent years, associated with a worldwide pandemic that has led to remote contact, began to develop in the 1960s led by Woodrow W. Bledsoe. The project, although somewhat rudimentary, leads to further research to train machines to recognise human faces (Hao 2021). Today, experts around the world are warning us that what appeared to be a great and beneficial investment in the short term may generate social problems due to the biases detected in many of the algorithms, and with ethical risks that have not been studied in depth (Goffi 2021). Research such as *About Face: A Survey of Facial Recognition Evaluation studio*, which studies over a hundred facial recognition datasets created between 1976 and 2019, concludes that the data collected is biased by political evolution, technological capacity, and revision in standards (Raji and Fried 2021). The rapid evolution of the systems in recent decades has obviated their restricted practice for very specific uses, resulting in an excessive application that is very difficult to control. Debate has been eliminated and energies have been devoted to the implementation of these systems without assessing their limitations, their scope or the importance of using historical information to predict the future of any citizen (O'Neil 2017) to communicate any evaluation process. Other wide-ranging research such as Gender Shades assesses the (in)accuracy of AI-driven gender classification products, revealing the need "for

greater transparency in the performance of any AI products and services that focus on human subjects" (Buolamwini and Program in Media Arts and Sciences (Massachusetts Institute of Technology) 2017) [1] Gradually, such fundamental issues as privacy and ethics have been overlooked.

Both governments and companies have entered a globalised market in which neither the rules nor the interpretations of the tool are made according to the same scale of values. The use of facial recognition techniques differs between countries such as the United Kingdom, the United States and the European Union. Faced with this lack of definition, in 2020 the European Parliament approved three proposals to regulate AI "in order to promote innovation, ethics and trust in technology" (European Parliament 2020) [2]

Media Art Criticism: lines of work.

Media art criticism of facial recognition technologies (FRT) is not emerging at present. Practices that question their use form a specific group within biometric art proposals focused on denouncing the limits of Artificial Intelligence. All of them are the result of the evolution of prevailing methodologies and tools in the last decade of the 21st century. They include, among other basic issues:

- How governments have had to manoeuvre along with large companies to perpetuate their power (Zuboff 2020) [3]
- Changing perceptions of ourselves, as well as our environment, as a consequence of the accelerating digital transformation - accelerated during the pandemic - have devalued our sensitive capacities. (Sadin 2018, 278) [4] This change in perception takes its toll on our privacy.
- Adapting to such a context of uncertainty, with such marked patterns, means that critical voices become blurred in a world overwhelmed by incessant digital inputs.

Multidisciplinary creators such as Trevor Plagen, Adam Harvey, Joy Buolamwini and Paolo Cirio denounce this situation both in their artistic practices and in essays. Current exhibitions such as *Paolo Cirio. Monitoring Control* at the FMAV, which presents different pieces by the artist aimed at sabotaging security and surveillance systems (FMAV 2021) [5]; or *Training Humans* at the Prada Foundation in Milan, which reveals the evolution of sets of training images from the 1960s to the present day are examples of how art centres are committed to reflecting on the subject (Crawford, Plagen, and Fondazione Prada 2019) [6]. The Ars Electronica Festival also includes a new

section *Artificial Intelligence & Life Art* which includes projects from our field of study. Paradoxically, some of their denunciations have had a greater impact on the general public through documentaries broadcast on large platforms: *The Social Dilemma* (2019) (Orlowski 2020) [7] or *Coded Bias* (2020) (Kantayya 2020) (Kantayya 2020) [8] denounce the discriminatory failures of the algorithms that intervene in facial recognition technology. It brings together the testimonies of specialists in the study of race and gender biases reported in various articles and reports. The denunciation of the social prejudices related to AI, and the data collection systems studied by Joy Buolamwini, researcher at the MIT Media Lab and founder of the Algorithmic Justice League.

Media Art's interest in the use of facial identification is beginning to intensify and renew itself, offering differentiated lines of work that sometimes complement each other:

1. Counter-surveillance works that teach spectators/interactors how to annul the effects of facial recognition technology. The work of Paolo Cirio is a good example, but there are also works by Zach Blas or Sterling Crispin, whose proposals seemed in their presentation to be closer to science fiction than to reality. In the case of Blas: *Facial Weaponization Suite* (2011-2014) and *Face Cages* (2013-2016) are also two good examples of criticism against the standardisation and expansion of RTFs under neoliberal practices. In both cases, unrecognisable masks are generated for the logarithms. The first constitutes a collective representation of all the features of the participants in a workshop, and the second is materialised in "facial cages" that oppress the face and adapt to the specific biases of their wearers (Blas 2015) [9], with the aim of denouncing "computer opacity in the service of the state" (Lee-Morrison 2019) [10]. Crispin's *Data Mask* series (2013-2015) also reverse-engineers a tangible response based on invisible data.

2. Those that focus on revealing how it all works tend to adapt facial recognition technologies. A good example is Trevor Paglen's *They Took the Faces from the Accused and the Dead* (2019), in which black and white photographs of convicts from the database of the American National Standards Institute, used without their permission, have served as a privileged source of visual training for facial recognition systems. Their proposal attempts to change our mental schema. They show the world how algorithmic identification systems have been trained (de Young Museum 2020) [11]. Adam Harvey and Jules LaPlace's *Exposing.ai* is another good example of disclosure practice: it tells any user whether their Flickr images have been used in surveillance and artificial intelligence research projects ((Harvey and LaPlace, Jules 2021) [12]. In *Humans of AI* (2009/2021), artist Philip Schmitt acknowledges authorship of the 34,248 Flickr images that make up the COCO Image Dataset and offers a certificate for the collaboration. This group also includes simpler proposals such as *The Flemish Scrollers*, 2021, by Dries Depoorter, in which the faces of Belgian politicians who use their mobile phones while attending parliamentary sessions are automatically tagged.

3. A small group, more experimental and less

fruitful so far, is made up of works that propose to reinterpret the uses of technology that contribute to social welfare. Let's not forget that facial recognition systems are actually neutral. It would be interesting if digital creation were to make a commitment to investigate this aspect in depth. Rafael Lozano-Hemmer's *Level of Confidence* (2015) is perhaps one of the few examples in which an algorithmic project proposes a new line of work using a facial recognition camera. The interactive piece has been trained with the images of the 43 students abducted in 2014 from the Normal Rural School of Ayotzinapa in Iguala (Mexico). Their disappearance remains a mystery to this day. So Lozano-Hemmer's proposal becomes a constant search for the protagonists among the facial features of the audience. An act that merely intends to maintain their story in our collective memory. (Lozano-Hemmer 2021) [13] These kinds of practices help to empower both creators and spectators about other functions of a technology that continues to maintain its essence as a tool of control, but which can undoubtedly address new challenges of global transformation.

Conclusions

Critical media art with regard to facial recognition systems, as Devon Schiller points out, can be considered an intellectual and ethical activity (Schiller 2020)[14]. These practices provide new ways of seeing how people are classified, labelled and even controlled on the basis of their face.

In times of pandemic, it is more necessary than ever to establish more robust solidarities in order to focus on combating "monotechnological culture, and to produce a technodiversity through alternative technologies and their corresponding ways of life and ways of inhabiting the planet" (Hui 2020)[15]. Undoubtedly, more information must be made available and more spaces for debate must be created. Creators cannot be the sole drivers of this change, but they can help to drive it. Multidisciplinary proposals that offer better use and results in fields yet to be explored should be encouraged without ever lowering the level of criticism regarding the lack of transparency and ethics.

The Sonic Body: creating embodied sonic performances within an extended reality context

Maxime Gordon

Concordia University

Montreal, Canada

maxime.gordon@gmail.com

Abstract

This paper presents “The Sonic Body”, a research-creation project conducted between May-September 2021 that studied methods of creating embodied sonic performances and installations within an extended reality (XR) context. I explain two prototypes created for the project, outline the strategies I used and rationale behind the design choices, and summarize the results of my research. The prototypes explore contrasting methods of engaging with sound in an embodied way: one employing the use of head-mounted augmented reality (AR) and the other muscle sensors and material interaction. As my methodology relied on a self-reflexive approach, I focus on my personal experience as an artist designing these prototypes. Two research questions guided this project and inform this paper: How can new types of interactive audio affected and enhanced by bodily movement and gesture affect the experience of listening and connection to the environment? How can such interactive listening systems be designed to better encourage this sense of connectedness? Ultimately, this paper showcases “The Sonic Body” project, conveys the findings of the research questions from the research results and offers insight into how AR and muscle sensing technology might be used to create a real-time, embodied sound art installation and performance.

Keywords

Augmented reality, sound art, muscle sensors, interactive music performance, sound

Introduction

While there is a history of audio focused AR applications there is little research in sound focused AR applications that emphasize embodied interaction for the purpose of creating a real-time sound-artwork. Furthermore, there is little research into how the affordances of mainstream AR headsets effect sonic design and interaction for embodied performance and installation.

Recent projects [1] [2] similar to “The Sonic Body” using head-mounted AR have not prioritized designing user interaction with sound from a perspective of embodiment. This project took up this design challenge and situates itself within a larger program of developing research in the area of sensory experience design for extended reality. I explored

how we could further what researcher Steph Ceraso calls “multi-modal” listening, “Multimodal listening is a bodily practice that approaches sound as a holistic experience” [3]. There is a tendency to view sound as solely to do with the act of hearing with our ears, but as explained by Ceraso, “sound is not experienced exclusively through a single sense; other parts of the body can be engaged during a sonic encounter” [4].

Preliminary findings from this project are that AR technology as it exists today is limiting for sound art performances and installations. This is not to say that the technology is devoid of interesting and novel experiences that lend themselves to meaningful sound interaction, but more research into areas such as the size and shape of the ‘playable’ AR environment could yield important results. In both performance and installation, it would be useful to further research using speaker set-ups instead of the built-in headphones in AR headsets to allow for more accessibility to the audience and non-participants. Also, bringing in bodily sensors like EMG sensors, as well as interactive tangible objects could allow for the development of more nuanced and meaningful gestures in AR sounding environments.

Research Prototypes

Experiment 01: A modular sounding environment

The first prototype was an experiment in using a person’s entire body to trigger sounds based on collision detection and proximity sensing. It was created using a Magic Leap 1 AR headset and developed in Unity using the Magic Leap Toolkit for Unity. I used Cycling’74’s Max for sound processing as well as for routing collision, proximity, and positional data using OSC from Unity. I used IRCAM’s spat5.pan~ module to pan sound sources. The resulting sound was outputted from Max on a 4-channel set up.

Description

A user wearing a Magic Leap headset moves within a pre-defined sounding environment and as they move, their body collides with and triggers various types of sounds. These sounds appear visually to the user as simple shapes and are

placed on top of the real world. Three types of sound sources are available for the user to interact with:

- 1) Stationary sound with proximity sensor (colored red in Figure 1)
- 2) Moving sound without proximity sensor (colored blue in Figure 1)
- 3) Stationary sound without proximity sensor (colored green in Figure 1)

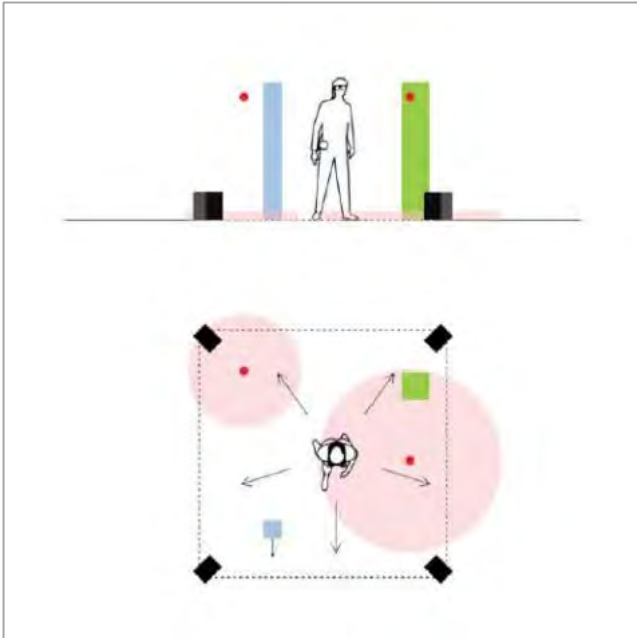

Figure 1. Diagram of a user in Experiment 01. The user moves around the space and sound is triggered based on when user walks towards (collision) or through (proximity) a sound source.

Infinite combinations of sound positions and sound movement paths are possible, and they are set up and uploaded to the Magic Leap headset before the interaction with the prototype begins. The position of each sound source is reflected in a Max patch utilizing IRCAM's Spat KNN panning algorithm. A sound will thus sound where it is physically in the virtual space (mapped to real space) which reinforces the spatiality of the sounding environments for the user and audience.

Headphones vs. speakers

I made the design choice to not use the built-in headphones found in the Magic Leap 1 headset but instead stream collision and proximity data over OSC from Unity into Max and play sound on a 4-channel sound set up. The reason for this choice was twofold: I wanted to be able to easily allow potential audience members to hear the sound produced in a way that did not require them to have headsets, and I wanted to program the gesture/sound interactions within Max as it offers more sophisticated sound processing capabilities than Unity. Most AR applications are built for solitary audio experiences – I wanted to subvert this with my project to allow for a collective audio experience for people not wearing a headset. This makes the experience more

accessible to a greater number of people as well as allowing for a more traditional performance of a sound piece.

Observations

In Experiment 01 there are two main modes of bodily interaction with sounds that depend on the virtual sensor applied to the sound source. For a proximity sensor the sound source's volume slowly rises or falls depending on how close to the center of the sound source sensor the user is. For a collision sensor, a brief or prolonged collision with the sound source plays the sound at the same volume and the sound loops for the duration the user is in contact with it.

With a proximity sound source the user can play with the sensing area of a sound. Running quickly in and out of the sensor bounds creates a very different sonic effect than slowly edging one's body towards the sensor's centre. I found that feeling and hearing the effect of moving my entire body towards/in/through proximity sound sources at different speeds to be engaging and gratifying. Changing the "sensitivity" of the sensor by either increasing or decreasing the size of its sensing area and thus creating a sharper rise or fall in volume had an interesting effect on my movement and I found that learning the differences between the properties and sensitivity of each sound source became a full body act that I felt could be learned and remembered.

The sound sources based on collision detection were quite simple to use and did not have the depth of experience that the proximity sensors had. More interesting results came from having the sound sources move on motion paths. Adjusting where the sound sources were in the environment and how fast they moved around the environment greatly affected how I would move around the space. Sometimes choosing to stand in one area and letting various sounds simply collide with me could produce a nice rhythm to the sound output. Quickly stepping out of a sound source's path would disrupt this rhythmic sound.

Figure 2. Unity project with four collision sound sources moving on predefined motion paths. The scene is 1:1 scale with the real world and mapped on top of a real-world location. A user triggers sound output by moving their body to collide with each of the sound sources.

Experiment 02: Sonic string

The second prototype was in response to my experiences interacting with the first prototype. In designing Experiment 01, I found it difficult to create meaningful gestures for both performer and audience. Typical head-mounted AR interactions rely on someone viewing virtual 3D objects placed in the real world and then interacting with these 3D objects through either the use of a remote or through hand tracking. The hand tracking technology in the Magic Leap 1 is quite impressive with initial testing but using the tracking

for an embodied interaction leaves something to be desired. This is because the field of view [5] of the headset is quite small, so you must be looking directly at your hands for the tracking to work, which doesn't allow for full bodied or varied movements. I decided against hand tracking for Experiment 01 because it was simply too cumbersome and brought me out of the embodied immersive experience I wanted to create. Also, while the hand tracking technology can allow for some meaningful gestures for the individual user, it is hard to make these gestures seem meaningful for an audience member who has no access to what the user sees behind the screen. With Experiment 02, I was interested in how to create meaningful gestures for sound interaction for both user and audience.

Following the research of Frédéric Bevilacqua et al. I attempted to "associate objects and actions, motion and sound" [6] through physically tangible means to increase a sense of meaning with my gestures. I also follow the work of Karmen Franinovic who explored "perceived affordances of an everyday object" [7] in the *Flo)(ps* project. My experiment examined the affordances inherent to materials from a sonic perspective and so the range of my motion/expression was limited to what I can do to/do with a given material. The material thus provides an artistic limitation as well as a starting point to understand and explore gesture. Experiment 02 involves a Thalmic Labs Myo armband and string to create an embodied sonic performance.

Description

A performer wearing a Myo armband pulls on, unravels, and ravel a length of string attached to the ceiling. As the performer performs the necessary bodily movements to do these tasks a soundscape is heard on a 4-channel set up. EMG signals and motion data read by the Myo armband are translated into sound in Max in real-time using the Gestural Sound Toolkit [8].

Figure 3. The performer wearing a Myo armband interacting with string to create sound output based on EMG signals.

Observations

In Experiment 02 having the tangible feedback of the string in the environment immediately made me feel connected to the gestures I was performing. Choosing to use the Myo armband instead of sensors on the string itself allowed me to focus on how my own body was affecting the sound and material. Programming the sound such that a stronger grip on the string provoked different more intense sounds vs. a lighter grasp and more delicate sounds made for interesting spontaneous gestures as well as range of gestures over a

period of time. From these preliminary results using muscle sensing on the body in combination with external tangible materials I was encouraged to bring EMG sensing as well as materials into the head-mounted AR environment. This however fell outside of the scope of this project and thus will continue in my future work.

Conclusions and Future Work

From my research I discovered ways in which AR technologies can hinder but also promote connectedness to our sounding environment. Since AR technology is just in its infancy, the Magic Leap 1 has many notable limitations: the glasses are cumbersome, very difficult to use with prescription glasses and the field of view is small. I found I could not ignore these limitations, as they highly impeded the sense of immersion that I wished to feel in tests I created.

While the technology is lacking in its immersive qualities it is still quite a novel experience to be able to see floating holographic-like objects juxtaposed with the real world – let alone be able to hear an observable effect when interacting with these objects. I found myself able to enjoy the interaction with these objects and notably the aspect of physical scale was one of interest. In Experiment 01 I had to put my body in the path of moving sound sources, as well as move around to hear different sounds/triggers. While this movement was perhaps not very elegant, the feeling of using my whole body across a large area and the speed at which I had to run around felt satisfying and immersive. I believe that more study into the size and shape of the 'playable' AR environment could yield interesting results, as would adding in 'real' objects into the environment. While it was interesting to use my body to trigger sounds I felt that it would be interesting to explore actually physically touching objects to have more of a tactile feedback. This led to the creation of Experiment 02 which was quite theatrical in nature, almost as if I was creating a performance for the string.

In my further research I plan to combine the findings from both Experiment 01 and 02 to create an embodied sonic performance utilizing AR, muscle sensors and tangible objects that is accessible to both performer and audience.

Author Biography

Maxime Gordon is a Canadian sound and new media artist. In her work Gordon is interested in exploring the boundaries of sound, architectural space, and the human body. Through sound art, performance, and installations or a combination of these media she creates immersive art works that offer a looking glass into various intersections of humanity and technology. Gordon’s work has been shown at Monom in Berlin (Germany), the Spatial Sound Institute in Budapest (Hungary), and the OutsideInsideOut residency in Stadt Wehlen (Germany).

Artistic Research in European Extended Reality Laboratories

Dr. Adnan Hadzi

University of Malta
Malta
ahadz01@um.edu.mt

Abstract

This paper analyses the use of Immersive Experiences (IX) within artistic research, as an interdisciplinary environment between artistic, practice based research, visual pedagogies, social and cognitive sciences. This paper discusses IX in the context of social shared spaces. It presents the Immersion Lab University of Malta (ILUM) interdisciplinary research project. ILUM has a dedicated, specific room, located at the Department of Digital Arts, Faculty of Media & Knowledge Sciences, at University of Malta, appropriately set-up with life size surround projection and surround sound so as to provide a number of viewers (located within the set-up) with an IX virtual reality environment. The set-up is scalable, portable and provide easy to use navigation and allow the user to move around within the virtual environment. The paper discusses how ILUM combines and integrates three research strands that are part of a major, sustained artistic or scientific focus of the partnering academic institutions, namely the Visual Narratives Laboratory (VNLAB at the Centre for Interdisciplinary Research, Filmschool Lodz), the Instytut Kultury at Jagiellonian University, Krakow, Poland, and the Spatial Media Research Group (SMRG) at the National and Kapodistrian University of Athens, Greece. In those labs researchers, artists, film-makers investigate and create different kinds of IX. ILUM provides the opportunity to situate artistic research in the context of scientific. The thematic backgrounds of these research strands and the infrastructure of ILUM serve as starting points from which the partners collaboratively create new communication content, exhibition settings and research as well as teaching materials.

Immersive Experiences in Social Shared Spaces

This paper discusses the use of Immersive Experiences (IX) within artistic research, as an interdisciplinary environment between artistic, practice based research, visual pedagogies, social and cognitive sciences. This paper examines IX in the context of social shared spaces. It presents the Immersion Lab University of Malta (ILUM) interdisciplinary research project. ILUM has a dedicated, specific room, located at the Department of Digital Arts, Faculty of Media & Knowledge Sciences, at University of Malta, appropriately set-up with life size surround projection and surround sound so as to provide a number of viewers (located within the set-up) with an IX virtual reality environment. Throughout the project, scientists collaborate to transfer scientific experimentation settings into the Immersion Lab that enable visitors to actively engage with and learn about these topics and methods of investigation. The paper discusses how ILUM combines and integrates three research strands that are part of a

major, sustained artistic or scientific focus of the partnering academic institutions:

- 1) The development of the ILUM as being oriented towards practice-based research in Media Arts: Interdisciplinary Immersive Experiences within Media Arts.
- 2) The second scenario and field of expertise is established through collaborative work with the Department of Cognitive Science, Faculty of Media and Knowledge Sciences, University of Malta, on Interdisciplinary Immersive Experiences within Cognitive Sciences.
- 3) The third scenario is the application of techniques, tools, and processes of ILUM in Interdisciplinary Immersive Experiences within Social Sciences, such as Heritage Dissemination activities and finally an outlook on envisaged IX productions within migration studies.

1) Interdisciplinary Immersive Experiences within Media Arts

In *Genius Loci* [1], Towards a Phenomenology of Architecture, Norwegian architect and theorist Christian Norbert-Schultz re-interpreted the ancient notion of Genius loci advocating a more sensitive approach to architecture in the direction of the symbolic understanding of places. Going back to taking into consideration the value of the 'character of place', and understating it in terms of heritage, would – Norbert-Schultz suggested – offer insights to a more sensitive and dialectic relationship between society, the environment and the forms of human living. In *Computers as Theatre* Laurel [2] introduced a totally new perspective on the then rather new domain of human-computer interaction [3], by combining drama studies with video-game design at the Atari corporation. Laurel's work brought a refreshing perspective to the emerging field of interface design. Laurel advocated to look for advice in formulas from the classic world noting how "designers of human-computer activities can borrow concepts and techniques from drama in order to visualize and orchestrate the structural patterns of experience" [2]. From a different perspective, interesting insights in this area can also be found in Char Davies' early experiments in Virtual Reality [4], like in Davies' *Osmose* [5] immersive VR installation. In a general context in which technology radically modifies the relationships between the visible boundaries – that we, at large, consider as a "screens" – and the moving image artifacts they are meant to display, the idea behind the traditional immersive VR setup is being questioned. A key area of investigation is, on the grounds of a long-established history of orchestration between spatial, visual components and storytelling, hence that of the possible contaminations between the diegetic space [6] of the audiovisual field and the narrative power of an expository medium. Furthermore, the very practice of sharing and creating information on social media, so characteristic of our times, tends to introduce a new space in which the real and virtual dimension overlap, interacting in new and unexpected ways.

2) Interdisciplinary Immersive Experiences within Cognitive Sciences

or the researchers, the key element is that the subjective experience [7] can be challenged using new technologies and IX that induce perceptual bodily illusions. Such illusions are interesting to study for cognitive neuro-scientific research of self-consciousness and provide an excellent way for communicating and explaining our scientific questions. Work in ILUM implements the experimental conditions for visitors to experience these bodily illusions and provides the public with a better understanding of the fundamental mechanisms of self-consciousness [8]. The main goal of the science communication project is to showcase exemplary research at the intersection of art and science. An example for such a field of expertise is established through collaborative work with Cognitive Sciences. The design of the User Experience [9], through cognitive analysis, is the first fundamental step to create an immersive experience. The cognitive science potential for researchers of the ILUM project are in researching and implementing content production pipelines at ILUM, concentrating on the creative aspects of IX research through (serious) game-like experiences using ILUM, disrupting dominant narratives, often unwittingly, promoting – by embedding stories, perspectives and artefacts representing cultures and communities that were previously hidden, or indeed (due to past prejudice in what might constitute legitimate historical narratives) altogether missing. Those stories, perspectives and artefacts will be positioned in juxtaposition to the most popular narratives. The new connections, meanings and nuances that will emerge from those juxtapositions will help demonstrate novel uses of IX technologies. ILUM develops a method in prototyping an experience for the inclusion of cultural perspectives and artefacts, which represent communities and groups that are currently missing or under-represented in the collections of cultural institutions.

3) Interdisciplinary Immersive Experiences within Social Sciences

One major aspect for ILUM is the engagement with Maltese cultural and historical sites. Museums are sites of knowledge and memory, heritage and culture. Museums and historical sites in the Malta also are publicly funded institutions that have a social responsibility to reach out to a wide range of demographics. However, participation in culture is often significantly lower among those from a lower socio-economic background [10]. There is strong evidence of arts and culture's intrinsic, social and economic value. The government expects that all publicly-funded arts organisations must increase access for people from disadvantaged backgrounds and open up arts and culture for all. Furthermore, even when visiting museums and sites of cultural heritage, many visitors only engage with the 'star' exhibits, missing out on other, equally important if less celebrated or spectacular elements of the exhibition, either because they do not have an incentive to visit certain parts of the exhibition or because items are hidden in the storage. This can lead to educationally limited visits of cultural and heritage sites. Therefore ILUM focuses on learning to set up IX solutions to counter key challenges faced by Maltese cultural institutions today:

1. Diversity of audiences and narratives displayed. The diversity of audiences does not currently reflect the demographics of Malta as a whole. A contributing factor to this challenge is a widely-held perception that the story of the past, as the dominant narrative currently presented by mainstream cultural institutions, is primarily that of wealthy, heterosexual, white males. As a result, audiences from different ethnic and religious communities, or with particular protected characteristics, can feel disconnected from this cultural narrative. Maltese heritage sites, museums and galleries are urgently seeking to address this through examining how cultural sites can better contribute to cultural and social developments by encouraging and facilitating diverse communities to contribute to culture within Malta.

2. Visitors only engage with 'star' exhibits, resulting to educationally limited experiences. According to Walzl "the process of establishing museums for the many goes hand in hand with transformation of museums which (...) 'change from being product-led to audience-centred'" [11]. Cultural institutions today seek to offer more engaging, enriching and relevant experiences to visitors, encouraging them to extend and diversify their visits. They want visitors to engage with the wider collection beyond the star exhibits, which would enrich the visitors' experience, offering a broader contextual understanding and instigating 'surprise encounters' with objects or ideas they might have not previously encountered, thus audiences would learn more and deepen their enjoyment of visits.

3. Physical space and resources limit the range of collections and archives that can be displayed. Cultural institutions tend to only display a proportion of their collection to visitors at any time. A great deal of it remains 'hidden' either because of a lack of space or because of the fragility of the artefacts. However, the 'hidden' artefacts [12] are often those which are most pertinent to the under-represented communities [13]. ILUM enables immediate accessibility and provides direct experiences for general audiences that range from school-age children to adults. The ILUM researchers have the opportunity to retrace the process with a possible adaptation to the Maltese context [14]. Crucial is that by bringing together images, sounds, and movement through interaction, an embodied relationship arises from reconstructed shapes of palaeolithic art [15], [16] and their synthesised movements. Critical points of development are the translation of heritage content [17], [18] into digital interaction modules, providing uninhibited access via animated media scenarios.

Another Social Sciences research project which benefits from the ILUM project is the Platform for Migration [19] at the University of Malta. In an increasingly integrated world, migration presents opportunities and challenges to communities, institutions and individuals alike. The mission of the University of Malta Platform for Migration is to offer a dialogical space in which researchers from different academic disciplines can work towards understanding all the evolving aspects of international migration, including that of belonging across generations. The long-term goal is to thereby contribute to an equitable, more sustainable and more inclusive society that brings benefits to migrants and their families, communities of origin, destination and transit, as well as their sending and receiving countries. Today the migration crisis renders the Mediterranean an opaque space, removed from the public eye, where the key founding values of the European Union (as per Art 2 TEU) are put under strain, making the Platform for Migration initiative all the more necessary.

The Platform for Migration can help to shed light and raise awareness among stakeholders, policy makers, and the general public about the unfolding crisis at the common maritime borders of the Member States. ILUM supports the Platform for Migration in data visualisation within immersive space for awareness raising purposes.

ILUM, considering the above discussed case studies, serves as a vehicle for the exploration of new narratives for spatial media-arts work, combining the modalities of musical and visual surround presentation with a full-scale interaction surface. A core idea is to provide a platform for a wide variety of researchers and artists to experiment in and develop artistic works specific to this multi-modal configuration. The installation system intended for a variety of research scenarios that include researching in the domains of social and cognitive sciences, and media arts, such as creative coding, interactive media, as well as computer music and algorithmic composition. Furthermore ILUM allows for experimentation in the artistic research domain, as well for generating experiences to be investigated from the point of view of composition, systems theory, and above all interaction and social behaviour within media environments.

juergen.hagler@fh-hagenberg.at, remo.rauscher@fh-hagenberg.at

Abstract

The COVID-19 pandemic poses challenges for students and faculty in educational contexts that focus on collaborative and creative practice. Courses that involve working in large teams and interacting in the field require new approaches to cope with limitations on in-person instruction. Building on the concept of *chained animation*, the case study *The Invention of Numbers* (2021) will be used to discuss how the concept can be adapted for hybrid teaching. In *chained animation*, students develop a common concept, realize individual parts in small groups, and assemble them into a short film, rather like an omnibus film. The core element is on-location exchange, especially in the animation studio. Covid-19 regulations have placed limits on these kinds of meetings and exchanges. To deal with those limitations, the creative method of *cadavre exquis* has been applied to the concept of *chained animation*. *Animated cadavre exquis* features a systematic form of collaborative filmmaking that requires little or no coordination between teams, making it particularly well-suited to the new classroom situation. This analysis demonstrates how to set up creative processes for large collaborative groups in distance and hybrid teaching and how the concept of *chained animation* can be adapted using the *cadavre exquis* method.

Keywords

animation, collaborative conception, participatory art, collaborative art practices, co-creation, crowdsourcing.

Introduction

The Covid-19 pandemic urgently requires us to rethink higher education; it poses particular challenges for both students and teachers in courses with a practical element. New concepts for collaborative projects are needed for courses that promote social and creative skills in addition to the acquisition of practical skills. This raises the question of how best to handle creative work in large teams within a framework of distance and hybrid teaching. An answer is offered here based on the example of an animation course in the Department of Digital Media at the University of Applied Sciences Upper Austria.

In the course *Analog Animation*, an elective in the 5th semester of the *Media Technology and Design* bachelor's program, the didactic focus has been on collaborative projects for several years. Building on previously acquired knowledge in photography and animation, so-called *chained animations* [6] have been created on various topics since 2015. This

form of animation is a method in which jointly conceived and produced individual parts are “chained” into a film. In contrast to conventional film productions, here all contributors are equally involved in the conceptual and creative process as well as the implementation. In 2016, the first *chained animation* was realized with 48 students working on the animated short film *Home* (2016), an animated poem about the wave of migration caused by the Syrian war. Additional short film projects with different didactic concepts of collaborative filmmaking followed: *Utopia Now* (AT 2017), *Draft One* (AT 2018), *Golden Cage* (AT 2019) and *Think Twice* (AT 2020). The *chained animation* concept requires in-person instruction in small groups and cross-group collaboration on location. The students develop the storyboard together in a workshop setting and realize the individual parts in small groups in the animation studio, which serves as a hub for exchange between those groups. Because in-person classes were strictly limited due to the pandemic, the *chained animation* process had to be realigned. The challenge was to maintain the collaborative form of conception and production despite limited opportunities for interaction. The creative method developed in surrealism, *cadavre exquis*, a playful way of producing images and texts in a group, was used and adapted for *chained animation*.

Collaborative Forms in Animation

Participatory Art Practice

The first forms of participatory art can be seen in the work of such artists as Marcel Duchamps and László Moholy-Nagy, who delegated works of art to others by telephone or through written instructions. Central components of participatory art practice include playing with instructions, communication (by speech, letter, telephone, social media, etc.), open-ended experimentation, appropriation or instrumentalization, various forms of intervention, and politically or socially motivated activism [4, 10]. Brown et al. [3, pp. 16–19] distinguish three forms of participatory art practice in the museum context. In *crowd-sourcing*, the audience is invited to contribute to an artistic product; in *co-creation*, the audience is directly involved in an artistic experience; and in *audience-as-artist*, the audience essentially takes control of the artistic experience. A stronger form of participation, in the sense of active involvement in the design process, is found in the creative method of *cadavre exquis*. In that method, images or

texts are created by several people passing the artifacts from one to another for further editing, without the later contributors knowing about the previous work. This playful collaborative method can fall somewhere between *co-creation* and *audience-as-artist*, depending on the procedural instructions.

Chained Animation

In contrast to traditional forms of animated film production [5, 9], in *chained animations* many or even all participants take on the role of director, which is similar to omnibus films, also called anthology or episodic films [11, 8]. This type of feature film is made up of several stories or films, usually by several directors, although there may be only one. One of the first films in this genre is Disney's third animated feature *Fantasia* (US 1940), a string of eight visualizations of classical music pieces based on the *Silly Symphonies* concept [7]. Collaborative experiments are especially prevalent in artistic animated film, borrowing from various participatory art forms. An important basic requirement for this kind of project is a simple and direct exchange of data and information. This is facilitated by a shared animation studio, as for example in the early collaborative animation projects at what is now the University of Applied Arts Vienna. For the animated film *Life Show* (AT 1990), for example, a dedicated animation studio was created that served as a hub for the entire production. Similar processes can be seen in "animation jams," where participants usually work together in small groups to create an animated film on predetermined themes in a short period of time. The various short films are usually assembled during production and "chained" together to form a coherent overall work. Working at the same time and in the same place allows for a lively exchange, insights into the productions and consultation on transitions between the individual parts.

Animated Cadavre Exquis

The creative method *cadavre exquis*, developed in Surrealism, was defined by André Breton as a game with folded paper in which pictorial and textual works are created collectively by several people [2, pp. 143–144]. The crucial characteristic is that what has already been created is passed on to the next person or group of people without them seeing what has been done so far. *Cadavre exquis* is a form of collaboration that requires little or no exchange of information between the individual participants. Its synergistic appeal comes from the deliberate disinformation involved. In a classic version of this creativity-promoting method, a sheet of paper is folded into sections, a participant fills in the first section, folds it over, and the following participants build on it and continue the work. Participants can discern some indication of what the preceding artist has drawn at the edge of the fold; the information handed over is reduced to a minimum and yet produces a result that can be highly cooperative. For animated film, digital communication and film production have made this game particularly convenient, whereas the hand-off used to be very time-consuming, costly, and limited. An early example of an animated *cadavre exquis* is the computer-animated film *Kettenanimation* (AT 1993), a production created by 45 Austrian artists according to the principle of this creative method with the following instructions: The first

filmmaker was given an image on a floppy disc that was used as the starting point for an animation sequence of up to two minutes. A production time of one week was allotted for this. After that, the last image was given to another person on a diskette, and after 45 weeks a 21-minute video had been created. The computer-animated short narrative film *Animation Tag Attack* (DK et al. 2012) was also created according to this principle, but with different rules. The current production step was visible to all participants so that each subsequent animator could decide on the basis of the current status of the film how and in what form the story should be continued. All participants had four weeks to produce a film of at least five seconds. Then the clip was uploaded to the blog and the next person in line could continue working on the film. The result is a ten-minute film, a diverse mix of techniques, styles and narrative strategies: "This movie is a celebration of the art of collaboration and of creative process" [1]. Animation director Matt Taylor took a similar approach with 22 animators in the promotional film *Rick and Morty Exquisite Corpse* (US 2017).

In summary, *animated cadavre exquis* can be categorized as a special form of *chained animation*. Both are extremely diverse in terms of their form, aesthetics, method, unifying elements, and techniques, and have similar essential characteristics to participatory art practices (playing with instructions, communication, structure, open-ended experimentation, playing with chance).

Chained Animation in Education

Between 2016 and 2021 we developed, organized, and initiated various *chained animation* projects in the course *Analog Animation* at the University of Applied Sciences Upper Austria, Hagenberg Campus, Department of Digital Media. For each course, we chose different approaches and distinctive requirements. All projects consisted of a fairly large number of participants (30–51) who worked on their concepts while attending a theoretical class and receiving professional coaching in production, editing, direction, and sound design. All of these departments were distributed among the students and only used to the necessary extent. Various topics were offered to the whole group and the students also offered some topics of their own. Final decisions were made democratically and broadly discussed, either in person during classes, or online on specially created social media channels or communication tools. Decision-making tools and communication channels varied depending on the needs of each project. Theoretical classes, literature, or inspirational reference materials were adopted accordingly. After this stage, each team or group worked on the storyboards which were again discussed and feedbacked in small groups or with all class members, then modified to fit the overall concept of the *chained animation*. The priorities were to avoid redundant similarities, find common themes and/or discover links across the narration. A head of communication was needed to keep the process well organized; this role was taken on by the lecturers or by a student volunteer. Either way, final decisions were always made by the students themselves. Interestingly, this was often done immediately before the beginning of the production or even "on the table" where concepts and materials were already fi-

	HOME (2016)	UTOPIA NOW (2017)	DRAFT ONE (2018)	THE INVENTION OF NUMBERS (2021)
JOINING ELEMENT	Theme, voice over (poem)	Topic	Object & theme	Theme, cadavre exquis
EDITING	Predefined (voice-over)	Post-production	Influenced by production	Predetermined by rules
MOTIVATION	High: current events	Average: socio-political	Average: Auto-reflexive theme can be abstract	High: on-site despite Covid-19
RULES	Strict: Predefined length but visual freedom	Average: conceptual freedom in interchange with departments	Very free: overall theme gives broad scope for creativity	Average: cadavre exquis
STRUCTURE	Lectures: direction & sound, Students: editing & post-production	Determined after production by artist	Departments for direction, co-direction, editing & sound	Direction, editing & sound: Coaching and students
PRO (+)	Common research, strict rules	Independent conception, socio-critical topic	Departments establish security	Collaborative processes during Covid-19
CON (-)	Strongly influenced by lecturer	Common vision suffers due to limited time for research	Critical identification due to abstract topic	Limited on-site interaction

nalized and ready for animation. At all times, the production process happened in the presence of at least one lecturer to guarantee technical and theoretical support during the two days in the studios. Hence this kind of “last-minute” decision making had several benefits for the students: they were able to experience the effects of “trial and error” on a practical level and were challenged to deal with the limitations of their materials of choice, which gave them valuable insights into real-life production processes.

The first *chained animation* is *Home*, an animated poem about the different meanings of the term “home,” contextualizing the refugee movement sparked by the Syrian war in 2015. 48 students created associative images based on semantically corresponding verses of the poem. The second case study, *Utopia Now*, is an animated dialogue of two thinkers striving for a vision of a “better tomorrow”. There was one big difference with regard to the prior project: the conscious absence of an audio layer or voice-over. The concepts were created freely and involved sketching a voice-over template to inspire the final wording of the dialogue. For the third *chained animation*, *Draft One*, we chose a self-reflexive approach to illustrate the creation process itself using one of the most profound MacGuffins of all-time, the “bouncing ball.” One of the biggest challenges in the collaborative process this time was to find the joining elements between the scenes while maintaining the overall structure (see figure number 1).

The Invention of Numbers

In the case study *The Invention of Numbers*, 30 students were divided into 9 groups. There were 3 sessions at the animation studio, each attended by 3 of the 9 groups so they could work on their parts of the animation project while complying with Covid-19 regulations. Based on an introductory session, the leitmotif “The Invention of Numbers” was presented as a conceptual framework and unanimously agreed upon. The assignment called for reflection on the “idea of

the number” itself and its scientific, mathematical, or political consequences or dependencies in private or public action. The ideas presented in preproduction demonstrated a high degree of identification with the topic and, despite a relatively isolated way of working, sparked intrinsic motivation. The communication platform Discord was used to coordinate all the participants, although in keeping with the *cadavre exquis* method, the individual groups were not aware of the way others had elaborated on the concepts. The order and assembly of the individual sequences was determined by the course instructors (see figure number 2) and presented to the students. As an additional task, each team had to select an object from their animated film as a transition to the next clip, which was passed on to the following team. The teams were given the transitional object immediately before production and had to adjust their concept based on it at the animation studio (see figure number 3). Flexibility, improvisation and spontaneity were particularly called for here.

The *chained animation* translated the method of *cadavre exquis* into film by having each production team pass a physical object from their animated sequence on to the next team, with the last two frames of the previous sequence serving as a reference point for a seamless transition. After the technical introduction and revision of the storyboards, the chronological order of the concepts was determined on the basis of narrative, technical or logistical aspects. Communication between the participants was handled entirely via the Discord communication platform. This is also where any voting or polling took place. After central collection and assembly of all contributions, the final film was presented via video conference. The decisive advantage of running a *chained animation* with 30 students, even with very little in-person work and limited consultation, was the deliberately broad conceptual approach and the *cadavre exquis* method, which allows for decentralized creative work on a collaborative product without physical contact. From the point of view of the collabora-

Figure 2: After the concept presentation, the course instructors determined the order of the individual animation sequences. Students selected an object from their sequence as a transition, which was passed on to the next team.

tive approach of *chained animation*, it was observed that there were more constraints than in previous case studies due to hybrid teaching and the limitations of online communication. The *animated cadavre exquis* nevertheless proved to be a very suitable form of collaborative animation that features the essential factors of *chained animation* (rules and certainty, communication and structure, identification and shared vision).

Figure 3: On two production days, teams of three to four students implemented their concepts for the animated film *The Invention of Numbers* in the animation studio.

Conclusion

The nature of the rules of *cadavre exquis* and their adaptation for use in *chained animations* made a thoroughly positive impression. In addition to successfully completing the collaborative film project, the majority of the participating students found this form particularly exciting and conducive to creativity, and rated the course a very successful example of hybrid teaching. The essential challenges were playing with chance, engaging with the unknown, and having the flexibility required to connect the individual pieces. Things that are subject to logical order in conventional production pipelines are here deliberately jumbled up in a creative method that requires all participants to think in new ways. Independence, limitations and spontaneity create conditions that are highly compatible with Covid-19 regulations, such as distance learning or limited in-person teaching. Various factors for spark-

ing intrinsic motivation can be observed or even classified in the collaborative processes. As the previous case studies have shown, a comparison of these factors or the applied rules can be quite instructive (see figure number 1). In contrast to previous collaborative approaches, the *cadavre exquis* method almost seems paradoxical. Whereas disinformation that is spread deliberately can cause limitations and obstacles, here it becomes a creative stylistic device that provides fertile ground for the creative or collaborative process.

Xenoactivism and Impious Machines: Digital Art as Aesthetic Model of More-Than-Human Politics

Abstract

Effective activism is predicated on its ability to summon strong emotions and desires, yet its affective palette appears depleted. Next to a fear for destruction of the planet, other emotional and affective programs seem to fade rapidly. Is it possible to develop an eros for a future dominated by hyperobjects like climate change, characterised by unravelling of traditional political structure, and populated by new technological monsters in the form of AIs and lifelike robotics? What kind of desires can provide cohesion to activist collectives? Digital art presents unique opportunities for practicing negotiations and desires within collectives to come. Within this paper we are proposing the notion of *Xenoactivism* as a conceptual ally to activists and digital artists alike. To this end the notion of xenoactivism seeks to productively hijack new materialist discourse around machines. Art practices are discussed as germinal agents for these unborn, nascent, and as of yet unproduced desires. These are desires for novel formalisms and abstractions that span anthropic, vegetal, faunal, and machinic phyla.

Keywords

Activism, Post-Humanism, New Materialism, Anarchive

Introduction

The future presents itself as a daunting place. Hyperobjects such as climate change challenge our notions of objecthood and temporality while existing political structures appear unable to cope with these challenges. Consequently, effective activist practice, conceived as political processes unfolding outside instituted political protocols, is a more crucial force than ever. However, a resurgence of activist energies seems paired with a crushing sense of futility. A sense of urgency is complemented by the insight that it already is too late. The overpowering need for an appeal finds itself confronted with the feeling that there are no political bodies worth appealing to. Resultingly, activists often find themselves curating emotions such as fear and hopelessness, or burn out within fields of aimless intensity.

This poses the question of how to craft a desire to live through the coming series of disasters while embracing the monstrous objects lurking in our common future.

The Trouble with Machines

Activism already is an activity not exclusively practiced by humans¹. Facebook algorithms, search engines, virtual assistants, and twitter bots, help us to incite hatred, protest state power, spread misinformation, or save the planet.

The degree to which non-human elements partake or even steer activist action seems poised to only increase. This raises the specter of a political process in which the grass-roots level is dominated by machines.

At the same time, political practice appears to be overwhelmed by this non-human element: As symptoms of an overwhelming ecological crisis become ever harder to deny, displace, explain away, and ignore, non-humans appear to dictate the terms within which human politics can unfold.

On the part of well meaning humans this is often framed as injunction not to “hurt the planet”, to “respect the environment” or similarly cater to the needs of a non-human entity.

At the same time, these alterous interests and demands are notoriously hard for human bodies to accept and address as part of their political processes. What do non-humans really want? They do not join a protest, submit petitions to parliament, or vote a government out of office. Should there be a section of politics dedicated to machines? Should the political process become more inclusive towards the desires of non-humans?

What kind of social structures would be able to allow us to translate non-human desire into intelligible demand in the first place? How to practice politics and activism in a way that recognises non-humans as friends, that conducts politics not only for non-humans but with them?

Activism and its Aesthetic Textures

Activism has always found itself as enmeshed with aesthetic practice. Separate from instituted protocols of power, its influence derives from its capacity to be seen, for its pains to be felt. However, at this moment, existing concatenations of aesthetic machines and activist practice often seem unproductive and redundant. They present themselves as factories of narcissistic desires in perfect alignment with a capitalist machine based on the control of platforms [8].

¹<https://superflux.in/index.php/calling-for-a-more-than-human-politics/>

Just as art practices can be reduced to a stream of Instagrammable events, activist practice can serve as producer of visual elements consumed by social media feeds. This trajectory has been set in motion through development of visual mass media. It has fundamentally shifted through proliferation of smartphones and social media, as activists themselves seek to produce these images and further their circulation.

Perhaps no image embodies this phenomenon better than the infamous “Riot Hipster”: Shot during the G20 protests in Hamburg 2017 it shows a male protester in front of pittoresquely burning barricades posing for a selfie with a recent generation iPhone.

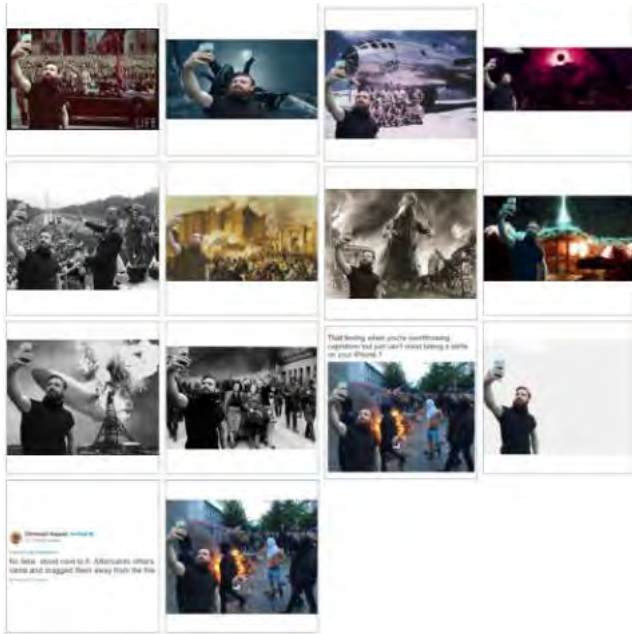

Figure 1: Riot hipster meme, knowyourmeme.com

Posted on twitter, the image quickly went viral, attracting ridicule and speculation concerning the protestor’s and image producer’s intentions. A powerful symbol for the paradox of narcissistic performance of radical identities through corporate platforms and devices, the “Riot Hipster” quickly became a meme in its own right, multiplying and modifying itself through the help of meme-generators and social networks (Fig. 1). Paradoxically, through its failure the riot hipster’s act ensured a degree of circulation of his image which far exceeded the effect expected of a ‘successful’ insurrectionary gesture.

Digital art documenting activism always finds itself situated in this uncomfortable position: Enmeshed with the digital structures it has to critique, witnessing and documenting the voyeurism and narcissisms of others while relying on these very same psychological predicaments in order to circulate itself within social networks. The level of the aesthetic thus emerges as a necessary yet at the same time, deeply unsettling base of effective activist practice.

In order to account for the status of technological and platform elements, two readings immediately present themselves

in the context of the above scenario: The riot hipster enlists the help of the phone in order to circulate his own image. At the same time he draws upon an environment created by activist practice, burning barricades and a crowd of protesters. The image is his effect, installing him as creator.

Conversely, platform elements can be cast in a more active role. Within this scenario, it is the platform which enlisted the riot hipster as its agent, feeding images to its algorithms, serving corporate interests, contributing to ad revenue, balance sheet, and business objectives. In this instance, the process of enlistment happened indirectly: The unnamed shooter of the riot hipster’s image comes in as a crucial mediator.

Following Massumi, it is possible to frame the aesthetic not as situated at the surface level but as an essential dimension within political processes of becoming [1]. The already constituted power of the platform, of aesthetic codes, and modes of identity performance make themselves known. They structure and penetrate into the spontaneously constructed space depicted while striating the mode of depiction.

What we are seeing is not a function of individual narcissism, or the mere effect of platform logic, but the workings of an aesthetic apparatus kept in motion by constituted power in the form of striated codes of self-performance.

As a result, the collective actually assembled is quite different from what its immediate human participants might proclaim. Facebook marches as part of the black bloc, the Apple corporate logo features as prominently as the extinction symbol and peace signs, iPhones make friends with burning trash cans and makeshift barricades.

If activist situations here appear as expectable ruptures of everyday life which are projected on the thin aesthetic layer of an Instagram feed, how could we move past this deadlock? Is it an overabundance of technological elements and corporate machinery that subverts activist intentions?

Learning to Love Machines

The perspective proposed here is not to oppose elements of the capitalist machine with those of activism but to ask for possible future strategies of rearranging structural components which are already effective today. As conceptual element allowing for a productive rearrangement of components we propose an appropriation of the term of the *machine*.

Coined by Deleuze and Guattari in their *Capitalism and Schizophrenia* [2, 3] book series and further developed through Guattari’s *Chaosmosis* [4], the concept of the machine allows for a productive dissolution of dichotomies between human and technology. Here, we draw on Gerald Raunig’s reactualization of the concept, specifically through *A Thousand Machines* [7] and *Art and Revolution* [6].

Raunig employs the concept in order to frame activism in the context of Euromayday protests. Through his discussion of “Mayday Machines” [7, pp. 75] Raunig demonstrates how the machine concept can be used to subvert entrenched forms of activism, prevent repetition of unproductive discursive rituals and negotiate novel forms of assembling collectives.

Raunig’s discussion here centers on precarization: Unproductive differences between calls for “full employment” or celebration of joblessness are productively subverted through

the Mayday machine. This allows for contradictions to become manifest, to be experienced, questioned, and mobilised.

Raunig describes a “revolutionary machine” which he analyses into components of insurrection, resistance, and *constituent power* [6, pp. 26]. Resistance as the necessary correlate of power, allows for insurrection to manifest and ultimately to upset ossified structures of already *constituted power*. Constituents through these structurally necessary ruptures within power structures become able to negotiate and constitute novel patterns of political structuring. These necessarily also always already operate with and against resistances from beyond and within.

Crucially, the machine is utterly ineffective, if one of its components is absent. Insurrection+resistance do not amount to an effective strategy if there is no constituent power to channel intensities, give rise to patterns, and produce new desires.

Code Machines

The work the machine concept is able to do in relationship to code (as in source code) is in fact similar: It allows coding bodies to experience the inherent conflicts and contradictions implied by the practice of coding. In so doing it wants to pave the way for novel forms of experiencing and aestheticising the work of assembling collectives of coders, thus exceeding the received paradigm of “hacking”.

Thus, I propose to frame elements of digital art with the conceptual prosthesis of the *Code Machine*: Elements of digital art contain elements of source code and data. Their function is to reconstitute these formal materials in a way that allows us to desire them, or desire them differently than before.

The concept of *Code Machines* thus seeks to productively hijack discursive formations surrounding the machine concept as developed by Raunig. It draws on connections and relationships made between political practice and the notion of machine, while playing with the (quantum)mechanical overtones implied by the choice of signifier.

Algorithms are not mere embodiment of human knowledge or goals. An algorithm is always more than or less than what its human masters want it to be. As any programmer knows, algorithmic materials quickly take on a life of their own, subverting their creators’ will, unexpectedly complicating processes of making while occasionally offering serendipitous solutions without prior elicitation.

Inhering within formalization thus is the potential for an unruly element, allowing for unexpected consequences and requiring for continuous intervention in order to uphold a certain order.

While the connection between digital art, activism, political processes, and future modes of constituting collectives might at times appear spurious, it is indeed substantial: When creating digital art collectively, we negotiate a set of rules, of formal procedures which become part of the collective. These are known, questioned, become subject to processes of collective examination and self-perception. Thinking in the direction of formal structure infects the reflection and negotiation process itself. While it does not become formal and technical, it begins to lend itself to (negative) concatenations, temporal overlap with code machines.

By doing digital art in the context of activism we thus experiment with models of interrelating formal material and code systems in a way that exceeds the bland aestheticism effected by the constituted power of platform capitalist regimes.

Constituent power is in need of these experimental-constructive modes of action if it wants to productively subvert constituted power in the form of a static concatenation of platform and state apparatuses. Ultimately, these practices challenge the distinction between activism and codified political process.

Xenoactivism

Using conceptual components tentatively developed above, it becomes possible to experiment with reframings of activist practice. To that end, the authors have tried on the concept of *Xenoactivism* in order to frame their own intertwinements of digital art and activist practices:

Xenoactivism is a practice concerned with the construction of machines. Machine here refers less to the notion of a mechanical apparatus and more to the new materialist notion of *abstract machines*.

In the context of xenoactivism this manifests as desire for future machines which create different flows of affect, materials, resources, information. Hopefully, these will be machines able to mitigate looming planetary disasters.

Constituents negotiate these repeatable patterns of organizing affective and material flows. Crucially, non-human constituents such as members of vegetal and faunal communities are conceived as equitable partners in these discussions.

A model for these processes of negotiation can be found in Soon & Tzu-Tung’s *Forkonomy*²: Digital materials such as open-source software are employed in situations of collective negotiation of economic systems. Constituent power is symbolically mobilised to negotiate the protocols used and constraints imposed by economic systems.

Movements such as horti-counterculture stretch into the realm of the vegetal [5]. Projects such as the *Economic Space Agency* describe ways of measuring value that include the Biosphere³.

This equitable nature is rooted in a realisation of mutual alterity. Balance sheets within a capitalist corporate apparatus are no more able to understand or react to the needs of indigenous communities than an animal keeper is able to express the interests and desires of the bodies she finds herself entrusted with. Since we are never able to fully account for our own desires, we have to make the effort to at least partially account for those of others. We cannot lay a claim of exclusivity on our desires, they never belong only to ourselves.

Vegetal and faunal soul, human unconscious, and calculating intellect entangle, embrace, and penetrate each other.

Xenoactivism: Towards a Future Constituency

Should activism be conceived as “convulsive beauty” creating something new? Is it forerunner to instituted political process? Tasked with breaking the predominance of humans before they ruin this planet?

²<https://siusoon.net/forkonomy/>

³<https://economicspace.agency/>

Aesthetics is always already present within practices of activism. This can unfold in the mode of stagnant narcissism or be forerunner to new and unexpected practices. By introducing and experimenting with the notions of code-machines and xenoactivism we hope to construct aesthetic models for future collectives.

In that sense, xenoactivism is about assembling a collective receptive to the strange desires of vegetal and animal communities. It thus seeks to effect and respond to mutual infringements of the realms of vegetal, faunal, and anthropic life. Just as theories of successive ensoulment modelled a connection of human and animal souls, xenoactivism tries to construct a productive relationship between these entities.

Working with digital structures, reflecting on their formal and material properties allowed participants to arrive at a new conceptualization of activist practice: Constituent power expresses itself through construction of formal rulesets which learn to materially respond to non-human bodies. Future constituencies thus comprise human and non-human citizens, spanning across human, animal, and machinic phyla.

The effectiveness of activism itself hinges on its capacity to create and (negatively) concatenate machines: The value of digital art lies in its capacity to analyze, problematize, disassemble and reassemble digital machines which modulate streams of affect and attention.

Crucially, there is a necessity to constitute economic machines. To organize flows of energies, nutrients, drain waste, circulate goods in a way that subverts the horrors of existing capitalist machines, while allowing for constituent power to manifest and modify itself.

Abstract

During the height of the COVID-19 pandemic, a creative and technical team used an emerging geological sensor technology to scan the subterranean landscape under a historic plaza in central France, originally the site of a Roman temple buried since Antiquity. This paper will present the resulting trans-disciplinary project that included artists, programmers, designers, archaeologists, geologists, academics, historians, cultural leaders and government agencies all working together to create a series of media works based on what has been hidden in the heart of Clermont-Ferrand for 2,000 years. Ground Penetrating Radar reveals through echo and its haunting visualizations were core to the foundational data used in the artworks but also its theme and metaphor. With the collected data, the team created a site-specific collage of trompe l'oeil anti-sculpture, virtual experiences, films, prints and performances. Place de la Victoire, a cultural heritage landmark, became the source and site of an inverted public experience for inverted times.

Introduction

"The ends of things and their beginnings are impregnably concealed from him in an impenetrable secret."

Blaise Pascal [1]

The 17th Century mathematician and philosopher Pascal wrote those words pondering the 'great hidden' in Place de la Victoire, the cultural heritage core of Clermont-Ferrand, France. By his time, a jet-black Gothic cathedral overlooked the Plaza, built from volcanic lava rock in the 13th Century. Both are still standing today, however the plaza itself rests on the ruins of a Gallo-Roman temple complex, specifically the inner 'cella', that dates back 2,000 years.

The commissioned artwork began with a Ground Penetrating Radar scan of the Plaza, revealing the structures below the surface. The public space artwork presented large-format optical illusions that used the forms of an archaeological dig to metaphorically represent the ruins and broken homes that lie below every victory [Fig. 1]. A series of Augmented Reality prints, lightboxes, films and visual experiments also resulted from the data.

Background

Two recent archaeological discoveries triggered the thematic direction for the project. In the past few years, a highly detailed Roman town and a 1,000-year-old Viking ship in Norway were both revealed without moving any soil. Both findings credited advances in Ground Penetrating Radar or Georadar. A humble engineering tool to find underground pipes for decades, recent improvements have led to an increased interest by archaeology as the apparatus now makes it possible to reveal buried objects in high resolution. Safe and non-invasive, GPR has evolved from manually waving a single antenna over the ground to towing multi-antenna arrays from all-terrain vehicles, pairing the measurements with satellite GPS. A crude technology has recently evolved and been appropriated for an entirely new purpose.

Victory Square is located next to the Cathedral of Our Lady of the Assumption in the historic heart of Clermont-Ferrand since its foundation in Gallo-Roman times. Over the centuries, different underground structures have revealed various phases of occupation, but the stones under the artwork hide the original temple complex, part of the larger forum. For this project, the site was GPR scanned in December 2020 at two different frequencies with archaeologists consulting on areas of suspected Gallo-Roman remains.

The Scan Technology

Archaeology's previous sole methodology—excavations—were time-consuming, expensive, and risked damaging the findings, if indeed there were findings at all. It is easy to understand why a non-destructive tool would be so quickly embraced by the field. Ground Penetrating Radar offered a way to map the underground without opening it.

Most important was the technology's newfound ability to produce three-dimensional displays. Identifying pipes, cables or structures in soil or concrete is much easier when represented as continuous lines in a 3D model. This is especially important in increasingly complex urban contexts where below could be multiple intersecting, dipping, or layered targets (pipes, rebar, *etc.*). The 3D modelling ability of the technology suddenly made the detection and classification of multi-layered targets much easier, particularly subtle features that were previously easily missed or misidentified. For this reason, the technology quickly jumped from military and subsurface construction to archaeology.

Electromagnetic pulses—radio waves—are transmitted into the soil and bounce off materials with varying dielectric properties. Different soil horizons, groundwater surfaces, man-made objects, and rock formations all 'echo' the signal

back differently to the antenna. The depth positions of these varied interfaces are calculated from the return time of the signals. Larger dielectric differences between adjacent layers result in larger amplitude of the returning signal waves. This contrast is recorded and transposed into imagery.

Figure 2: Raw Colorized Time Slice and Block GPR Data © Copyright Scott Hessels 2021

The radar pulses are set for distinct depths and result in 'depth slices' or 'time slices' that are fractions of the total data collected by the GPR. A 'slice' is an extract of the dataset with all the datapoints with equal depth (z), or width/height (x/y). The reflected waves are collected from different points of width (x) and height (y) on the surface and matched to the reflected waves' return time/depth (z) and amplitude. When a 3D display is generated, the computer examines each profile and fills in the gap between it and its neighbor with generated data. This interpolation produces a rectangular block of data that formed the core of the artworks produced [Fig. 2]

On-site Methodology and Resulting Dataset

The research was conducted using a 400 MHz receiver antenna with an SIR-3000 GPR system. The sensor recorded 100 scans per second, each scan was sampled 512 times with each sample condensed out of 16 bits. The instrument travelled in a zig-zag mode across a 23x23m surface, recording 92 narrow line scans. Nine depth slices were recorded to 4 meters deep in increments of .5 meters.

Each data point of a time series is ascribed to a position x, y, z and echo amplitude. The result was 307 675x677px images or 140,000,000 vertices, each coordinate with an xyz position that was partnered with a color to indicate amplitude. The z coordinate is calculated from the two-way travel time in nanoseconds measured by the radar and the dielectric constant: wave propagation velocity in ground equals light speed/sqrt (dielectric) and depth equals half the two-way travel time times the propagation velocity. This produced a point cloud with a 1cm distance between each point vertically and 3cm between points horizontally.

It took six months of failed attempts to convert the data into a format that could be used within design software. The project was the first to attempt this leap from scientific data to creative potential and therefore was both literal and figurative 'uncharted territory'.

Figure 3: Design exploration from a GPR layer © Copyright Scott Hessels 2022

The Public Art Experience: Trompe L’Oeil

“Science is to the visual arts what mathematics is to music; it is an underlying structure that informs the potential for aesthetic expression, an expression that in turn enhances and enriches our understanding.” Jeffrey Shaw [2]

The resulting data images were poetic and haunting, abstract to anyone unfamiliar with reading geoscans. To an artist, scientific data can be released from its usual requirement to inform and simply be intrinsically beautiful. Even the limitations with the technology itself translated into metaphor. For example, in the dataset, the surface layers are very distinct but become blurry as the radar attenuates as it propagates through the medium; once below 3m, the signal to noise ratio is not enough to image anything. The deeper the history, the hazier the memory.

A more literal visualization of the dataset was determined to be best presented as prints in an exhibition where the entire process could be clearly detailed for the public. The outdoor experience in the plaza was uniquely tailored for COVID times. The site’s significance meant that the artwork needed to be constructed with materials that would not damage the place and were safe for public interaction. The artist and festival agreed that an open work, with no need for guards nor security, was preferable. The simplicity and endurance of an emerging technology of large-format ground adhesives was selected. Large ‘stickers’ were suddenly becoming ubiquitous, increasingly used as both indoor and outdoor ground markers to separate people in queues and other spaces during the pandemic. The strong, waterproof adhesives could be custom cut to the images and removed at the end of the festival with no damage to the surface of the plaza. The layout meant that the public could be safely distanced, contact-free, out in the open, and have both a physical and virtual experience. It could also produce the 21st century requirement of a selfie.

The artist began conceiving of illusionary portals placed on the plaza surface that would reveal the ruins of an abandoned mansion. Enormous trompe l’oeil prints of disappearing staircases, rooms, wells, and shafts referenced the geometry of archaeological digs. Developed with a graphic

designer based in Budapest, six anamorphic entrances into an imagined world below were created. With a globally distributed team to realize this work, the coordination of the local arts festival helped the project pass through many filters including governments, commercial interests, environmentalists, educators, scientists, art historians, preservationists and more. In April 2021, over 180 square meters of optical illusions were laid over Place de Victoire and opened to the public. The site quickly became widely photographed and attended, with impromptu dance performances, group stagings, children playing, and multiple types of interaction, all within France’s very strict social distancing laws enacted at the time. The project remained in place until total lockdown was reinstated in France, a few weeks later. The site-specific work occurred in a very small and very opportune moment in the pandemic timeline.

The Museum Experience: Augmented Reality Prints and Lightboxes

Figure 4: Detail of *Below Victory: Light* © Copyright Scott Hessels 2022

Following the site-specific event, the artist then studied the data itself for the best areas to be highlighted through creative visualizations. Each depth slice had a unique topography and was meshed with various color schemes and textures applied; the information was so rich that nearly 50 different designs resulted from readings of echoes at varying depths. One layer slice even became the branding design for the upcoming 2022 festival, its strange mix of data waveforms and geological phenomena making for a unique art/science image [Fig. 3].

Combining all the vertical slices and their interpolation revealed the actual structures below the surface. 3D models of the temple’s cella and courtyard, directly formed from the GPR data, were hidden in fantastical natural settings. An augmented reality overlay revealed thin lines of 17th century text from philosopher Blaise Pascal intersecting and running parallel with technological data about the site [Fig. 5].

Lightboxes of models from the data were also created. The connected datapoints glow in the images, as if discovered gold underground, and act as a metaphor for the knowledge and partnerships that have been generated by the project [Fig. 4].

Figure 5: One of 4 Augmented Reality Prints from *Below Victory: Memoria Hospitis* © Copyright Scott Hessels 2022

Conclusion

The collected artworks, including blended physical and virtual elements, considers how loss is deeply integrated, and quickly forgotten, with each success. The bricolage of conceptual, scientific, aesthetic, and historical sources created a moment to consider what is silently buried below our triumphs. The GPR science provided a new point-of-view and led the site-specific artwork to become an inversion of a public sculpture, not an object nor a statue but a sealed urban memory below the surface, literally revealed through an echo.

The result is Place de la Victoire as a spatial conjunction; now but also then, here but also below, real but also virtual. Art often reveals a new perspective, and this project achieved this both metaphorically and literally. An intersection of art, science, heritage, and emerging technologies allowed visitors to look directly down and see a parallel world visible through the echo of the hidden ruins.

This promising new scanning technology also reinforced larger themes of appreciation of cultural heritage, adaptation of science for innovative creative ideas, interactive public experiences that span social media, and a deeper responsibility to understand complex history. Collectively, the project became a unique shared encounter for socially distanced times.

Author Biography

Scott Hessels (b. 1958) is an American filmmaker, sculptor and media artist based in Hong Kong. His artworks span different media including film, video, online, music, broadcast, print, kinetic sculpture, and performance. His films have shown internationally, and his new media installations have been presented in museum exhibitions focusing on technology as well as those presenting fine arts. His recognitions include patents for developed technologies, references in books and periodicals on new media art, and coverage in cultural media like *Wired* and *Discover*. He is currently an associate professor at The School of Creative Media and executive producer of the Extreme Environments Program which organizes art/science expeditions to environmentally significant sites.

Algorithmic Vision and the Dialectic of Visibility

Abstract

This article proposes to analyze the definition of the human being through the 'eyes' of machine learning models dedicated to the recognition and classification of people. For this, the image of a dialectic of surveillance and social control is offered based on the constant visibility of those affected and the invisibility of those who benefit from this system. The algorithmic vision emerges here as a privileged place to exercise this power, but at the same time as the place of vulnerability, from where it is possible to transform this dialectic and the power relations that it determines. The article then proposes a reflection on the different counter-surveillance strategies that take advantage of creativity and aesthetic experience to think about other power relations, that is, about other possibilities to think about what a human being is today.

surveillance, control, algorithm, visibility, invisibility, adversarial examples, human, non-human

Algorithmic Vision and the Dialectic of Visibility

In the West, not only because of the predominance of an 'ocularcentrism' (Jay, 2007: 26) but also because of the cloak of objectivity that has been assumed, vision is the meaning par excellence to know the world. This preeminence is adopted in the research and development of Artificial Intelligence (AI), which partly explains the current popularity of functional applications aimed at image classification or object recognition and detection (WIPO, 2019).

This epistemological preponderance was recognized by the military interests that animated cyber and AI research. Before the first conference sponsored by the Macy Foundation in 1946, computer vision was already considered "one of the most important military instruments that the armed forces possess." (Edwards, 1997: 199). With the development of current systems that take advantage of the potential of algorithmic vision, we should also add to the appointment the police forces and the techno-corporate market forces. Indeed, functional applications with greater resources for research and development are today destined to the fulfilment of surveillance and social control tasks [1], thanks mainly to the effectiveness of algorithmic vision in the recognition, classification and categorization of people, things and situations.

Machine learning (ML), based on artificial neural networks (ANN) and deep learning (DL), is inspired in classification and 'pattern recognition, developed by Oliver Selfridge in his Pandemonium and later applied by Frank Rosenblatt on the Perceptron. ML, DL, and convolutional neural networks would definitely achieve their fame when, in 2006, Geoffrey Hinton took up the ideas of Rosenblatt's Perceptron and Yann LeCun's research. As a result, "in just seven years, the accuracy of classifying objects in the data

set increased from 71.8% to 97.3%, exceeding human capabilities." (Gershgorn, 2017).

The effectiveness of these automatic vision machines (Virilio, 1999: 26) is indebted to another aspect that links AI with other practices of surveillance and social control. Today it is claimed that the DL is a "statistic on steroids." (Press, 2020). And this is because statistics "is eminently a science of classification." (Farr, 1985: 252, cited in Bechmann and Bowker, 2019: 4). Foucault asserts that statistics were established "through the police (...). The police make statistics necessary, but they also make them possible", since the police exist to monitor and control "the activity of men." (2006: 370). Nowadays, thanks to complex statistical calculations, ML and DL have become "omnipresent techniques that constitute new forms of surveillance and governance" (Joler and Pasquinelli, 2020).

So what, then, is the reality for this automatic vision so closely linked to surveillance and control tasks? And, in that context, what, then, is a human being for the algorithmic vision?

The human being and its algorithmic recognition

The operation of the algorithmic vision is based on complex statistical calculations inside neural networks, trained with millions of images in order to carry out the correct classification of the input data. During your training, the parameters of the network are gradually adjusted so that the weight of the 'bias' tilts the classifier towards the desired response. In this way, the machine can identify a person on the basis of his statistically emerging characteristics; that is to say: a human being is for the algorithmic vision a mathematical abstraction of the patterns that emerge with each training image. This automatic vision is thus characterized by what Hito Steyerl (2016) has called "automated apophenia": the machinic perception of patterns within a set of random data.

In the 'eyes' of the machine, human beings cease to be recognizable by observable biological characteristics to become the numerical materialization of a statistical hyper-abstraction, initiated in visually perceptible data, later converted by the deep neural network into a humanly unrecognizable numerical entity. The similarity of visual patterns, which was always for the human being a matter of relations between figurative characteristics, stops working in favour of an automatic perception that already has nothing familiar to our sensitivity: "not seeing anything intelligible is the new normality." (Steyerl, 2016)

Visibility and Invisibility: The Dialectic of Surveillance

What can be seen can be controlled. This statement is increasingly present in the algorithmic vision. On the contrary, the invisible departs from this power. On the one hand, our current 'computational regime' has become a system "practically invisible to our eyes" (Bridle, 2020). What should be presented under the reflections of an actively vigilant society is, on the contrary, beyond our

visual reach. Despite its incarnation on screens of all kinds, on mobile devices or gadgets familiar with our closest environment, the true functioning of AI appears to us as something invisible and unintelligible.

On the other hand, there is a permanent demand to make the human being, his life and his image, something immediate, constantly accessible to automatic perception. Cyber absence is now suspicious, just as disconnection becomes a punishable act of rebellion. As in "1984", we are required to have a constant cybernetic exposure and connection, in such a way that it is always possible to trace the path of our movements, decisions and desires. We are faced with a system in which the people under surveillance have little or no control over the technological system that watches over them.

This is the dialectic of visibility and invisibility in the context of an actively vigilant synthetic gaze: while the vast majority of the population is required constant exposure to the 'eyes' of the machine, the surveillance and control systems, as well as the people, institutions and, in general, the interests that animate this entire network, remain completely invisible before the 'eyes' of the public. A power based on coloniality and gender, race or class discrimination is articulated on this dialectic, which reinforces the hierarchies and historical discriminations that millions of people have suffered. Algorithmic insight extends this tradition with statistical precision that promises to keep everything under control.

According to Byung-Chul Han: "You cannot see differently without exposing yourself to a violation. Seeing presupposes vulnerability". (2015: 27). If all technology produces its own accident (Virilio, 2010), that characteristic of the algorithmic vision is its vulnerability (Carlini and Wagner, 2017) to recognize and classify correctly.

What strategies are possible to hack that hyper-abstraction that today defines us as humans for algorithmic vision? How do we become non-human to the machine? How to give face and body to that which has escaped from our gaze and, thus, from our vigilance?

Visibility and invisibility strategies

What is at stake is not only the underpinning of a totalitarian and discriminating surveillance and control system but also an ontological proposal related to the ability of the machine to recognize what is presented to it. In the eyes of the machine, we are recognized and classified based on certain bodily characteristics, in such a way that the transcoding of these computationally calculated features has the potential to change algorithmic reality. The Adversarial Examples (AE) are erected in this sense as a fundamental part of the possible strategies for the invisibility of those people forced to their visibility.

First identified, defined, and named in the field of computer vision in Szegedy, et al. (2014), the investigation of EAs began with the discovery of a "counter-intuitive" characteristic of ANNs, namely, their possible instability with respect to the introduction of small disturbances within the images of the dataset. By changing or attacking certain pixels, for example, it is possible to incite visual

agnosia and deactivate the recognition and classification mechanisms.

According to Goodfellow, et al., (2015), both linear and non-linear RNAs are susceptible to being deceived by AE. "Adversarial vulnerability is a direct result of the sensitivity of our models to well-generalized characteristics in the data." (Ilyas et al. 2019: 1). This means that the AE are not errors, but indeed accidents, that is, characteristics intrinsic to the training of the classification models. The AE will thus become a possibility to imagine the "rebellious subject or the anomalous event that escapes classification and control". (Joler and Pasquinelli, 2020).

From the first attacks with physical objects (Kurakin et al., 2017; Sharif et al., 2016, Brown et al., 2018) in real scenarios (Papernot et al., 2016; Papernot et al., 2017, Eykholt et al., 2018); with objects printed in three dimensions (Athalye et al., 2018); or with images of other users (Smith et al., 2015), today these strategies have been expanded and refined. Guetta et al., (2021) have implemented an even more effective attack on facial recognition models, employing common makeup. Others (Su, et al., 2019), have discovered that single-pixel data completely transforms the reality of the algorithm. And, although different in its methods but similar in its purposes, the VFRAME collective [2] has created the Dface application to make any face in an image invisible, making it impossible to use it for surveillance and control purposes.

On the other hand, and to complete the repositioning of power relations within the visible/invisible dialectic, recent years have witnessed a wide and diverse movement of aesthetic and political practices that question the operation, location and secrecy algorithmic control and surveillance systems.

In tune with the work of Trevor Paglen in *Limit Telephotography* (2006)[3] and *The Other Night Sky* (2010)[4], where he tries to reveal the material places of surveillance and social control; or with that of Harun Farocki in the film essay *Gefängnisbilder* (2003)[5], where he shows the dialectic of the "watchful eye" (Farocki, 2008), nowadays other strategies have forced the hidden powers to incarnate in subjects, groups or institutions, legally responsible for the surveillance and exclusion system from which they benefit. Levendowsky (2021) has proposed a legal strategy, based on copyright infringement, - which is what companies do when they create datasets without the authorization of people whose faces are used for training facial recognition models. The most interesting thing about this strategy is the obligation of companies hidden behind a complex legal apparatus, to respond publicly. An initiative with similar claims is *Reclaim your Face*, by Paolo Cirio (2020)[6], which seeks not only a ban on these recognition technologies but also the legal responsibility of those who benefit from them.

What is the proposal?

The transformation of the dialectic and the repositioning of power relations within it is closely linked to strategies that take advantage of creativity and aesthetic experience. The artistic proposals reviewed here are a clear example of how the totalitarian look of the algorithmic vision can be deceived, evidencing its vulnerability.

This accident typical of ANNs puts the ontology of the human being in suspense as a recognizable entity through statistical inferences that identify its "patterns" in a dataset. The series of numbers that allows the machine to know exactly what a human being is or is not, is the numerical chain that today ties millions of people to incessant vigilance. However, a simple change in this chain allows us to think about the political potential of invisibility.

The effectiveness of surveillance, then, depends on this algorithmic definition of the human. The core of the question is located in this numerical definition: its transformation becomes the possibility of altering the algorithmic reality and the positions within these power relations. The place that completes this dialectic is shaped by the unveiling of what remains invisibility.

Conclusions

The algorithmic vision has brought with it a new definition of what a human being is. Today, in the "eyes" of machine learning algorithms, the human being is a completely different entity from what he has been before. Regardless of the possible benefits of this new definition, this article

historically discriminated people and groups.

The dialectic between visibility and invisibility proposed by the algorithmic vision at the service of technocorporations and security agencies determines the positions of the subjects within the power relations that crystallize there. Faced with this, this article has wanted to highlight the importance of those creative proposals, which take advantage of the possibilities of the aesthetic experience to think about strategies of counter-power and counter-surveillance from technological activism, approaching the possibilities of the algorithmic vision to imagine and perceive other realities.

Finally, the possibility of thinking about the human and the non-human necessarily passes through the places from which these definitions are produced. In this case, the entire system that allows the algorithmic vision to function. Likewise, the possibility of thinking about other relationships not only between humans, but also between humans and non-humans, goes through creative strategies that dare to question, and at the same time understand, the mechanisms of algorithmic power. Today, what is possible is a reconfiguration of power relations, within which the very idea of who we are is at stake.

Umwelten: Shifting agencies among the human, the non-human, and a machine learning algorithm

Puneet Jain
Concordia University
Montreal, Canada
puneet798@gmail.com

Abstract

This work is a research-creation project that invites a human, a non-human (a touch-me-not plant), and a machine-learning (ML) algorithm to question and re-formulate the relationship among themselves using the concept of ‘umwelt’ given by the German biologist Jacob Johann Von Uexküll. Through this project, the human and the non-human are brought in the same physical space (with different umwelts) to interact with one another and an ML algorithm, each having an agency to change others’ environment and hence, their umwelts. Such interactions are manifested on the screen (using a text writing platform developed as a part of this project) where the typography of the text dynamically changes over time based on such interactions, encapsulating a space where a non-linear and confusing typography symbolizes the overlapping, collision, and entanglement of the umwelts of these organisms - depicting the shifting of agencies among the human, the non-human and the machine learning algorithm over time.

Keywords

umwelt, senses, perception, human, non-human, machine-learning

Introduction

The concept of Umwelt (meaning “surrounding world” or “environment” in English) was given by a German biologist, Jacob Johann Von Uexküll. According to Uexküll, an organism should not only be treated as a objective entity or physio-chemical being (as per biology) but as a being whose existence is established based on the behavior in the environments it inhabits. Therefore, according to Uexküll, an animal together with its environment forms an ‘umwelt’ - a sensory bubble that is shaped by the sense-perception of the organism in that particular environment. For example, according to Uexküll, something as simple as a flower can be a sign of aesthetic to a human, a pipe full of liquid for an insect, a place to navigate for an ant, and a home for a bee [10] - the same flower yet perceived differently depending on the umwelt of the organism. Therefore, this sensory bubble not only limits the perception of an environment for a particular organism but also shields the organism from our observation. In other words, Uexküll strongly criticized the existence of a reality outside one’s own subjective experience (or beyond the sensory bubble or umwelt).

Figure 1: The set of the project, Umwelten

In contrast, natural sciences like physics have strongly believed in an objective reality and hence anthropomorphize the non-humans as ecosystems or as habitats. Such a viewpoint as claimed by the Feminist scholar Donna Haraway leads to a profound belief in human exceptionalism and bounded individualism [3]. Furthermore, as Environmental scientist Haydn Washington puts it - “It [Anthropocentrism] removes almost all moral standing from the non-human world, seeing it purely as a resource” - amplifying a troubling idea of philosophical ownership of humans over the non-humans [12].

Umwelten, as a research-creation project thus playfully provokes this ideology by inviting a human, a non-human, and a machine learning algorithm to interact with each other in the same physical space (with different umwelts) to re-formulate their relationship with one another through a shift of agency over time. While Uexküll limits the concept of umwelt to animals and humans, this project expands it further to the sense-perception of a machine-learning classification algorithm as well, an algorithm that senses images and classifies them into categories. Through a text writing platform developed as a part of this project, the interaction between the human, non-human, and the machine learning algorithm is visualized in the form of a dynamically changing, confusing, and non-linear typography over time on a screen - a typography emerging from the shifting and sharing of agency

among the three entities. In the sections that proceed, a brief related work is described which is followed by the set up of the project, reflections from the audience interaction with the installation of the work, and the conclusion.

Figure 2: A static shot of the dynamically morphing typography displayed along with classification probabilities from the machine learning algorithm and typing speed as visual outputs on the screen

Related Work

Engineers and artists have built a plethora of interfaces to communicate with non-humans through multiple modalities such as sound and touch. The Plantron [2] by Dogane is a bio-electric interface that analyses values of electrical changes measured from plants and converts them into audible sound, reflecting how humans affect an environment and ecosystems through bodily interaction or artificial intervention. Project Florence, a plant-human interface [8], uses human language (though restricted to English) as a medium to initiate a communication between the plants and humans. Wahby [11] has presented a bio-hybrid approach of using autonomous distributed mechatronics to shape the growth of natural climbing plants. Cyborg botany have also been studied recently by Sareen et al. [7] that uses biological processes of plants to act as sensing mechanism for human-non-human interactions.

While there is always an ambiguity of expectations when interacting with the non human (also explored by Triebus et al. in a recent installation [9]) most of these projects do not escape the anthropocentric view and in fact use it at their resource for a deliberate communication with the non-human. Vanessa Watts [13] claims such a thought process to fall under a hegemonic Euro-Western epistemological-ontological framework, contrary to Indigenous (Haudenosaunee and Anishnaabe) cosmologies according to which land, humans, non-humans cannot be separated from each other - each existing by circulating an agency among one another. With a dominant culture of amplifying political economy and productivity, scientifically oriented 'objective' pursuits of

communicating with the non-human portray a falsified belief of ascertaining truth [6]. Tim Ingold [4] has defined such a feature of production as a "subjection of an extractive process to intentional control".

Umwelten (while fully aware of the incapability of escaping the objectification of the non-human) opens a dialogue between the human, the non-human, and the machine learning algorithm by pushing the human to adjust to the spatio-temporal scales of the non-human. Hence, questioning the hegemony of agency between the human and the non-human. The text writing platform developed as a part of this project allows the human to type while the plant and the machine learning algorithm have the agency to alter the typography (spacing between letters, color of the text, font size of individual letters) over time, a time different from the clock time for a human to perceive - the computational time of the machine learning algorithm and the time-scale of the touch-me-not plant.

Set Up

The set up consists of a *Mimosa-pudica* plant, a machine learning algorithm, a human, a camera along with a custom-made text writing platform where a dynamically changing typography on the screen symbolizes the interaction between the aforementioned entities. The plant, a camera facing the plant, a monitor (to see the typed text), and a physical keyboard (for the human to type) were all placed in the same physical space in close proximity to each other as shown in Figure 1. Furthermore, each one of them are described in detail below:

Mimosa-Pudica (touch-me-not plant)

The non-human chosen for this project is a touch sensitive plant, *Mimosa Pudica*. Also known as a touch-me-not plant, the leaves of the plant fold inward (close) or droop when acted upon by an external stimuli (wind, a poke by a human hand etc.) and re-open in approximately 8-10 minutes of human clock-time. Moreover, the leaves of the plant are also susceptible to droop in the absence of sunlight (during night) and re-open in the presence of sunlight.

Machine learning algorithm

Assuming the touch-me-not plant has two specific states of existence with leaves open and with leaves closed, 150 images of the plant were captured in those two specific states in different lightning conditions (during the course of a day). Hence, two image data sets were created each having 150 images and labelled with two categories - *Mimosa Open* (images which have leaves open) and *Mimosa Closed* (images which have leaves closed).

Using Google Teachable Machine [1], a machine learning classification algorithm was trained using the aforementioned image data sets. The image data set was used as an input to a machine learning algorithm to learn the states of the plant, using which a mathematical model (or a machine learning model) was trained. After the model was trained, any new

image of the plant as an input to the model would predict the state of the plant with respective probabilities. The state (Mimosa open or Mimosa Closed) with a higher probability output was assumed to be final prediction by the trained model. In order to test the trained model with new images of the plant, the plant was placed in different settings and light conditions and additional images were added to either of the data sets (and re-trained) to improve the machine learning model and achieve a testing accuracy beyond 99 percent. The model trained was later exported as an open source link and used in a p5js script (the script that runs the text-writing platform).

Camera

A Logitech camera (720p, 30fps) was set facing the plant to capture images of the plant frame by frame and send it to the machine learning algorithm in real time. The camera was glued to the same table (as shown in Figure 1) where the plant was placed and was free to rotate on one of the horizontal axis. The degree of freedom along the one of the axis enabled participants to play with the camera and its placement to capture images of the plant at different angles and thus observe dynamic changes in the typography on the screen.

Human

The audience members (the human) were invited to type through a physical keyboard and doing so one could observe the text appear on the screen in real time (See Figure 2). The appearance of the text, however, was not homogeneous, static or linear on the screen as it depended on several factors described in the later section. One of the factors which the human could control was the typing speed which had a direct correlation with the color of the text, font size, and spacing between the letters - resulting into a dynamically morphing typography on the screen even when the user has stopped the typing.

Text Writing Platform

A text writing platform was created using an open source javascript library (p5js) so that the work can be accessed and replicated easily by anyone as it is hosted on the internet publicly. The p5js library provided inbuilt functions to modify the background color, color of the text, the size of the font, and positioning of the letters typed by the user in real time.

Factors influencing the typography on the screen

The typography on the screen depended on several parameters (or factors) and would even change even when the audience has left the installation space. The factors are described in detail below:

Typing speed of the human

As the audience members typed through the keyboard, the typing speed was calculated in words per frame (the frame rate here refers to the time duration between the consecutive images clicked by the camera). The typing speed was then

mapped through an exponential function to the spacing between individual letters, color of the text (from 0 [black] to 255 [white]), and font size of the text. The typing speed was one of the factors which gave the human an agency to alter the typography on the screen.

The images captured by the camera

Although not a direct influence, the images of the plant clicked by the camera had an indirect influence on the typography on the screen as these images would be an input to the machine learning algorithm (also called the machine learning model) thus having the agency to alter the typography on the screen in real time. Since the classification algorithm detects pattern in the neighboring pixels in the image internally, the placement of the camera, the angle of the camera pointing towards the leaves of the plant, the lighting conditions in the room (which would affect the quality of the image) were all implicit factors which would result in a dynamic change in the typography of the text.

Predictive probabilities by the machine learning algorithm

The images captured by the camera act as an input data for the trained classification algorithm. Internally, the algorithm uses convolutional neural networks [5] to classify the images into categories. In our case, the machine learning algorithm will be called a binary classifier as any input image to the algorithm outputs two probabilities for the respective labels (that is, Mimosa Open or Mimosa Closed) denoting whether the algorithm detects the leaves of the plant to be open or closed based on the images captured by the camera in real time. One should note that the algorithm internally does not understand the images by context, but detects pattern in the pixels of the image to map it to the respective categories, thus outputting the probabilities as a measure of confidence in detecting whether the leaves are open or closed. For example, an input image of the plant might give an output as 0.8 for the category 'Mimosa Open' and 0.2 for 'Mimosa Closed', depicting that the algorithm is 80 percent sure that the leaves of the plant are not folded but open. These probabilities are also displayed on the screen in real time for the audience members.

These probabilities are again mapped using a mathematical function to dynamically influence the typography on the screen thus giving an agency to the machine learning algorithm along with the human and the non-human. One should also note that even when the camera is not pointing to the plant, the algorithm still outputs a prediction, further explaining that the algorithm does not understand the context but have an ability to sense (a sense to recognize pattern in a pixelated image) the environment through images, hence, having a different *umwelt* than a human.

Interaction with Audience and Observations

This work was exhibited at Ars Electronica Festival in Austria in September, 2021 under the theme EMERGENCE/Y. However, due to COVID-19 travel restrictions the work was both

Figure 3: Two participants interacting with the installation

physically manifested in India, exhibited at authors home for the local audience to interact and also showcased at Ars Electronica in the form of a video installation. For the local exhibition in India, due to COVID-19 restrictions only two participants (age 11 and 13) were invited and the set up and working of the installation was explained beforehand. Both the participants had freedom to type and play with the plant (poke the leaves etc.) and observe the changes in the typography of the text on the screen. Since the participants were filmed but not interrupted during the interaction, following observations were made:

- Both the participants divided their task during the course of the interaction. One of the participants typed while the other played with the plant.
- Although not intended as a method of interaction, one of the participants changed the orientation of the camera to forcefully see variations in the typography.
- The influence of the typing speed on the text acted as a gamifying factor, since the participants tried typing faster to influence the typography more dynamically in real time.

Conclusion

A customized text writing platform is developed as a research-creation project to bring a human, a non-human (touch-me-not plant) and a machine learning algorithm into the same physical space but with different umwelts - to question the agencies they have over each other. While the human influences the typography on the screen by varying typing speed on the text writing platform, the agency is also circulated among the touch-me-not plant and the machine learning algorithm as they dynamically alter the typography along with the human but at different time-scales (the computational time of the algorithm and time-scale of the plant). Hence, borrowing the concept of umwelt by the German biologist Jacob Johann Von Uexküll, this project manifests the overlap and entanglement of the umwelten of the three organisms through the text writing platform - depicting a shift of agencies among the human, the non-human and the machine learning algorithm.

AI Art and the “Transparent Author”

Raivo Kelomees

Estonian Academy of Arts, Tallinn, Estonia
raivo.kelomees@artun.ee

Abstract

Artificial intelligence (AI) technologies seem novel in an artistic context yet, by exploring certain proposed new terms, I aim to demonstrate that the practice of ‘relinquishment’ of creative activity has its roots in art history. The following questions will be addressed in the paper: can such a ‘relinquishment-technique’ be considered a universal mechanism for artistic inspiration? Can we find something similar in surrealist techniques? Is the author disappearing or becoming ‘transparent’ when abandonment of creative activity occurs? Does AI-based art assume the transparency of the author and is it possible that artworks can be created by other artworks? The terms ‘linear’, ‘circular’ and ‘closed-loop’ concept transfer will be analysed with regard to interactive artworks.

Keywords

Artificial Intelligence Art, Surrealist Techniques, Transparency of the Author, Interactive Art, Linear Concept Transfer, Closed-loop Concept Transfer.

Introduction

There has been much discussion about how artificial intelligence (AI) revolutionises everything, ranging from day-to-day situations to mass production, including creative practice, and the automatising of users’ online behaviour: “It recommends what we should see, listen to, read, and buy” was noted by Lev Manovich in 2018 [1]. AI technologies exert an influence over our everyday choices, the ways in which we represent ourselves and how we perceive others. Another quote from Manovich [2] that should be kept in mind as a backdrop to this article is: “What defines whether something is “AI” is not a method but the amount and type of control we exercise over algorithmic process.” In the subsequent discussion I would like to use the term ‘intermediary technologies’ to describe the various methods, tools, mechanisms, software and technologies that humans utilise to obtain information from the external world and to carry out their creative practice. These intermediary technologies are situated between humans and the external world and serve to vary or enhance human behaviour allowing it to be more effective, rapid and informed. To a certain extent all previous technologies—beginning with writing—were enhancement technologies which influenced humans to better understand the world and communicate with each other. These are well-known McLuhanesque concepts, relating to how the means of transmission of a message influence the message itself.

The paper will discuss the various mediating technologies which function as support systems for intelligent artistic behaviour. Several creative technologies, exemplified below, illustrate ways of externalising mental and creative activity. These techniques of externalisation, relinquishment and automatising of creative activity are common denominators in the various analogue methods used historically in art practice and intellectual entertainment to uncover new creative opportunities. In the examples below we can recognise similarities with AI in the manner in which the responsibility and authorship is ‘given away’ or ‘relinquished’ and the author becomes ‘transparent’ as the mechanisms and techniques take responsibility over the final outcome.

Material and Conceptual Intermediaries

The phenomenon of authorship is a relationship between an author and their work. The authorship, when represented in terms of a ‘concept transfer’, could be depicted as a *vector*, an imaginary arrow, which connects the author and the artwork and represents a variety of **material and**

conceptual intermediaries (tools, materials, technology; rules, methods, algorithms). As a rule the author is understood here as a biological person, a human being. The artwork can be a physical object which has emerged due to the unique activity of the author, or could be a sort of immaterial artefact such as a digital artwork or a performative or processual ‘object’.

On the *vector* from author to artwork we could ‘mount’ different tools, technologies, processes and intermediary events and the resultant artwork could be considered to vary in its ‘distance’ from the author. For instance, drawing refers to the use of manual tools to leave traces on the surface of that which is called the artwork. In this transformative process there are not many elements: author, pencil, paper and time (drawing could, of course, involve a variety of other tools and surfaces). In more complex creative practices this *vector* refers to a computer, software programme and/or other technologies. The software could function with different degrees of autonomy and if AI-based then it could actually replace the author. The various means of AI-based creation involve different degrees of artistic participation, ranging from providing an authorial support function (as is typical with photo editing software) to the total replacement and imitation of the author. In extreme situations the author is little more than an instigator of the process of creation which is not dependent on his or her decisions. In this case a prerequisite is the transfer of the creativity principles and rules to the autonomous system, and that it is capable of learning them.

Technologies of Creation as Technologies of Transformation

From drawing tools to artificial intelligence the methods and media used in art practice have evolved. This can be exemplified by a variety of intermediate forms, but the underlying point is that every mediating technology situated between author and artwork that changes creative practice also changes something in the author and the artwork. The artist creates and changes the work, but this work itself changes the author: a feedback loop is formed between the technology of creation, the author, and the work, which forms an almost closed system that effects change in all the constituent elements.

The novel and playful possibilities brought about by new technology can inspire a sense of excitement and exaltation in the author, but its importance lies in its function as a **transformation technology**, not simply as a **transmitter technology** to turn an idea into materiality, because it changes the transmitter and transforms both the creator and the creation. Most authors have experienced—and are eager to repeat—the effect of **self-transformation through creative activity** which takes place with the assistance of technology.

The Externalisation of Authorship

The utilisation of technical methods and autonomous technologies that are capable of imitating an author’s creative activity produces a situation in which we can say that the **author has relinquished the authorship to an external mechanism**, a computer programme, an AI, or in more general terms to an external agent. The authorship is shared between the artist and this external agent. In the context of traditional art this seems problematic, since there is an expectation that the author controls and produces the artwork from beginning to end. This ‘relinquishment’ of creative activity is a rather artificial construction which raises questions about the extent to which it is taking place. For example, we can say that in abstract and action painting the artist has handed over decisions on how the paint and/or objects fall on a surface to chaotic processes if we consider

practices based on gestures and physical acts, such as those performed by Jackson Pollock, Niki de Saint Phalle, Gustav Metzger, Arman, Daniel Spoerri, Hermann Nitsch and others. Nevertheless, Jackson Pollock exercised control over the paint to a certain degree despite his drip-based technique. Pollock stated that there is no accident in his paintings, no beginning and no end [3], but a study of Hans Namuth's film offers the opportunity to disagree with the artist: although the throwing of paint onto the surface was conscious and deliberate it is impossible to claim that each drop's landing was completely controlled by Pollock. The emergence of the image is both controlled and non-controlled at the same time: the artist exercises a general control, but the entire creative activity contains chance-based episodes caused by the inexact trajectory of the falling paint drops onto the surface.

Pollock could be defined as an 'intuitive' artist, who had no experience in systemic art, as was suggested by Philip Galanter [4] in his article "What is Generative Art?".

Surrealist Techniques as a Randomisation of Creative Practice

In the surrealist techniques of *frottage* and *grattage* the control over the making of an image is given over to accidental and random events. In *frottage* the artist attempts to 'print' chaotic visual effects by placing the paper or canvas over rough surfaces and rubbing with charcoal or pencil: the result exhibits an unexpected visuality which is reminiscent of landscape. In *grattage* the visual image is revealed by scratching or scraping into lower surface layers of the canvas. *Decalomania* is also chance-based, in this process the surface is covered with thick paint and then paper, aluminium foil or glass is placed over the top and removed. The result could provide the source for a possible follow-up painting or can be considered a ready-made artwork in its own right. These techniques were practiced actively by **Oscar Dominguez** and **Max Ernst**.

Figure 1. Oscar Dominguez *Untitled* (1936)

Many other techniques and methods exploited by the surrealists are worthy of mention here. *Automatism* is the general term for creative practice in which the creator 'switches off' their reason and control. *Bulletism* is similar to inkblot drawing and painting. *Calligramme* is a writing practice using words. *Cubomania* was invented by Gherasim Luca and involves a painting being cut into squares which are randomly put together. The *Cut-up* technique involved newspaper words being cut out and reassembled into a new story. *Entropic graphomania* was the practice of connecting the words on a page by drawing lines between them so as to 'write' a new story. The *exquisite corpse* has probably inspired the most popular

usage amongst visual artists, and is performed by several participants in a process of collaborative drawing—numerous digital interpretations of this activity have been produced during the last twenty years which allow participants from different locations to contribute to one communal drawing. *Indecipherable writing* can be mentioned here as a peculiar method of nonsensical writing practice which is performed spontaneously, imitating the manner of writing but with visuals devoid of recognisable signs. Many other techniques such as *soufflage*, *paranoiac-critical method*, *étrécissements*, *surautomatism*, *triptography*, *outagraphy*, and *involuntary sculpture* were employed by the surrealists. Most techniques were based on spontaneity, freed from artistic intention and will, allowing things to happen and examining the results afterwards. 'Post-creation' revisions and corrections were frequently applied, particularly in the case of *decalomania*, which was mostly utilised as an inspiration-technique for the generation of randomly-looking landscapes.

The 'Relinquishment-technique' as a Method for New Ideas

In the above examples of surrealist techniques there is a relinquishment of authorship and the episodes of creative activity occur with the assistance of manual visualisation practices: the author/artist gives away control and later takes it back. The author intervenes after the period of relinquishment, reclaims the work and continues from the new situation, but this is no longer the same work and it could appear surprisingly and inspirationally fresh and new. Different kinds of relinquishment of authorship occur in the case of audience participation artworks. Interactive art exemplifies this most clearly: the artwork's existence is defined by the 'collaboration' between the viewer/audience and the physical entity of the artwork. This entity could be called the 'pre-artwork', a term which I use to describe the participation-enabled technical-material entity before the participation actually takes place. Ironically we could argue that a pencil lying on paper is also a type of pre-artwork in the sense of a 'pre-drawing'. This argument can be colourfully advanced by a quote from Michelangelo: "The sculpture is already complete within the marble block, before I start my work. It is already there, I just have to chisel away the superfluous material." [5]. Combining pencil and paper in the activity of drawing results in a drawing, a similar situation to the function of an interactive piece which comes to life because of participation. There is however a marked difference: the drawing activity is not presented as an artwork in its own right unless it is staged as a performance. Experiencing interactive art, however, means being in the territory of the artwork, inside the artwork. Thus the interactive artwork is by nature performative, engaging for participants and performative for spectators.

Certain specific categories of technical and computer-based art such as algorithmic and generative art show this relinquishment act most clearly. Theoreticians have claimed that generative art could be performed manually, but they consider the term in connection with technique-based art practices. Algorithmic art is connected to digital art and could be considered as 'instruction-based' or 'rule-based' art. The instructions for the creative act emanate from the 'external machine' to which the artist relinquishes (totally or episodically) the creative activity, inputting some form of raw material to this 'instruction machine' and obtaining a result. This 'machine' could be metaphorical, or it could be an actual machine. It could be a written list of instructions or rules about how to make something (rather like a cooking recipe) but could equally take the form of programming code which runs on computer hardware. A classical example of algorithmic instruction is Tristan Tzara's *How to Make a Dadaist Poem* (1920) in which he describes, line by line, actions which should be performed in order to create a chance-based poem. In the same manner Sol LeWitt's [6] sentence "The idea becomes a machine that makes the art" is a metaphorical description of conceptual art. The idea could take the form of instructions, a sequential order of

proposed actions, which result in a final work that could be different each time the instructions are carried out.

POUR FAIRE UN POÈME DADAÏSTE :

Prenez un journal.
Prenez des ciseaux.
Choisissez dans ce journal un article ayant la longueur que vous comptez donner à votre poème.
Découpez l'article.
Découpez ensuite avec soin chacun des mots qui forment cet article et mettez-les dans un sac.
Agitez doucement.
Sortez ensuite chaque coupure l'une après l'autre dans l'ordre où elles ont quitté le sac.
Copiez consciencieusement.
Le poème vous ressemblera.
Et vous voilà "un écrivain infiniment original et d'une sensibilité charmante, encore qu'incomprise du vulgaire."

AA L'ANTI-PHILOSOPHIE ET TRISTAN TZARA.

Littérature 15, juillet-août 1920

Figure 2. Tristan Tzara's *How to Make a Dadaist Poem* (1920)

The Relinquishment of Combinatorial Activity

Computer programmes are the most complex form of representing instructions, consisting of a successive chain of actions which the computer is tasked to perform. Artists also sometimes think in terms of rules, acting almost machine-like and algorithmically, deriving each new action from the previous step whilst relying frequently on intuition and the impulses of non-rational and accidental actions. By episodic relinquishment of the creative activity and handing over the decision-making to the machine, the machine/computer/AI acts, or a line of instruction is executed, without interference from the artist.

Understandably, relinquishing combinatorial activity to an external mechanism or allowing combinations to happen by chance are well discussed themes in the field of art history. There exist a significant number of chance-based artworks and even artistic trends in which the non-planned action of the artist is intentional, is documented and performed (examples being Marcel Duchamp's '3 Standard Stoppages' of 1913-14, Niki de Saint Phalle's 'shooting paintings', Viennese actionism actions and paintings, and Daniel Spoerri's 'snare paintings'). In addition, there are plenty of interactive and multimedia works which allow multiple 'endings' whereby the audience can complete the artwork in a different way each time. In Bill Seaman's 'The Exquisite Mechanism of Shivers' (1991), which was converted to multimedia CD-ROM in 1994, the user can combine discrete video clips into short video sequences which are complemented by a combinatorial sentence of text. In Ken Rinaldo's 'Augmented Fish Reality' (2004) the audience is 'viewed' by fishes in rolling fish-bowls which can be physically moved according to the swimming motions of the fish themselves. Numerous artworks reflect this open structure which becomes the basis for continual variations of the work, yet at the same time these works are able to function as closed self-referential loops, as is evident in Ken Rinaldo's piece in which the 'data' that the artwork processes is an integral part of the artwork itself—the movement of the fishes. A similarity exists with certain AI artworks such as Mario Klingemann's 'Memories of Passersby I'. Based on classical portraiture, this work is "... an autonomous machine that uses a system of neural networks to generate a never-ending, never-repeating stream of portraits of non existing people." [7] There is no input to this work from outside the piece itself, hence it is essentially a closed work, it is not open.

Here I wish to return to my earlier proposal of an imaginary vector representing the 'concept transfer' from the author to the artwork, in which the term 'intermediary technologies' is used to describe the conceptual, material and technological transformations 'between' the artist and the final work. This process results in a consistent artwork. We can distinguish between the different forms in which this 'transfer' of ideas from author to artwork can take place. The most primitive form could be called the 'linear' concept transfer, typically occurring in the traditional art-making

process: the work is made by the artist and it remains as such forever.

"Linear concept transfer"

Figure 3. "Linear concept transfer".

In interactive art the work exists as a series of transformations. Theoretically, each interaction with the work is a different realisation of the concept which is reflected back upon the author or audience. We can call this a 'closed-loop concept transfer' since each realisation is able to feed back modifications to the concept produced by the software and hardware of the work.

"Closed-loop concept transfer"

Figure 4. "Closed-loop concept transfer".

In these artworks the interaction takes place by means of 'intermediaries' assembled by the author, and the author may even become part of the installation and be involved in the interaction, becoming one of the many variables with which the user interacts. This is typical in artworks that contain performative elements and the artist's physical presence. Examples include Stelarc's performative and interactive works and Sonia Cillari's interactive work 'Se mi sei vicino/ If you are close to me' (2006) in which the performer's presence is part of the installation and therefore the concept—audience members can move the performer or move themselves around the performer, creating real-time animations on screen.

Interactive art

Figure 5. Interactive art "closed-loop concept transfer".

In interactive and AI-based art the author's position could be described as 'transparent'. The author in these artworks seems irrelevant due to the fact that the artwork produces creative combinations autonomously, without interference nor the need for any initial input from the author. This latter case is hard to imagine because even in AI-based art the responsible person or initiator of the input maintains a

presence. The aforementioned work by Mario Klingemann, for example, was conceptualised, designed and programmed by the artist. In the introductory video for this work Klingemann presents an analogous example: “If you hear somebody is playing a piano, would you say that piano is the artist? No.” [7] The same applies to works made using AI. Even if such works generate constant variations of visuality which are not pre-determined by the author, it is still the author who has instigated the process which could theoretically maintain its transformative existence forever. In that sense the ‘transparency’ of the author does not imply complete absence but rather the absence of the author’s influence over the content of the work. The situation in which an artwork is designed by another artwork is a somewhat theoretical case. Although Klingemann’s project ‘plays’ its transformations via a closed framework of dataset portraits and neural networks, it is possible to imagine a more open work which compiles its dataset autonomously by retrieving information from a network in real time. In this case the unpredictability of the result is again increased and the author’s role shifts even further, becoming more transparent.

AI art and the “transparent author”

Figure 6. AI art and the "transparent author".

Conclusion

The aim of this paper has been to discuss the relinquishment of authorship in traditional art practices, by analysing how this has been exploited in earlier creative practices and to question whether the situation is different with AI-based art. The answer turns out to be both yes and no. The technology used in such artworks is certainly new, and the cultural context in which the results are presented is different. The types of transformation produced using AI techniques can be surprising, for example the generation of imaginary faces and non-existent people, but even this is not impossible for traditional artists to accomplish by using their own techniques to ‘synthesise’ and visualise non-existent faces. In that sense it is hard to consider such types of work as a specific achievement of AI, although AI is incomparable in its productivity and the variation in the visual artefacts it can generate. An interesting case could arise where the artwork is designed by another artwork, such that the creative activity is instigated and maintained without any help from a human artist.

Biography

Raivo Kelomees, PhD (art history), is an artist, critic and new media researcher. He studied psychology, art history and design in Tartu University and the Academy of Arts in Tallinn. He is senior researcher at the Fine Arts Faculty at the Estonian Academy of Arts and professor at the Pallas University of Applied Sciences. Kelomees is author of *Surrealism* (Kunst Publishers, 1993) and article collections *Screen as a Membrane* (Tartu Art College proceedings, 2007) and *Social Games in Art Space* (EAA, 2013). His doctoral thesis is *Postmateriality in Art. Indeterministic Art Practices and Non-Material Art* (Dissertationes Academiae Artium Estoniae 3, 2009). Together with Chris Hales he edited the collection of articles *Constructing Narrative in Interactive Documentaries* (Cambridge Scholars Publishing, 2014).

Perlin Noise and Sovereign Land: *Minecraft*'s World Generation Algorithm and Colonialism

Chris Kerich

University of California, Santa Cruz
Calgary, Alberta
ckerich@ucsc.edu

Abstract

This paper explores the connection between procedural generation technologies, specifically those used in world generation in 2011's *Minecraft*, and colonialism. Specifically, it examines the ways that the Perlin noise generation algorithm generates a world that exists specifically for the player's extraction of resources, and provides control mechanisms so that the world is never too wild or untameable. The paper concludes with reflection on some methods by which these colonial ideas might be subverted in games that use procedural generation technology.

Keywords

Procedural Generation, *Minecraft*, Colonialism

Introduction

One of the things that digital technologies do more than ever is create worlds for people to inhabit. Sometimes these are worlds of work and production, sometimes they are of community and socializing, and sometimes they are of play and leisure. In no application is this more literal than in video games, where often there is an attempt to replicate the exact materiality of the world. Historically this has often been done in an authorial way, with artists individually placing every stone and every tree. However, with the increasing scope and scale of many contemporary games this approach is becoming fast outdated and procedural models have taken precedence, where terrain is generated algorithmically.

The many different methods by which different games approach terrain generation span such a broad range that addressing them all is outside the scope of this paper. Instead, I would like to focus on some of the revealing aspects of the terrain generation of one specific game, 2011's *Minecraft* (Mojang 2011), which remains a prominent example of procedural terrain generation. As Sabine Harrer, Daniel Dooghan, and many other scholars have pointed out, *Minecraft* is also a clear example of the colonialist ideas embedded in modern game design. [1][2] Harrer points out the procedural slavery enabled by the game systems, and Dooghan similarly points out the extractivist models that underpin the game design. It should be no surprise, then, that these ideas also extend to the procedural generation of the terrain itself — the very world of *Minecraft*, in a literal sense, is built with colonialism in mind.

Generation

Arguably, the generation of a world in *Minecraft* begins with the seed, a string of characters and numbers that determine the output of every random factor in the creation of the world. Normally, it's hard to predict the output of a random number generator, but a seeded random number generator will always produce the same results, given the same seed. This reproducibility has a number of effects: in

development, buggy or broken worlds can be easily reproduced and debugged. After release, players can share seeds of interesting worlds so that their friends can generate the same ones. This encoding of the world into a finite string is a way of keeping these worlds controlled and in many ways, owned by giving them a pseudo-name that can be possessed. As Harrer writes, this naming can be an act of colonial control, as the unknown world is brought into existing knowledge systems, in this case, brought into a Perlin noise generation framework. [3]

This name/seed is unique in that it is both intelligible to a human reader, in that it uses the Latin alphabet and Arabic numerals, and also intelligible to the procedural generation algorithm which uses it as a seed. The primary aspect of the *Minecraft* world generation is the Perlin noise function which creates the majority of the topography of the world. *Minecraft* is already a grid-based world, where 3D cubes make up just about everything about the terrain. Perlin noise applies another lattice over this grid, and at different points in this grid, randomly determines the slope of the terrain. [4] Then, these slopes are interpolated between to create smooth connections, creating the hills, valleys, and other terrain components.

There's no real limitation to the size of the world created by the process, only that of computational storage and memory. In *Minecraft*'s case, generation corruption begins at about 12 million blocks from the origin point of the generation, but terrain is still generated much further. At this point of generation, the world is entirely made of stone and water, which will later be converted into other kinds of materials in a later stage of the generation process. At this point, it's an infinite empty world awaiting content, nearly only existing as a mathematical representation of curves and height. Crucially, despite its pseudo-infinity, it is still controlled — by the seed, and by the generation algorithm thus far. This control is essential, as we'll see in the next step of generation.

Population

The world is then filled with quite a lot of content — first, different regions of the world are assigned different biomes, which impose restrictions on the generated world and also convert different blocks to materials corresponding to that biome: snow in the tundra, sand in the desert, etc. Under the ground, caves are dug using one of a set of different cave carving configurations. On top of the ground, features like villages are constructed using other sets of generation rules which are semi-biome independent.

Importantly, this is when resources are allocated in the caves, and on the surface. Placing these resources after world generation is a deliberate choice, it means what's in the world is dependent on the shape of the generated world, as opposed to the world's shape being altered by the things that are in it. This subordinate relationship between resources and the world further drives home the fact that these resources exist only for extraction by the player —

the world doesn't care about or need them at all. The act of extracting these resources thus bestows a great benefit to the player while having no negative effects on the world, justifying it as both the right thing to do and something the player is entitled to do.

The only time that entities, monsters, animals, etc., are placed in the world is during play, with a player already in the world. In this way, while the game may depict them as having houses or "living", they're truly as much strangers to the world as the player. This further reinforces the player's right to the resources of the world, these monsters and creatures don't use them, and in fact aren't even responsive to their existence (except in the one exception of the Piglin's desire for gold). The riches of the world are only accessible to the player.

Conclusion

A named, controllable world yet with infinite resources that can be harmlessly extracted. These are the worlds generated by *Minecraft*'s procedural generation algorithm. They reflect the colonial drive to control the unknown and extract resources from it. Games need to take a more thoughtful use of procedural generation technologies to avoid replicating these colonial ideas.

Elizabeth LaPensée, Outi Lati and Maize Longboat suggest the notion of sovereign games as one method to avoid these shortcomings, involving Indigenous designers in various capacities and emphasizing self-determination as a core aspect of development. [5] *Minecraft*, developed in Sweden with a lead developer who holds beliefs so toxic that he was disinvited from his own game's 10th anniversary¹ certainly does not meet the criteria of a sovereign game.

What other paradigms are possible for procedural generation in games? Could the resources come first, with a world generated to do justice to the complicated ecosystems that generate around them? Could worlds generated provide histories, like those in the generated worlds of *Dwarf Fortress* (Bay 12 Games, 2006), that provide complicated ground for the player to traverse, instead of empty? Could world generation begin from something other than a shape or seed, and could they be freer to develop in uncontrolled ways?

We can only hope the future of game development leads us to answers to these questions and to more sovereign games.

Reinventing the Colonial Gaze Employing AI: a Case Study

Marinos Koutsomichalis
Cyprus University of Technology
Limassol, Cyprus
m.koutsomichalis@cut.ac.cy

Abstract

This short paper accounts for a case study of artistic research revolving around Cyprus' colonial past and inspired by present day decolonial affairs. The endeavour pivots on a hybrid AI system, trained on text from colonial handbooks of Cyprus (originally published when Cyprus was still part of the British Empire) and employing a custom image dataset meant to reflect this colonial view of the island. AI then generates new colonial 'gazes' of Cyprus upon demand. Output text and imagery is used in a number of physical and digital artefacts and events that are presented herein.

Keywords

Digital Colonialism, Decolonisation, GAN, Text to Image Synthesis, Text Synthesis.

Introduction and Background

Affairs of digital colonialism have been well fleshed out in a number of resources and AI-driven systems have been shown to be biased, racist, or sexist on many occasions. More, they generally fail to account for non-Western realities and cultural perspectives. Such affairs are currently researched in a number of contexts, *e.g.* related to economic and political neo-imperialist practices [5], the impact of information and communication technologies on non-western knowledge systems [8], or third-world user-data exploitation [3]. It has been then suggested that a very real opposition is in place: one between increasing control and freedom and concerning persons, populations, and entire geographic regions [1]. This confrontation is simultaneously relevant at many different levels of cultural and political organisation and manifests itself by means of controlling digital assets, data, computational power, and a variety of other means. Such concerns are very relevant to AI-related research that has been repeatedly shown to proclaim western symbolical, ethical, and ideological values. Benjamin [2] shows succinctly that AI algorithms are a very contemporary manifestation of a discriminatory architecture wherein racist assumptions are made intrinsic to the world's technological infrastructure.

'CY as AI Saw it: Reinventing the Colonial Gaze' artistic project by the author and Alexia Achilleos is part of 'Cyprus as AI Saw it' wider thematic concerned with decolonial re-interpretations of the Cyprus history, see also [4]. This endeavour employs a modified AttnGAN text-to-image genera-

tion model based on [7] and the RNN text generator pipeline introduced in [6]. The latter is trained on text from colonial handbooks of Cyprus, originally published when Cyprus was still part of the British Empire and reflecting an overly orientalist gaze of the then newly annexed British colony. Cyprus is presented therein as a degenerate country whose people are in urgent need of salvation. Trained on such a corpus, the model generates new colonial descriptions of Cyprus that become the input of the subsequent GAN-driven text-to-image pipeline. This subsystem relies on a bespoke dataset that is meant to reflect the local reality since, not surprisingly, the readily available image databases largely fail to account for Eastern Mediterranean landscapes/culture (they generally produce images that are more reminiscent of the Western cities that host the big tech companies that distribute them)—also see [4]. The resulting AI hybrid is then left iterate, generating original colonial views of Cyprus upon demand.

The output text and imagery are used in a number of related artistic outputs, exhibitions, events and artefacts that are detailed herein. The deeper motivation behind such a project is to creatively interrogate affairs of post-colonialism in a local context as well as to comment on the aforementioned concerns of digital colonialism concerns in an empirical and critical fashion. The artists intend to contribute to this broader discourse as well as to give agency to a rather idiosyncratic geographic region that only exceptionally (if at all) appears in present day AI research. It should be noted that they do not approach the local (post-)colonial reality as neutral outsiders; they are not speaking on behalf of some oppressed other in some other part of the world. Rather, they are themselves based in the region under scrutiny and, thus, they are themselves subjected to relevant ongoing post-colonial concerns and questions of local identity.

A (de)colonial book

Figure 2 illustrates the 'CY as AI Saw it' book that comprises AI-generated text and imagery. The book is partly intended as a conceptual statement, fulfilling a circle starting with a series of 19th century books published by Cyprus colonisers and concluding with this publication featuring imagery and text generated by an AI trained on the former. In this fashion, the book interrogates how the dominant colonial views of Cyprus resonate contemporary AI-driven techno-scientific

Figure 1: Installation at Tetramatyka festival, Lviv UA.

Figure 2: CY as AI Saw it book.

culture to produce contemporary (de)colonial narratives. The book comprises 57 A5-sized pages inside a hardcover case. The pages can be shuffled in arbitrary fashions so that readers may intuitively explore this material and the different kinds of (de)colonial narratives it may set out.

Installation

Figure 1 above illustrates the ‘CY as AI Saw It: Reinventing the Colonial Gaze’ installation exhibited at the Tetramatyka festival in Lviv (Ukraine). The installation comprises a wall with numerous 3x3 inch prints of AI-generated photos (in photo paper) and text (in heavy white paper), some of the colonial handbooks used to train the AI pipeline, the ‘CY as AI Saw it’ book, QR codes to download smartphone applications (to be discussed below), as well as small craft envelopes, photos, and text printouts for the audience to interact with — as explained below. Figures 3–4 demonstrate examples of printed media.

Assembling own (de)colonial narratives

Having surveyed a ‘CY as AI Saw it: Reinventing the Colonial Gaze’ exhibition, audiences are encouraged to take a few (de)colonial ‘gazes’ with them as mementos. Craft envelopes, spare photos and text printouts are available so that each individual may assemble *in situ* their own tiny (de)colonial narrative—see also Figure 5. Engaging audiences in such a fashion draws, of course, on relational aesthetics, doing-it-with-others, and participatory approaches to art. In this context, nevertheless, and alongside the book, they should be also understand as an articulation of post-digital objecthood: a cybernetic AI system produces digital artefacts that are then transformed into actual objects audiences may physically engage with, holding them into their hands, shuffling

Figure 3: Sample imagery.

them around, and even creating their own micro versions of the work as a memorabilia.

(De)colonial gazes on the go

Further hybridizing the project with more exhibition modalities, the artists also distribute a smartphone version of the project: an Android and an iOS app. This mobile app iteration serves users with new colonial text/image upon demand. On touching the screen they are presented a new AI-generated image alongside its generating text or just a piece of AI-generated text. Figure 6 illustrates a screenshot from the iOS version.

Conclusions

As briefly outlined in this short paper, ‘CY as AI Saw it: Reinventing the Colonial Gaze’ revolves around Cyprus’ colonial past and pivots on a hybrid AI system, trained on text from colonial handbooks of Cyprus to generate new colonial ‘gazes’ of Cyprus upon demand. Resulting imagery and text have pollinated a number of artefacts and presentation media so that in its totality the project becomes a multimodal aesthetic experience inviting audiences to engage with smartphone apps, books, printed matter, and an installation in space. In this manner audiences are given multiple opportunities to engage with the generated material as well as with *ad-hoc* narratives thereof—either assembled by the artists (the installation wall), random processes (shuffling the pages of the book, mobile app), or by audiences themselves (selecting printed matter and assembling narratives on the fly). That is to say, that employing a variety of physical, digital and hybrid media, audiences are encouraged to interact with the system, producing unique (and often individuated) (de)colonial gazes of Cyprus.

The women are generally about two and a half feet southwood, was a favourable position, the actual advantage of extensive space.

Figure 4: Sample text.

Eventually, the project attempts to re-examine the historical relationship between coloniser and colonised. It touches affairs of (digital) colonialism, and brings forth an alternative (de)colonial narrative as a tactic to regain agency from a local point of reference. Then, ‘CY as AI Saw It: Reinventing the Colonial Gaze’ becomes a concrete attempt to critically engage with the possibility of alternative realities and research paradigms within AI-programming (and through a Cypriot lenses). That is, this work extends the body of research discussed in [4] and proceeds into the direction for future work announced therein: further raising concerns of digital colonialism in AI research.

Acknowledgments

The author wants to thank Tetramatyka festival of Audiovisual art for commissioning the herein described work.

Abstract

This artistic research project approaches the environmental transformations suffered by the Llobregat Delta natural park from the soundscape, using the acoustic science of cymatics¹ as a tool with the aim of generating visual cartographies on the water of the Llobregat River itself, which show the creation of wave patterns, making visible the transformation of the environmental sound heritage, and the changes due to the systems of economic growth.

Keywords

Cymatics, sound art, cymatic cartographies, acoustic-ecologies, visual sound.

Introduction

Barcelona, like other large metropolises in the world, has grown by developing unsustainable economic, urban and industrial models that have expanded its borders to the natural spaces that surround it. The enormous growth of the port and airport of Barcelona in the last 20 years has delimited and modified the physical space of Llobregat Delta, transforming its ecosystems and modifying the acoustics of one of the richest environmental zones in southern Europe, declared a ZEPA area by the European Union.

Figure 1. Delta of Llobregat Natural Park, with the Port in the background and a plane in the final landing.

The research presented sheds light on the concept of economic power and the relationship that individuals as part of society develop with nature through attentive listening. This artistic research project uses the acoustic heritage of the Llobregat Delta space as an oasis between two industrial giants. Using acoustic ecology and the transfor-

mation of soundscape records in cymatic cartographies, photographic images are presented as unique traces of the place through the visualization of wave patterns that by their shape, composition and structure, will determine the origin of the sound.

The images obtained in this process are analogous to sound spectrograms, focusing on the visual structure of sounds through the propagation of wave patterns on the materials themselves, generating sonic traces or imprints through the sound of the ecosystem, on the water of the Llobregat River. It is very important for the construction of these cartographies the use of the river water, since through the deposition of sediments, it is the main cause of the formation of the Delta and its ecosystems of Mediterranean walls, pine forests and wetlands. Schafer states: "The rivers of the world speak their own language. The gentle murmur of the Merrimack River, 'Whirling, swirling, and falling downward, kissing the shore in its wake,' was a sleeping balm to Thoreau. For James Fenimore Cooper, the rivers of upstate New York often flowed slowly into rocky caverns "producing a slack sound, resembling the firing of a distant gun." [1].

Art referents

As we approach an artistic research project attempting to develop a visual mapping based on the acoustic ecology of river ecosystems, it becomes crucial to define some artistic antecedents as origin elements.

Schafer affirms: "Acoustic ecology is the study of the relationships between living things and the environment. Acoustic ecology is therefore the study of the effects of the acoustic environment or soundscape on the physical responses or behavioural characteristics of the creatures that live in it. Its particular aim is to draw attention to imbalances that may have harmful or adverse effects on health. [2].

In the contemporary artistic context, we found various examples of artists who work directly with soundscapes and different aquatic ecosystems, with the aim of mapping and creating artworks in which listening to environment and the surroundings become the constructive axes of his plastic discourse. The artwork by Ursulla Biemann [3] *Acoustic Ocean* (2018) uses a hydrophone positioned between the ocean and the land, to focus on the sound ecology of the marine and underwater environment from a scientific perspective. Other sound artists such as Annea Lockwood [4] and her projects *The sound map of the Danube* (2005) and *A sound map of the Housatonic river* (2010), or Chris Watson [5] with his work *The Ice Mountain* (2020), shows the need to address environmental challenges, complementing the listening process with visual maps of different places.

¹ The science of cymatics studies the visual representation of sound waves on matter.

Metodology

In the field of soundscape as an artistic practice, we regularly find projects focused on listening processes that also generate visual cartographies as a documentary of the space where the recordings have been made. These cartographies are usually materialized in the form of drawings, maps, videos, the relocation of objects, photographic documentation of the place and descriptions, intended to help guide the viewer's listening. This act proposes an exhibition focused on the artist's point of view, which influences the viewer's imagination.

In this way, the perception of the listening sound environment is altered, which has been objectified during the recording process by the choice of location and the orientation of the recording equipment. Acosta affirms; almost certainly because of this added impossibility of evoking the unknown and in the absence of other sensory stimuli, records or CDs are often accompanied by texts that are descriptive of the situation or simply poetical. The images also help because, with that generosity for illusion that is so much our own, we can imagine ourselves in that place that sounds like that [6].

Through the sound recordings generated in the same locations but in different temporal stages (during the Covid-19 pandemic in which massive confinement took place and in periods of economic activation without lockdown), the aim is to show the effect of environmental noise as a phenomenon that directly affects the non-human ecosystems inside the natural spaces at Delta of Llobregat. Espinosa states: "A bit by a bit, the differential sound features that, as in maps, gave us clear profiles of the different regions and places on the planet, have been disappearing" [7].

Using scientific laboratory equipment, the recorded soundscapes have been transformed into vibrations. Using a Pasco mechanical wave oscillator coupled to an oscillation bath containing the water of the Llobregat River, the different soundscapes are projected, making resonance. With zenital photos taken in a dark room and the use of an LED ring flash, nodes and wave patterns on the water surface can be seen, showing how different sound sources can produce differential wave formation.

Figure 2. This image shows the experimental procedure in the Acoustics Lab, where the soundscape is converted into a wave-form.

These cartographies take the form of abstract photographs showing wave patterns, which do not provide contextual information about the place of recording and differ from traditional visual supports, only allowing the viewer to imagine the recording spaces without offering a preconceived idea of the space. The sound of the environment is then incorporated into contemporary sound aesthetics and an experience ensues through mental abstraction, contravening the usual rule, we encounter, in which the experience of the soundscape is enhanced through contextual information.

In this way, my goal is to induce the exact opposite experience through abstraction, making it impossible to imagine exactly what the acoustic reflections are about. The images I obtained are conceptually reminiscent of a spectrogram; however, unlike a spectrogram, which can contain a long period of sound in a single image, these images provide precise fractions of a few seconds duration snapshot.

Figure 3. Industrial soundscapes create geometrical forms on water.

Conclusions

One of the most important conclusions obtained during this research has been to verify that human action has acoustically cohered many of the sound spaces of the environment, making it increasingly difficult to locate the unique traces that determine these ecosystems.

I have observed that in soundscapes dominated by a natural sound environment, the sound registers are usually formally quite uniform. The predominant frequencies in these systems generate soft and constant ambient sounds. Thus, when water undergoes the oscillation process with these sounds, it enters into resonance quickly and durably over time. Therefore, they tend to adopt an organic visual structure, in which we observe many entangled nodal lines (see Figure 2).

In contrast, when industrial soundscapes predominate (sounds of airplanes, ships, automobiles, industry), the structure of the recorded artificial sounds tends to be much more intense, interrupted and less continuous over time. When oscillation begins, the fluid takes much longer to resonate and form stable patterns. The shape of the waves varies intensely and produces peaks of high amplitude and moments of low intensity due to the variety of frequencies. Visually, this results in very intense but short-lived resonance processes, leading to the formation of geometrically patterned structures that fade away very quickly (see Figure 3).

Ferran Lega has a PhD Cum Laude and received the extraordinary doctorate award from the University of Fine Arts of Barcelona, specializing in sound art and the use of acoustic science of cymatics as a tool for artistic expression. Since 2009, he has combining his artistic practice with teaching. In 2019 he started his full-time career as a professor of digital design and creative technologies at the University of Lleida. His artistic works have been exhibited at Botín Foundation, Santander (2009), ATM contemporary, Gijón (2009, 2013), Art Eka, Madrid (2012), Colorida gallery, Lisbon (2013), Tàpies foundation, Barcelona (2013), Tortosa Museum (2016), Lo Pati art centre, Amposta (2016), Arts Santa Mònica, Barcelona (2017), CMMAS Mexico (2017), IEL, Lleida (2017, 2019, 2021), Roca Umbert, Granollers (2017), MEM, Bilbao (2019), Bideodromo Bilbaoarte (2020), Sant Andreu Contemporani, Barcelona (2020), CCCB (2021), La Capella Arts center, Barcelona (2022), Leucade Gallery, Murcia (2022), among others.

The vanishing of remix concept in machine-driven text

Dr. Alessandro Ludovico

Winchester School of Art, University of Southampton
Winchester, UK
a.ludovico@soton.ac.uk

Abstract

In this paper, the process of remixing is analysed through the evolution of machine-driven text transformation approaches. Starting from semi-random early techniques for the composition of poetic or experimental literature, the process of associating and composing preestablished pieces of text, sourced from analog and then digital repositories, will be investigated. A continuity emerges from the combinatorial experiments realised by the *Ouvroir de littérature potentielle* (OuLiPo) group in the 1960s to the later software that has advanced remix possibilities up to the contemporary attempts to establish an almost autonomous “automatic publisher.” The increased sophistication of the algorithms and the growth of available sources have affected the plausibility of the produced texts, including a technical analysis of style, laying the foundation for its simulation. More recent tests, using unusual or different technologies to produce texts, will be included. In the essay, I will analyse the remixes of text’s evolving structure since the early experiments in the 1960s, the role of machines in effectively emulating a writer’s style and their essential support to generate credible fakes, particularly deepfakes.

Keywords

remix, publishing, deepfake, experimental literature, generative text, generative poetry, software art, electronic literature.

Can machine-driven texts be defined as a “remix” of content?

Machine-driven texts, or texts produced by some degree of automation, have been around for a long time. The idea of automatically elaborating texts and generating new texts through an algorithm, albeit a very simple one, was attempted as early as the fourth century AD.[1] Throughout history, the application of mathematics to literature has produced a wide range of experiments, from the application of rules and the permutation of elements, such as Nanni Balestrini’s historical combinatorial poetry *TAPE MARK 1*, discussed later, to the current sophisticated elaborations of

large amounts of data by machine learning algorithms, such as the heralded “AI-based text generator Generative Pre-trained Transformer-2 (GPT-2)”. But only a few of them can be described as possible “remixes”, i.e. as processes in which samples are extracted from pre-existing material and combined into new forms according to personal taste. [2] These remixes have different structures and purposes, while recent developments run the concrete risk that the difference between the remix and the pre-existing material disappears in the immediacy of digital machines. My main question is therefore: can machine-driven be defined as a “remix” of content?

The shift of focus: from code to database

Beginning in the 1950s, early experiments with programming code to generate texts in various forms and styles mostly focused on a combinatorial approach. They produced a collection of texts that had a distinctly uncertain or redundant style, depending on the nature of the randomness implemented. They were usually based on a set of fixed rules that were applied each time the code was executed. “Chance” shaped these experiments by associating words with what was essentially a given literary structure, such as a single sentence, a poem, or a letter.

Tristan Tzara’s 1924 Dadaist poetry manifesto, for example, encourages Dadaist poets to cut words out of a newspaper, put them in a bag and take them out one by one. In his cut-and-choose process, he uses a combinatorial method in which all possible combinations of words are reduced to one.[3] He also creates a “database of patterns” in the bag and algorithmically, albeit in a very straightforward and random process, produces a text that is often nonsensical. The patterns are merely functional, filling in a carefully laid out scheme as if they were “shuffling” in a fixed matrix. But in this process, the “sampling” is so minimal, reduced to single elements, that any perceptible reference to the pre-existing work (the remix component of the “spectacular aura” [4]) is irrevocably lost, except for the structure. These are thus “permuted new works” rather than remixes, as they retain a reassuring and consolidated, but at the same time quite rigid structure.

The turning point in this strategy was the availability of larger databases of samples and the development of hardware and software that allowed the use of longer samples and thus the creation of more complex compositions. An example of this is Stéphanie Vilayphiou's "La carte ou le territoire", where she finds all the sentences (or fragments thereof) of Michel Houellebecq's plagiarised "La carte et le territoire" in other books in a kind of conceptual combinatorial remix (same samples from different sources/history), which would have been impossible without a database like Google Books. Over a few decades, the mechanisms have remained largely the same, even with modern machine-learning techniques that use more sophisticated algorithms.

Sampling in 1961

In the 1960s, texts were increasingly combined in more sophisticated ways, in proportion to developments in hardware and software. It seems rather coincidental that in the same year, 1961, two different works that could possibly be called "machine-driven remixes," were released in two different ways.

The first is the iconic Raymond Queneau's "Cent Mille Millions de Poèmes" (One Hundred Thousand Billion Poems). It is an experimental book consisting of ten sonnets where each page is divided into horizontal strips with a single line that can be turned over independently, offering the reader 1014 possible unique poems. Each time a strip (or series of strips) is turned, the reader can read a slightly or completely different poem in turn. Queneau calculated that it would take 190,258,751 years to read all the possible combinations.[5] He co-founded the avant-garde literary movement OuLiPo (Ouvroir de littérature potentielle) and used mathematics as a source of inspiration for literature. The content of this unique book is generated by a calculated, software-like process that shuffles the different strips/lines. Yet it is the reader, not a machine, who chooses. It goes beyond the combinatorial aspect of most late Oulipian works, which faced the challenge of writing according to strict rules, such as "lipograms" (excluding one or more letters) or applying the S+7 rule (replacing each noun with the seventh noun listed after it in a dictionary). Technically, "Cent Mille Millions de Poèmes" is a combination of samples (the stripes/lines) that can be recombined by the reader at will and never exhaustively. The mixing can then go on indefinitely, always with a plausible and different result. The peculiarity of this work, however, is that its structure remains fixed and each result formally collides with the "original", as do all possible elaborations. Although the work could easily be transformed into some software programmes, its strength lies in the implementation of these ideas and mechanisms in a slightly modified printed book. The book itself acts as a machine, and the reader actively uses it to select and produce the content.

In 1961, there was another literary experiment that attempted to use the possibilities of computer programming to create a credible literary work: "TAPE MARK 1", developed by the Italian writer and artist Nanni Balestrini. For

this work, Balestrini, together with engineer Alberto Nobis, developed a computer programme for the IBM 7070 that would have combined three different poems by Michihito Hachiya, Paul Godwin and Lao Tse into a new "original poem". There was a meeting in Milan, in a bank office where the computer was housed, attended by the semiologist Umberto Eco and the avant-garde musician Luciano Berio. The computer produced more than three thousand remixed variations of the three poems, but Balestrini decided to select only one of them as a representative result to be written about in articles and art catalogues. He also intervened minimally to select the computer edition and correct some grammatical errors. Technically, the poem should have consisted of six verses, each composed of four metrical units. TAPE MARK 1 was remarkably on display in the historic exhibition Cybernetic Serendipity at the ICA London in 1968, and here Balestrini imagined computer processes as tools to open up the space of composition to another, more sophisticated and partially automated level. He put together a proof-of-concept that conceptually echoed the Open Work theorised by Eco, a publication in which he asserts that for this type of work "the possibilities which the work's openness makes available always work within a given field of relations." [6].

This work was reconstructed in 2017 by three Italian hackers, Emiliano Russo, Gabriele Zaverio and Vittorio Bellanich. They reprogrammed the original algorithm in Python on a Raspberry Pi hidden in a wooden box that contained a small monochromatic CRT monitor that visualised the output. They gave it to Balestrini, who liked it so much that he wanted to include it in his solo exhibition at the ZKM in Karlsruhe [7]. The reconstruction with modern technologies makes the "remix" process inherent in the algorithm even clearer. The team technically and aesthetically "remixed" Balestrini's work fifty-six years later by combining its principles and references, such as the monitor and the wood for the box, with contemporary technologies, such as the electronics inside and the chosen programming language. It is significant that the author not only acknowledges the remix, but symbolically re-appropriates it by including it in his official solo exhibition, while retaining the full name of the recreators.

Remixing author's style

These early experiments show two different methodologies of remixing: one is based on the potentially infinite interchangeability of samples once they are compatible with each other and within the stable environment in which they reside. The other is based on creating a solid but fluid structure that can accommodate more complex samples so that they create a more dynamic result. Both are based on a structure that guarantees combinations and gives mixed results. In the following decades, the focus has shifted primarily to producing trustworthy output that can be recognised as human-like. Computer-generated output has often sought other human's trust as their final validation of quality. And trust in literature essentially means a projection of what is written

onto a person, the author, and onto his or her perceptible 'style'. To discuss this particular aspect, it is worth looking at one particular work: *The Death of The Authors*, 1941 Edition, by Femke Snelting and An Mertens (part of the Belgian Constant collective) from 2012. This work undeniably refers to Roland Barthes' "The Death of the Author", on the level that it seems to technically embody its main argument to the extreme.[8] It is a generative software that produces a freely downloadable novel based on various texts by Virginia Woolf, James Joyce, Rabindranath Tagore, Elizabeth Von Arnim, Sherwood Anderson and Henri Bergson. Snelting and Mertens become the ultimate "screenwriters" (in Barthes' definition), building on the programming code that elaborates the final result. The work was published on 1 January 2012 to celebrate the authors' works becoming public domain, as they all died in 1941 and their works were protected by copyright for up to 70 years after their deaths. According to Snelting and Mertens, the aim was to point out that copyright itself blocks much more than unlimited reproduction. [9] To highlight this aspect, they ironically refer to the act of working freely with the work of dead authors as a "macabre form of liberation".

The perceived presence of the author has been analysed at length by Foucault. The "status" we give to an author "when we began our research into authenticity and attribution"[10] is that of a presence closely linked to the author's name and serving as a "means of classification"[11]. The author's name is essential even in the remix process, as it is the main, irreplaceable reference for the texts to which it belongs, or, in other words, to "group together a series of texts and thus distinguish them from others." [12] The author's name "remains at the contours of texts -separating one from the other, defining their form and characterising their mode of existence." [13] Finally, the function of an author is to "characterise the existence, circulation and operation of certain discourses within a society." [14]

The remix of different authors thus has a direct effect on their overall work. Should Balestrini's work (even if it is explicitly derivative) be included in the bibliography of Hachiya, Godwin and Tse? And what about Snelting and Mertens' endless and equally derivative compilations of Woolf, Joyce, Tagore, Von Arnim, Anderson and Bergson? According to the criteria in force, they should not, but from a creative perspective that would seamlessly include "new" works, this very concept of an "author bibliography" could be challenged.

The structural remix of fakes

If the 'trust' we instinctively place in print is one of the crucial elements of publishing, then the sophistication of the output produced and the underlying computational power and access to useful data are essential to remix publishing. A true literary remix needs the pre-existing samples (the data) and possibly the pre-existing structure (the vessel in which the original author's style is embedded) and other compatible data to elaborate.

Eric Drass' *Cut Up* magazine embodies this concept. It was conceived as a printed guide for *The Great Escape*, a music festival held in Brighton that featured 300 (mostly unknown) bands. The festival usually lacked any kind of reference or background information on the bands, so audience members had to reserve judgement on the bands before seeing them perform. His *Cut Up* magazine was distributed free of charge and featured computer-generated band profiles. As he explains, *Cut Up* magazine was a way of "algorithmically filling the 'critical void' [...]. The reviews were created using a mix of historical reviews from the UK music press and data gleaned from Last.fm. Even for an unknown band, there would usually be a few listens logged at Last.fm which helped describe the genre of music and perhaps a few song titles. Using this data, I algorithmically generated music reviews - using text taken from reviews of bands of the same genre to keep the tone consistent [...]. I printed 128 fanzines, each with 16 unique reviews of bands playing at the festival, with details of the performance and a random mark out of 10. In this way, a band could feature in multiple copies of the zine, with wildly differing reviews. I went to the festival and handed them out to the fans. An act of algorithmic de-tournement". [15]

Remix in machine learning-based texts

There is an ecology of literary bots on the internet, especially Twitter bots that incessantly remix content from databases or other online sources. One of the most famous examples, now defunct, is *Pentameton*, a bot that collects tweets in iambic pentameter and arranges them into pairs, with poetic and sometimes surprising results. These bots are an evolved version of the early *Ou-LiPo* experiments. In the 1980s, Italo Calvino, who was an active member of *OuLiPo*, turned against a schematic approach that had already been extensively explored, even with the limited technologies of the time, for a more subversive approach. He praised machines that would produce "disorder", meaning something other than slavishly following the classicist rules. [16]

At the beginning of the 2020s, in a media ecosystem that is increasingly vulnerable to manipulation thanks to the orchestrated or spontaneous spread of "fake news", remixes of textual content play a conceptually important role.

In this context, it is useful to define the term 'deepfake', which was introduced to categorise synthetic content (mainly videos and, to a large extent, audio) in which a person is 'replaced by the image of another person'. [17] The sophistication of the technology here overcomes trust, as these videos and audio recordings look and sound real and can mislead even an attentive audience. An equivalent text product is currently being developed by OpenAI, a non-profit research company. Called *Generative Pre-trained Transformer-2* (*GPT-2*), this machine learning system is capable of generating text based on short prompts and a corpus of forty gigabytes of text sourced from various internet sources. The researchers chose to release a much smaller version to avoid the risk of the software being used to "generate deceptive, biased, or abusive language at

scale".[18] One of the highlights of this software, apparently, is that it did not "lose track of what it was writing about as it generated output keeping everything in context".[19] It perfectly embodies the "new logic of speeded up cultural remixability enabled by computers." [20] At this level, the potential to confuse, mislead and manipulate the reader is greater than ever. Moreover, this technology potentially puts the historical validation of works in a very difficult position. The disorder Calvino mentions is paradoxically enabled by the essential structure of Deepfakes. It is a structural "disorder" that makes the spectacular aura disappear: The final result is indistinguishable from the pre-existing work, so that they only acquire the same status.

To quote Foucault again, "The Author is a certain functional principle by which in our culture, one limits, excludes and chooses,"[21] and then "is therefore the ideological figure by which one marks the manner in which we fear the proliferation of meaning".[22] The uncontrollable dissemination of meaning, possibly triggered by deepfakes, takes on forms that call into question the very notion of the author as well as the entire remix process.

Conclusion

What the deepfakes bring about is the final, true disappearance of the preexisting work concept and the trust we place in it. These kinds of productions affect a relatively small number of people, but they redefine the nature of the material used before and during the remix process. In Deepfakes, the former existence of materials is hidden both technically and through the seamless simulation of elements such as the writing style (or the face in videos or the voice in audios). At the same time, it is conceptually removed by being believable to a mass audience that does not question its authenticity.

The concept of remix has previously been understood to mean the recognition of samples or the recognition of "preexisting" original material, intrinsically validated as "original".

But deepfakes systemically avoid any explicit and verifiable source or reference to what was used in their process. To speak of an "original" then seems simply a challenge, while the concept is deeply shaken: Only sophisticated algorithms can distinguish a credible fake from an authentic production. The acceptance and accumulation of deepfakes in our visual and written culture would mean an increasing layering of fake but recognised pre-existing material that we can no longer verify over time.

These potentially infinite new digital productions of "originals" would seriously challenge any classical remix practise and question the historical attribution of their samples. Paradoxically, the only remaining valid pre-existing originals would increasingly become a thing of the past, with their records of existence and production still authenticated. The machine-driven texts of the post-digital age are thus remixes without references. Their content is created through the sophisticated elaboration of earlier forms and styles that look and feel like a new original. As these new

originals become the norm, they may redefine the categories of work, pattern and authorship that we still use today.

Abstract

In 2022, the *Laboratorio de Luz* (UPV) will be 32 years old, and it is a good time to reflect, and to share that reflection, on the contributions and positions of the work carried out by this group of researchers and artistic collective that is considered one of the first university, Art and Science nodes on the Spanish scene. Re-thinking our work in this presentation framed within the “artist talk” format also implies reviewing the conditions of possibility that existed in the Spanish context 30 years ago and those that exist today for art research-science-technology.

Keywords

Laboratorio de luz, Media lab, Media Art, ACTS, STEAM.

Introduction

The *Laboratorio de luz* grew out of an earlier group called the *Laboratorio de luz y Color*, created in 1986 by the artist and professor of painting José María Yturralde, which expanded the approaches that Yturralde himself introduced in his Color-Light Seminar, seminar that he taught in a non-regulated way at the Faculty of Fine Arts of Valencia from 1983 to 1986.

José María Yturralde held a fellowship during 1975 and 1976 at the Center for Advanced Visual Studies at MIT. In 1979 he became a professor at the Faculty of Fine Arts in Valencia and excitedly transmitted an idea of a university to us, understood as a space for connection between art, science and technology, with studies on the environment and energy systems that resonate with us today current sustainability policies.

Clearly interested in this intersection of University, Art and Science, at the beginning we moved as a funambulist between the evolution of art and science, with the determination to open new possible paths in the development of artistic practice as research.

At the university, we linked teaching and research, which in a sense complemented an idea of teachings dislocated between the teaching of art and what art teaches us, from the friction hinge between both sides an important thread arises open to reflection.

Research at the *Laboratorio de luz* has been mainly linked to the development of R&D projects with a clear application in artistic practice, carrying out research in art and for art [1], whose approaches emphasize the role of image and

sound technologies, as well as the questioning of perception and light.

But we were also concerned about the dissemination of knowledge and in 1992 we started the magazine *Arte: proyectos e ideas* [2], in which the idea of university was reviewed, artistic projects presented by their own authors were disseminated, and re-readings of works or ideas that we considered referential at that time. The magazine is still open in its e-magazine version on the group's website [3].

Wish for the future.

In the 1990s, already as *Laboratorio de Luz* (without color), we began to introduce technological devices in the works we made, because we believed that this placed us on a path to the future, while maintaining conceptual winks with historical artists that we liked. As in the work *Proyectante de sombra* (1993) [4], whose title alludes to Marcel Duchamp's *Notas del infraléve* (1914).

Figure 1. *Proyectante de sombra* (1993). ©laboratorio de luz.

In this piece we question the role of light and the difficulty or insufficiency of reading. On a prominent wall of the *Arteleku* exhibition hall (Donosti, Spain, *Iluminaciones profanas: La tarea del arte*) a text made with phosphorescent paint was hidden by the light that occupies its entire extension, the text remained imperceptible due to the strong illumination from a theatrical cut reflector. In this way light desecrates its own function by hiding with its rays the element that in itself is an enlightening agent: the language.

The action of the spectator, voluntarily or by chance, activated the change by means of a pair of sensors, allowing for a few seconds the absence of light to see/read the work, but

the time of clarity was brief and the cyclical structure of the text hinders the continuity of the reading.

Another example of this search for the future, and at the same time a link with works of the historical avant-garde, and which also alludes in a certain way to the vacuum, is the piece *Modulador de Luz 2.0* (2006) [5], whose title refers to the work *Modulador* by László Moholy Nagy (1930) and was presented in the exhibition *Banquete Nodos y redes. Laboral Centro de arte y producción industrial* (Gijón – Spain).

Figure 2. User interacting with *Modulador de Luz 2.0* (2006). ©laboratorio de luz.

The installation was presented as an empty stage space with three microphones hung from the ceiling. When a spectator/user transmits sounds through the microphones, he or she may draw the theatrical light, or perhaps take it away from someone else who is interacting at the time, as a light fight.

But the behavior programmed for the lights, in relation to the sound, favors unforeseen games; different roles and attitudes of light can be given depending on the times that these data of the tone, timbre or intensity of the sound have been recorded throughout the day: sometimes quickly, intensely and sharply, sometimes hesitantly or timidly and with blurred edges, the light is directed towards one microphone or another, simulating a social physics of actions and reactions in which the desired illumination is not always achieved for all the spectator-actors.

Without the interactivity of people with technical devices, these works would remain empty, illuminated white wall, or strange empty stage. Interactivity is fundamental for us.

All perception involves interacting with the stimuli that generate it and the environment in which those stimuli are produced. Through the senses we collect data (inputs), our mind encodes and / or reflects on them (processes them) and as a result they can modify our knowledge, behavior, state of health, mood, etc., (output), is in other words, the cognitive, cultural and psychological is incorporated into perception,

while what is perceived can transform these fields, if the interaction has had a true effect on us.

In the context of digital media, the notion of interactivity grows above all in the technical factors, transforming the spectator, with his interactivity, the process of development of the work. It is to be hoped that this level will be added to the others, so that this experience of human-machine, spectator-piece interactivity is not restricted.

Timeline Art / Computer Science / Art-technology.

The art world carries with it a long, long, history and tradition. Centuries of works of art that are preserved in museums. The field of informatics or computer science, although its origins can be traced back to Sumer with the abacus as the first known calculation tool, as we understand it today digital computing is very, very, young, born in the sixties of the twentieth century approximately. The weight of tradition shapes an artistic discipline that walks slowly, solidly. The youthfulness of computers sciences allows for rapid and much more fluid growth.

Because of this fluidity in the growth of computer technology, digital devices have advanced so fast that the supports of those first works have become obsolete, old and, therefore, out of that idea of the future that motivated them. After more than 30 years of activity, today we are looking for a balance between this desire for the future that runs forward without looking too much to yesterday, and the durability of the works, so we are updating versions of those that have become technically obsolete.

The conservation or preservation of digital art works is an important field in which we will not stop off much in this text, but we invite anyone who may be interested to sound out it because it is growing academically with very interesting criteria. We will only stop at one of our works to point out what was learned in this process of updating the piece.

Entre_Cabanyal

The work *Entre Cabanyal* (2002) [6] is an interactive installation that was originally programmed with Macromedia Director 8.5 software, on a PC with Windows 2000 and a Miro DC30 video recorder, all now obsolete. We had to update it for the 1998-2015 *Cabanyal Portes Obertes* exhibition. *Cultura y Ciudadania* that was held at *Centro de Cultura Contemporánea del Carmen* in Valencia in July 2021.

The work has been reprogrammed with C ++ language, because the use of proprietary software would probably limit its maintenance in the future, and under the Linux operating system, also open source, because both Windows and Mac are increasing the incompatibilities in their new operating

systems. The video files, as they had the proprietary codec of the Miro DC30 capture, we had to export them through FFmpeg, by the terminal, frame by frame, later reconstructing their original format DV PAL 720 x 576, square pixels, without fields, and with the JPEG 2000 codec for having less loss for future adaptations. The rest of the assets were incorporated into the new configuration without modification.

Figure 3. *Entre_Cabanyal* (2021). ©laboratorio de luz.

This updating process allowed us to see the importance of elaborating a detailed documentation of the interactive works in view of possible updates due to obsolescence of the devices. We also wonder if *Entre_Cabanyal* (2021) can consider a new work or as a new version of *Entre_Cabanyal* (2002). When installing the work in the exhibition we understood that any artistic installation that is not site-specific, each time it is installed in another space, is transformed, even if there have been no changes in its software or hardware, it will always be experienced differently by the influence of the qualities of the exhibition space.

Tools for art-technology-interactivity and teaching.

The crossover between teaching and research made us see the need to develop applications or software for the teaching of interactive art and to facilitate its use by students with little knowledge of programming languages. *Gamuza* [7] and *Mosaic* [8] are the 2 softwares developed by Emanuele Mazza that have emerged as a result of research projects subsidized by the Spanish Ministry of Education and Science.

What is *Mosaic*? *Mosaic* [8] is a visual programming environment in real time with objects that are connected with wires, and, among these objects, it inserts some destined to program in Lua, Python, GLSL Shaders and Bash languages. It is intended for creative applications, live performances, interactive installations and, above all, for teaching interactive art.

Interdisciplinarity and commitment.

The *Laboratorio de luz* has also been and is sensitive to social and environmental political commitment.

The project *Bajo la Manga* (2020), is situated between sound composition, mapping and live cinema. It was presented in October 2020 at the exhibition *Reset Mar Menor*:

Laboratorio de Imaginarios para un Paisaje en Crisis, as the result of an interdisciplinary research project about a unique environment of great environmental richness facing a situation of serious deterioration. The project brought together artists, scientists and citizen platforms with the purpose of collaboratively rethinking this territory, understanding the visual arts and their intersection with other disciplines as triggers for thought, critical action and the creation of alternative narratives. One year later we know that the situation of the *Mar Menor* (Murcia- Spain) requires much more attention and care.

Figure 4. *Bajo la manga* (2020). ©laboratorio de luz.

Draw a new idea of the future.

The *Laboratorio de luz* from the UPV, has grown from three members in 1990 to more than 20 researchers today from different departments and their participation varies according to the proposals that are being developed: working between the collective and the individual.

The new drawing of the laboratory follows the same pattern of its foundation, but trying to highlight its interdisciplinary structure.

Since its foundation, it has carried out more than 14 research projects funded by national (Spanish Ministry of Education) and international (European projects) public calls for proposals.

In recent years we have seen the need to direct the capacities of art and technology towards the goals of sustainable development. The potential of technology to build this path is essential and enormous, to imagine devices that are at the service of new social, ecological and economic models.

Art is one of the best vehicles to take science out of the laboratories, to transmit scientific information to the population, and to advance science without forgetting to bring the consequences of this research to the scale of human senses and experiences, citizen science.

Abstract

This paper is an account of *Future Forest Diorama*, an artistic research project and residency taking place at the experimental station of Can Balasc. Written from the artists' point of view, it reflects on the challenges and opportunities that arise from inhabiting scientific environments, and the specific type of situated knowledge such environments afford. It advocates for more systematic accounts of the methods and tools invented on-the-fly by artists during art-science residencies to respond to the growing demand for methods of trans-disciplinary collaboration.

Keywords

Artistic research, art residency, epistemological pluralism, speculative design, complex networks, human and non-human, hypernatural, bio art, collections.

Introduction

Future Forest Diorama is an artistic research project and residency that took place at the Can Balasc experimental station in the Collserola Natural Park near Barcelona between June 2021 and March 2022. Granted through a joint call for projects from scientific and artistic partners (La Escocesa, art center situated in the Poblenou neighbourhood, and CREAM, a major Ecology and Forestry public research center), the goal of the residency was to develop fundamental research required to design and build an interactive artwork, a bio-socio-technological assemblage consisting of a network of three smart terrariums built inside discarded home appliances. Our goal was to study botanical communities present in the Mediterranean forest that surrounds the station, and to populate our terrariums with groups of plants selected to trigger interaction among species. Akin botanical networks, terrariums would be connected to each other, monitor activity in their surroundings and develop survival strategies inspired by cooperation models present in botanical communities. They would monitor their surrounding environment using movement and temperature sensors and communicate with each other through a local machine-to-machine network, triggering light, sound, and humidity effects in response to activity within space. Such responses, in return, would impact the plants' growth and development inside the terrariums, and influence the participants' movements within the exhibition space. All processes are interdependent.

The residency at Can Balasc experimental station offered us the opportunity to observe plants in their natural settings, to access specialized knowledge from scientists, to

grow selected species using different techniques, to build the first prototypes of our future terrariums, and to delineate spaces of knowledge shared by scientists and artists. It also revealed the potential of artistic residencies as critical research within traditional scientific spaces: that of challenging unquestioned assumptions, revealing blind spots and mapping shared zones of inquiry.

As artists-researchers, we are interested in deconstructing the power structures responsible for the ecological crisis humanity is facing today. We seek to challenge the nature/culture divide, to undermine the positivistic scientific principles based on separation and control [1] upon which modern sciences have developed, as well as the classical, representational understandings of art that only reinforce dominant cultural values. We are not interested in producing a new static representation of the forest; nor in accessing data to generate visualizations that only engage with participants at the sensorial level. Building upon botanical knowledge and the potential of entangled bio-technological systems, we aim at exploring the possibility of recreating the conditions of emergence of a forest-like experience.

Instead of representation, we strive for performative understandings of artistic practice and research, “a contestation of the unexamined habits of mind that grant language and other forms of representation more power in

determining our ontologies than they deserve". [2] Against extraction, we seek to trigger and support botanical communities and synergies; to explore potential, speculative, desirable futures, where beauty takes place beyond what centuries of western (human) culture has taught us to admire. Inspired by the marginal streams of thought of early British cybernetics, technofeminism and hacker culture, we will build ontological theatres to explore and expand visions of what more-than-human relationships might be like in post-anthropocentric worlds. [3]

Taking the Forest-Art-Technology triangle as a starting point, and building upon the notions of network, interaction and homeostasis shared across botanical, social and technical realms, we will speculate with future, cyborg-forest scenarios where technology supports and enhances co-evolution across species. The wealth of signals and interactions between plants, terrariums, physical space and human agents will define the relational space of a potential forest beyond anthropocentrism, an intertwining of physical, organic, social and cybernetic processes and subsystems. Such a system produces its own aesthetics [4].

The Forest and the Museum

Forests hold a particular status in modern Western culture; that of idealized places of regeneration, untouched by humanity's destructive power. They play the significant role of Heterotopias, counter-spaces that compensate, in a symmetrical relationship with everyday places, their unwanted qualities. [5] But in their becoming icons of a preserved world, forests also inevitably become the center of attention for scientific inquiry, technological domestication and socio-cultural merchandising. [6]

The principles of segmentation and extraction predominant in scientific models inherited from the Enlightenment are based on the myth of an abstract environment, one that leaves the relational, in-between space of process and evolution unaddressed. Within this dualist value system, the museum plays a significant role. In her influential article "Teddy Bear Patriarchy: Taxidermy in the Garden of Eden, New York City, 1908-1936" [7], Donna Haraway deconstructs the human notion of nature through a historical analysis of the formation of the Museum of Natural History and Carl Akeley's research on taxidermy. Haraway focuses on the way the great dioramas that populate the museum were built, and on how the pursuit for preservation of natural environments led to the hunting of the specimens that would represent animal species. Later, those magnificent works of art, culmination of humankind's representational capacities, were observed through a glass, a prophylactic barrier between spectators and the vivid scene, perhaps also protecting them from a dark discovery.

Hacking the heterotopia

Infrastructures such as Forests and Museums produced categories, taxonomies, non-human mobilities and immobilities that radically altered the dynamics of life. But there is no going back to a pre-modern world - nor do we want to. Instead, we want to hack dominant frameworks of thought, undermine their underlying power structures and reverse their effects, transforming them in mediums of life through the melding of natural and technical ecologies. By revisiting the iconic archetypes of the diorama and the forest, we want to explore alternative futures offered by our cyborg, post-natural world, to develop strategies of defense, care, survival, and restoration.

We do not want to make another pretty picture of the forest as a lost 'natural' world, because if, as artists, we reinforce idealized representations of the forest as 'external environments' separated from places inhabited by humans, we also amplify the threats that put forests' survival at risk. Instead, we want to set up a relational space, create the conditions of inter and intra-actions between beings. [8] The aesthetics of our *Future Forest Diorama* stands at maximum distance from bucolic images of wilderness while remaining loyal to the way forests think, that is, through a wealth of semiotic processes entangling living beings, human-made objects and technology. [9]

We refuse isolation and alienation. Taking encapsulated worlds as a starting point, we want to deploy scientific, technical and aesthetic means to bring about emergent entwined, speculative worlds that dynamically adjust living conditions, cooperate with each other and communicate with their surroundings. Where plants from different times and places can meet and collaborate; where technology supports biodiversity and evolution, rather than competition and human profit. A reverse garden, where the plants are the gardeners. [10]

Creative strategy

Our strategy builds on two critical methodologies, deployed across technical, biological, and aesthetic planes: mutual aid against segmentation and control, and situated knowledge against dualism and the myth of objectivity.

Mutual aid: [11]

The speculative worlds we are building do not reproduce natural settings and conditions. Yet, we will design them with care for natural communities in mind.

- Community building Inside the terrariums. With help from scientists from CREAM, we are designing speculative communities informed by botanical knowledge and models.
- A future forest. A responsive system emerging from the entanglement of physical, organic and cybernetic processes and sub-systems. Such a system, based on an evolutionary, (rather than casual) grasp of time,

does not aim for a pre-defined visual output, nor does it rely on visual syntax.

Situated knowledge: [12]

We want to critique the myth of objectivity, the becoming universal of a position that only reflects a very specific portion of humanity, and the dualism of the inside/outside divide. There is no objectivity because any observing agent is already a subject; no outside, because the limits that separate any being from the rest vanish when observed at the right order of magnitude. Therefore, we are rooting our project in a specific setting -the experimental research station of Can Balasc at the Collserola Natural Park.

Throughout the research phase, we worked with CREAM's team to design viable ecosystems inspired by Can Balasc's past and present conditions. The research station provided us with a concrete grounding and initial conditions (air and soil composition, temperature, humidity, types of plants...), and an active *umwelt* to build upon [13]. We studied the most common species and collected seeds that, after germination and growth, were used as a base for our terrariums' first prototypes.

Figure 2. Research on local species. Photo © Carola Moujan

Networks in science, art and technology

Whilst modern botanical science focused strongly on individual ontologies, pre-modern botanical knowledge was instead more interested in processes, analogies and the space between individuals: relational ontologies. In contemporary ecological sciences, relational concepts such as *botanical community* defined through energy flows rather than taxonomical classification, are essential to study evolutionary and adaptive phenomena within specific spatial settings that could not otherwise be addressed [14]. The concept of community and its underlying values of

Figure 3. Planting process. Photo © Agustín Ortiz Herrera

cooperation and enhanced capabilities are shared across social and botanical worlds. Moreover, network science and theory provide useful models to represent interaction between species and speculate with evolutionary scenarios. Significantly, such models are also at the basis of many technological developments as well as artistic experiments where interaction with the public is paramount.

We do not seek to use technology only from an instrumental standpoint, nor do we rely on collaboration with scientists as a simple way to access specialized knowledge. What we are aiming for, is an entangled methodology where the cultural barriers that separate constructed notions of art and science begin to dissolve. The conceptual tool of the network across different disciplines reveals a shared space where common interests and concerns can meet.

Building the tools for collaboration

Willingness to build common spaces of inquiry is shared today by many artists and scientists around the world. The number of opportunities and initiatives for transdisciplinary collaboration seems to be increasing at an exponential rate, yet several recurrent obstacles need to be overcome before maturity is reached. Beyond the above-mentioned philosophical, disciplinary, and cultural barriers, there are a great number of disparities and misconceptions that stand in the way of continued and productive collaborations. Even though a considerable body of inquiry about artistic research has already been developed, it remains largely unknown beyond a narrow circle of specialists. Many times, excessive focus is put on the foreseeable outcomes of collaborations: what will be produced, who will benefit the most from the process, what each actor is expected to provide... forgetting that research-creation is speculative in nature, “a practice that does not seek to describe, explain, or solve problems [...] an ‘event’ that creates concepts that problematize. Concepts are not pre-given or known in advance”.[15] The major benefit comes from the process, from the questions

Boundaries in networked digital societies: Membranes as a new model of boundaries focusing on nonconscious cognition

Su Hyun Nam

Konkuk University
Seoul, South Korea
suhyunnam.s@gmail.com

Abstract

Boundaries have provided humans a frame of understanding and foundation for social structures – like hierarchies, classes, and races. Acknowledging the development of technology has brought significant changes in human life, this paper explores a new model of boundaries that fits into a networked digital society and reexamines the idea of boundaries/borders as a solid wall that separates, segregates, isolates, and disconnects. Instead of a concrete wall, this paper suggests considering membranes as a model for boundaries in the technological era because of their semi-permeable and fluid nature, as well as their active engagements in relations/interactions between heterogeneous bodies. This idea of membranes in a technological society is exemplified in political borders, control mechanisms, and human-nonhuman cognition. Katherine Hayles's discussions of cognisphere and nonconsciousness illustrate the semi-permeability of the boundaries between human and technological cognition, highlighting their interdependency and continuous inflows/outflows of information on the nonconscious level. The author introduces the process of creating an interactive art project *Surrogate Being* to demonstrate how the author experienced such a membrane-like boundary between heterogeneous yet interconnected modes of (digital and biological) memories about the same place.

Membrane, Boundary, Border, Cognition, Human-Technology Relationship, Autopoiesis, Cognisphere

Introduction

While classifications are pragmatic and inevitable for efficient communication and knowledge organization, the concept of boundaries and borders to set limits and mark areas has been challenged and reexamined across a wide range of fields, including philosophy, humanity, sociology, politics, and science. The linguistic turn in the early twentieth century emphasized representations and languages by continuing the ideological legacy of dualisms that divided objects from matter and meaning from language in the same way that sees mind and body as separated entities. The semiotic

classification has drawn artificial boundaries in natural and fluid phenomena of the world as “a fixed, determining, and inhuman grid imposed upon life, rather than a living force”, and culture is a world mediated by (linguistic) representations – imposed upon and immersed in nature.[1] To overcome the limitation in the traditional conception of boundaries derived from linguistic epistemological structures, this paper looks into a cognitive relationship between humans and technology at the nonconscious level, which support the idea of membranes as a new model of boundaries in a digital society. As opposed to the linguistic turn that imposed languages, significations, and intelligible frames on nature, this approach seeks an insightful reinvestigation of boundaries by imposing nature upon culture.

The word *cell* exemplifies the contrasting conceptions and functions of boundaries in nature and culture. In biology, a cell is the smallest functional structure, enclosed by a membrane, which is a semi-permeable boundary, but a cell in culture and society often refers to a small room to lock up and isolate a prisoner. A prison cell is one of the institutional structures of disciplinary societies as presented in Foucault's panopticon – a paradigmatic architectural model of modern disciplinary power. Considering that the advancement of technology has made control systems invisible, I argue that biological cells with a semi-permeable, fluid boundary better represents technological society than cells for disciplines with an isolating concrete boundary. In societies of control, a body is not disciplined under a closed institutional system but controlled by data. Deleuze notes, “individuals have become ‘dividuals,’ [...] data,” which can be endlessly divided, subdivided, and recombined. These control mechanisms may seem liberating compared to enclosed institutions in disciplinary society; however, a “dividual” as data is interconnected within a complex system and shifting network while unceasingly monitored through advanced technology in an open environment.[2] Boundaries in societies of control became invisible and penetrable while still actively (and more powerfully) engaging in control.

Boundaries as Membranes in the Digital Era

Humberto Maturana and Varela assert that autopoiesis is a common characteristic of organization in all living organisms, which regulate their own systems within their boundaries like a cell membrane. According to Maturana and Varela, autopoietic machines (referring to living organisms) generate themselves through constant change and dynamic interactions in networks of relations among components. Boundaries in autopoiesis emerge from a dynamic process of self-regeneration and self-regulation and simultaneously participate in such systemic mechanisms. The most fundamental example of the autopoietic machine is a cell, which regulates the mechanisms of its entities/molecules and maintains the system within boundaries (membranes). I argue that biological mechanisms (autopoiesis) and structures (cell membranes) are the most suitable and compatible model for our highly networked sociocultural structure and boundaries.

The semipermeable nature of membranes enables their role as “a gate allowing transport into the cell of essential nutrients and movement from the cell of waste products.” [8] A membrane is a natural boundary that organisms build to protect themselves, keep its constituents in, and block unwanted substances from entry. Unlike boundaries in disciplined societies, membranes are dynamic, fluid, and semipermeable. Defining spatial and temporal boundaries is not the only role of a membrane; it also participates in chemical processes such as transporting organic matter and respiration. This integration of cell components and membranes closes the gap between different views on boundaries in intra-action and autopoiesis, as a boundary is seen as an active component rather than an apparatus to disconnect. I claim membranes that maintain and regulate the system as well as engage in the chemical process could demonstrate how boundaries between different individuals, nations, and bodies function in a highly networked global society.

It is worth noting that these biological barriers have various levels of permeability. Membranes let small, soluble, and nonpolar molecules like O₂ and CO₂ permeate, while large or polar molecules are not allowed to pass through the lipid bilayer. The role of membranes is similar to the purpose of political borders in that they inspect and regulate what is allowed to cross the border, and both membranes and borders demarcate and define an entity such as a nation, individual, or cell by holding constituents within the boundary. Goods, animals, and people are scrutinized at international borders to determine their eligibility to cross, but certain constituents can be seamlessly transferred and exchanged across borders, such as digital information and the online community. People around the world send and receive digital data without border control. During the COVID-19 pandemic with the highest level of travel warning, online communication allows people in different nations to stay connected and share their experiences. Human and technological cognition are interconnected and pass through their boundaries – skins in human bodies and inter-

faces in technology. In a networked digital society, boundaries are not an impregnable fortress, but rather fluid, organic, and semipermeable membranes.

Emerging Questions on Ethic and Privacy

Humans and technology compose a cognitive system together in a highly networked society, and N. Katherine Hayles calls such a complex cognitive system made up of unceasing communication between humans and machines the *Cognisphere*. [7] In the cognisphere, the highest level of cognition, which has been considered as humans' exclusive field, is largely influenced by technology, and in fact, “human awareness comprises the tip of a huge pyramid of data flows, most of which occur between machines.” [7] Digital information and communication technology process a great amount of information much faster than human consciousness, analyzing and learning patterns from big data. Furthermore, intelligent machines interact with humans in a natural and flexible way through various interfaces resembling analog/non-digital experiences, and digital interactions have become more intuitive with advanced technologies such as Natural Language Processing (NLP) and Natural User Interface (NUI) to compile human voices and gestures. The interface as a boundary can be an example that fits the membrane model, as it keeps constituents inside (digital media), is selectively permeable (input and output data), and engages in the processes of the system (interpretation of information). While the interaction between humans and technology is mediated through interfaces, cognitive processes between them flow seamlessly in a continuously shifting network.

Digital information, software and apparatuses are integrated in most of contemporary cognitive/information systems, and accordingly, boundaries between human and machine cognition became blurred and unsettled, including decision-making and free will. Humans often make a choice based on their evaluation of interpreted and processed data by networked computers and technological agencies (e.g., digital forensics), and advanced computers like AIs (designed by humans) are capable of analyzing patterns and making decisions themselves (e.g., YouTube algorithms that suggest the next video to play). Hayles also notes that the U.S. surveillance program, which has now become a global issue, demonstrates the shifting boundaries between human and technological cognition, especially the legal and ethical ambiguity of the violation of privacy. The ontological distinction between humans and machines is further complicated as machines study and acquire expertise (e.g., expert systems) or personal memories to respond, act, and make a decision by proxy.

In a networked digital society, the conception of surveillance has also been reshaped along with expanded/shifting boundaries of a self with digital data recorded on mobile devices, credit cards, and emails. During the COVID-19 pandemic, the South Korean government's integration of digital information in epidemiological investigations has been prominent among their methods of slowing the spread of the virus at the early stages of the pandemic. When a person

with COVID-19 provides vague and opaque information as to where he or she has been in a survey for contact tracing, Korean epidemiologists traced the GPS history of their phones and looked into credit card transactions and records of surveillance cameras to obtain more accurate information. It is a complex question to ask if their privacy has been violated or if they initially “agreed” to engage in digital networks and surrender their data by using mobile devices and credit cards. Such personal digital information is mostly a stream of numbers that technology can display instantaneously upon command, but the same data to a person with a much more complex cognitive capacity (such as self-awareness and feelings) can be associated with intimate memories or secrets to hide at the risk of the public good, even during a global health crisis. Technology presents merely a vast set of numerical data, yet it is humans who turn it into a story.

The Distinction between Memory and Data

Pages of numerical data can be personal, precious memories or a secret history when combined with the complex human mind. Therefore, the boundary between human and machine cognition does not separate them, but rather allows them to exchange data and share the cognitive process, simultaneously keeping their distinctive nature in themselves, like membranes. Digital information systems, enmeshed with human cognition in the cognisphere, have made the presence of the boundary fade from our senses, but it is still actively present in the human-technology relationship, not only participating in the cognitive process but also holding unexplored possibilities in it. The project *Surrogate Being* (2019) investigates the cognitive gap between humans and digital technology to mediate the disparity through the process of recreating my hometown of Suwon in Korea. I often recall memories of one specific area in the town where I lived in my childhood, and I believed that the nostalgic image in my mind was intense and concrete. When I decided to recreate the place in a virtual space, however, I realized that the vivid image came from my reminiscence with various sensory experiences such as the mood, smell, and temperature – not merely from the visual. Visual references from online (such as Google Street View) were incompatible with my memories because concrete images provided by the interactive map did not evoke the intensive and profound feelings I had for the place. I created the virtual hometown in a 3D space as a place to mediate this discrepancy by weaving the complex and affective mode of awareness in my imperfect memories with *nonconscious* digital information.

My memories have faded and become distorted over time through consistent and dynamic interaction with the world, but digital images display themselves only through a mechanical interpretation of information – a set of binary digits that represents color data on each pixel rendered into images without deviations. Memories of my hometown must have been influenced by the encounter with the disinterested digital images of the place, which are sharply different from the nostalgic images in my mind. In fact, my mind existing within the shifting boundary never stops interacting with the

world as well as with the parallel memories in digital space. Through the process of recreating my hometown for *Surrogate Being*, I learned to work with technological cognition and to recognize underlying interaction with it on a nonconscious level as a part of a process of contemplating the cognitive coevolution of the network that humans and machines compose together. Such inseparability of human-technology cognition makes the boundary between humans and technology invisible and indistinguishable and dismantles the traditional conception of human morality, free will, and the conscious mind.

Nonconsciousness of Cognizers

The idea of *cognisphere* attests that human cognition is largely influenced by technology as well as other biological life forms and guides us to understand our mind as a part of a multilayered, interconnected, complex ecology of cognition, challenging the binary opposition of human and non-human. In such unceasing interactions, memories of my hometown are not and indeed never were intact. They have been transformed, warped, and faded over time through my interactions with the world, even at the very moments when I navigate the virtual hometown with uncanny feelings. My memories are influenced by my affective and sensory experiences in the physical space as well as indifferent digital landscapes I encountered during the exploration of the virtual world. Since it is dynamically integrated with technological systems in its development, human cognition and behavior are increasingly entrained by digital information and data processing, but humans are not cognizant of these underlying processes because most of them occur at the nonconscious level.

Even though nonconsciousness is intangible and unperceivable on the surface, its role is powerful and extensive,

positioned at the wider middle position under consciousness according to Hayles's tripartite framework, which breaks down cognition into three different layers: mode of awareness, nonconscious, and material process.[5] Nonconsciousness underlies all conscious actions and thoughts without being noticed, but it processes information much faster and deals with much more complex and dense signals than consciousness can handle. Located at the frontier of our bodies in contact with reality, the boundary between the external world and nonconscious human mind is much more sensitive and responsive than the conscious mind. Nonconscious cognition illuminates the fact that our bodily actions, mind, and feelings are not fully under conscious control and extends the idea of cognition far beyond human consciousness. In this way, focusing on nonconscious interactions with nonhumans sheds light on various modes of neural activities in other biological life forms and even technical systems, leading to more comprehensive and inclusive understanding of the complex cognitive networks with nonhumans beyond the boundary imposed by the human's conscious mind.[5]

As the binary distinction of humans and nonhumans not only isolates humans from everything else on the planet [9] but also displays human privilege, Hayles proposes an alternative distinction of cognizers and noncognizers that balances the relationship. Given that cognizers never stop interacting with each other on the nonconscious level, the humans/nonhuman distinction arbitrarily disconnects the continuous flow of cognition. Cognizers, including humans, plants, animals, and technological systems, have the capacity to make decisions to various degrees, and this capacity displays the cognitive properties of *flexibility*, *adaptability*, and *evolvability*, which are not present in material processes.[5] The alternative distinction between cognizers and noncognizers foregrounds cognitive capacities, and thus lets us interrogate the meaning of cognition in the technological era in a way not centering on humans and draw a proper boundary in the networked cognitive system.

Membrane between Human-nonhuman Cognition

Technology is one of the most peculiar nonhuman cognizers as it is a nonliving/nonorganic entity that significantly influences human consciousness. As the term *cognisphere* connotes, the cognitive networks that combine human and machine cognition compose not an entity but an environment, where their unfolded cognitive processes and activities constantly interact and transform. Humans and machines play dual roles for each other, as an environment to be affected and as a dynamic actor to affect. Analogous to the relationship of life and environment on the Earth, their cognition assimilates each other, and their adaptation is multidirectional. Digital systems are often designed based on analogues to human life, and human cognition adapts to the technological mechanisms – e.g., a two-finger operation expecting a zoom-in function on a map or image. Nigel Thrift proposes the term “technological unconscious” to refer to

such habits regulated and shaped by technological environments and to acknowledge human cognition beyond its boundaries stretching into the environment.

Given the limitations of the Freudian notion of unconsciousness as a part of consciousness, especially oppressed and traumatic memories, Hayles suggests modifying the term to *technological nonconscious* and acknowledges the cognitive capacity of technology.[6] Foregrounding nonconscious cognition, which rapidly and unceasingly processes a huge amount of data through interactions with human/nonhuman cognizers, legitimizes the borderless and nonhierarchical network of humans and technology with shifting, fluid, organic, and permeable (membrane-like) boundaries. A long history of human and nonhuman dualism, linguistic representation, and scientific classification has shaped our understanding of the world, which has led to the invention of the most influential cognizer in the cognisphere – technology. Continued reexamination of the frames and boundaries we live within should be one of our duties as conscious humans to maintain sustainable relationships with all cognizers on the planet. I argue that a new concept of boundaries as membranes let all human/nonhuman cognizers breathe as a whole system and live together within a cognitive ecosystem – as cell membranes do.

Abstract

This article proposes to reflect on artistic creativity in the artificial dimension, experienced under the dynamics of co-creation, in which a new interactor emerges from cyberspace - we call it the new craftsman. The article will discuss characteristics of a scenario in which the development of artificial works seems to suggest the repositioning of the authorial discourse, articulating changes that allow us to assimilate the metamorphosis that symbolizes both a new generation of techno-images and a new moment for art-science, through a new poetics that manifests itself in a context of expanded hybridization between bodies of different natures: both organic and inorganic. Starting from the time frame that is established in the 1960s, we propose a discourse oriented to reshape the relations between human and non-human beings and suggest ways to think Artificial Intelligence (AI) in an attitude that values the differences between biological and synthetic thinking. We conclude the article by suggesting the reasons why we believe that creation with AI seems to be the greatest revolution since the advent of photography.

Keywords

Authorship; Artificial intelligence; Machine creativity; Computer art; Machine art; Media art; Art criticism

Introduction

In face of the techno-scientific developments in the last decades, whose significant temporal mark gains dimension at the dawn of the 1960s, which glimpse in the computer-based solutions a new partner to make art with instead of making art through, arises the need to reflect upon creativity in the artificial dimension, a virtualized space whose operations are mediated, in a certain sense, by inorganic entities.

The origin of this thought, which finds in generative art and computer art its main exponents, was established between Europe and the United States from the pioneering works of George Nees (University of Stuttgart, January 1965) whose doctoral thesis, defended in 1969 under the supervision of Max Bense, is believed to have been the first

publication on computer art [1] Candy, Linda, Ernest Edmonds, and Fabrizio Poltronieri. *Explorations in Art and Technology* (London: Imprint and Springer, 2018), 5.; Frieder Nake (at Wendelin Niedlich's installations, Stuttgart, April 1965); and A. Michael Noll and Bela Julesz (Howard Wise Gallery, New York, April 1965).

The isolated attitudes observed in this period played a fundamental role in the foundation of machine-art, and resulted, a few years later, in what would become the true landmark of numerical creation – the timeless Cybernetic Serendipity (1968), an exhibition that had among its objectives to present ways in which human beings could use computers and new technologies to enhance their creativity.

As if it had been handpicked, the 1960s would still count with the beginning of Harold Cohen/AARON's (1968) journey as another pioneer enthusiast who, joining (perhaps in a first moment without even being aware of it) the Bavarian hegemony, contributed so that the interest in arts partially generated by numerical systems could gain dimension and scope and thus paved the way to the contemporaneity that today disposes of highly complex entities – intelligent interfaces to support artistic creation, as well as autonomous creation interfaces.

Before we continue, it is appropriate to emphasize that the term “machine” is used figuratively in this paper. The term is used interchangeably to represent both intelligent entities and algorithms, which manifest themselves through machines, which are in turn the interaction terminals that allow HCI (human-computer interaction) relationships to be realized. Machines are the hard dimension (or hardware) that reproduce in physicality the impulses of software, which is the legitimate controller of the process, “the invisible glue that holds everything together”. [2] Lev Manovich, “Estudos do Software (2008)”, in *Teoria digital: dez anos do festival internacional de linguagem eletrônica* (São Paulo: Imprensa Oficial do Estado de São Paulo e FILE, 2010), 182–194. All art that is recognized in the new media framework is software-based, be it robotic art, sensor art, or generative art. The explanation is necessary because it allows the use of a common

expression, "machine art" (even if sensitively imprecise), that can go through all the movements.

Having made this remark, it is observed that since the 1960s, the attitude of anthropomorphizing machines and technifying human beings has revealed itself as an

irreversible trend as virtualized entities become more and more intrinsic and integrated into daily life, operating mutations that lead to a cyborg-like embodiment and allow us to experience what Roy Ascott called cyberception, a perception that can be considered deterritorialized by accentuating and assimilating the “technological amplification”, resulting in the “enrichment of our powers of cognition and perception”. [3] Roy Ascott, “Cultivando o Hipercórtex”, in *A Arte do Século XXI – a humanização das tecnologias*, ed. Diana Domingues (São Paulo: Editora UNESP, 1997), 336-344.

The awareness of cyberception seems to constitute a fundamental element that allows for engagement and approximation with virtualized entities, immaterial elements that present themselves under the generality of Artificial Intelligence (AI) and that regulate and control a vast and growing portion of daily operations.

In this sense, it seems timely for both artists and researchers to think and articulate contemporary strategies capable of promoting new forms of relationships with non-human entities. The scenario that is based on the paradigm we call “new craftsman” – an expression that symbolizes the set of operations that are not only developed in the software-hardware frontier, but also in the flesh-calculus dimension – imposes itself as a central element to discuss the disembodied artistic creation that proliferates in our hyper-connected age.

The symbiotic creation in these terms, which implies a hybridism between human beings and inorganic entities, favors the recognition of bodies of different natures [4] Rachel Zuanon, “Biointerfaces inteligentes: transdisciplinaridade e transversalidade em arte-arquitetura-design-ciência-tecnologia”, in *Transdisciplinaridade nas Ciências e nas Artes* (Santa Maria: Editora PPGART, 2020), 234-247., an avant-garde thought that understands humans and machines as beings with equivalent values in the creative dimension. While assimilating the machine as an entity of distinct nature, the approach also allows us to think of artificial intelligence as something different and, consequently, to hope that from this difference unexpected creations may emerge.

Discussion

What the numerical entities (new technologies) offer - and new technologies are constantly emerging - are potential means by which artists can express themselves. However, and at the same time, the more one perceives the technological evolutions, the more tenuous seems to be the line that delimits the frontiers of creation. As they are not mere extensions of the body, prostheses that allow the execution of tasks in the most tool-like sense of the expression, intelligent entities need to be recognized as partners.

The use of the terms communication and collaboration applied to machines, terms so commonly associated with human relationships, seems to be rapidly becoming more natural as virtual operations become embodied and personalized, and, in equal measure, as bodies are embodied in digitized geographies.

The urgency of repositioning the role of the human being in face of the rise of the new craftsman, a paradigm that presupposes the establishment of a relationship in expanded hybridization, gains traction as we observe the growing number of artistic creations made in tandem with inorganic entities. Important questions appear from this recognition: what is the role of human beings in contemporary artistic development associated with machines?

And “what constitutes the authorship relation an artist bears to a work, when on one reading the artist may have created little of its content”? [5] Sherri Irvin, “Appropriation and Authorship in Contemporary Art”, *The British Journal of Aesthetics*, Vol. 45, No. 02, accessed October 20, 2021, 10.1093/aesthj/ayi015, 127. These are curious questions. Was Harold Cohen the author of his paintings or was AARON the main producer? It is no secret that Cohen said he was surprised by the works of his digital partner: “Clearly the machine is being creative, the program is being creative in that every time it makes a drawing, it makes a drawing that no one has ever seen before, including me”. [6] Harold Cohen, Interview with Ray Kurzweil, *The Age of Intelligent Machines*, The Massachusetts Institute of Technology Press series, 1987. Cohen didn't know what to expect, there was a mysterious element, works in a state of suspension.

When the Parisian collective Obvious allegedly misappropriated from programmer Robbie Barrat a complex algorithm designed for image-making, produced by using that code a series of portraits, and auctioned off the Edmond de Belamy canvas for over \$400,000 in 2018, the question arose as to who produced the work. How to attribute authorship in this case or, more profoundly, how should we position ourselves to deal with the non-human in the face of such questions? It would be very convenient to say that the artist is the one who programs the algorithm, or even to grant both the collective and Cohen the authorship title (reproducing an attitude like the one adopted by the conceptual art movement), but both hypotheses lack depth.

Of course, the results of artistic experiments (the cause or the code) are humanly programmed, but the consequence or “what is claimed to be the work of art - is not done directly by a human being. The algorithm, not the human, is the ‘artistic’ agent”. [7] Mark Coeckelbergh, “Can Machines Create Art?” *Philosophy & Technology*, Vol. 30, No. 03, accessed October 20, 2021, 10.1007/s13347-016-0231-5. One can see that the problem has no immediate solution, and that any attempt to shout certainty seems to prove unstable. Would it not be the case to openly address artificial creation?

Towards a different kind of intelligence

Artists-researchers like Leonel Moura (Portugal, 1948) adopt a position that attributes to machines an important fraction in the creative process by considering valid an “idea of autonomy in which the machine is capable of its own creativity”. [8] Leonel Moura, “Self-made art (n.d.)”, Leonel Moura's website, accessed October 20, 2021,

<http://www.leonelmoura.com/self-made-art/>. This point of view is in line with a preliminary attempt to address the questions presented, which suggests appreciating artificial intelligence as a form of organization of ideas different from those of human beings. It seems obvious, but it is reasonable to stress this aspect.

The character of difference would allow, so we suppose, a way to expand the relationships between humans and machines into a kind of amplified hybridization, in which the character of competition between the different bodies could be replaced by the exercise of collaboration. By understanding AI not as a mimesis of thought, but as an aid in making connections, creation with intelligent entities seems to make more sense. In our case (that of artistic creation), replicating human intelligence in a virtual way and applying this multitude of efforts to the poetics does not seem a very coherent move. If the idea is to replicate in silicon form a human intelligence, wouldn't it be better to remain creating from human-human relations?

On the other hand, if we seek in AI a different, motivating, and unexpected intelligence, perhaps this approach will contribute in a way in which we would act more like humans and less like machines. Faced with the recognition that inorganic intelligence has not reached the perfect simulation of human intelligence and that, therefore, it is not a replica of organic logical operations, it may be possible to infer that human-machine associations seek the unforeseen, that they pursue original forms of creation and go beyond the conventional poetic exercise. In this way, we address a reasonable solution to the problem of authorship and, equally, to the way in which the human being can relate to the non-human.

This stance recognizes that the artificial will always be artificial, but, at the same time, does not exempt the human being from the responsibility of assuming that a creation was made collaboratively. Persisting, the artificial will always be a gathering of all human knowledge (and all ignorance and misinformation), even as we realize that a new wave of AI emerges in leaps and bounds from the computer depths allowing algorithms to be able to formulate creations in an unattended, unsupervised manner, deeply disconnected from the natural dimension and free of anchoring with the human-produced repertoire.

AI can be understood, therefore, as a gathering of all the silliness and wonder extracted from the natural dimension. And it is a very well-made assemblage, one that somehow seems to make sense about the world and that invites us to empathetic reasonings and approaches about its modes of creation.

The point is not to anthropomorphize technology through discourse and understand it as something organic, but to understand that certain inorganic creations can touch us, help us, make us more human, illuminating our own creativity by promoting latent connections and tensions whose connections were, at some point, awakened by an agent outside biological thought. This proposition does not seek to disqualify human creation, but to identify if and how we can be

better when we associate with machines, since this association is irreversible. The argument seeks to reveal symptoms of incoherence that arise from the false conclusion that artistic creation, precisely in the scenario presented here, is independent and based exclusively on synapses and epiphanies.

The necessity of the recognition that, in a certain sense, works of art (or any other creative manifestations) developed with machines are not necessarily the exclusive creation of the artist, "but the product of the generative process - a self-precipitating structure" [9] Henry Clouser, "Towards a Dynamic, Generative Computer Art", *Leonardo*, Vol. 21, No. 2, accessed October 15, 2021, <https://muse.jhu.edu/article/600627/pdf>. is determinant for this theoretical formulation that is organized in opposition to current conventions. It seems in this sense inconceivable not to recognize that creation with machines implies co-authorship and, consequently, that it also implies a new thinking about how relations between humans and non-humans can be organized.

It seems to be shallow to assume that artificial intelligence is merely a translation of human intelligence and that inorganic imagery/textual/sound creations are coded expressions of humankind; no. AI is a different kind of intelligence, which despite having at its core the goal of mimicking human intelligence remains constantly flawed. However, if we shift the interest from the desire for mimicry to a desire for difference, we will begin to walk a prosperous path, especially in art. The flaws themselves may turn out to be delightful and desirable accidents.

We can neither expect nor desire an artificial intelligence to be equal to a human one. For that there are humans, and they are very good at what they do (even when they take questionable or harmful attitudes towards others, they do it efficiently).

Conclusion

We believe, first and foremost, that from these man-machine collaborations it would be more appropriate to hope for novelty, unthinkable associations, silliness. In short, to crave the new. The break of paradigms and a revolution in the artistic dimension cannot be conditioned to a set of operations that repeat the same logical forms of thought.

Artificial poetics should not reproduce organic poetics, it cannot be a pastiche of biological thought. Instead, it must seek a different anthropological condition that approaches a technological symbolism [10] Mario Costa, "Pour une nouvelle esthétique", (paper based on a talk presented at the ISEA2000, Paris, France, December, 2000). *ISEA2000: 10th International Symposium on Electronic Art*, <http://archive.olats.org/livre/etudes/etudes/nouvEsthetique.php>. a new aesthetic that moves from the predominance of subjectivity grounded in man to the openness allowed by instrumentalized collaboration.

AI needs to continue to be developed for a hyper-connected world, and the challenge to artists is to subvert its

original applications so that it can do dumb things down, operating a movement in which the researcher “unveils the essence of technique and allows it to manifest itself in the modes of the aesthetic” [11] Mario Costa, “Corpo e redes” in *A arte no século XXI – a humanização das tecnologias*, ed. Diana Domingues (São Paulo: Editora UNESP, 1997), quoted in Walter Zanini, *A arte de comunicação telemática: a interatividade no ciberespaço*, ARS (São Paulo), 2011, accessed September 22, 2021, <https://doi.org/10.1590/S1678-53202003000100003>.that drains the program of the black box [12] Vilém Flusser, *Filosofia da Caixa preta: ensaios para uma futura filosofia da fotografia* (São Paulo: Annablume, 2011).or even that subverts “continuously the function of the machine or the program that he [the artist] uses”. [13] Arlindo Machado, “Arte e mídia: aproximações e distinções”, *Galáxia*, No. 04, accessed September 27, 2021, <https://revistas.pucsp.br/index.php/galaxia/article/view/1289>.

It is necessary to leave it loose to create, to conceptualize and make sense about things, about beings and about the world differently than we would do. Certainly, a lot of works obtained in such a way will result in digital *Merdes d'Artiste*, and this is the main symptom of its elegance forged under stochastic perspectives.

It is hoped that this discussion will contribute, even if only slightly, to the formulation of paths towards the resolution of several problems associated with artistic creation with artificial entities: how we can relate to non-humans in the creative sphere; how to think systems as bodies of different natures; how to attribute authorship on the man-machine frontier; and how to evaluate the creative process in inorganic systems.

Finally, one must acknowledge the proliferation of a new aesthetic, and it is perhaps safe to conclude that AI applied to artistic creation is, maybe, the greatest revolution in the field since the invention of photography. The main differences and challenges are that now we will probably have an army of Baudelaire’s along the way.

Author Biography

PhD student in Visual Arts at the Institute of Arts, University of Campinas (Unicamp). Current research interests are focused on the investigation of new technologies and artificial intelligence in image generation, articulating the role of the artist and the role of the machine: human beings and inorganic intelligent entities are here considered bodies of different natures, somewhat equivalent systems. Issues such as machine coauthorship, subversion of technology by the artist, and the problems associated with the standardization of technologies, controlled by oligopolies, are part of the discussion surrounding the paradigm of the “new craftsman”.

Decoupling design from the industrial paradigm

Abstract

We suggest that a critical examination of computer-human design, as a field developed under industrial requirements, could be helpful at addressing the problems derived by the industrial development of digital technologies. Since it would seem difficult to conduct current problem-solving logic under the unprecedented yet probable conditions derived from industrialization problems -as energetic and material scarcity-, this examination could also aid in tackling their derived emergent (social and environmental) effects by exploring new situated approaches.

Keywords

Human-Computer Interaction, Human-Centered Design, Extractivism, Un-design, Techno-solutionism

Reasons for degrowth

There is almost consensus among the scientific community about the origins of climate change as human-induced phenomena. The increase of global temperature has been caused, among others, by large-scale deforestation and, since the industrial revolution, the massive use of fossil fuels, or the release of huge amounts of fluorinated gases. Its side effects span as increasing unbalancing environmental issues: acidification of oceans, ice melting, sea level rise, disrupting atmospheric anomalies, mass extinction of species, loss of biodiversity, or high human migration flows due to harsher climate conditions, to mention a few. Altogether, conditions that threaten even survival on the planet.

This historic change is rooted in the modern western industrial logic of extraction to accumulate. Colonialism provided European nations with bulk and inexpensive materials and labor, that industrialization transformed to develop technologies, which would in turn allow for larger and more efficient modes of ubiquitous exploitation. Transforming anything on the planet into resources and stimulating consumerism enabled the extraction of surplus value and growth under a competitive logic of wealth accumulation. Thus, this growth has manifested itself very asymmetrically among the different societies and between their citizens. [1]

In the last two centuries, the planet has witnessed an unparalleled use of non-renewable energies and polluted landscapes. The product of such intensification was and is

waste: broken ecosystems, suffering and ecocide among the disenfranchised actants of this finite planet. Information technologies are underpinning global production and are embedded in consumerism in many ways. Though seemingly immaterial and harmless, these have heavy material implications in this ravaging system. Around these technologies new, yet connected to the former, exploitation regimes have emerged. Under the guidelines of industrialized Human-Computer Design (HCD), IT infrastructures - hardware, their interfaces, the algorithms behind them, and the datified information flowing through- have become part of the environmental and social crisis-fueling practices. [2]

In the last decades, there has been increasing concern about the natural reservoirs of energies and materials used to progressively develop industrial growth. Currently, there is research pointing at an impending depletion of most of these. We have crossed the peak of fossil fuels, we are approaching rapidly the peak of uranium used in nuclear plants, and renewable energies, like sun or wind, don't yield by far the same EROI (amount of energy by amount of energy invested, in short). Besides this, the yield of rare minerals, necessary to produce renewable energy technologies, as well as general ubiquitous computing technologies, is also supposed to shrink rapidly. [3]

The infrastructural and energetic crisis we might face, together with the possible threatening environmental conditions explained above, pose a hard to work through scenario.

How new industrially designed regimes contribute to collapse

Colonialism, although still a reality, has evolved into coloniality, to produce extra-territorial forms of exploitation through data. Such outsourcing reproduces again asymmetric flows of wealth and waste. [4] This data is then used for behavioral capture and manipulation. [5] Mainly to foster consumerism, but even to influence institutional power. The psychological consequences that these practices have just recently started to surface. [6]

This digital power is concentrated in a couple of companies that have a bigger impact, in all kinds of spheres, than countries way larger than them. The new paradigm of power revolves around the concept of platform. To extract patterns (for example, to feed the cutting edge of automation: AI) in order to later produce per-user (or archetype)

customized “experiences”, very large datasets need to be extracted and aggregated. This is relayed through careful design of their interfaces and experiences. The more time users spend, the more can be extracted or persuaded. Through massive investments, digital platforms can stay inexpensive (until necessary) or gratis, in attempts to monopolize the market. Moreover, many of these platforms are owned by umbrella corporations, so data is shared between companies. Once they have wiped competition, the monopoly is free to change policies, pricing, etc. [7] Mediated by the platform, new forms of labor have spawned. From the so-called gig economy to crowdwork. Unregulated work, micro-managed automatically through the platform, again to allow lower prices and stimulate consumerism. Within an accelerated growth oriented logic, and rampant effects, blurrier extraction and waste. Still on the same size planet. [8]

As quickly mentioned above, the planet, as a closed, balanced system, doesn't seem to be any longer capable of sustaining this mode of coexistence. Some authors hold that moving towards sustainability implies a shift towards degrowth, at least for the small part of the global population at the top of this trophic chain. In order to extend the current regimes of opulence, some bring up untested technologies for terraforming the atmosphere, achieve CO2 capturing, or just crave for new clean energy technologies to come soon. But as mentioned above, probably there will be not enough energy and resources to carry out such colossal digitally underpinned endeavors, no matter how growth-involved actors try to delay broad acknowledgment and measures. [9]

Alternative approaches at designing within limits

Despite preceding research, there has been, as part of the “third wave” of CHI, a growing interest among the CHI community, to deal with the inherent industrial logic of design.

This research has been trying to understand and circumvent some principles underlying design. Most notably and with overlapping works, we find Information Technologies For Development (ICT4D), Slow Design (SD), Sustainable Human-Computer Interaction (SHCI) and Collapse Informatics (CI).

SD aims at addressing the issue of consumerism by addressing speed of disposal through personal and emotional attachment to products. It approaches critically one of the main principles of industrial development, the necessary obsolescence of products to sustain continuous energy and material digestion-based growth. [10]

ICT4D has been focusing on how to improve living conditions (against monstrous economical and political forces) in “developing” regions. Since normally this is carried by foreign researchers, participatory design is unfolded to avoid cultural assumptions. It tries to enhance poor resource-available populations by using easily available technologies. [11]

SHCI has been mainly theorizing, envisioning and discussing how design should be adapted in order to alleviate the unsustainable environmental conditions, explained in the introduction, by correlating them with new design approaches, methodologies, or metrics. It's research deals mostly about contributing to a more sustainable future. [12]

CI emerges from the hypothesis that sustainability is no longer possible. Foreseeing a hypothetical collapse (of infrastructures over time) CI tries to anticipate design guidelines with the aim of contributing to smoothing increasing scarcity conditions and generating resilience for the transition. [13]

Lastly, we want to mention a heterogeneous collection of work we can call Undesign, that deals with possibilities to design less, design low-tech to remove hi-tech, or stop designing sometimes. [14]

Yet, while the phenomena at stake get worse, these efforts have proven relatively successful, with an increasing sense of frustration due to the scattered conclusions, lack of overall agreement and few disruptive outcomes [this changes sustainable HCI]. These issues have led several authors to suggest HCD should borrow from social sciences and philosophy with the purpose of framing sustainability in a bigger picture. [15] Some of the issues, at least the social ones, could be fixed by almost just by political, legal and economical means as some authors denote. But we still believe there is room to contribute from critical technical practice. [16]

Examining HCD as an industrial discipline

We argue that when referring to HCD, we actually refer to Industrial HCD. However, as in many other areas of design, the industrial connotation is omitted. In the next sections we explore whether it could be helpful to notice how design principles are infused with an industrial logic. Such logic was forged in the rise of the industrialization period.

Design blooms in the transition from crafts to industrialization. This new production system shifted from crafts and incorporated labor division to increase efficiency. This way it could use unskilled workers and machines to mass produce commodities. These products would be acquired by generic people, unlike prior tailored production. The great wars left an immense industrial productive system (specially in the USA unaffected by war) that was put to work quickly. Under a new worldwide peace period, it was adapted to transform resources into commodities (instead of war stuff) for the population, now transformed into consumers. Hence, the position of (industrial) design got more and more weight. As a new discipline required new knowledge, that had to be produced to keep the workforce productive in a competitive market. Thus, design came in to fulfill a productive need.

Industrialization and engineering expanded with time as new technological fields emerged. Among other disciplines, digital engineering disciplines, from electric engineering to software architecture or interaction design. But

we argue, the same industrial constituents persist inside the CHD logic. We find that decoupling environmental-threatening industrial principles from the larger concept of planning/design can be insightful.

Design constituents

“We didn't work on time travel, teleportation, and antigravity. They are not important problems because we do not have an attack. It's not the consequence that makes a problem important, it is that you have a reasonable attack.” [17] In this statement (about designing scientific research) by Hamming, we see clearly how common in (HCI) design is to make problems emerge when there is a foreseeable technical solution to it, like in the popular proverb “if all you have is a hammer, everything looks like a nail”. [18] We argue that HCD inherent logic -of industrial nature- tends to search for new problems that can justify the development of new technologies. The work done around Undesign or around introducing friction delves into alternatives. [19]

As a productive task, design's main goal is to plan and foresee feasible products that get adopted. Ekbia et al refer to marxist argumentation “production creates the consumer” to suggest how, by designing production, actually it is that consumers are designed. [20]

User-Centered Design (UCD), spurred by the influential research of Donald Norman -using behavioral psychology concepts-, is probably the most popular framework in CHI fields to conduct a design process. We find revealing the use of the term user instead of consumer, when actually they are almost exchangeable. In doing so, it obfuscates the economic roots of design in the industrial productive system.

We suggest that the notion of consumer is relevant when addressed as resource exploitation. Centering a design process around the needs of the exploiter seems rather unsustainable. Creating an extractivist consumer/user makes total sense, from an industrial point of view, because the ultimate goal is to generate surplus value from the digestion of resources. Tomlinson proposes a shift towards suffering centered design. [21] Instead of a human (or maybe non-human animal) user, the author asks to design around the different forms of animal suffering. We have used the notion of exploitation to extend (human and non-human) animal suffering to biosphere damage and geological disruption, since they are all interconnected, as stated in the introduction.

Likewise, the notion of resource detaches energy sources, materials, animals and people from their ecological context. Through power relations it reduces these actants to something consumable. In a design that aims to produce sustainable, environmentally respectful outcomes, actants shouldn't be under a power relationship where they could be potentially harmed by being forced into another technological system, but be co-producers with their own interests.

Conclusions

Another way or relationship for digital technologies with the planet is probably necessary to increase sustainability, and even maybe unavoidable because of the effects industrialization had and is having over the very ecological systems it relies upon. Developing these would require a conceptual shift, probably in design principles as well. We have tried to delve into such a shift by examining some of the constituent parts we understand underpin industrial design nowadays. We suggest that further research into these questions from the prism of de-industrialization could be relevant. Furthermore, we find this kind of reframing fundamental if we want to move from a blind and growth development-oriented industrial logic towards a sustainable form of design that does not contribute to systemic disruption and in addition allows us to thrive in a potential scarce-limited scenario.

Authors Biographies

Raul Nieves (PhD candidate) is a designer/artist researching modes of unveiling, confrontation and dismantlement at the ever-moving technoscientific frontier of capitalism. His work has been featured internationally as talks, exhibits, installations, and performances.

Dr. Enric Mor (PhD) is associate professor at UOC (Open University of Catalonia) where he teaches human-computer interaction, human-centered design and creative coding. He is the director of the master’s degree in Interaction Design and User Experience. His research is focused on technology-enhanced learning, human-computer interaction and design. Currently, he is researching across the fields of media art and interaction design.

Joan Soler-Adillon (PhD) is a Catalan artist and associate professor at Universitat Oberta de Catalunya (UOC), in Barcelona. He has held previous academic positions at Universitat Pompeu Fabra (Barcelona) and Royal Holloway, University of London (UK). His research and practice revolve around digital interactive media and its manifestation in digital art –particularly interactive installation, an experimental approach to interactive storytelling and documentary, and Virtual Reality. From a full-body interactive game run on an inflatable slide to a VR-based experimental documentary, he has worked on a myriad of projects with a focus on behavior design and interactivity, and on fostering audience collaboration and participation.

The Art of Urgency: Cultural Mediation as a Vehicle for Socio-Ecological Transition

Abstract

The climate emergency has led to a growing recognition of the need for a socio-ecological transition. This recognition has strong cultural dimensions, shaped by representations and narratives as potential vehicles of change. Cultural mediation is a way of connecting these realms. It can stimulate exchanges between actors (citizens, organizations, policymakers), and ultimately help produce dynamics of change and new solidarities.

ARTENSO, a research centre in art and social engagement, explored the possibilities of these intersections by conducting documentary research on the relationship between artistic and ecological interventions. It illuminated the relationships between art, culture and social-ecological change, both in their conceptual dimensions and through practical considerations. It developed a tripartite typology to map initiatives that bring about transformations in the current social and environmental context.

This study suggests that artists and cultural organizations can become agents of social change by exploring new methods and processes. Often conceived and presented separately, engaged art and ecologically responsible practices are nevertheless dimensions that, when articulated together, can challenge society on environmental issues, question the relationship between populations and the environment, and advance the fight against climate change

Keywords

Cultural mediation, socio-ecological transition, map

Introduction

The climate emergency has led to a growing recognition of the need for a socio-ecological transition. This recognition has strong cultural dimensions, shaped by representations and narratives as potential vehicles of change.

Cultural mediation is a way of connecting the social and the cultural. It can stimulate exchanges between actors (citizens, organizations, policymakers), and ultimately help produce dynamics of change and new solidarities. Is it conceivable to develop a paradigm in which cultural mediation bridges art and science, in which the public interacts sensitively with its environment while appropriating ecological ideas? Is it possible to create a favorable context for a transition that is not only fueled by discourses of loss and deprivation?

ARTENSO, a Montreal-based research center on art and social engagement, explored the possibilities of these intersections by conducting documentary research on the rela-

tionship between artistic and ecological interventions. It illuminated the relationships between art, culture and social-ecological change, both in their conceptual dimensions and through practical considerations.

It mapped initiatives that bring about transformations in the current social and environmental context. It developed a typology to unfold the recurring goals and emerging axes of initiatives that combine artistic and ecological practices.

This study suggests that artists and cultural organizations can become agents of social change by exploring new methods and processes. Often conceived and presented separately, engaged art and environmentally-engaged practices are nevertheless dimensions that, when articulated together, can challenge society on environmental issues, question the relationship between populations and the environment, and advance the fight against climate change

Methods

This research aims to answer these questions: How can we combine arts practices with ecological practices? Who are the actors whose practices combine artistic and ecological dimensions? What are their objectives? What forms do the practices of ecological art movements take?

This research was divided into complementary stages:

- A first literature review on the socio-ecological transition, specifically on the genesis of the concept of transition and on the different dimensions that this movement takes in Quebec;
- A data collection whose objective was to bring to light a maximum of initiatives falling within the "culture and transition" axis;
- A first phase of data analysis to identify recurring objectives from the initiatives listed and to create a typological grid;
- A second literature review, oriented by the intersection of art and ecology, was carried out in order to clarify this axis of research and to make more rich the "culture and transition" nexus;
- Six interviews with actors in the arts and culture sector in Quebec and France. This step made it possible to expand the database and enrich the reflections in the document.

The use of the notion of "socio-ecological transition" was used in this research, as it is embedded in cultural and social practices. Although relevant, the notion of "just transition" is rather anchored in an energy perspective and has therefore not been favoured. Culture is an essential element in the emergence of a community of solidarity, particularly in the creation of shared narratives as a foundation for a strong sense of belonging. It should be noted that creating and strengthening the social fabric is as much an objective of the

cultural sector as of the socio-ecological transition. Moreover, the creation of social links is an indispensable asset for us to adapt to the upheavals we are experiencing and will experience.

The term "socio-ecological transition", although it can be defined in different ways, generally includes the following elements: 'the idea of moving from one state to another', which leads to the need for 'significant systemic change' in order to achieve 'a balance between human needs and the capacity of our planet to meet them' (OVSS, 2019, p. 3). Based on these dimensions, the following definition was adopted: Ecological and social transition is a process that leads to a change in production, consumption and living patterns towards a more equitable sharing of power and wealth. The transition aims at a transformation of the development model by building a more respectful, ecologically sustainable, socially equitable and economically viable society (Round Table organized by TIESS, 2017).

Initially, a rhizome research, without central element and evolving in several directions, was carried out in order to bring to light a maximum of projects, organizations, events and artists whose objectives or work are oriented in the articulation between art and transition.

More than 100 initiatives were identified and divided into three groups (Artists and Collectives, Organizations, Research Centres) Some of these are in the form of organizations, which themselves are working on a variety of projects mentioned earlier. These initiatives are presented in the next section.

Results and Discussion

In this section, we underline the three groups that bridge culture and environmental matters and that we covered in this survey, and illustrate their primary objectives.

Artists and Collectives

Definition

- Artists who explicitly build bridges between their artistic practices and environmental issues. The portrait of artists listed includes artists whose entire artistic process is rooted in reflections on ecology.

Main themes

- To raise awareness of environmental issues and eco-citizenship;
- To denounce realities related to ecological issues through artistic experimentation;
- To draw attention to certain issues through artistic practices of 'upcycling'.

For example, The Nuage Vert project by the HeHe collective consists of projecting a laser image onto the fluctuating contour of a cloud of factory smoke to form a plume of green light. This project was carried out in Helsinki, in 2008, on the emissions of the Salmisaari power plant and, in 2010, on the smoke emitted by the Saint-Ouen incinerator, near Paris.

Figure 1 HeHe, Nuage Vert, 2008. Photo : Antti Aahonen.

Organizations

Definition

- Cultural organizations that created a project related to ecological issues;
- Environmental organization that draw upon art in some fashion;
- An organization created at the intersection of the fields of art and the environment.

Main themes

- To stimulate community interaction through cultural mediation;
- To inspire better ecological practices through artistic practices;
- To support the development of artistic and ecological practices.

For example, Cape Farewell is an international non-profit programme based in the UK that works internationally, bringing together artists, scientists and informants to stimulate a cultural narrative that will engage and inspire a sustainable and vibrant future society. Artist David Buckland created the Cape Farewell project in 2001 to generate a cultural response to the climate challenge.

Figure 2 Rachel Whiteread, Embankment, 2004. Photo : Sjoerd ten Kate.

Research Centres

Definition

- A research-creation centre with an ecological component;

- A research laboratory whose main focus is 'art and science';
- Event or project within the framework of a research centre that deals with art and ecology.

Main themes

- To encourage collaboration between researchers, artists, artist-researchers and cultural mediators in environmental science research;
- To promote the integration of interdisciplinary knowledge in bridging art and science;
- To experiment with the possibilities of transforming territories.

For example, the LAAB research group is located in Saint-Mathieu-de-Trévières, north of Montpellier, and has been active since 2007. Exploring the combined tools and skills of art, science and engineering, LAAB is focused on experimentation and dedicated to creation. The collective's pieces are designed to expose the very expressiveness of the living.

Figure 3 Sabrina Issa, Églantier, LAAB, CRAC Occitanie, 2020.

The documentary research and the interviews reveal that there is currently a favourable conjuncture in the impetus of a socio-ecological transition, in which the arts and culture sectors are involved. All the interviewees agree on the inseparable links between culture and transition, and at the same time stress the importance of pooling knowledge and developing a support network. Three elements emerged from this research and deserve particular attention: the scale of practices, the need for coherence and the centrality of the narrative.

Practices

Urban spaces, territories and neighbourhoods are central to the reflections associated with the transition, particularly in their cultural dimensions. The environment in the sense of territory, living environment or particular context, by already anchoring itself as transversal pillars of doing and living together, encourages social practices combining culture and transition. Consequently, the city appears to be the preferred scale of intervention and will be called upon to play a leading role in the framework of future socio-ecological transformations. The urban space is the theatre of creation and implementation of public policies. It is home to a pool

of human, technical and political resources, which are crucial to the full implementation of the transition. The sustainable city is not possible without a change in the attitude of human societies, in order to take measures for future societies.

The interviews made it possible to identify practices to be developed in order to further link the arts and culture sector with the issues of the transition. Some participants stated that it was necessary to green the cultural sector by supporting the role of culture and creativity in policy-making and participatory governance. Fostering cultural involvement in regeneration and environmentally oriented urban infrastructure in response to environmental challenges is becoming inevitable. The new linkage between transition and culture requires the inclusion of a cultural dimension at every stage, from citizen participation to city infrastructure, emphasizing its essential role as a laboratory for testing and developing new approaches. Some projects will make ethical choices that will lead to criticism, but the ability to make mistakes must be retained. According to one participant, there is an obligation for artists and environmentalists to enter into conversation, as society needs to move towards a stronger cultural sensitivity, while the current models for thinking about transition are outdated. Another participant proposed to encourage the dimension of art as a social tool, since art is an educational tool. Promoting eco-education among the youngest definitely includes raising awareness through art.

Coherence

In England, Julie's Bicycle has been working to develop Creative Green Tools specifically for the arts and culture sector. These tools, which calculate the carbon footprint of cultural organizations, are already widely used in the UK and Europe. Knowing one's ecological footprint is a first step in becoming aware of the problem, in order to take action and change one's practices. These tools enable the cultural sector to create concrete environmental policies and effective, structured and quantifiable action plans. The project aims to change and influence other cultural actors to do things differently and better.

It is clear that the arts and cultural industries sector is currently as much part of the problem as the solution. It is a polluting sector and a major producer of waste, which can no longer ignore its greenhouse gas (GHG) emissions, and consequently its participation in climate issues. Several organizations have emerged in recent years to integrate eco-responsible practices into the arts and culture sector, such as Écoscène in Quebec. They encourage the cultural milieu to question itself, accelerate awareness and stimulate the creation of tools to do things differently. For one participant, the arts and culture sector must become aware of its "unconscious biases". Art is part of the problem and part of the solution; the first step is to become aware of the consequences of one's own practices. Consistency between practices and message is essential: first you become aware of your footprint and biases, and then you can change your practices to raise awareness.

Narrative

The ability to transform our representations and challenge our imaginations is a central element of art. The 2006 report Art in Ecology - A Think Tank on Arts and Sustainability

reminds us that researchers and environmentalists value the skills and techniques of performance and music, visual arts, storytelling and written language, in communicating knowledge. One participant added that it is essential to be able to communicate what you do in order to show your potential. A second participant pointed out that it is not futile to deal with ecology through art, as cultural representations must evolve and change. One participant also noted that artists need to explore how to propose alternative visions, especially in a process of engaging with the public to create new visions or solutions, and thus create powerful experiences that truly help to change our relationship to the world. The power of art lies in its great potential for awakening and its ability to touch the emotions. Without instrumentalizing artistic practices, it is becoming essential in the current context to value art that supports a new vision and questions the status quo.

The notion of story and narrative must be more central as a major power of culture and the arts. We need to revise the way we tell stories and tell ourselves, since the scientific and catastrophist approaches do not work. Furthermore, it is time to diversify the ways of imagining and representing what is happening and where we are going. In this sense, it is essential to turn to those whose job it is to tell the story, and this in all artistic disciplines, as much in visual art as in dance. At the heart of the possibilities of culture, there is a role for artists to play. This capacity to reach out, mobilize and raise awareness must also make it possible to reach those who are traditionally far removed from the discourse on transition. This can be done by stimulating citizen participation, and specifically through cultural mediation. In the report *Culture and Climate Change*, culture is presented as the only way to involve citizens in the challenges posed by climate issues, notably because climate change is a cultural challenge. Cultural because it is embodied in everyday life, in habits and in the way we live together, as well as in the transformation of cultural representations. Once again, narrative is at the heart of the possibilities for change.

Conclusion

In sum, what place can be made for arts and culture in the socio-ecological transition? According to one participant, people need to feel that they are "working" for something better, for a better world. This representation can be created by artists. However, the mandate is ambitious: to transform the imaginary of the end of the world to create a positive representation of a future. A more ecosophical reflection of artistic practices allows us to collectively rethink our environment in its natural, social and psychic dimensions. Finally, it is essential to apprehend all forms of life with wisdom and harmony, and to think more broadly about transition and culture in order to shake up imaginations and create new ways of doing and being that are resilient, sustainable and just.

For the future, it would be relevant to ask to what extent cities and territories can engage in the linking of artistic and ecological practices. How do socio-ecological transition practices, as social and cultural practices, enable the creation of communities? How does art, or any cultural dimension,

contribute to the reduction of social fractures? To what extent does it participate in the construction of a narrative leading to innovations for the development of our societies?

Abstract

The maker culture, flourishing around the world across the last decade in the form of public, corporate and underground maker-spaces or diverse DIY/DIWO workshop programs presents one of the most important trends in experience-based learning, which often takes place not only informally, but also unconsciously, for example through embodied cognition. Upon this background and along several cases of projects, artworks, institutional alliances and initiatives, the article presents an emerging model for experiencing and learning through interdisciplinary collaborations between art and entrepreneurship. These practices are demonstrating new possibilities for disciplinary crossovers permeated by artistic thinking, such that are particularly fruitful for social, but also for technological innovation, which is confirmed by the current DIVA project as treated in the article. Art Thinking proves to be a key novel approach in the innovation cycle that may be integrated into formal education curricula, business practices and community learning alike, which was proven by the recently finished MAST project as discussed in this contribution. A concrete convergence of the above principles and concepts is finally presented through the concept and process of the current project xMobil as an example of blending maker methodologies with the art-thinking based crossover innovation approach.

Keywords

Cross-innovation, art thinking, making, interdisciplinary, embodiment, art practice, crafting, innovation, art-sci-tech.

Introduction: Maker mentality can radically change the way we do things

The maker culture has been flourishing around the world across the last decade in the form of public, corporate and underground maker-spaces, diverse DIY/DIWO workshop programmes etc. It presents one of the most important trends in experience-based learning that often takes place not only informally, but also unconsciously, for example through embodied cognition. The projects and examples presented in the following, highlight and affirm the concept of the maker mindset and the approach of the artistic kind of thinking (Art Thinking) that has been proven to enhance the resilience and positive disruption of both the social and the business sphere, even more so if expanded onto the novel concept of craft thinking as the quintessence of embodied cognition. [1] If well integrated into the so-called Crossinnovation between art and business, Art Thinking can positively inform a both socially and technically relevant Maker Culture.

All knowledge sharing activities that are based on maker-centered learning teach students or any other learner both hard (discipline-specific) skills and soft skills, such as critical thinking, collaboration, and communication in an interdisciplinary way. The idea of the maker mindset is that learners develop creative confidence and a sense of agency — becoming aware that they have the ability to creatively solve problems on their own and jointly with their peers. These projects and practices seem to be fostering an auto-didactic approach especially among the lifelong learners who are particularly proactive in focusing on what they like and what genuinely interests them without the guidance of

masters (such as teachers and professors) or institutions (such as schools).

On the other hand, crafting practices – which involve a lot more technique, knowledge of material, actual manual practice than design, and craft thinking understood as “embodied creative experience” or “embodied cognition” – emphasize the importance of materiality and tactile perspective aspects in learning, intellectual activity, and meaning-making process. They promote the integration of life and meaningful work, a particular “knowing-in-action” that revolves around how to do something. They also bring about reflexivity because we are thinking about what we are doing (especially when doing it, learning it for the first time) and reshaping the action while doing it. Craftwork is one way to bring people out of isolation, it is turned outward to the community, it is the way that local and international communities can learn together and connect; the way we do certain things, the process itself reveals a lot about ourselves and our communities, including the values involved. [2]

The recent pandemic has brutally hit not only the creative sector and some business realms, but society at large. Nevertheless, in many cases around the world, we see examples of people who have responded with resilience through spontaneous and innate creativity. In a period of ongoing lockdowns and uncertainty, making arts and crafts, tinkering and innovating has started flourishing in unforeseen spaces; from garages to kitchens and living rooms, to studios and backyards, as a pastime or to regain one’s livelihood, from amateur hobbyists to professional artists and makers. A range of actors has been redefining existing practices and the spaces they inhabit. Significantly, acts of making help maintain dignity in times of distress. [3]

During lockdown it became evident how fragmented we are locally, and how broken-apart local communities and institutions have gotten within just a year. It is important to promote and empower the informal arts and crafts practices, as a segment of culture that can be found in every community. It is usually embedded (but thus invisible) in a broader local cultural context of the city or a country, and its history. Metaphorically but also quite physically, the culture that is exercised in the garages, kitchens and backyards or in people’s homes has replaced public and corporate provision: there people spent much more time during lockdown than before. [3] They worked from and at home, solving problems (and creating freely) from what (and in collaboration with whom) they had locally. And these practices seem to be carrying on even after (or between) lockdowns, indicating a fostering of new models of learning and collaboration, of producing and innovating.

Taking a culture of making in the center of our actions promotes active citizenship, shared values, inclusion, and intercultural dialogue. It brings people together, including new target groups like unemployed people and to a certain extent also migrants, and helps us (and them) feel part of a community. The proverbial joy of making and the awareness of the common comfort springing from creative actions both have the potential of different cultures and sectors coming together to overcome the social differences that divide us. Behind the gates of the garages, a lot of knowledge, skills and innovations have accumulated in secret over decades. The cultural and creative industries also

have the power to improve lives by publishing new tools, transforming communities by active citizen-engagement and generating spillover effects in other sectors of the economy. [4] This shall be discussed in the following via two key projects; DIVA that supports the cross-innovation processes between art and business, and MAST that integrates art thinking and the profile of the innovation catalyst into the innovation process:

From problem making to strengthening the European economy (DIVA)

In the following the article explores and presents an emerging model for experiencing and learning through interdisciplinary collaborations between art and entrepreneurship. These are opening new possibilities for art-thinking-based crossovers particularly fruitful for social, but also for technological innovation, which is being confirmed by the *DIVA project*. The project's full name is *Development of Innovation EcoSystems and Value Chains Supporting Cross-Border Innovation through Creative Industries*, with a duration between 2018 and 2022 and budget of 3,5 million Euro this Interreg initiative unites 15 partners from Italy and Slovenia, ranging from creative hubs, intermedia producers, universities and chambers of commerce, to hi-tech companies.

The maker mentality involves a lot of similar approaches to those of artists, since both need a good measure of problem-solving-oriented thinking. While artists are not necessarily geared toward finding solutions, they tend to make problems evident, they tend to rephrase them and shed light at an issue from several (often unconventional) angles. For that reason, Art Thinking can provide an alternative thought process to a more analytical type of thinking. Thus, it is not surprising to find out that artists tend to find solutions for non-existing problems or make problems where there are none. Speculative art takes into consideration what we know now and makes predictions on the future and proposes solutions to problems that have not yet arisen, or might never. At the *Berlin biennale IX* the installation *New Eelam* took inspiration from the startup culture and the real estate market's contemporary problems to create a speculative solution, addressing the audience with an existential ambiguity. [5] On the other hand, we can find artists that highlight the problems of today, which are hard to see. For example, the artist Joana Moll often deals with the invisible in computer technology, her work *CO2GLE* aims at highlighting the vast amount of global warming that is generated from seemingly innocent actions, such as using Google or other search engines to find information. The project aims at showing how much CO2 is being released into the atmosphere while using such engines. [6] Similarly making something virtual physical might help to illustrate the commercialized aspect of social media as can be seen in the work *Quick Fix* taking the form of a vending machine selling followers for social media. [7] On the other hand, we can recognize that even speculative or the exploratory nature of an artist can generate works that are more akin to start-up ventures with clear market goals. This can be seen in the work *Dulltech* which played on a real need in the intermedia art community and responded to it with a Kickstarter campaign, resulting in both an artwork and a true capitalist venture. [8]

In this sense, artists possess a unique approach to problem-solving, since their goal is not necessarily solution-oriented. Art does not need to resolve issues, art can simply make (the actual) problems evident. "Generally speaking, technical research focuses almost exclusively on new technical possibilities: What new things can be done? How can they be done faster or more efficiently? By contrast, artistic and design work tends to focus on the social and cultural meaning of the technology that is under development." [9]

In a world of constant racing against the latest innovations, and keeping ahead of others, Europe seems to have recognized that to achieve a paradigmatic shift in the economic sector, innovation has to take a more prominent role in economic politics. This is why in the last decade the European Union started multiple well-funded initiatives to foster the interaction between the creative and industrial sectors. It is true that artists have ever since and constantly intersected with the working environment and were kept intrigued with technological advancement, but only in the last twenty years policymakers realized the potential behind it. In 2012 the *Cross Innovation* project was funded under the INTERREG IVC scheme. [10] The project made a survey across 11 European countries (Amsterdam, Birmingham, Rome, Berlin, Tallinn, Warsaw, Vilnius, Stockholm, Linz, Lisbon, and Pilsen). It was one of the first organized initiatives that developed a toolkit and manifesto to bolster cross-sector interactions. Unfortunately, the initiative has gradually lost momentum and a fair amount of organization dwindled, shifted, or completely stopped after some time. The *Cross Innovation* website has been recently shut down and the only way to reach the content is through web archives.

The above does not mean the cross-sector approaches are unsuccessful, but it rather shows that due to the nature of business not all endeavors are equally long-lasting. An increasing number of creative hubs and the increasing interest of Universities (Aalto's Design Factory and Fablab, Paris's University CRI Hub, Gothenburg University's Business & Design Lab) to pursue their own inter-sectional hubs shows a big need and will in shattering the boundaries between traditional sector-based practice and research. Furthermore, the EU keeps funding projects aligned with this idea. Thus the *DIVA project* has been designed to create a methodology and implement pilot projects that connect the creative sector with more traditional businesses in a disruptive way, and through shoulder-to-shoulder cooperation between art and entrepreneurship. [11] The aim is to accelerate innovation and bring novel products to the market, finally finding a more resilient model for the European economy. This is further proven to be the European strategy in the latest round of proposed fundings, such as the *Creative Europe 2021-2027* mechanism or the *New European Bauhaus* initiative.

The *DIVA project* is now in its concluding stage, launching fifteen pilot projects, of which one is presented further below in Section 4. So far DIVA was able to identify through its own mapping case studies that clearly show there is a strong benefit in using the creative sector as the driving force behind innovation.

The Innovation Catalyst profile integrating Art Thinking on eye level (MAST)

Art Thinking as a key approach in the innovation cycle that may be even integrated into formal curricula offers a way to prioritize not only the artistic skills and tools, but also the concepts and methods that essentially transform the innovation process. [12] According to Sloterdijk, it is precisely thinking art, science and technology (AST) together that has the potential to generate an expanded knowledge consciousness. While technology is very much about rational knowledge, art is often operating with sensual, bodily knowledge — while science, on its part, is mainly about factual knowledge. A creative process taking place in between them provides the possibility to generate better visions for our future society in need of a more daring approach to innovation, such that entails a complex holistic embodiment that includes non-rational bodily and emotional conditions. To be open to such visions evokes the unforeseen and the unknown, raising more questions than giving answers — which the artistic approach has been always particularly efficient at. While design focuses on products or services that respond to needs, art is a discipline

that often integrates varied kinds of knowledge and experiences, including radical (self-)criticism and questioning of the entire frame of action (or thinking). Thus, and as shown above, artists often seem mischievous or even counter-culture, but in reality, due to their questioning nature, they tend to rethink what seems to be obvious.

Hence, the assumption of the added value of Art in the otherwise predominant Science-Technology blend — which can have a positive impact only if art is considered to have an equal stake at the least — was placed at the core of the *MAST project* idea. [13] It aimed to build a *Master Module in Art, Science and Technology* oriented towards innovations compatible with the Social Europe agenda which is based on the twenty principles of *The European Pillars of Social Rights*. These reflect the current European priorities aspiring to new and more effective work-related rights for citizens, converging in fair working conditions, social protection, and inclusion. [14]

The MAST consortium thus created a trans-disciplinary international Masters-level study module through a two-year-long series of workshops and public events, co-funded by the European Commission. These served as pilot tests for the later on accredited curriculum, where students alongside cutting-edge engineers, scientists, social activists, and artists keep producing both daring prototypes and radical thinking, such that addresses Europe's ambition towards meaningful innovation and social equity. In these pilot course runs sustainable social innovation models were first tested in critical ways, and then accredited within a cross-disciplinary syllabus presented further in the text. MAST promotes a clear interdisciplinary vision and an academic practice that aims to integrate social values into the entire chain of technology creation and social innovation alike.

The Cross Innovation Network (CIN) describes cross innovation “as a collaborative and cross-sectoral innovation process with the cultural and creative industries (CCI), businesses and other actors of the public or private spheres.” [10] In slight contrast with the above mentioned MAST project, the creative industries in this case act as so-called “innovation catalysts” in a collective role, and not as a single personal profile (MAST conceives the Innovation Catalyst as the module's graduate). [15] The CIN puts forward the skills of tackling “an increasingly volatile, uncertain, complex and ambiguous world,” while MAST's definition of an innovation catalyst refers to someone who understands and experiences creative imagination, emotional or corporeal intelligence, and has a deep understanding of aesthetics along with critical thinking; a conception well in line with the core elements of artistic thinking as devised by Buschkühle emphasizing that “sensitive perception, personal imagination, and critical reflection – inspire each other but can also be in conflict with each other;” and pointing to the fact that “the quality of will and manual skills are important factors in developing artistic thinking into creative results.” [16] On an institutional level by contrast, the CIN seeks to connect “public intermediaries, research institutes, study programs, experimental maker spaces, to private Cross Innovation agencies.” [10]

MAST also defocuses from the currently dominant paradigm of design (thinking), and postulates it – within the innovation cycle holistically conceived – as a stage that only comes after Art Thinking, i.e. when the artistic practices and the broad aspects of the humanities have already been considered. It does so not to diminish the importance of technology and design, but rather to embrace the fact that *moving minds* is ultimately more important to the AST nexus (than the actual making practice of technical innovation that may be said to *move matter*). Art thinking provides a series of dilemmas, intuitive observations, questions, paradoxes, etc. that are demanding more conceptual answers which do not necessarily offer a final result, and which do not necessarily lead to a solved challenge. This differentiates Art Thinking from the dominant and recently broadly mainstream Design Thinking that strives for problem-solving and thus (always) offers a

possible scenario or product development — for a known challenge.

The key curricular novum in the MAST module is a consistent introduction of Art Thinking as a core stage in the innovation or catalysis process. The key objective for the student is to become able to apply art-thinking methods and tools, combining them with design thinking to develop (or essentially improve) critical and unconventional breakthrough processes, services, and products. In order to avoid a mercantilist understanding of art-making within the innovation context, the present position supports a description of the artistic production only concerning other practices, which means not looking at the artwork as such but instead discussing the artistic approach towards making or doing things, i.e. as production of meaning. Such an approach involves a conscious, differentiated, and critical treatment of artistic thinking in and by itself.

xMobil, an example of blending maker methodologies with the art-thinking based crossover innovation approach

As a concrete convergence of the above principles of Art Thinking and Cross-Innovation that inform a both socially and technically relevant Maker Culture, the article finally presents the concept and process of *xMobil*. This (DIVA pilot) project aims to produce a working prototype of a solar-powered investigative-art module in the format of a car trailer that empowers creativity and innovation in remote locations. Therein it combines the work of professional artists, designers, architects, and engineers who act as mentors to students and pupils coming from diverse educational programs, and are the actual authors and implementers, the makers of this innovative product (and process as such).

The mobile system is to be derived from a standard car trailer, containing equipment for AV production and playback (DJ, VJ, video, + VR/AR), also designed to support research in Art-Science-Technology projects, including basic natural sciences, field sociology, and visual anthropology. It is geared towards the development of social and technological innovations in limited-access conditions or in (remote rural and natural) locations without electrical supply, thereby also expanding the local outreach of *ISOLabs*, a large-scale (so-called flagship) project of the European Capital of Culture (ECoC) *Go!2025* program that combines several tactical-media artistic approaches such as signal interception and jamming, advanced unmanned aircraft surveillance and environmental vigilance. Contemporary environmental sensing and recording instruments on biological, chemical, physical or visual levels have expanded the human ability to understand the components of what we deem “nature”. Together with *xMobil*, *ISOLabs* thus aims to “completely expand our view on complex biospheres and grasp them as ecosystems, showing that we need to encapsulate cultural, historical, and geological realities alike.” [17]

The art-thinking based design and fab-lab prototype development of *xMobil* will take place in the *Xcenter*, the hub of creative practice opened in September 2021, founded in partnership with the Nova Gorica municipality (*e-hiša* - House of Experiments, Youth Centre), the University of Nova Gorica School of Arts, Kersnikova Institute (both the latter institutions are involved also in MAST and DIVA) and several strong local businesses. *Xcenter* occupies the most central town location (pedestrian zone) in direct context with Nova Gorica's cultural improvement district, a key concept of the *Go!2025* program. It offers an important space for the ECoC activities with different generations engaging in new-tech innovation intertwined with art and design, offering STEAM-based workshops and mentorships, DIY and start-up support as well as a co-curated gallery space. According to regional industry and sponsorship support, several units of *xMobil* shall be

produced through 2023 and 2024 through local cross-sector collaboration.

xMobil thus presents a concrete convergence of all the above-discussed principles and concepts that should bring about a both technologically and socially sound innovation process, and a product (prototype) that will cross-connect artistic, scientific and technological assets in a culturally inclusive and community-sensitive setting.

Even if at the point of writing, MAST is finished while the DIVA project is still ongoing and its pilot *xMobil* is only starting, the above reasoning allows to assume that the maker mindset validating embodied cognition as combined with Art Thinking, within an innovation process, may enhance both individual and community-level resilience. It offers a way to prioritize not only the artistic skills and tools, but also the concepts and methods that essentially transform innovation not only as a process, but also as a concept. Moreover, if strategically aligned in long-term institutional alliances and coded into both educational curricula as well as public strategies or business models, these concepts may bring about a positive disruption of the tech-business spheres, not least by showing that (and how) any innovation should also have a worthwhile social impact.

Abstract

In Canada, healthcare and health professions education, in particular medical education, are grounded in structures of coloniality, oppression, heteropatriarchy and a variety of “-isms” (racism, sexism, ableism, classism). [1,2,3] Like other parts of the world, deep-rooted and enduring health disparities exist for many different groups. Change is needed urgently. CHIME aims to be a physical and social space where a wide range of stakeholders - members of marginalized groups, professionals from a variety of domains in and outside healthcare, as well as students and trainees, and other interested members of the general public - can together creatively and safely explore healthcare problems, test potential solutions and propose equitable, just alternatives to the status quo.

Keywords

Public health, health equity, advocacy, medical education, design in healthcare, innovation, participatory research, collaboration, health humanities, decolonization.

Introduction

Epistemic racism can be described as the “positioning of knowledge of one racialized group as superior to another”. [4] It is a problem that is skewing the educational environment of future physicians. Given this Eurocentric, -ism-riddled brine that trainees, clinicians and patients alike are being pickled in, it is little wonder that deep-rooted and enduring health disparities exist for many different groups across Canada. The list of affected groups is too long: Indigenous peoples; those living in rural, remote and Northern areas; sexually- and gender-diverse groups; those experiencing poverty, homelessness or housing insecurity, mental illness or addictions; racialized and immigrant peoples; and those who are body- and ability-diverse. [5-11] The existence of these widespread health inequities is unsettling and unacceptable. Something needs to change in healthcare delivery and education – urgently and swiftly. While daunting, the need to surmount challenges associated with decolonizing healthcare and medical education is great.

Multi-faceted approaches are needed to achieve the required changes at both the upstream level - training new generations of physicians, as well as mid- and downstream levels - providing equitable access to care and services needed to mitigate negative impacts of disadvantage and alleviate current health burdens faced by marginalized populations. To help address this challenge, we have conceived an approach that combines public and population health, medical education, arts, humanities, and design. Based on a collaborative practice model, the CHIME Design Lab (Community-centred, Collaborative Health Innovation partnered with Medical Education) aims to create a physical and social space that encourages participation from the widest possible range of people – from those identifying as members of marginalized groups, to professionals from a variety of domains (e.g. health, design, humanities), to trainees from these disciplines, as well as policy makers, and other interested members of the public. This way of working creates a community in service of the community. It brings together people with shared concerns but with diverse viewpoints, lived experiences, competencies and knowledge bases. This is a space where, together, people can creatively and safely explore healthcare problems, test potential solutions and propose equitable, just alternatives to the status quo. (Figure 1)

The question may arise: why design? Answer: our entire world is designed. Everything in it, including our health and education systems, has been designed. Design gives us a language to talk about the activities involved in creating intentional change. It can also describe the range of activities, knowledge and skills required to imagine and realize this change. Whenever we create “technologies, organizations, processes, environments, ways of thinking, or systems – we engage in design.” [12] Understood in this way, design is an activity we all do and which concerns us all. It is also up to us to decide whether something has been well-designed, whether it needs to be redesigned, and if the latter is the case, in what form? For what purpose? For

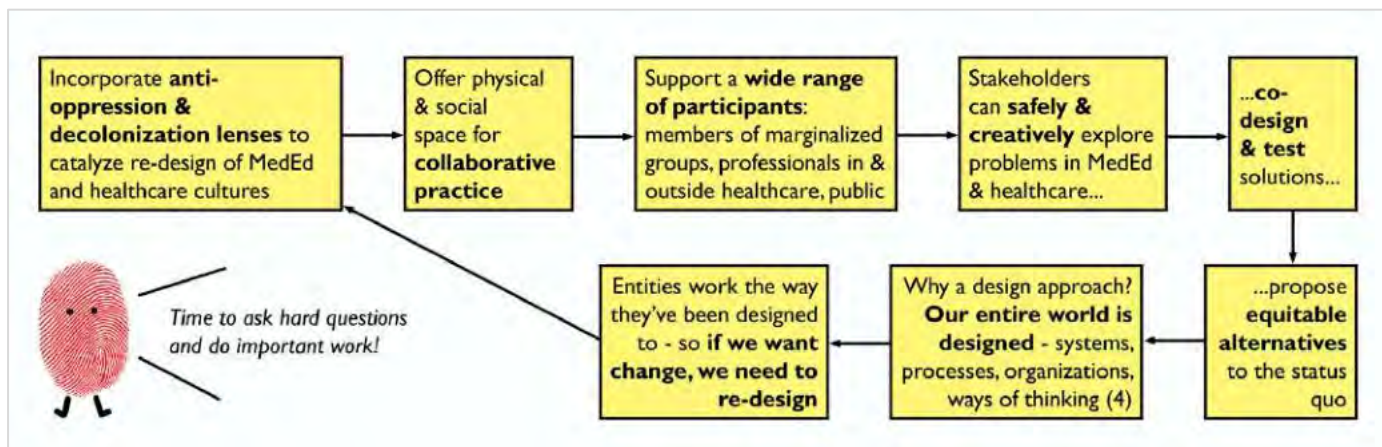

Figure 1. Proposed roadmap for CHIME Design Lab activities.

whose benefit? Why, and how? As Stolterman and Nelson (2014) has cogently observed, design is “at its root, a form of democracy ... the democracy of self-determination ... the kind of democracy that can embrace the growing diversity and complexity of human interests in today’s world. Design provides the possibility that each and every person’s individual good can be considered within the framework of the common good”. [13] This empathetic, collaborative ethos aligns well with the goals of equitable public health and social justice praxis of the CHIME Design Lab.

Methods

The CHIME Design Lab is a large-scale project that aims to engage health professionals, including trainees, as well as members of diverse, marginalized or equity-seeking groups, and other stakeholders to collaborate together in real-world settings to problem-solve complex health-related issues and reduce inequities in health outcomes.

Part 1 - Prototype Development

We are currently conducting a scan of relevant literature to identify high-quality sources describing promising social entrepreneurship models and design approaches directed to addressing health inequities and social justice, relevant to community and public health. This encompasses both peer-reviewed publications and “grey” literature (unpublished, or informally published material). We have cast a wide net to identify a broad range of leading-edge ideas, inclusive of position papers, pilot evaluations, published research findings and reviews, considered along with related perspectives from critical health humanities, social sciences scholarship, arts and health, and research-creation. Through this effort we aim to identify promising directions and opportunities for: 1) creating health equity through a health design lab approach involving community members; 2) engaging health science students in collaborative, participatory methods leading to novel approaches directed

to addressing healthcare inequities and social justice challenges; 3) introducing anti-colonial and anti-oppressive lenses to guide emancipatory design praxis in community and public health.

The broad range of approaches and evidence identified regarding impactful and effective opportunities for addressing social justice at the intersection of community and public health and medical training will be synthesized and shared via a layered knowledge translation approach (e.g. infographic, podcast series, academic publication, project website). The results of this review will also inform the development of a preliminary CHIME Design Lab prototype that will be piloted, evaluated and refined.

Part 2 - Pilot Testing and Refinement

Concrete strategies for designing and evaluating social, change-oriented CHIME Lab Design processes, including clear agenda and accountability structures, will be outlined. A health equity-seeking community group interested in collaborating on testing the CHIME Design Lab process will be identified, along with a cohort of interested medical trainees and practitioners, design colleagues, and community stakeholders. Community-based workshops and focus groups will be held. Project objectives will be refined in response to community issues and concerns. Processes, activities (including capacity-building efforts), and outcomes (planned and unplanned) will be documented and tracked, to ensure a humble, reflexive openness to ongoing learning together. Emergent insights and understandings will inform ongoing refinement of CHIME over time.

Preliminary Findings, Future Imaginings

Early scans of available literature have identified the importance of: openness and commitment, diversity and inclusiveness, empathy and play; processes that support wide-ranging, comprehensive thinking and ongoing

learning; advocacy and community empowerment; sustainability; and ongoing reflexivity regarding issues of power, privilege, access, belonging, and what it means to truly be human. Several programmatic, highly impactful and promising examples are highlighted here as exemplars.

Recognizing the need for progressive practices directed to improving fragile healthcare systems around the world requires an understanding of both local and global, social and political forces that impact health. The “accompaniment” process, referring to long-term relational commitment to listening to people in order to learn what they need to survive and thrive in their communities, has been described as being foundational to the success of “Partners in Health”. Co-founded in 1987 by Paul Farmer and Jim Kim Yong (who were medical students at the time) and a number of their friends, this international healthcare organization follows the lead of the local communities it works with to help bring high-quality healthcare, and dignity, to people in many of the poorest countries in the world. [14] Likewise, medicine's social accountability mandate has challenged medical education programs to introduce dynamic curriculum changes that prepare physicians to provide care that is responsive to the cultural, economic, and psychosocial realities of diverse patient populations. [15] To address this need, an innovative and creative approach to developing relevant and needed curricular content was created by medical educators at the University of Alberta. The DISCuSS model (Diversity, Identify, Search, Create module (with community engagement, Sustainability, Social accountability) provides a community-engaged, iterative approach to curriculum development directed at promoting health equity. Medical educators, community groups, and students work together on socially accountable curriculum modules that have helped medical students feel more prepared to serve marginalized groups. [16] Makerspaces also offer a model for promoting innovation in this area by bringing broad-ranging stakeholders together to explore and expand understanding of a social justice-related problem space, from which new innovative solutions may be explored and fabricated. [17] The catalyzing power of the arts has also been noted in relation to engaging diverse groups in exploring challenging health issues and helping to elevate understanding and ways of moving forward, contributing to advocacy efforts and policy change. Examples include an arts-based research project directed at heightening awareness and understanding of the impact of head and neck cancer, and community responsiveness to the needs of patients and their families, as well as <Immune Nations>, a multi-year, research-creation project completed in 2017 that explored complex views and forces informing vaccine hesitancy (<http://www.immunenations.com>). [18] Relationships between art, advocacy, action and change have been explored with respect to many health issues, including stigmatized conditions such as HIV/AIDS. [19]

Among other aspects yet to be identified, it is anticipated that, as part of the CHIME Design Lab methodology, attention will be given to processes of empowerment, contribution, and recognition. In addition, there will be focus on hands-on, creative processes leading to new ideas, attainment of needed resources, and new partnerships including - when needed - political support, to achieve necessary change and transformation for those who have the most at stake. Recognizing the important role and unique power of the arts and narrative storytelling in expressing complex emotions and experiences in accessible ways, multiple artistic forms will also likely be used in various ways across different CHIME-based projects. [20] Our aim is to expand understanding and work to change the conversation regarding different public health concerns, and help align action and policies to support “health for all”.

Toward Better and More Equitable Healthcare Futures

Ambitious approaches are needed to transform our culture and create better healthcare futures for all. Due to their scope, complexity, and political nature, inherently “wicked” social justice-related issues present significant challenges for designing transformational practices. There is a need to create structures and processes that lead to new ways of thinking and working that can amplify engagement and innovation. The goal is to overcome barriers to ensuring equitable access to dignified, quality healthcare and healing for all. Meaningful collaboration among all those who are part of CHIME projects will broaden the horizons of possibility for equity-seeking groups and community members, including outreach workers and activists, as well as upcoming generations of health professionals, designers and social innovation entrepreneurs, and others interested in working toward better and more equitable healthcare futures. In his award-winning essay “From mirroring to world-making”, Kenneth Gergen outlines a provocative understanding of inquiry, re-conceptualizing its aim as “future forming”, not directed “to illuminating what is” but rather directed to making, or creating, “what is to become.” [21] Aligned with this perspective, and mirroring synergies between arts and health, we view the collaborative reflexivity informing CHIME as a form of “practice artistry” supporting “sensitivity to, and caring for, the world”, to influence not yet imagined better, possible, more equitable healthcare futures. [22] We cannot wait to get started!

Authors’ Biographies

Savita Rani is a Desi woman and first-generation immigrant settler in Canada. She is chief resident physician in Public Health and Preventive Medicine at the University of Saskatchewan, and is the current Vice-President of the Canadian Association for Health Humanities.

Pamela Brett-MacLean is an associate professor in Psychiatry at the University of Alberta. She is director of the Arts & Humanities in Health & Medicine (AHHM) program in the Faculty of Medicine & Dentistry.

Patrick von Hauff is a professional designer in health professions education at the Faculty of Medicine & Dentistry at the University of Alberta. He is committed to design as a crucial and universal means of participation in society.

Lori Hanson is a professor in Community Health & Epidemiology at the University of Saskatchewan. Her research and teaching focus on issues related to the political economy of health that arises through community organizing, locally and globally.

Virtual museums: heritage and future of mediated UX?

Summary

This article intends to carry out an analysis of the factors that have inherited the experiences of face-to-face visits to museums with those that are developed through virtual platforms. This analysis has been developed using a hermeneutical analysis of categories applied by the authors through multimodality with the intention to expand the reflection on this subject, as well as to provide a broader point of view. In addition to this, we have identified how in recent publications other authors have been expressing similar points of view, which allows us to generate a comparative framework. The interest in these study categories is oriented on the potential that museums have in promoting virtual settings, outside of physical spaces that can promote the construction of deep meaning in learning at different levels of training. Furthermore, we carried out a review of the connotations that different virtualized experiences in museums have, and how these can promote different levels of construction of meaning based on what the subject is explained, what they feel or experience during their virtual visit. A classification is then proposed in which the multimodal typologies of virtualization are connected with the possibilities of construction of meaning through museums.

Keywords

Museum, Experience, Virtual, Virtual Museum, Learning outside the classroom, Multimodality

Introduction

As presented by Bonnefoit and Rérat [1], the advent of electronic media in the 1980s and the Internet in the 1990s promoted substantive transformations in domains related to communication, creation and management and transmission of knowledge. Progress has been made in projects of virtual museum around the world, incorporating technologies and providing participants with a series of interactions that promote different levels of experience. However, it is important to point out that the principles of the museums mediated by technology could be dated since the decade of the 60's, in which, according to some reviews carried out by authors as Schweibenz [2], they report the importance of certain categories against the novelty of electronics for museums. It was at that precise moment that different approaches emerged. Some of these approaches were museum research through computers, electronic museum, and computerized guides as predictions of the near future.

It is in this context that different improvements associated with the way of developing technology have been adapted, not only to the way of presenting collections, but also of making works. The beginning of the web brought as one of the first steps trying to develop spaces that would allow people to learn about matters related to the museum or its collections, but it was considered a violation of the concept and space itself of the museum and the intellectual property of the works. It was even considered as a codependency of the physical space on the possibility offered by the screens. For example, pointed out that physical and metaphysical experience mediated by screens, diminishes someone's ability to appreciate texture, dimension, and even color. Mitz [3] goes further and affirms then: "the media delivers information, which does not coincide with the totality of the experience that a museum can provide". However, these

positions in the continuous development of mediation activities through social media and other types of modalities in the early 2000s, promoted robust changes in the way of projecting the use and exploitation of media forms used with different purposes. According Huhtamo [4] during the first decade, search engines with the keyword "virtual museum" had a dramatic growth close to 1000%, which allows us to appreciate the increased interest in designing systems for the creation of museums on digital platforms. Now, in this ecosystem of concepts where the electronic, the digital and the virtual emerge and are associated with the concept of the museum, it is important to ask, if the user experience (UX) in a museum could virtual or not. If it happens to be virtual, under what characteristics of mediation this with the purpose of promoting through the aforementioned characteristics a purpose that increases, enhances or complements the face-to-face experience.

Museum Virtual Spaces

The recent concept of digital sampling studied by Manovich [5] raises a valuable question regarding the way in which we conceive the construction of representative samples of cultural value and in which we return to the very epistemology of the conception of collection. How significant is the face-to-face experience for a museum visitor today? This, in regards to the mission of a museum presented by the ICOM (International Council of Museums) [6] and debated by authors Bonnefoit and Rérat [7]. This allows us to understand that the opening, conservation, acquisition, research, communication, and exhibition is the way in which the patrimony of the humanity can have value, only when the interest for the development of knowledge through the construction of meaning is privileged. It is here where the discussion changes reference and ceases to validate the relation between virtual and in-person and focuses instead on taking advantage of the fulfillment of the mission of museums regardless of the environment used [8] verifying that modal forms in semiotic contexts [9] can be better used.

Therefore, it is important to understand that there may be multiple classifications of virtual museums as proposed by the Virtual Museum Transnational Network [10]. These classifications can be based on aspects such as: content, types of interaction technology used, the duration of the virtual experience, the type of communication, the immersive possibilities, the format of transmission, the accessibility to the public and sustainability. However, returning to Mitz's [11] initial debate, the experience is not interpreted as a typology of classification and analysis.

Considering what has been mentioned, we have proposed three *scales of experiential propagation* that allow a virtual system focused on a museum to make use of different modal forms and through these a different experiential scale is provided as observed in the central circles of Figure I. The first exhibition scale was the first modality that was implemented, since the 90s and with the appearance of computer networks, an important interest is fostered in building experiences that allow data, knowledge in general and logistical aspects of a museum to be mediated by

communication figure for the museum, but later on it included photographs and even videos about the collections, which began to build a level of propagation of the experience that we have called exhibition, inasmuch as its value resides in the contemplation and its corresponding interaction with the information of the object. In this type of experience, we highlight the extensive use of linguistic, visual modes [12], and even intersemiotic [13] modes such as audiovisual. Within this modality that we have called exhibition, there would be all those that reproduce the exhibition room and in which the navigator cannot do much more than walk around the room with their cursor and / or approach and move away from the pieces of art. We can also refer to the first virtual museums that were limited to the exhibition of the work as pure information, it is the case of the Web Museum, Paris - Founded in 1994 (<https://www.ibiblio.org/wm/>). In that intersection of circles that shows the different scales of experience, we understand that it is relevant to focus on those examples that expand the level of experience, which are at that intersection. This is the case of Google Art and Culture that is found in that exhibition plan of information display, but with a first level of interaction, allowing the navigator to choose their viewing experience based on the detail they want to explore in the chosen work of art.

The following two levels have evolved since virtual reality (VR) and augmented reality (AR) systems have been developed and are beginning to show some utilities with a focus on museums. We separate them in two because, depending on the type of museum, the decision can be made about one or another way for propagating the experience. Then, the second level: simulation, focuses on recreating the object and its behavior in order to appreciate in detail and experiment in virtual environments and also face-to-face. A wide and detailed use is made of visual modalities [14], generally intersemiotic modalities accompanied with gestures and spatiality in the subject. Science or art museums in general are very common, the concentration of the subject's experience is based on developing a level of interaction that makes it possible to make meaning on a phenomenon or some characteristics of a three-dimensional work. This level of experiential propagation has been called by us simulation because it consists of a recreation strategy to make meaning with it and all through simulation. In short, it is a step beyond the exhibition, since it implies a greater degree of interaction, of participation of the navigator approaching the works of art.

Finally, the third level of the propagation of experience is the one that in perspective [15] is incorporated generating a process of habitability in space. Only what is inhabited is experienced and from there the degree of immersion becomes a highly important component, since it is what allows building. It is then the space, its spatiality, and gestures [16], that makes it very important, taking two different experiential directions: the total recreation of space, that is an empty space is used to travel through virtual reality devices, or the existing experience is expanded, giving the visitor an interactive addition according to their profile, interest, or motivation. In either case, the experiences articulated in intersemiotics with the visual and perhaps sound when a component of playability is additionally incorporated into the interactive proposal. In this case, we mention the strategy of the *Lázaro Galdiano* Museum that through an augmented reality application displaying a pirate, helps children explore and expand their experience in space. We have called this level of propagation, experience, because it brings together the necessary elements for the construction of meaning through its inhabiting of space. We find conceptual support similarity to this classification in the distinction between artifact and cultural activity through the digital

observed that the relation with digitized artifacts was born in other media and in our case, they are made for the exhibition ones; digital artifacts, such as those conceived in this way, associated with the idea of simulation and finally, cultural experiences, where processes of digital experimentation are mixed with in-person visit, showing a clear trend in our way to propagate what is called experience.

Virtual Representation Approach

Representing a scenario constitutes the greatest challenge. Through the questions what to represent? and how to represent it? A strategy is established. This strategy goes beyond the virtualization and approaches the scenario of representation from which the experience of a user will mediate. As mentioned above, in most cases we talk about virtualizing, that is, transforming into identified modal forms with meaning for the target community. Perhaps, it is precisely for this reason that we have a clear conceptual void because our approach is technological, but if we assume a people-centered approach as in design, and even more, centered on living beings, we can consider that we are forgetting the fundamental piece. We are bringing ideas to transform the concept of virtualization, by mediating experiences, as it is presented in the central circles of Figure I.

In this sense, the first thing that should be pointed out is that the ways of building experience should not be considered as exclusive, we can mention that those ways that identify the what, the how (of the transmission), and also the what for, favor the development of the consultation activities and the construction of experience in a virtual museum. This means that the limits, as can be seen in Figure I, allow modal additions to be made between the different levels of propagation of the experience that benefit the user's profile, and the way of providing experiences in a way that encourages the making of meaning. It is for this reason that we prefer to call it level, without any of the previous levels being more or less important but bearing in mind that some will be more adequate for a certain type of making of meaning.

Following the above, we can understand how the representation approach of the first level focuses on information. This means that the development of all virtualization activities is in transmitting information through interaction. From the perspective of Szuprowicz [18] this approach to interactivity is called textual, and this is why it requires from the subject a cognitive interaction implied in the identification between the meaning of what is read and the way of doing it.

It is important to understand here that reading is understood as a broad form of action that goes from the linguistic to the visual. What is important is that it must be textual, visual or interactive. In any of the cases, the previous capacities of the subjects are being used when intervening. That is, the conceptual density of the texts, the interpretive difficulty of the images and the intuitiveness in the use of mediating interfaces must correspond to the ways in which the participants relate to the space, responding to a specific cultural form that allows diluting technological barriers.

In the second case, the levels of experiential propagation by simulation. We will talk about the modes of representation that in the perspective of Szuprowicz [19] have the ability to promote interactivities of a technical nature, in which based on a specific mediality, it can vary from spatiality, gestures and visuality, as it occurs in a VR or AR system, a specific experience is provoked by the subject. However, it is not the only possibility, science museums and laboratories tend to create devices that, although they are analogous, provide a

phenomenon through interaction with the subject. In this sense, technology is used to demonstrate through exploration with a scale model (temporary, spatial, or functional) a way of transmitting knowledge. In this sense, it may be different to contemplate to experiment, even with a simulated model. Well indeed, the simulation would be halfway between the exhibition and the experience, for this simulation to occur, the navigator must enter a greater level of experience, a greater intervention with which he builds meaning, his own meaning, within the limits established by the simulation. Within this category, we would find all those museums that provide the user in their web spaces with pieces and works of art simulated in 3D so the navigator can and must necessarily interact for the construction of meaning, then the scale of experience is completed, otherwise, such simulation would be meaningless.

Finally, in the third level of experiential propagation, a tendency to elaborate a scenario is developed, so that the user constructs a way of making sense with the space through their interactions. The experience of the situation of course is greater, and in this direction, it is possible to construct a series of points of view that integrate spatiality and gestures, but of a body type, not only manual as in the previous case. Additionally, the information and the ways of narrating provide specialized scenarios of interaction that could be both inside and outside the museum. A situation is fully represented in its context, the user becomes an assistant to the situation and undoubtedly this provides the visitor with an experience of a high level of meaning, since the immersion makes it feel as though what was narrated was indeed lived. In this type of modality, as we have pointed out, it appropriates, rather a bodily implication, a co-creative implication, of story construction in the given context. We can place the numerous augmented reality apps in the context of gamification, which can only develop their experiential scale in interaction with the room, with the space, with the context itself that the interaction allows the user to create their own, their own sense. In this direction we can highlight the apps of the Science Museum in the United Kingdom (<https://www.sciencemuseum.org.uk/games-and-apps>) that presents the visitor with different challenges using augmented reality to help them think like a scientist, so we can understand that the user's involvement here must be complete. The Harddiskmuseum V Space (<https://space.harddiskmuseum.com/about.html>), founded by the artist *Solimán López*, allows us to understand other logics of museum construction, as each work is constructed from the metaphor of a "hard disk", where data are works of art and where experience is built from interaction with them. As we can see, the development of virtualization activities, although could be seen as evolutionary and incremental, we cannot necessarily affirm that one scale or another is more or less relevant. The dependence of this criterion is always around the construction of meaning. Therefore, we understand how through the definition of an interaction design strategy, it is possible to define the level of relevance in the use of one or another dimension or, on the contrary, to create an appropriation of these categories trying to present different points of view in the process.

Objective: Making Meaning

As it was proposed from the beginning, what we present here implies that the museum experience should always be significant, regardless of the modal way in which it is intervened, face-to-face or virtual. From this point of view, we see how the user experience can take different scales of construction of meaning, which, aligned with the expectations of management and transmission of knowledge, constitute highly powerful didactic tools to

construction of meaning that involve the participants in different ways. That is, we understand that the construction of meaning is an ability to take many types of data and through a synthesis process, building an image that is cognitively processed to make judgments [20]. It is this image that constitutes an interface that enables the recognition of people's actions to determine, with it, the cognitive and cultural dimension of their actions. Let's see how we understand these classifications through what we call the virtualization target. As it can be seen in the peripheral circles in Figure I and starting with the first level of experiential propagation, we understand that the objective of virtualization is in the need of making meaning in the interaction of users through data that is transmitted to them. This presents information that in general terms is irrefutable, such as type of technique, year of elaboration or the historical context of the work or collection. Then it is understood as objective knowledge [21].

In this perspective, the data that is transmitted is learned by its temporal or spatial qualities, such as, for example, how it was made, how long it took to be developed, how it was implemented, how many people intervened, among many other things. In general terms, the data is measurable from some qualitative or quantitative dimension, and this makes it turn into knowledge.

The experience through the interaction with an object is of personal nature, it allows acquiring and experiencing what is known in literature as subjective knowledge [22]. In this sense, we can understand how the different interactions with objects in a virtual museum provide information that only an individual who interacts with them can identify.

Figure I. Virtualization objectives through the experiential propagation scales for museums. Source: self-made.

Finally, knowledge that is not achieved through transmission, but that is experienced in the physical or virtual environment, and how the scenario is promoted through this. Here we clearly show that we are not talking about the museum as a physical or virtual space, but about the experience of being a participant in a battle in a historical museum or with the painter at the time of experimenting with his work in an art museum. These spaces allow to embody an experiential knowledge that is reflected in a deep meaning on the part of the participant.

Conclusions

This document presents a different point of view to the debate between the presence and the virtuality of museum visits. In the evolution of the systems, replicating a face-to-face experience is very convenient and it is the first step to

fail to understand that virtual museums can offer other alternatives for the construction of meaning that would complement the face-to-face visit and that could even offer separate experiences according to the particular profiles of the visitors. The International Council of Museums states that if the historical patrimony that a museum contains is for its opening, preservation, acquisition, research, communication, and exhibition, we cannot ignore that certain museums, certain collections and certain face-to-face experiences are impossible for a large part of the world's population. It is precisely there where the importance of virtual museums becomes relevant, when it is able to recognize that it has more to offer than physical space. ICOM itself recognizes this when it states that the term museum is a place to select, study and display the material and intangible evidence of humanity. The discussion then is not focused on space, it is focused on the user experience and its use in the world. Understanding the logic of people interaction in museum spaces, in any of the modalities described, will be understanding their behavior patterns, in regards to the culture and their expectations of knowledge, in a context of cultural references affected by globalized homogenization.

Abstract

One of the biggest challenges of our time is for humans to really understand how does a human action propagate through another complex natural system? What is the difference between human and ecological time? Algaphon is an online and offline installation wherein algae bubbles that ring at minnaert frequency near algal filaments are rendered audible through a hydrophone. The installation comprises of aquariums in Tokyo, New York and Linz, each with different species of algae. The aquarium lighting is connected to participatory action -- Online visitors leave a voice dialog that is translated into photosynthetically active radiation (PAR) variations in a remote aquarium. The algae bubble response to this human speech is then recorded and emailed back to the visitor for them to engage in a reflective dialog with algal species.

Keywords

climate change, ecological time, biological functions, algae, seaweed, interactive art

Introduction

The progress of science in the last few decades can be primarily attributed to the crossroads of disciplines and a flattened knowledge distribution. Contrasting phrases of real and imagined, photographed and painted, perceived and estimated that would have been at contradiction to each other, now suggest a profound rapport between each and a continuous tension at play. A tension, to which we have tried to put a name for years, vaguely between art and science: intermedia and creative technologies, media art and more. At the turn of the last century, the fields of biological and cybernetic systems started tapering, ushering us into a completely new era with hybrid fields such as optogenetics, sonogenetics and more.

In the recent years, as we close the gap between technology and our own understanding of biological functions, Weiner's hybrids [1] become ever more clear where 'machine parts become replacements, integrated or supplemented' to an organism's body image. While industrial revolution largely taught us synthesis of artificial materials [2] and processing of silicon, recent advances on biology [3] are providing us with methods that will be enable properties of bionic materials [4, 8] that are yet to come. In that context, it is essential for us to understand biological functions of nature around us by piecing them into units similar to how we study our own human body.

Concept

Urban environments and manicured nature, with no sight unseen of native organism diversity [5], have led to forgotten evolutionary histories and a reduced understanding of ecosystem relations. The aquatic plant biosphere especially bears a collective amnesia [6, 9, 10] from the humans of its evolutionary roles. It wouldn't be erroneous to use 'out of sight, out of mind' in the context of the biosphere of aquatic plants. While the contributions of these early species have been tremendous [7] to shaping higher plants, they haven't received a lot of focus in their role from non-scientific communities.

Our work refocuses the attention on algae species and reflects on the role of these species in climate change in specific coastal regions, through very specific micro-capabilities. We were first inspired by algae sounds recorded underwater in the bay and river waters at the East Coast (East River / Hudson River) and West Coast (San Francisco Piers, Sausalito, Point Reyes) areas in the US. These microalgae traditionally form and release oxygen near their macroalgal filaments (Fig 1.). When this oxygen is released, the relaxation of the bubble to a spherical shape creates a sound source that 'rings' at the Minnaert frequency.

Figure 1. Bubble image right before it leaves the filament of Sea Lettuce algae. © Harpreet Sareen, Franziska Mack, Yasuaki Kakehi

These natural soundscapes across the ocean and the bays are now varying and are more erratic [8] than ever due to ocean acidification and rising temperatures. When a habitat is transformed by human endeavor in some manner, it shows in its voice over time. Our motivation was to create a system that communicates such ambient biological sounds about hidden/submerged information in our ecosystems.

We manifested this by first recording tank-based passive acoustic experiments with the algae *Salicornia gracilaria* and similar species. Our hybrid (online interaction interface + offline macroalgae aquariums) installation, Algaphon, makes such marine algae sounds evident to a wider public domain, especially as a result of their direct action, and invites the audience to critically reflect on the role of underwater aquatic life in our ecosystems.

System Design

Algaphon is a hybrid installation wherein algae bubbles that ring at minnaert frequency near algal filaments are rendered audible through a hydrophone. Our setup (Fig 2.) comprises of an aquarium (10-20 gallon capacity), programmable LED lighting (5500k, 80-100W) mounted at a distance of 10-12" from the water surface and macroalgae species in the water. Normal maintenance routine is carried out for the algae such as keeping steady water flow using wavemaker, maintaining 73-76F temperature and dosing micronutrients such as NO₃/PO₄/Fe/Mg. Standard 12h on/off lighting routine was followed during the duration of this exhibition. When the light is turned on, algae photosynthesis produces oxygen that gets dissolved in water. After 2-3 hours of light being turned on, dissolved oxygen levels reach a threshold following which algae starts producing bubbles as a result of local supersaturation of oxygen in water.

Figure 2. Bubble image right before it leaves the filament of Sea Lettuce algae. © Harpreet Sareen, Franziska Mack, Yasuaki Kakehi

We replicated this aquarium setup in three cities: New York (Two 20 gallon aquariums with *Sea Lettuce*, *Red Ogo* and *Burning Bush*), Tokyo (10 gallon aquarium with *Sea Lettuce*) and Linz (10 gallon aquarium with *Caulerpa Prolifera*). We designed an online interface where users can record an audio message, that is converted by a *stepwise thresholding method* into Photosynthetic Radiation (PAR) values and relayed to an active aquarium. We found through prior experiments that average time for our macroalgae species to fully respond to light (with frequent observable bubbling) change was 450s (~8min). Consequently, a 3sec audio waveform translates to light variation duration of ~2700 (~45min). Based on this we limited the audio input from each user to a maximum of 3 seconds to eventually manage the number of recordings/visitors. We connected each of our aquarium setups to an online web interface and rotated the active aquarium based on time zones.

Experience Walkthrough

The audience was invited online (Fig 5.) and offline (in New York and Linz) to record their audio messages during a major art festival. These visitor audio messages were then converted to light variation scenes and played over active aquarium.

Figure 3. Visitor recording an audio that is queued to an active aquarium. Live video feed of the aquariums is seen in the background, as streamed from our web platform. © Harpreet Sareen, Franziska Mack, Yasuaki Kakehi

Bubble variations occur as a result of PAR variations over an aquarium. The algae audio bubbling *response*, recorded via hydrophones, was live streamed on our website (Fig 6.) during the full duration of the exhibition. Each algae response, occurring as a result of user input, was saved locally (~45min audio/visitor input) and also sped up to a min long audio. Because of the queued nature of responses and long response duration, the visitors do not hear an immediate response. The audio response is sent in two modes, in algae time (~45min) as well as in compressed time (~1min), over email.

Your response in algae time

Photosynthesis takes time! That's why we've translated your three-second voice message to 45 minutes of light variations. Attached, you can find a recording of the bubble sounds that occurred within this timeframe.

Your compressed response

In addition to the original recording, you can listen to a compressed one-minute clip.

Figure 4. Snippet of the email response showing responses in algae time as well as a compressed response. © Sample person, Sample person, Sample

When the user receives the response (Fig 4.), the note also invites them to think of the difference between human action and ecological reaction time difference, as well as to think of time scale between humans and non-humans.

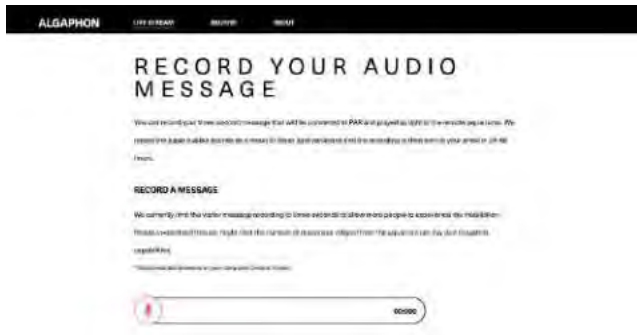

Figure 5. Screenshot showing the web interface for Algaphon. Live stream automatically switched from New York to Linz to Tokyo, based on time zone and aquarium on/off periods.

Fig 6. Screenshot showing the web interface for Algaphon. Recording interface where visitors could record their audio online.

Conclusion

Algaphon is an online and offline installation wherein algae bubbles that ring at minnaert frequency near algal filaments are rendered audible through a hydrophone. The installation comprises of aquariums in Tokyo, New York and Linz, each with different species of algae. The visitors record an audio response, that is converted into light parameters that propagates through algae to produce bubbling events. These bubbling events are on a different timescale than from the initial visitor input. These acoustic responses are recorded and sent to visitors, with the asynchronous nature of these responses highlighting the biological media. The significance of this work manifests from the algal relations with marine ecosystems, where environmental contamination often stimulates algae growth. Making such algae photosynthesis audible will in turn help us understand the extent of activities in urban/wild environments over a short and long-time spectrum.

Corresponding Wood Tools: Speculative Fabulations of Material Correspondence in Woodworking

Jihan Sherman, Michael Nitsche

Georgia Institute of Technology
Atlanta, Georgia, USA
jihansherman@gatech.edu; michael.nitsche@gatech.edu

Abstract

The rise of materialism questions the position of humans in relation to their surroundings. We engage craft practices as rooted in material encounters that directly affect crafters on various cognitive and physical levels. In these encounters, the crafter's body is also material which interacts on its own terms. The body's condition, and the material-at-hand act and correspond with each other. We argue that this contact is an in-the-moment material one, a shared moment of production and becoming. Based on this theory of material encountering, this paper presents the *Corresponding Wood Tools* project as "speculative fabulations" exploring the ways in which this correspondence can be made visible. It argues for re-shaping the encounter in woodworking to allow new reflections on shared themes, such as care and collaboration.

Keywords

materiality, new materialism, material correspondence, craft, speculative fabulations

Introduction

The turn to the material has not only opened up new positions and agencies for formerly "dead" objects but it also questioned the position of the human in relation to them. *Corresponding Wood Tools* follows this question in its own ways by centering on craft practices to provide speculation on our encounter with a particular material: wood. Re-shaping this encounter opens up novel perspectives on questions of collaboration and care..

Craft has always served as a cultural and sociohistorical reference. It captures practices that have shaped societies, industries, and inspires novel hybrid fabrication techniques. At the same time, craft practices are rooted in material encounters that directly affect crafters on various cognitive and physical levels. In these encounters, the crafter's body is also material which interacts on its own terms. These terms do not always map onto cultural histories or cognitive abstractions but are immediate reactions of muscles and nerves. During these encounters, the forces of the body and of the material-at-hand flow back and forth – they correspond with each other [3, 5, 6]. In this correspondence

both, interactor and material perform their own agency. Following the turn to new materialism and feminist critiques in Technology Studies, we purport that this contact between the human and the world is an in-the-moment material one first. Craft is well suited to explore these encounters as it emphasizes the co-becoming of both humans and artifacts through shared processes. As Richards argues for pottery: "Personal transformation, or the art of becoming a human being has a very special counterpart in the potter's craft [8]." Craft is always relational. Depending on the particular craft, these processes vary, but even between different craft practices a shared condition is that they are defined by a direct encounter between interactor and material that is *slowed*, *extended*, and *direct*. There is a "slow, probing touch of materials at the fingertips that eschewed instant, false security" [10] and that becomes a defining moment for craft. Slower and embodied conditions create opportunity for material-to-material encounters. In contrast, digital practices often speed processes up, optimize fabrication and minimize the encounter between maker and material, diminishing the opportunity for material correspondence. The challenge for material-based interaction design is to support this encounter instead of diminish it. The *Corresponding Wood Tools* project responds to this challenge. It provides "speculative fabulations" [5] of material correspondence between wood and humans. For Haraway, such speculations are a process of giving and receiving in order to "stay with the trouble" in the wake of the Anthropocene and Capitalocene [5]. They make kin between human and non-human.

Building on such theories of material encounters, these design projects were conducted to continue a critical reflection process and make key themes accessible. They are speculative, process-based, and critical in the realization of the material encounter. Their goal is to give voice to a thinking and making practice where *all* materials can have agency. In its attempt to "stay with the trouble" [5] by focusing on the process of encountering and bringing forth, the project aims to make material correspondence visible, or better: tangible. It rebalances risk during the making process to reimagine issues on care and collaborative material practice.

Method

The design of *Corresponding Wood Tools* grew out of reflections on wood tools on the one hand, and the challenge to include risk, care, and harm as principles of material correspondence on the other. Its design aims to open up speculative fabulations that unfold in the experience itself. Two classic wood tools are reimagined, saw and chisel, as facilitators of material correspondence in woodworking (see Figure 1). Both are connected to devices of care: a blood pressure machine and warming blanket in order to redistribute risk and harm across both human body and wood material during the encounter. The design emphasizes the co-emergence of both participants, crafter and artifact, in this encounter. It does so through notions of shared risk and care. *Corresponding Wood Tools* are not considered final objects in themselves but part of a reflective, experiential, and theorizing process.

Figure 1. *Corresponding Wood Tools* are speculative fabulations of material correspondence.

As a research through design project, *Corresponding Wood Tools* first asked how we look and experience wood from a microscopic investigation (see Figure 2) conducted in a material science lab.

Figure 2. Material Science explorations: oak wood magnified x100, x500, x1K, x5K.

Next, it turned to wood's role in material culture, scientific and observational approaches, and material experiences [4]. This phase of the project combined research into cultural histories of wood, social experiences, technical tools (Figure 3) as well as attention to wood's material properties: grain direction, growth rings, and structure. The focus remained on the material throughout to emphasize how external frames and inherent qualities can inform our participation within the material encounter.

Figure 3. Sketch examination of woodworking tools.

The next phase turned to practice, asking how woodworking and its tools shape the material correspondence and the immediate material encounter. As a response to these questions, a prototype of the project was designed and implemented to support the theorizing process.

Project Design

The key questions for *Corresponding Wood Tools* were: 1) How do we make material correspondence more visible? 2) How can shared criteria such as risk and harm be distributed across *all* materials within the encounter?

To answer these questions, the project introduces a loop of actions that extend material activity flows in woodworking. The goal remains to share qualities, such as material risk across both, the human body and the wood body. Sharing risk flattens hierarchies of subject-object distinctions embedded in traditional woodworking tools. Typically, these tools feature a “safe” area for the human and an area of “harm” for the wood. Tools such as chisels or saws have parts aimed at the wood that represent harmful activities: cutting, removing, or transforming. The parts directed toward the human represent comfort and protection from material harm: ergonomic handles, covers, or insulation. *Corresponding Wood Tools*' design alters these tools as its intervention method and posits that re-balancing this distribution of risk makes aware the active correspondence between materials. At the same time, the encounter has to remain productive. Material correspondence as a process cannot fall into mere abstraction but has to remain close to woodworking practices.

The project set up includes three main components: the base, the armband, and the wood tools (see Figure 1, left). The base includes a blood pressure machine that has been altered and connected to an armband that the crafter wears. The armband and the blood pressure machine are controlled by an Arduino microcontroller that drives two output conditions, *tightening* and *warming*. Both are connected to the action of the wood tools onto the wood material. In that way, the armband connects the body material, through the woodworking tool, to the body of wood. As one acts upon the wood, the armband, in turn, acts upon the body. It makes apparent material correspondence as an inter-body experience where care and harm are different but apply to both sides on their own terms. This is realized in two conditions: the *Warming Saw* and the *Comfort-band Chisel*.

Intra-action with Saw and Chisel

The *Warming Saw* (see Figure 4, left), is a flush-cut saw with an embedded accelerometer. It relates the sawing motion that removes wood material to the arm of the crafter's body. The friction of cutting is sensed through the saw and when that rate of sawing exceeds a specified threshold, a heating pad in the armband is activated and warms the woodworker's arm. Friction onto the wood is translated into heat upon the body. When the sawing motion slows below this threshold, or stops all together, the heating pad automatically cools down again.

The second tool, the *Comfort-band Chisel* (see Figure 4, right) has an embedded proximity sensor in a chisel. This sensor detects the cutting movement of the tool as the crafter manipulates the wood. This, in turn, tightens a band around the crafter's arm during chiseling. The tightening band is realized through a modified at-home blood pressure machine, originally a tool of care for the human participant.

Figure 4. The *Warming Saw* warms the body during sawing and the *Comfort-band Chisel* tightens around the arm during chiseling.

The sensor's data triggers the blood pressure machine to inflate the cuff which presses onto the arm of the crafter. Compression onto the wood translates through the chisel into pressure upon the body. If chiseling is maintained for a full cycle, the user's heart rate and blood pressure are measured and displayed. Status updates are provided not only from the gradually changing piece of wood but also from the changing human in the form of medical data.

Corresponding Wood Tools are speculative interventions developed for awareness not pain; for shared action, not disruption. The armband tightens and warms, it does not cut or burn. In a related approach, Benford et al. make the case for uncomfortable interactions clarifying that the "ultimate goal of such interactions is not to cause long term suffering or pain, but rather to underpin positive design values" [2]. We extend this notion of uncomfortable interactions from the social cultural experiences (with which Benford et al. are concerned) to material encounters. Chisel and saw are intended to bring awareness to the material correspondence as it occurs between the body material and wood material. Physical change is instantiated and documented as inter-related and corresponding over time. Transformations take place across all materials intra-acting with each other [1] and are brought into relation by the woodworking tools and the intervention processes applied. Discomfort is a means of bringing forth shared engagement and to emphasize the encounter of agencies embedded in the woodworking process. It is "troubling existing categories of form, function, purpose, and being" [9]. Through this "troubling," *Warming Saw* and *Comfort-band Chisel* are speculations on the material encounter as it happens.

Notably, the functionality of traditional woodworking is not interrupted. Saw and chisel remain working tools and their own forces and agencies remain intact. But they also become bridges for a reflection on notions of harm and care. We see both as interrelated: heating pad and arm cuff can be soothing but also uncomfortable or harming. To allow awareness of these experience, the changes are not instantaneous but deliberately unfold over an extended period. The time it takes the heating pad to warm up, and the time it takes the blood pressure sensor to detect a full reading map onto the time it takes to saw or chisel the wood. The qualities and functions of the body (heart rate, blood pressure, warmth) are connected to the qualities and forces of the wood (grain, heat, rigidity) through practices of craft (chiseling, sawing). Digital media help to facilitate these connections into correspondences. They amplify that encounter.

Critical Reflection

The resulting material encounter is one of haptic directness and our approach diverges from human-centered interaction design models with its focus on intra-active and emergent material collaboration. The project targets neither usability – it does not optimize the practice of sawing or chiseling – nor experience – it does not sufficiently take situation or context of the interaction into account. Instead, it builds on craft-based *direct* encounters that emphasize shared forces working onto each other over *time*. The encounter we facilitate is intensely personal. It cannot be tracked, for example, by established usability studies. Not surprisingly, initial responses of users engaging with the project were immediate. Participants found the activity "actually kind of

relaxing” or they voiced concern about the practice itself and their role in it: “How fast should I saw?” “Am I in good enough shape for this?” It would be tempting to connect concerns of speed and worries about one’s own body fitness back to the themes of care and risk, but we are cautious to read interpret them as evidence. *Corresponding Wood Tools* presents a research through design approach that focusses on the immediate flows *between* the wood material and the body material. The participants’ reflections are already one step detached from this initial tangible correspondence. They already show social framing (“good enough shape”) that were not the focus here. Through its focus, the project serves as speculative fabulations toward the development of a new materialist thinking in design. This differs from related models, such as Giaccadi and Karana’s *materials experience* [4], or Wiberg’s material-centered approach to interaction design [11]. While these models treat materials as central to interaction and acknowledge them as active participants, they build on a pre-existent body (human or object) or center on an experience (social or cultural). Our focus on the material-to-material exchange avoids such hierarchical or goal-oriented relationships. It targets not the human or the wood but the relation *between* humans and other materials. It is intra-dependent and steps away from a purely human-experience-centered thinking.

The *Warming Saw* and the *Comfort-band Chisel* support materializations of such a relational understanding. CUTTING is not a form of agency that a human has over a piece of wood. Instead, it is the moment of overlapping activity of human, chisel, and wood, defining relations only. With the *Comfort-band Chisel*, the body HOLDS the wood and operates the chisel, the chisel CUTs the wood, the accelerometer on the chisel SENSES the movement, which is PROCESSED by the Arduino, that ACTIVATES the blood pressure reader, which TIGHTENS the cuff onto the body, reads the blood pressure data, and DISPLAYS it. Much like an Actor Network Theory (ANT) system [7], these relations could be broken down further, e.g. in the case of the blood pressure reader. Differing from an ANT system, we emphasize that each part only comes into being through the intra-actions and we highlight the processes that manifest this interdependence. The whole encounter constitutes the *material correspondence*: human and wood bodies interrelate within a shared time frame where each individual intra-action loop presents a moment of correspondence. The arrangement of these encounters allows us to trace, critique, and design more material-aware interactions. In that way, *Corresponding Wood Tools* challenges the nature of the material encounter, through the speculative fabulation exercises. They engage the agencies of both, the human and non-human materials participating without a single goal, such as user experience or product optimization.

With this shift, we are not suggesting to reduce interaction design to the body as thing and optimize e.g. ergonomic design only. Instead, we advocate for an approach that considers 1) the body as material, 2) in correspondence with other world materials that also perform agency; and 3) that the focus of interaction design has to be on the intra-action between the two, not “material-” or “human-centered” but taking the demands of new materialism into account by 4) emphasizing the emergent dialogue in-between. Interaction design cannot focus on optimization for the human body as this would override such a correspondence. By fundamentally engaging this material correspondence we come to better understand the co-creative, co-productive processes that support a shared becoming. Such a focus on a shared emergence calls us to move beyond the hierarchical risk distribution that prioritizes the human only.

Acknowledgements

We would like to thank the Institute for Materials at Georgia Tech for sharing their lab and resources for the materials science explorations early in this research and the Digital Craft class in the Digital Media department at Georgia Tech for their helpful comments and discussion.

Deep Space: Re-signifying Vale de los Caídos

Prof. Elizabeth Sikiaridi and Prof. Frans Vogelaar

Hybrid Space Lab

Berlin, Germany

office@hybridspacelab.net

<https://hybridspacelab.net/project/deep-space/>

Abstract

The “Deep Space: Re-signifying Valle de los Caídos” project addresses the re-signification of this most controversial Francoist monument. As part of our long-term investigation “Deep Space” dealing with memory politics, controversial monument and heritage in the Digital Age it focuses on creative processes and digital tools.

By unlocking the potential laying at the intersection between arts, technology, memory studies and sciences, the project has cracked open the interwoven, historically painful meanings of the monument, envisioning its possible futures.

The project started with the workshop “Deep Space: Re-signifying Valle de los Caídos” (2018, in Valle de los Caídos and Madrid) with a special focus on networked digital and physical tools that allow transforming the site without physically touching it. These tools also enable the integration of sidelined voices within the vision of a polyphonic monument, counterbalancing the site’s totalitarian narrative, paving the way from recognition to reconciliation.

As such, the project’s creative, trans-disciplinary and innovative approach paves the way towards more integrated, collective processes of memory making.

Memory in the Digital Age, Hybrid Heritage, Controversial Monuments, Inclusive Memory-making, Augmented Reality

Deep Space: Re-signifying Valle de los Caídos

Valle de los Caídos

Valle de los Caídos (“Valley of the Fallen”) is the large-scale memorial monument in the Sierra de Guadarrama close to Madrid dedicated to the “fallen” of the Spanish conflict, conceived by the Spanish dictator Franco.

With its 152-meter-tall cross, visible from more than 30 kilometers away, and its “basilica”, a 263-meter-long crypt with a 52-meter high vault cut out of the granite mountain rock, Valle de los Caídos is one of the world’s most controversial monuments.

The structure was built between 1940 and 1959, partly deploying forced labor of Spanish republican political prisoners. Next to the remains of over 33.000 fallen from both sides of the conflict (gathered from mass graves across the country), the Basilica featured in its most prominent spot until October 2019 Franco’s grave - and, next to it, the grave of the Falangist leader Antonio Primo de Rivera.

Piercing the granite mountain, the basilica-crypt opens onto an esplanade with scenic landscape views. ‘Pilgrimage’-style paths and drives provide access to the Valle de los Caídos monument. Such pathways are embedded within a sophisticated large-scale landscape design in a territory still bearing remnants of the barracks of the prisoners of war.

Cenotaph

In Spanish society and politics, over the past few years, discourse and controversial public debate on the transformations needed at Valle de los Caídos intensified, also due to the Spanish government’s decision to exhume Franco’s remains. However, the solemn extraction of Franco’s grave leaving the memorial untouched merely creates a cenotaph, an empty burial monument for the dictator.

Most Controversial Active Monument

Therefore, we witness an urgent necessity to change the narrative of the site, especially as it is still an ‘active’ monument - every day, at 11am, the Benedictine monks taking care of the site celebrate mass - and until Franco’s exhumation in 2019 - in front of his grave and in his honor. And it is still a pilgrimage destination for today’s nostalgic Francoist far right extremists.

The monument retains its topical, prominent spot within public debates: yet, its controversies and historical wounds are far from being reconciled through collective memory processing. Especially, there has been no artistic approach to find new possibilities and paths to transform and reinterpret Valle de los Caídos.

Creative International Transdisciplinary Workshop

At the center of such a heated biased public discourse surrounding its future, Valle de los Caídos is paradigmatic of the difficult processes of re-signifying controversial monuments. As such, it proved an especially compelling case study for the long-term “Deep Space” exploration and intervention program that deals with politics of memory, controversial monuments and heritage.

In October 2018, a year before Franco’s exhumation, we organized the Madrid workshop “Deep Space: Re-signifying Valle de los Caídos” focusing on how to transform and re-signify this Francoist monument.

Interdisciplinary and international, the workshop explored the potential that lays in the integration of creative formats, methods and digital tools in processing heritage. The workshop program aimed at developing creative processes, concepts, and ideas that can break through the discussion and transform the symbolic power of the site and focused on artistic, architectural, landscape, and media proposals.

The workshop brought together Spanish and international creative professionals, such as architects, landscape architects, media designers, artists, curators, with historians, art historians, political scientists, ethnologists, forensic archeologists, heritage and cultural studies experts, psychologists and psychoanalysts.

It promoted an inspirational atmosphere where participants reflected on a typology of creative/artistic proposals. A typology of proposed tools functioned as a test environment for opening up perspectives related to the Valle de los Caídos transformation.

Outsiders' Approach

The “Deep Space: Re-signifying Valle de los Caídos” workshop derived its strength from the potential of an “outsider” approach to bring a new perspective to a contentious and intractable situation. The epistemological contribution coming from an outsider perspective can nuance controversial debates, especially if the latter are characterized by impasse and a lack of recognition of certain phenomena.

This has been the case, for instance, for France’s involvement with and commitment to the Republic of Vichy, mostly addressed by foreign scholars and researchers including Robert Soucy, Eugen Weber, Zeev Sternhell, and Robert Paxton. As an example, in his account of Vichy France, Robert Paxton illustrates how Pétain’s French government pursued its own authoritarian and racist agenda in line with Hitler’s ideology.

Cinematographic art provides the means to filter and distance oneself from events, crafting an “outsider gaze”. French filmmaker and journalist Lanzmann’s widely acclaimed, over-9-hours long documentary *Shoah* broke open the discussion on the crimes perpetrated across Poland’s Holocaust sites. Released in Paris in 1985, Poland did not receive it well, deeming it as a charge of complicity in the Nazi genocide.

Taking a more classical academic research approach, Poland’s anti-Semitism and involvement in the Holocaust is researched and reflected upon by Jan Gross, a Polish-US historian and by Polish-Canadian historian Jan Grabowski, both of whom left Poland.

On Dutch colonial history in Indonesia, Swiss-Dutch historian Remy Limpach remarkably pointed out the extent and sheer scale of Dutch war crimes, undermining the compactness of Dutch historical accounts of colonialism.

With these breakthrough historiographical precedents, the workshop acknowledged that local history is painful and difficult to process, and that a polyphony of perspectives – featuring both insiders’ and outsiders’ voices – may contribute to more holistic, better integrated accounts.

The workshop created a framework where international experiences informed the Valle de los Caídos transformation process. At the same time, the focus on such a concrete and very current case study as Valle de los Caídos provided the opportunity to develop insights bearing a broader relevance for dealing with monuments and heritage.

Towards a Polyphonic Monument

Complementary to the general public discussion mainly questioning the most appropriate location for the remains of Francisco Franco and Antonio Primo de Rivera, the “Deep Space: Re-signifying Valle de los Caídos” workshop focused on, the mostly anonymous, ‘fallen’ and on the convicted that hauled up the lumps of rock.

The existing official printed, online and on-site communication of the monument today fails to integrate this troubled history. There is no onsite information on the prisoners of war that were forced to work at the building site or on their families living in nearby barracks on the Valle’s grounds.

Furthermore, there is no mention of the fact that the remains of fallen from the Republican side of the conflict were moved to the Valle de los Caídos from mass graves spread all over the country unbeknownst to their families.

The lack of recognition of the controversies characterizing the monument and its construction is especially problematic, stemming from appreciating that for any process of healing and reconciliation a moment of thorough acknowledgment is imperative. Informing the monument with the victims’ point of view casts a totally different light on it and is therefore essential for its re-signification. Documenting and communicating the history of its making would transform Valle de los Caídos into a testimony of totalitarianism and a tangible proof of its authoritarian mark, beginning the transition from acknowledgment and recognition towards reconciliation.

An approach integrating voices from the Republican side, from the victims of the Spanish conflict meets today’s search for alternative narratives and historiographies. Such developments in memory making and collective processing echo the more general, further reaching call for more inclusive historical accounts.

Within this paradigm shift on whose narratives acquire prominence in history, such an approach strives to include voices from national liberation movements in the context of postcolonial processes and perspectives enriched by queer and gender studies.

As digital tools enable decentralized, democratized processing in the form of co-created, bottom-up initiatives, we are witnessing an explosion of interest on memory and its multifaceted dimensions. The power relations intrinsic to the writing of collective memory are becoming looser and blurred, because the pervasive and accelerating digital turn of memory making is allowing for a multiplicity of voices to be heard and become alternative narratives.

As a consequence, this trend implies that memory making is morphing into a hybrid practice whose future is interwoven with physical and digital features and whose agents are becoming increasingly diversified.

Workshop' Outcomes

The reliance on artistic practices and applied disciplines transgressing the arts field, such as architecture and media, to approach controversial heritage investigates how these disciplines and their interaction may contribute to the re-construction of memory, exploring the potential of integrating diverse methods to process historical wounds.

The 2018 workshop started to crack open future visions for the monument, drawing on the co-creation of digital and analog memory-making practices, with the three working groups proposing new meanings and envisioning creative processes which have the potential to cross-fade the controversy.

One group focused on the mapping of the monument in its surrounding landscape, developing proposals for paths and viewpoints, creating new perspectives, aiming at making people aware, as they move through the Valley of the Fallen, of its painful history. The second group stretched their design thinking into 50 years from now, in 2068, and envisioned a future for the monument including the possibility of it becoming a Research Center, a venue hosting an Art and Engagement Program, and a Global Centre for Peace and Interpretation.

A third group dealt with the idea of creating a ‘Digital Archive’ which would allow to gather, access and store bottom-up collaborative and interdisciplinary contributions on the monument’s morbid history. This would foster dialogue, counterbalancing the site’s totalitarian narrative with the networked polyphony of democratic voices, accompanying the decline of the monument – the pixels deconstructing and corroding the stone.

Hybrid Tools

Drawing on the acknowledgment that digital tools open up and transform memory making, the workshop focused on their capability to inform the monument and to process its transformation without physical intervention.

The “Deep Space” program in general explores this potential of state-of-the-art digital technologies, aiming at developing creative digital tools for re-signifying controversial monuments, for dealing with historical heritage and politics of memory.

Digital technologies include Augmented Reality/AR (the physical reality being "augmented" by computer-generated perceptual information) or Virtual Reality/VR (an interactive computer-generated experience taking place within a simulated environment), Mixed or Hybrid Reality/ XR (the merging of real and virtual worlds to produce new environments and visualizations where physical and digital objects co-exist and interact) and Augmented Virtuality/AV (an interactive experience of a real-world environment where the objects that reside in the real-world are "augmented" by computer-generated perceptual information).

Such hybrid, combined physical and digital, technology tools offer the possibility to process the transformation of a monument without material interference. For example, with the aid of Virtual Reality and Augmented Reality, the digital boundaries of the Valle de los Caídos could stretch to include the archeological traces of the barracks where convicted had to live whilst building the monument.

Other tools include databases of interconnected archives for scholars and the public, information collection and storage solutions for crucial witness in the form of oral history, as well as interactive educational platforms. Such technologies support an on- and off-line public discourse surrounding the memorial itself, enabling the communicating and processing of proposals for the long-term physical transformation of the site.

AR @ Valle de los Caídos

The next step in the project is the development of an Augmented Reality app for contextualizing and supporting the resignification of the controversial Francoist monument. An AR application, with which visitors can onsite explore the hidden layers of the monument’s complex, controversial history, would make visible what Franco tried to hide at the site.

The onsite presentation of its history with the help of an AR application would make Valle de los Caídos a tangible testimony of Francoism, breaking its totalitarian narrative, transforming it into a polyphonic memorial, supporting its long-term transformation processes.

Large-scale Controversial Memory Sites

Such an AR application would be of great relevance for the resignification process of Valle de los Caídos. It can also inform the processing of other contested monuments and sites internationally and thus be very relevant to the ongoing discourse on inclusive (memory) spaces and to the urgent social need for inclusive heritage and memory-making

‘Augmenting’ physical memory sites into more polyphonic spaces is an important and urgent challenge. The project is a case-study for the reinterpretation and transformation of historically loaded and controversial physical monuments and sites with the help of digital tools.

As we are currently witnessing a surge of iconoclastic actions against monuments glorifying controversial, exploitative, and unresolved history worldwide, it is urgent to develop inclusive tools and methods to reckon with testimonies of controversial past and its unresolved historical wounds.

The project pioneers the development of new methods and digital tools for re-signifying and transforming controversial physical monuments and sites. Such digital tools are especially relevant for the re-signification of large-scale physical sites of memory – in the scale of a landscape (f.e. Valle de los Caídos) and in the urban scale. The project opens therefore paths for the inclusive re-reading of larger territories (for example, under a post-colonial perspective).

Future Heritage

The focus on such digital creative tools allows us to envision ever-expanding domains for cultural heritage and memory-making in both time and space, potentially eliminating boundaries to engagement and visualization. This allows for radical re-signification of physical monuments via digital, networked archives. The workshop kick-started the “Deep Space” exploration, focusing on how future heritage sites could look, feel, sound like, and how their digitally enriched features could affect memory-making processes.

The Weird, the Cute and the Dark: How to Account for Aesthetics When Working on Awareness about Design Patterns

Guillaume Slizewicz, Sandy Claes

Espèces Urbaines, Intermedia, LUCA School of Arts
Brussels, Belgium
guillaume.slizewicz@luca-arts.be, Sandy.claes@luca-arts.be

Abstract

This paper presents the design and set up of the robotic media arts installation 'Accept All'. We discuss how this art piece bears legacy of previous work in both media arts as the academic field of Human-Computer-Interaction (HCI), and touches upon contemporary topics of political awareness, trust and data representation. Accept All covers five different aesthetic design choices for robot design, each contributing to the topic in its own way. The last part of the paper proposes to explore the paradoxical stance that media artists have to adopt when dealing with issues such as dark patterns.

robots, cuteness, weirdness, vernacular, biomimetics, public awareness, media arts aesthetics, interest-triggering, audience

Introduction

In the aftermath of highly publicised scandals such as the Snowden Leaks, Cambridge Analytica and Clearview, public scrutiny has focused more and more on surveillance technology and the right to privacy [16, 2, 22]. Media artists have accompanied this shift by using their practices to "open the black box", "revealing the hidden infrastructure", or "deconstructing the framework" of these technologies. The media art pieces produced often took the forms of back-bone electronics, visible electrical cables and screens, removing all casing to amplify their statement while being visibly different from corporate productions (e.g. the transparency grenade by Julian Oliver [6]).

We are interested in assessing how other aesthetic features, such as those used in interaction design in the commercial realm, may be deployed in a media arts context. For example, interaction designers and "growth hackers" are equipped with "dark patterns" [15], i.e. design patterns and strategies from behavioral psychology that are deployed in ways to deliberately deceive the user. These patterns are largely invisible, and therefore difficult to expose as their effect is psychological. It is a challenge to assess what kind of aesthetics is the most susceptible to appeal to a large audience when trying to raise awareness about them.

In this paper, we explore different aesthetic features to question the design of dark patterns through the design and development of Accept All, i.e. a performance that merges robots, public awareness building, dark patterns and privacy concerns. In the following text, we propose a complete description of the performance, its inspiration and the political

challenge it alludes to. After this description, we offer a brief reflection on the relationship with the audience in both the art and digital sector, acknowledging the similarities between the two and asking whether it is responsible to use the tools whose effect one is trying to mitigate.

State of the art

The installation Accept All builds on the works of artists and scholars on the themes of sentience, HRI (Human-Robots interactions), and its political consequences.

The relationship between humans and robots and exploration of the sentience of objects have a long history in the media and digital arts. The installation presented here can be seen as the descendent of the tortoise by William Grey Walter. This tiny robot, created in the forties, exhibited autonomous behaviour thanks to its light sensor. The tortoise is used by Jussi Parikka as an example of non-anthropocentric design [17, 7], meaning that animal, non-human behaviour and features inspired it. Today, firms such as Boston dynamics still refer to this inspiration from animals. Recently, the conjugation of cheaper technology and a vibrant open-source community made these subjects even more present.

Many artists have also explored the link between robots and visual recognition, for instance, Golan Levin in his installation snoot [11] or Ken Rivaldo and its paparazzi bots [19]. Today, the more political side of surveillance has been the playground of practitioners such as Dries DePoorter, with his installation Jaywalking [13], or Kyle McDonald with the artwork exhausting a crowd [10]. Scholars have also described and analysed the relationship between cuteness, animals and robots [5, 4, 1, 9] and the human bias to take care of things that present certain aesthetic features. Works on the efficiency of materialising concerns and data in public space to raise awareness have also taken the form of research projects such as the chemical in the creek project [18], electronic urban wildlife [14] or Yellow Dust [3]. The aim of this project was to merge those strands of inspiration to create an interactive installation, staging weird robots in order to raise awareness on a specific issue.

Political Context

In 2016, in an effort to rein in digital surveillance and micro-targeting and with a view to protect its citizens privacy, the European Union implemented the GDPR, a new regulation

for data protection. This new regulation forced websites to get consent from their audience before recording their activity and sharing it with third parties. 5 years after its implementation, this regulation has resulted in inescapable, hard to use pop-up that welcome you on most websites, degrading the “surfing experience”. Through dark patterns, several websites advertisers are trying to get a quick consent of their audience [15]. One of the most visible ways to do it is to offer a big, easy to click, prominent “accept all” button. This option carries the promise of not having to deal with customisation or spend time looking for the reject all button, it is also synonymous with the lassitude and mental drain these micro-targeting processes impose on us.

The artwork presented hereafter is a ludic reflection on how these tracking devices that are present online might manifest themselves in the material realm in the future. During the pandemic, we saw new use of robots in public space, mainly drone and legged or wheeled robots ensuring that social distance is maintained, reminding people of the curfew, sometimes disinfecting via UV[20].

We can imagine that, just like screens invaded the public space in the past decades, robots might do that in the next ones. What if they are used by advertisers, will we see the same type of micro-targeting? To make people think about these issues, we wanted to draw them into an interaction with robots in the exhibition space.

Vernacular Robotic Design.

Aesthetics Accept All is a performance in which 5 Robots, with different physical features, roam freely inside the exhibition space. As they encounter an audience member, they follow them and play their sounds. Each of the 5 robots have a different score that mirrors its appearance.

One of the objectives of the performance was to propose alternative visions of robot aesthetics: more evocative and vernacular ones, and use those to bait people into our experience. The performance was held at Le Pavillon, a center for digital arts based in Namur, Belgium, during the finissage of their exhibition “Humans Machines”.¹ The exhibition venue and time favored a more familial and local crowd than normal new media/digital art venues. The fact that the exhibition took place during COVID even accentuated the local focus, as few people could fly or drive in from other countries. From the beginning on, one of the desires of the Pavillon Team was to have artwork that could be accessible to a large range of people. From our side, we wanted to use this opportunity to present robot designs that were different from the traditional electronic consumer product while not adapting a too-raw or cutting edge presentation that could scare people away. We wanted our robots to have specific identities, yet be accessible.

We draw inspiration from the animal kingdom, especially in terms of features (eyes, horns, fur, antenna, skeleton). We also joined forces with local designers so they could propose their own visions, appealing to audiences outside academia/

¹“The exhibition questions the implications of the development of artificial intelligence technologies and their limitations in the imitation of natural processes, human behaviours, and creativity.”

new media arts. In total, 2 teams of 2 designers were invited to create a “shell” for the robots. After being briefed on the general intention of the performance (technology, yet inspired by biology), its context and its aims, they first offered drawings and rendering of different possible paths. These paths were discussed with the other members of the projects and led to improvement, after which we met for a full day of work together during which the shells were completed.

In terms of sounds, we first tried to implement AI-generated voices through the speakers on the robots but quickly realised that those were difficult to hear and decipher and would make the performance harder to understand. We thus resorted to using sounds from a video game library, adding a different sound color to each robot and showing a much more vibrant palette: going from camel sound to metallic percussion, an array of organic and artificial sounds. In total five robots have been created:

“Iridescent beetle”: with long steel antennas and a body made of iridescent plexiglass (figure 2)

“Fun Dog”: characterised by 3D printed head, horns and vertebra, aluminium bones and a small plexiglass dome as an eye (figure 3)

“Death star” created with an aluminium dome and laser-cut fringes (figure 4)

“fringe cathedral”: made of textile fringes, a disk cut via CNC and brass rods (figure 5)

“Tervuren wood”: made of natural fibres and a disk cut via CNC and brass rods. (figure 6)

The robots were conceived so as to make all the electronic components accessible for debugging and to be easily built. They used off-the-shelf components and accessible manufacturing processes that one usually finds in a Fablab (CNC, laser cutting and 3D printing).. From our observations, these designs seemed to “work”: they triggered interest and surprise and drew people into the interaction. People went as far as naming them, for instance, people referred to the robots as a bull, an hawaiian R2D2, a star wars robot, an african mask or a justice palace (from the similarity with an old building in Brussels). These designs, on top of being vernacular robotic design, had a real evocative power (figure 1).

Technology Each of the robots is autonomous and its computing capabilities are run locally. Equipped with a coral board running SSD Mobilenet V2 Object detection model, trained on COCO 2017 dataset [12]. The robots see through a small camera and the image is analysed by the board, allowing them to detect humans. Via a python script using openCV, a serial message is sent to an arduino board that controls four DC motors, activating the wheel of the robots, allowing them to move and keep a certain distance from the audience. Sounds are played through an embedded speaker when the robot detects that an audience member is close enough.

Interactions The interactions with the robots ranged from ignoring it to playing with it. People usually went through different actions to try and make sense of their behaviour. We often observed that people put their feet in front of it to see if it would budge; some of them waved at it (see Figure 7).

Young kids had more reactions to it and presented a mix of fear, interest and excitement. They often crouched to be “face

Figure 1: Three of the robots ©Guillaume Slizewicz.

Figure 2: Iridescent Beetle, ©Murielle Lecocq.

to face” with the robot (as shown in Figure 8) and led them somewhere via their movements. Adults seemed to be more self-conscious, apparently torn between their curiosity about how it worked and their desire to adopt the “right” attitude. For instance, some placed a piece of paper in front of the camera to see how it would react.

Other adults deliberately ignored the robots, despite its sounds screamed at them. This last occurrence might represent how we will/would filter out this type of interaction in the future. As we developed a good “noise filter” for visual advertisement on the internet, we might do the same for robotic ones in public space. Some people acted on the intuition that the robots would have the same senses as animals, calling them by made-up names such as “cookies” despite the absence of sound sensors on the robot. They were probably reverting to knowledge on how to act with puppies, cats and dogs, the other sentient beings we are the closest to.

People also use technology as mediation with the robots, taking pictures of them and posting them on social media. The social posts gave a small window of understanding how they saw them; some of the captions read “They have more charisma than you. Period”, “ His name is Georges, Georges, the baby dragon.” All these made clear that we managed to trigger interest and even connection between our machines and the audience. However, the cute or weird aspect of them might have played in our disfavour when it came to underlining the concern at hand, namely the extension of the surveillance apparatus in public space.

The role of Aesthetics when revealing inner workings in everyday environments

Raw or technology-revealing aesthetics is often deployed as a design pattern in media arts, which is most often experienced in a controlled environment such as a gallery, art festival or exhibition. Yet as our everyday environment, for example our home, office space or streets, is also increasingly augmented

Figure 3: Fun-Dog ©Guillaume Slizewicz.

with invisible sensors that track our every movement, there is a large potential to reveal tracking technology and other sensing machines in situ, to the audience at large. In this paper, we explored different aesthetic aspects, and how they triggered responses from the audience at large. Here, we discovered that the deliberate link to animal form aspects, whether they were cute or weird, triggered attention and caused viewers to reflect on its meaning (placing them in the new character/unfamiliar animal of T. Shibata’s classification [21]). In fact, the designs that were most recognizable as animals, seemed most effective in revealing the working of invisible traces and the dark patterns behind them. We expect this was due to its more apparent presence.

Activists and artists raising awareness on a specific topic are occupied with the challenge of triggering the largest number of people’s interest and making them care about a cause. In this way, they are similar to marketers and advertisers, who are, according to the formula, “competing for eyeballs”. Some of the techniques of the activist, artists and the mar-

Figure 4: Death Star ©Guillaume Slizewicz.

keters/advertisers are indeed the same: staying on the thin fine line between the already-seen and the too foreign.

The performance *Accept All* was designed as a bridge between media arts and these practices. As with most art dealing with those subjects, it must strike a balance between using fair and accepted interest-triggering tricks and underlining how these are used sometimes for other purposes. As described above, it tried to implement this with two main components: the first is to work on the weird as a feature triggering curiosity (as a follow-up on the concept of interest-triggering devices [8]), and the second is by using cuteness as a dark pattern to lure people in. We believe our use of these techniques is legitimate and naive, but would like to propose to deepen the reflection on what the desirable boundaries are for those implementations in the media art scene.

Conclusion

Through the analysis of the performance *accept-all*, its inspirations, its theme, and its creation process, we propose here an alternative way of creating autonomous robots to raise awareness on surveillance and dark patterns in public space. In a second part, we highlight our reliance on such patterns for awareness creation, hence acknowledging the paradoxical stance inherent to artists working on those topics.

Acknowledgments

The prototype of the robots were developed in the framework of Innoviris Brussels under Grant Agreement Anticipate 2017 52A (SUCIB). The performance *Accept-All* was made possible with the support of Kikk festival and Le Pavillon Namur.

Abstract

How can art educators fulfill human potential in the process of teaching and learning in online art studios? How can they transmit their passion and enthusiasm for art making in virtual environments teaching and learning to cultivate human potential in the virtual classroom? This paper investigates the ability of remote art learning to unlock human capabilities. Based on the definitions of human potential, we specifically examine three aspects of learning behaviors and environments within this study. First, we focus on students' self-discovery, self-directed learning, and self-efficacy. Second, we investigate the concepts of connection and communication, which are integrated into the virtual classroom. Lastly, we explore the unique characteristics of the educational environment for virtual teaching and learning.

Keywords

Virtual art education, studio art, human potential

Introduction

How can art educators fulfill human potential in the process of teaching and learning in online art studios? How can they transmit their passion and enthusiasm for art making in virtual environments teaching and learning to cultivate human potential in the virtual classroom? This paper investigates the ability of remote art learning to unlock human capabilities.

According to Gardner (2020), human potential that can be unlocked in the classroom refers to a variety of human cognitive capabilities students have to learn lesson content, find motivations to improve their academic performance, and eventually grow to become empowered citizens. The critical components of human potential are "intellectual, creative, communication based, value-based, and activity" (Leonidova, 2019, p. 174). It is also important to connect human potential to developing cognitive capabilities within diverse social interactions. Considering these social interactions, the "capability approach" (Sen Amartya, 2005, as

cited in Rogach et al., 2018, p. 805) can promote the empowerment of citizens with regard to the digital citizenship of students.

Based on these definitions of human potential, we specifically examine three aspects of learning behaviors and environments within this study. First, we focus on students' self-discovery, self-directed learning, and self-efficacy. Second, we investigate the concepts of connection and communication, which are integrated into the virtual classroom. Lastly, we explore the unique characteristics of the educational environment for virtual teaching and learning.

Discovering Students' Selves in Art-Based Learning

In online environments, individuals may discover opportunities to recognize their inner selves. A student's self-directed learning plays a critical role in distance education whereby students can become more deeply aware of themselves by focusing on their own needs and learning process (Arghode et al., 2017). Effective virtual teaching can help students make connections between their personal experiences and perspectives and their grasp of academic content supports. Self-efficacy refers to an individual's belief that they have the competence to complete the work assigned (Bandura, 2010). Self-efficacy provides as intrinsic motivation for learning, so students who have higher self-efficacy generally manage complex tasks more successfully. In online art education, each individual student's self-expression and self-efficacy are supported through e-learning activities, such as selecting, viewing, reading, and posting text and images.

Technology Use and Classroom Interactions

Turkle (2011) examined technology-based interactions among people and noticed that human relationships are changed as "technology offers us substitutes for connecting

with each other face-to-face” (p. 11). She stressed the difference between connection and communication in today’s wired world and suggested that many people stay connected to each other all the time, but they hardly communicate. As a result, “cyberintimacies slide into cybersolitudes” (p. 16). Reconsidering the meaning and role of human breath in virtual spaces, Turkle emphasized the importance of conversations and insisted that we must strengthen our person-to-person dialogues. Numerous researchers have examined Turkle’s arguments in relation to teaching students in virtual environments. Some, like Emanuel and Challons-Lipton (2013), support Turkle’s ideas, insisting that educators seeking to explore the transformative capacity of digital teaching practices need to reexamine the concept of connection. Other scholars (Breen, 2018) believe that today’s students are a different generation who started using technologies at a very young age and are already strongly engaged with virtual modes of communication and digital environments.

Moving Across the Physical and the Virtual

Today, students approach living, learning, and communicating in ways that differ from those of previous generations. These differences are particularly noticeable regarding their understanding of the boundary between the real and the virtual, presenting new challenge to online art educators. Considering the challenges, Chambers and Sandford (2019)

noted that “increasingly complex social landscapes play a central role in young people’s negotiation and performance of identity, and that transitions within, between and across social spaces represent a challenge for educators that has perhaps not fully been appreciated” (p. 926). Identity formation and the experience of spaces are closely related to each other. When young people embrace multidimensional, spatialized, and shifting identities and navigate transitional spaces, the boundaries between real space and virtual space are blurred (Chambers & Sandford, 2019). The division between an offline physical self and an online virtual self expands to embrace new realities and practices. This is one reason why digital space has great potential as an art pedagogical space because it works in tandem with the various processes and constraints.

Conclusion

Students can reflect on their identities and connect themselves to learning while creating art pieces in the virtual classroom. To encourage students to express their identities, art educators orchestrate interactions among participants that include sharing, interpreting, and critiquing. Furthermore, creative projects that invite students to critically examine their cultural environments enhance their self-awareness and self-reflection. Asynchronous activities in online courses can offer students the opportunity to refine their self-efficacy by giving them flexibility to choose their own learning pattern.

The Voice of the Machine Audience

Anthony Stagliano

Florida Atlantic University, Department of English
Boca Raton, Florida, United States
astagliano@fau.edu

Abstract

Smart devices in the home, like Amazon's Alexa, and Apple's Siri, form a non-human but increasingly present *audience* in our daily life and activities. This hidden audience expresses a certain voice, in the agential sense, by cultivating and shaping how we address it. This is an acousmatic voice in Michel Chion's sense of it, and is worth thinking about as a rhetorical form, with such media devices shaping and coaxing our behavior, blurring the line between speaker and audience, human and non-human, agent and machine.

Keywords

Sound Studies; Digital Personal Assistants; Surveillance; Voice; Persuasion; *acousmètre*

Introduction

In his book *The Voice in Cinema* Michel Chion describes something he calls the *acousmètre*, the voice of an invisible speaker. [1] Chion, building on the work of experimental composer and theorist Pierre Schaffer, is interested in what Schaffer called "acousmatics," that is, the event of being audience to a sound whose source is not visible. Schaffer reactivates the archaic term *acousmatics* in an effort to describe a different kind of listening than normally is understood by it, while Chion extends it to the relationship between sound and image in 20th century media culture and practices, a world often described by the ocularcentric phrase "visual culture." For Chion, the *acousmètre* is one tool by which we can examine the dependence of "visuality" on the circulation of and constitutive power of sound, on the circulation of and constitutive power of voice.

Unlike in previous decades, the acousmatic scene we find ourselves in now has a widespread machinic audience, from voice to text technologies, voice command remote controls and televisions, to increasingly common AI "assistants" such as Apple's Siri and Amazon's Alexa. These last few, of course, return the acousmatic favor and themselves produce voice-like sounds that have no specific visible source (I mean, of course, besides the device emitting the sounds, which is often designed to disappear into the background anyway). Chion theorizes the *acousmètre* in relation to Fritz Lang's Dr. Mabuse films, which, in a couple ways, is the perfect metaphor for the present situation. The anti-hero of these films, Dr. Mabuse, composed around himself a network of machine audiences, such as surveillance devices, and a network of spies, all of which extended his perceptual capacities well beyond his own ability to see what he needed to see and *hear* what voices he needed to

hear. That is, the unseen voice that the term *acousmètre* is meant to describe, has another kind of "voice," that is an ability, an agency that is also shared by an unseen listener—in this case, our machine audience represented by voice activated "smart" devices.

I am suggesting that the machine audience we have now, Alexa, Siri, voice-activated devices, is itself the *acousmètre*, in a double sense. First, and more obviously, many of these imitate speech, and pretend to *be* by *being* only in that voice. This aspect, while often uncanny, is less interesting to me here than the other. That of influence, *persuasion*. When we say, colloquially, that someone or some group of someones needs to be able to make claims that are heard and acted upon we often say, of course, that they need "voice." It is this side of the machine audience's voice that I will be after here, performing a necessary and intentional equivocation on the word *voice*. That is, their voice is ambiguous, or more precisely, double and doubled.

Mabuse, Digital Personal Assistant

It's not for nothing that Chion in introducing the *acousmètre* in *Voice in Cinema* he uses Dr. Mabuse as his primary cinematic example. Mabuse, protagonist of Fritz Lang's early masterpieces *Dr. Mabuse, Gambler*, and *The Testament of Dr. Mabuse*, is, of course, cinema's first criminal mastermind, with almost supernatural powers of observation, and a network of spies and surveillance devices throughout the world as well as a reputation for the power of mind-control. Much of Mabuse's terrifying reputation comes from two distinguishing characteristics: first, his disembodied voice giving orders to those in his network, most of whom have no idea who (or where) he really is. This is what Chion has in mind in calling Mabuse the *acousmètre*. Another source of his power, though, and linked to this first, is his ability to listen in on a host of conversations which he is not visibly present to, and to make changes in the world based on the knowledge acquired in that (unknown, unseen) listening. Similarly, the potential for our machine audiences, our Alexas, our Samsung TVs, to cause alterations in the way their interlocutors do ordinary, daily, unthinking tasks is itself a subtle voice this audience has, and Mabuse-like, shapes the world around itself and its needs. This voice is indeed material and irreducible to its signification, as Chion and Mladen Dolar both note with the natural voice, the organ of human speech, since the voice of these machine agents is constituted by circuitry, microphones, code, interface, and storage. So, when Chion argues that it is too often

that we forget the voice as medium, it is also important to attend to the voice of the medium, its expressive and rhetorical mode of shaping all those around it. Such a shift in emphasis, which I am merely aiming at provoking today (instead of fully exploring), helps shift our theorization of voice away from the speaking subject, and toward a wider sort of relations, in an effort to include the (machinic) audience in what voice is.

Always Listening

For example, about two years ago, news began circulating that “Smart TVs,” that is, televisions with sophisticated voice command capabilities, were always *listening*, and, perhaps more alarmingly, *storing* and *transmitting* what they “hear.”

Samsung warns, in their most recent SmartTV Privacy Policy:

If you enable Voice Recognition, you can interact with your Smart TV using your voice. To provide you the Voice Recognition feature, some interactive voice commands may be transmitted (along with information about your device, including device identifiers) to a third-party service provider (currently, Nuance Communications, Inc.) that converts your interactive voice commands to text and to the extent necessary to provide the Voice Recognition features to you. In addition, Samsung may collect and your device may capture voice commands and associated texts so that we can provide you with Voice Recognition features and evaluate and improve the features.

Such practices have raised more than a few eyebrows, since the question of one’s private conversations at home being stored, transcribed, and transmitted to a variety of entities is chilling enough. Samsung, for their part, have changed their SmartTV listening practices, so that all of the listening and storage I just read only occurs if you hold down the voice command button on a remote and then speak. Meanwhile, privacy advocates aren’t comforted much more by the practices Amazon employs with its “digital personal assistant” Alexa, since it is constantly listening, though, like Apple’s Siri only transmits what it hears when the specific activating command is spoken. If you were to say “Alexa” in the room, your Amazon Echo would be activated and listening for the next command, which it would then send to Amazon’s servers for processing. Perhaps you want to know the weather in Salt Lake City this weekend; Perhaps you want to hear a particular song, maybe *Despacito* yet again. The gamble Amazon and other makers of voice activated “smart” devices is that you’ll eventually weave that possibility into your daily routine, retooling your habits to include, and sometimes around, the invisible presence of Alexa, Siri, your Samsung TV, your Cortana.

Indeed, a rather breathless pair of articles in *The Economist* in 2017 point to a future in which the graphical

notions of user interface that we are familiar with in our daily interactions with electronic devices begins to give way to vocalized interactions with an invisible, but ever-listening audience. Such devices would have, and currently in many cases *do have*, a tacit voice, instead of an unseen vocalization, expressing itself, an unseen listening, *expressing itself*.

That first unseen speaker, the nefarious Dr. Mabuse, predating Bond villains but also the institutional apparatus of national spy agencies, knows that *hearing* and *seeing* are at least as important, in certain circumstances, as being heard and seen. One late entry in the Mabuse canon of films is *the Thousand Eyes of Dr. Mabuse*, which takes place, largely, in a hotel where Mabuse has installed sophisticated surveillance systems, not entirely unlike the wired “Smart Homes” we are building for ourselves with Alexa and her ilk.

In this mute voice, the *acousmètre* turned on its head, voice is not simply *in* the speaker who is then *simply* heard by the machine audience, but rather is stretched out between them, distributed, perhaps unevenly, but nevertheless to each. In its capacity to always be listening and shaping itself around the voice of its master, and *at the same time* shaping that voice, subtly no doubt, the machine audience at the very least is a participant in the constitution of the “voice” in question, and may indeed have a *voice* of its own at stake here.

Conclusion

The point I have been making is that there is a certain power, a sort of world-making agency, inverting the *acousmètre*, in such unseen listening, just as Chion noted it within the unseen speaker. It is in that sense that this sort of *listening* is *expressive*. It is in this sense that the machine audience with which we deal now is Chion’s *acousmètre*, instead of in its capacity to speak without being visible. It has and expresses voice in its ever-present *listening*, just as Mabuse did.

And yet... the paranoid vision I have been pushing here is only part of the story, since the different access enabled by voice recognition technology cannot be shunted to the side in some ableist forgetting. To take one quick example, a software company calling itself Nuance offers a proprietary and robust voice-recognition and voice-to-text software suite, specifically marketed as “accessibility” software, pitching both toward an audience with a manifest need for such solutions as well as those who want to “give their wrists a rest,” and “end the pain of typing.” Keeping in mind those for whom typing is genuinely painful, or those for whom it is, for whatever reason, not an option, or for whom a variety of daily tasks dependent on tactile mobility and/or on vision are out of reach or difficult, the shared voice expressed between the user and the voice-activated device, should not be devalued even when we at the same time ought to keep in mind the more dystopian possibilities they enable.

For my purposes here, it is more important than litigating whether these things are, on balance, good or bad, to

raise the question of such mute devices *in their unseen mute listening* shaping and enabling daily habits and activities, participating in the making of one's world, and thus, expressing, unseen, a kind of voice, a kind of agency, a kind of Mabuse-like control.

Mapping the atmospheric in school buildings: Digital art-based participatory inquiry with youth

Laura Trafi-Prats & Elizabeth de Freitas

Manchester Metropolitan University and Adelphi University
Manchester, U.K. and New York, U.S.

l.trafi-prats@mmu.ac.uk and defreitas@adelphi.edu

Abstract

Creative experiments with wearable technologies and speculative engagements with digital sensory data foreground the need of reinventing learning environments to reclaim sensory and somesthetic relationality, while interrogating the passive collection of sensory data by sensors ubiquitously embedded in everyday spaces and learning processes. This paper discusses an arts-based project of mapping the sensory-affective dimensions of school environments in collaboration with a group of participating-students (16-18 year-olds). The mixed media maps offer dynamic digital representations of staff and students' experiences of the school buildings, shedding light on problematic spaces in the built environment. The paper discusses processes in which digital-sensory devices allowed young people to further their attunement towards previously unconsidered aspects of school atmospheres, while exploring the pliability of their sensory capacity in reconfiguring and reimaging those environments.

Keywords

Atmospheres, wearable media, sensation, affect, school architectures, learning environments, participatory art-based inquiry, mapping, diagramming, speculative data.

Introduction

As a term 'atmosphere' originates in meteorology to name the earth's aerial envelope, but also refers "to the emotional tone of a space or spatial constellation" [1] In architecture, atmosphere pertains to the seemingly immaterial dimension of sensation and affect and contributes to the relational quality of a building or environment. Through the arrangement of specific choices of material, light, sound, objects, odors, a space can feel expansive or tight, intimate or distant, exposed or concealed, vibrant or eerie [2] The affective qualities of atmospheres are not necessarily given in advance, but have to be expressed through spatio-temporal events, in which diverse and multiple forces conjoin or enmesh, to disclose what 'appears' as elemental, but is better conceived as generative, in the space-time atmosphere [3,4]. Therefore, atmospheric sensing requires immersion in space-time events along with the cultivation of skillful embodiment and techniques of capture that can amplify and intensify sensory practice [5]. Atmospheric envelopment is a focus for many artists working with eco-sensory and relational environments. From a design perspective, these environments need to be created technically "to modify and mediate the exposure of bodies to an outside" [6] At the same time, the atmosphere is felt aesthetically "exposing bodies to elemental forces that, ... are characterized by a degree of allure and enchantment" [7]. Developing practices of attunement to atmospheres has both political and pedagogical relevance, because it cultivates capacities to become involved, withdraw from, puncture or modify the exposure to particular atmospheres whose infrastructural arrangements can exclude and control, or open up new modes of belonging, movement and thought [8, 9, 10].

In this paper, we focus on the affective atmospheres of school buildings. This interest emerges in the context of a project funded by the UK Economic and Social Research Council, exploring young people's relationship to architecture and the built environment. We discuss a series of workshops designed to map the sensory/affective dimension of school buildings. Student participants worked with the authors to engage the building as a site for experimental rendering, mapping diverse sensory/affective atmospheric layers, and folding these together into digital dynamic diagrams taking the shape of maps, graphic animations, films and 360 photo-narratives. Each workshop facilitated a series of collective art-based experiments around concepts like location, perspective, flow, time, memory, hapticity with the student participants and involved the use of wearable media-spaces [11]. The media included video, sensors (sound, air and dermal temperature), spatial and object scanners, 360° images, and mapping apps, which were used not as representational tools but as ways of creating passages between spatial and temporal modes of becoming (history, memory, matter), The collective exercises of disclosing these atmospheres revealed unknown aspects of young people's affective experiences in school buildings. It extended sensing possibilities [12], while offered creative opportunities to make something of these atmospheres palpable.

Researching Affective Atmospheres in School Buildings

School architecture plans and blueprints visualize the occupant experience but cannot anticipate how the environments come to matter in the lives of staff and students [13, 14 15, 16]. In particular, there is a need for research that generates rich alternative visualizations of the spatial practices and sensory conditions that shape school life, and to better understand these complex learning ecologies [17,18,19]. Sensory engagement with school buildings is an under-examined factor in connection with learning, achievement and students' social life. Additionally, sensory engagement is something that has been significantly altered in post-pandemic conditions [20, 21 22]. OECD survey data on the built environment and effective learning environments (LEEP) indicates a need for more case studies and better research methods. This is additionally important, in the wake of Covid-19 and social distancing measures, as relationships to school buildings are increasingly mediated through digital platforms and embedded bio-tracking technology that become part of everyday spaces and processes.

Sensory data in school buildings is ubiquitous and often collected passively with no opportunity for young people to modify, punctuate, intervene in or creatively subvert data creation. We suggest that sensor technologies could be creatively explored "to invent learning environments that reclaim affective and somatic relationality" [23]. New modes of collective and participatory inquiry are needed that attend to the sensory-

affective learning environment, making tangible the ways in which student and staff experience school corridors, bathrooms, cafeterias, laboratories, auditoriums, etc. These new modes of inquiry refashion digital data as vibrant, material, and open to be crafted in speculative ways in compositions with analogic and artificial data. By proposing a slow, artful and artisanal engagement with data and the digital, this collaborative study of school buildings creates an alternative space for young people immersed in smart buildings subject to computational managerialism in which data is equated to truth, objectivity, reality, extraction, and indeed modulation of affect, characteristic of control societies [24].

The paper draws from theories developed by Elizabeth Grosz [25], Elizabeth Ellsworth [26] and Luciana Parisi [27], to consider architectural space through the creative capacities of digital media. Rather than presenting architecture as a stable container, we emphasize the dynamic indeterminacy of place, and the power of the imagination to recast the sensory shape of envelopment. Sensing bodies force a rethinking of architecture as space-time event, encounter, and movement, which reaffirms both the infinite potential for spatial variation and the many corporealities that can be spatially expressed. Both Grosz and Ellsworth suggest that the imbrication of architecture and media is key in rethinking buildings beyond containment, and media beyond representation. Parisi directs our attention to the generative force of digital media in opening up imagined spaces. Accordingly, we discuss the ways in which our

research project used a variety of media for exploring spatial practices and in(habit)ation, studying and tracking the sensory/atmospheric experiences of flow, time, light, sound, texture, associated with various key thresholds found (as well as imagined) in classrooms, daily itineraries, hallways, dining halls, etc. while exploring young people's pliable attunement and divergent reshaping of school spaces through imaginative and technical engagements.

We will show and discuss a series of artifacts from the workshops, developed as part of the participatory ethnography of a building in Liverpool, UK, and which also became part of the art and design curriculum for the young people who participated. We also discuss interviews with the staff and students about the buildings, with particular attention to their spatial tactics for moving through a highly-charged environment. These various journeys and trajectories are captured in the layering of maps, as daily routines through corridors, but also as related to envelopment, and the experience of arrival and departure, in which doors, parking lots, and bus stops, figure as both affective thresholds and sites where personal data is collected. Finally, we discuss two installations in architecture schools, where the software experiments in mapping, and the mixed-media dynamic diagrams of student movement, were displayed.

Possi(A)bilities: Augmented Reality Experiences of Possible Motor Abilities Enabled by a Video-Projected Virtual Hand

Abstract

We introduce “Possi(A)bilities,” an Augmented Reality concept and system that presents users sitting at a table with animated visualizations of a virtual hand projected on the tabletop next to the user’s own hand. As a combination of possibilities and abilities, possi(a)bilities focus on the motor abilities of the human hand in the synchrony between the physical and the virtual, and constitute into a medium for examining and reflecting on the nature of diverse abilities that become possible when transcending the physical world and the individual’s agency. Ultimately, possi(a)bilities question assumptions, norms, and accepted definitions of motor ability and skill in the context of hybrid, physical-virtual worlds.

Keywords

Augmented Reality, Mixed Reality, video projection, motor abilities, hand function, virtual hands, Extended Reality.

Introduction

The human hand is a multifunctional instrument used to identify objects, manipulate and interact with the world, and extract information from the world via tactile sensing, active haptics, prehension, and skilled movements across a continuum of sensorimotor activities [8]. Fundamental to understanding human performance, the concepts of motor ability [3] and motor skill [12] are key for applications in motor planning and control, for characterizing individual differences in psychology [1], but also for designing interactive computer systems that adapt to and match users’ abilities [22] or repurpose the surface of the hand for input and output [6].

Either grounded in an application-oriented perspective [4, 6, 22] or taking the form of artistic expression [5, 10, 10], the diversity of the motor abilities of the human hand represents the basis for rich interactive experiences with the world. In this work, we use Augmented Reality (AR) to explore new possibilities for expressive hand movements at the intersection of the physical and the virtual. We make two contributions: (1) a technical system designed to sense, record, and visualize hand movements on a tabletop by using computer vision and AR (Figure 1), and (2) a conceptual exploration of possibilities for the motor abilities of the human hand, *i.e.*, “possi(a)bilities,” in the synchrony between the physical and the virtual world, on which we capitalize to challenge the current understanding of motor ability and motor skill.

Figure 1: Our Possi(A)bilities system enables the experience of a video-projected virtual hand on the tabletop in front of a sitting user, where the virtual hand performs movements that are either synchronized with or decoupled from those of the physical hand next to it. By implementing a diversity of possi(a)bilities, *e.g.*, synchronized movements, delayed reaction time, or grasping with a smaller virtual hand, our system encourages reflection on the possible motor abilities of the human hand, readily observed by the user in real time.

Related Work

We relate to prior work from AR and interactive computer systems that have employed the human hand as an I/O surface [6, 16] or used visualizations of the users’ hands as part of interaction techniques [4, 19, 20]. We also relate to art installations that employed images of the human hand.

Visualizations of the user’s hands interacting with a computer system are useful in distributed groupware, where multiple users share the workspace. In VideoArms [19], remote collaborators can see the solid arms of other users, digitally captured by a video camera. KinectArms [4] captures and displays arm embodiments on tabletops using the Kinect sensor, and implements several visual effects, such as shadows and gradients, outlines and transparency, and motion traces. PlayTogether [21] is a video-projection interactive system enabling remote users to play board games and engage in collaborative drawing. IllumiShare [9] is a peripheral device resembling a desk lamp designed to share physical and digital objects on arbitrary surfaces to support collaboration between remote users. Hand visualizations have also been employed in interactive computer systems to assist users when

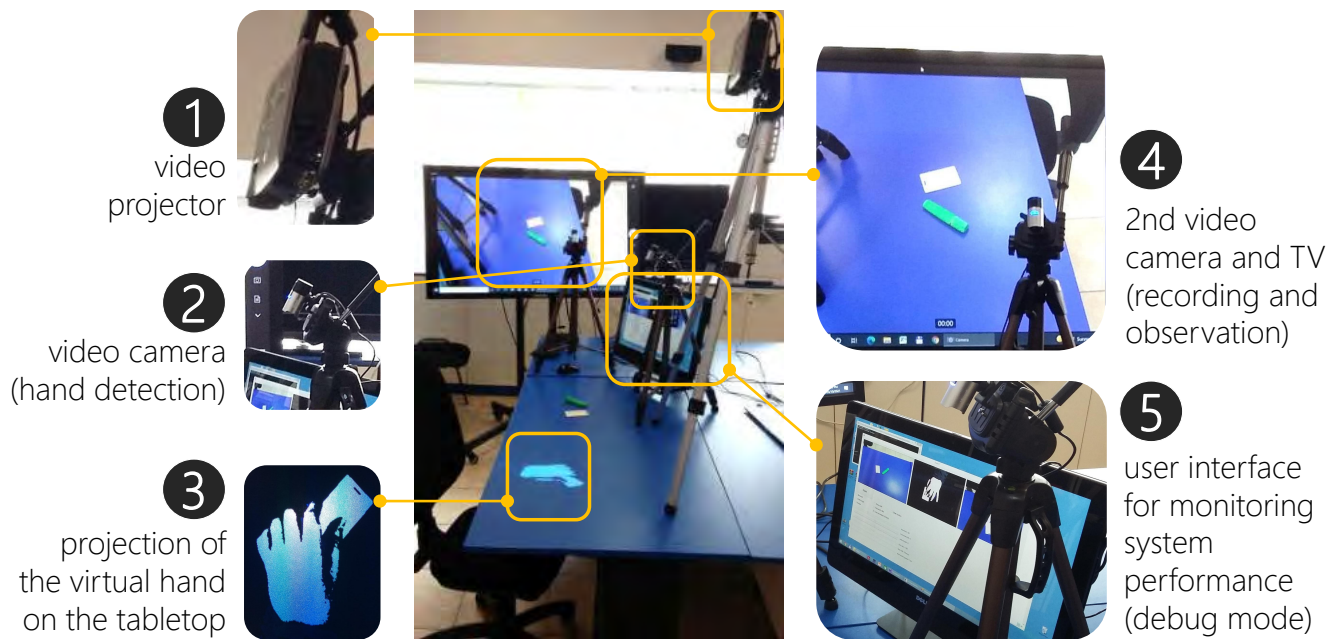

Figure 2: Illustration of the Possi(A)bilities system. On the left, system components creating the Augmented Reality experience for the user: a video projector (1) and a video camera (2) are connected to a PC that controls the virtual hand (3) projected on the tabletop. On the right, system components for debug mode operation: a second video camera (4) for observation and the user interface (5) presenting the results of the various image processing steps, from video acquisition to hand segmentation.

performing or learning specific tasks. For example, Sandnes *et al.* [15] and Rogers *et al.* [13] used video projections on the piano keyboard to support learning piano. Wigdor *et al.*'s [20] “under the table” interaction technique for tabletops makes use of visualizations of the user’s hand positioned under the tabletop to enable touch input from both the top and bottom surfaces of the table. Suzuki *et al.* [18] presented a system that projected virtual hands of experts to serve as guidance for manual workers in factories. Korn *et al.* [11] built a system that video projected instructions directly onto the workspace and evaluated it for people with impairments.

Researchers have also used the human hand as an input/output surface for interactive applications. For example, OmniTouch [6] is a wearable system enabling multitouch interactions on everyday surfaces, including the human hand. A shoulder-worn video camera and projector enable users to draw on the hand, select options from hand-projected menus or interact with applications via controls and UIs projected on the palm of the hand. LightGuide [16] also uses video projection on the hand to guide the user in completing the desired motion, such as during exercises or physical therapy.

In neuropsychology, Suzuki *et al.* [17] implemented an AR version of the rubber hand illusion [2], where movements of the real hand were mirrored by a virtual hand. Rosa *et al.* [14] also used AR to present a virtual hand while both the physical hands were visible to the user, known as the supernumerary hand illusion. Such illusions have been used to understand the experience of body ownership following multisensory integration across the exteroceptive and interoceptive domains.

The expressiveness of human hand functions has been celebrated in art projects employing video projections. Examples include Gary Hill’s “Hand Heard” [7], a five-channel wall-

sized installation showing images of an over-the-shoulder view of a person gazing at one of their hands; Pablo Gnecco’s “Gesture-Gesture” [5] exploring the visual language created with the hands, where three-second videos of hands captured from visitors are video-projected on a wall; and Elina Katara and Sanna-Mari Pirkola’s “Hands (video still images)” [10], where viewers sitting at a table watch video episodes projected onto the surface of a white table cloth: “hands appear in the video and surreal, dream-like things begin to happen.”

Unlike this prior work, the goal of our system is to present users with the experience of a virtual hand that, when aligned with the physical body, demonstrates a variety of possible motor abilities. In this context, possi(a)bilities encourage reflection on what motor abilities and motor skills are in the synchrony between the physical and the virtual.

The Possi(A)bilities System

Figure 2 presents our system, Possi(A)bilities, consisting of a video projector (Dell 3400MP), video camera (Microsoft LifeCam Studio), and a desktop PC (Dell Inspiron 5348, Windows 8.1, Intel Core i5 2.9GHz, 8GB RAM). We developed a custom C# Windows application that detects the user’s hand above the table, processes the image of the hand, records and stores its movements, and projects a virtual hand featuring various visual appearances and behaviors, described next. We employed the Accord.NET framework¹ for image processing, such as background subtraction and binarization to detect the hand against the tabletop and image manipulation to mirror, resize, and reposition the virtual hand inside the projection.

¹<http://accord-framework.net>

Figure 3: Visualizations of possible motor abilities enabled by a video-projected virtual hand: (1) *mirrored copy*, where the virtual hand mimics the movement of the physical hand; (2) *delayed reaction time*, where the virtual hand replays the movement of the physical hand with a configurable lag; (3) *superposition* with the virtual hand projected on top of the physical hand; (4) *pose decoupling* when the virtual hand is projected on the physical hand, but adopts a different pose; (5) *copy*, the virtual hand is an exact copy of the physical hand; (6) *location decoupling*, the virtual hand is shown at a different location on the tabletop with respect to the user’s body; (7) and (8) *size decoupling*, the virtual hand is shown larger or smaller than the physical hand; (9) *synchronized object manipulation*, when the virtual hand mimics the movements of the physical hand manipulating a physical object; (10)-(12) *desynchronized manipulation*, when the virtual hand performs a different action (a recording) compared to the physical hand in relation to the manipulated object; (13)-(15) time-consecutive snapshots of the user leaving the table, while the virtual hand remains in place (16) to perform a recording of the user’s most recent action.

The virtual hand represents the image of the user’s physical hand, programmed either to mimic the movements of the physical hand or to play a recording. Figure 3 shows several motor abilities illustrated by the virtual hand’s movements in conjunction with those of the user’s physical hand: mimicking the movement of the physical hand with a one-second lag creates the experience of a delayed reaction time (Figures 3.1 and 3.2); superimposing the virtual hand with a different pose, from a previous recording, suggests motor opportunities for the physical hand (Figure 3.4); a smaller virtual hand aligned with the physical body enables the experience of smaller grasps (Figure 3.8); and playing a video recording with the virtual hand manipulating a postit, while the physical hand holds a pen (Figure 3.12), highlights the intertwining of the physical and the virtual; when the user has left, the virtual hand can persist (Figures 3.13 to 3.16).

Discussion and Future Work

The Possi(A)bilities system engages the user both as an actor and a spectator. As an actor, the user controls the movements of the virtual hand, which mimics the poses and gestures of the physical hand, and the characteristics of its visual appearance, such as the size of the virtual hand. As a spectator,

the user watches how the virtual hand adopts poses and performs movements from a repertoire of previous recordings. The combination of physical–virtual and live–recorded action turns Possi(A)bilities into a medium for exploring, examining, and reflecting on the motor abilities of the human hand enabled by possibilities for human action beyond the physical world and the individual’s capacity to act independently. Possi(A)bilities also challenges commonly accepted notions of motor ability [3] and motor skill [12] in hybrid worlds that relax the world’s physicality and individuals’ agency:

- What specifies motor ability in a physical-virtual space?
- Who owns the motor skill of a virtual hand?
- What new motor abilities and skills are possible with bi-manual synchrony of physical and virtual hands?

Thus, Possi(A)bilities opens several avenues for future work:

- Extend the Possi(A)bilities system to enable interactions between the physical and virtual hands. For example, a physical pen could be used to write on a virtual postit (Figure 3.12), creating a new motor ability available only in the interplay between the physical and the virtual.
- Integrate Possi(A)bilities with control systems, where the virtual hand could be used to interact with physical objects

from the table, *e.g.*, touching a desk lamp with the virtual hand turns on the light, reaching a TV remote control with the virtual hand enables access to the TV. In such application scenarios, the motor abilities of the virtual hand have a physical impact in the physical world.

- Understand user behavior and perceptions regarding the virtual hand visualizations of the Possi(A)ilities system, including users that have lost specific abilities of the hands because of illness or injury, *e.g.*, spinal cord injury that has affected movements of the fingers or wrist.
- Explore Possi(A)ilities for other scenarios besides a tabletop and for other body parts, for example, visualizing a virtual foot projected on the floor next to the user's body.

We look forward to such future explorations towards redefining motor abilities and skills in new physical-virtual worlds.

Online Possibles: Internet Spaces in a Postdigital World

Erandy Vergara-Vargas
Université de Montréal and Printemps numérique
Montreal, Canada
erandy@printempsnumerique.ca

Abstract

When the Covid-19 pandemic hit, artists and institutions moved online while trying to recreate the experience of art and the gallery experience on screens. For the most part, this shift of attention to the internet as an exhibition space lacked the experimental quality of net art forerunners and their unique explorations of space where gravity is irrelevant and references such as vertical/horizontal, bidimensional and three-dimensional are outdated. This paper explores the notion of Possibles in relation to screen-based art and asks what kind of spaces can be imagined as we move towards a post-pandemic future.

Keywords

Space, Net Art, Virtual Reality, Covid-19 Pandemic, Online Spaces, Virtual Worlds

Introduction

“Imagine you are falling. But there is no ground,” wrote Hito Steyerl in *The Wretched of the Screen* (2012). I often dream about that. I’ve also daydreamed about an artwork defying Cartesian space, linear perspective and figurativism where I experience a free fall and the support system I take for granted is absent. I think in particular about such an experience of space: how would it be to move around and what would this look like?

Been There, Done That

When the Covid-19 pandemic hit, artists and institutions moved online while trying to recreate the experience of art and the gallery experience through computers, pads, and cellphone screens. Overnight, artists were encouraged to perform or show their work online, and galleries rushed to hire programmers to create a vast array of virtual spaces. At the same time, there was increased interest in art created specifically for the internet, and many curators and institutions discovered or remembered the artists who had been there and done that (net artists). For the most part, however, this shift of attention to the internet as an exhibition space lacked the actual experience of net art in its own time and internet speed; it also lacked the experimental quality of net art forerunners and their unique explorations of a space like no other - a space where gravity is irrelevant, and references such as vertical/horizontal, bidimensional and three-dimensional are outdated.

As I checked out online shows, I wondered why I was an arrow, why I was moving through rooms that looked like the “real thing”, witnessing the privileged linear perspective and

many of the references Renaissance artists embraced and modern artists rebelled against so long ago.

I kept wondering what kind of online spaces would emerge if the premise was a body falling where there is no ground or the vast referents that net artists used or created from scratch. Indeed, net art pioneers such as Heath Bunting, Jodi.org, Olia Lialina, Brian Mackern, and Eva & Franco Mattes pushed the envelope by opening the multi-dimensions of the internet decades ago.

For example, in Olia Lialina’s *Summer* (2013) we see the artist swinging back and forth, infinitely looped. Cut out against a gradient background of blue and white, the swing is hung from the browser’s location bar. The animation’s eighteen still images are located on twenty-six different websites, with each site redirecting the browser from one server to the next, displaying the images in sequence and thus creating a cross-domain animation. The work is scattered across the internet, making it impossible to watch offline. The speed and rhythm of the image sequence, the animation itself, depends on internet speed. As such, the work is fragile, just one downed node can break the work.

I am also inspired by the resurgence of VR pieces. I believe that many of these pandemic online galleries and VR works use new technologies to create worlds based on old ideas. This is problematic because some of these spaces are based on a specific worldview: that of Western tradition with its conventions of Cartesian space, linear perspective and figurativism. For instance, in recent VR projects we observe a tendency to create hyper-realistic 3-D worlds, often devoid of the faults, imperfections, and messiness of the real world. They are inhabited by cool avatars or representations of pretty (usually white) people. Furthermore, an astounding number of current VR and 3-D worlds do not invite a carnal, critical, or emotional engagement. We are back to a place where spectators contemplate the beauty created by the artists where we can only surrender. This is in contrast to the work of VR pioneers such as Char Davies, Michael Naimark, Lawrence Paul Yuxweluptun, and Jeffrey Shaw.

In the late 1980’s, Jeffrey Shaw produced *The Legible City* (1988-91). This multimedia installation allows viewers to navigate a simulated city by riding a stationary bicycle, thus connecting the physical and the non-physical through the users’ actions, which are translated into images that recreate navigation within the city of Amsterdam—the architecture is represented with texts related to the history and stories associated with a given building.

Charlotte Davis’s *Osmose* (1995) is an early and remarkable example of an immersive and interactive virtual

reality. The installation employs a head-mounted display (HMD) and a motion sensitive vest that monitors the users' breath and movement. Originally, users are presented with a three-dimensional Cartesian grid, which provides the coordinates for orientation. Users navigate the space vertically by inhaling or exhaling and torso movement determines their horizontal location. The experience lasts fifteen minutes. After, the real world slowly fades in, completely occluding the virtual world. Davis' strategy to employ users' breath and movement as interface is extremely significant. The interface establishes the level of interaction and reaffirms the participant's corporality. The virtual world responds to a regular breath with a smooth state opposed to an agitated breath. Additionally, it responds as users lean or turn.

While early net art and VR pieces produced novel conceptions of space and oriented bodies away from the normative upright posture of the human body, their creative drive was forgotten during the Covid-19 pandemic and the art world's frantic move online. But we are now more than a year from the start of the pandemic and the burning question is: what have we learned from net and VR artists and the pandemic, and where do we go?

Now What?

Let us imagine what space means in a postdigital and post-pandemic world. Contemporary artists have produced a number of net art, videos, and other forms of synthetic worlds beyond Cartesian space, linear perspective, and realism, or they have engaged with these referents critically, because many artists understand that the issue is not about aesthetics as much as it is about exploring space creatively and politically.

Henri Lefebvre's *The Production of Space* (1974) and recent theories of space within geography (Smith and Katz, 1993) insist that social relations and material practices produce space. This conceptualization enables a reflection on how the actual interactions of people in any given space form part of its production. Thinking about internet culture, pulsing as millions of online users create and remix content, the idea of the internet as a space produced through interactions and practices is all the more relevant.

For example, Jakyung Lee's *Exodus* (2020) is a web piece that extracts images of bodies enjoying seemingly private moments like lying on a beach. Using these fragmented figures, the artist forms a defective but endless synthetic environment, composed of random human bodies, whose whereabouts cannot be tracked. They are estranged from their location and lost in the immensity of the internet. No matter how far we move along the traces of cached photographs, everything we/our controller can reach is the

receding horizon. At the same time, we can hear the sound of waves, but there is no ocean in sight.

Jiwon Ham's *Transient Home* (2020) is an experimental documentary tracking the continuous experience of displacement shared by a group of young people. The interviewees tell the stories of their semi-nomadic lives, while their experiences take the shape of random spaces formed by volumetric 3D-capturing techniques. *Transient Home* evokes a series of spaces that never get formed, just like the homes of these young subjects. As we listen to their stories and familiar sounds like preparing a meal in a domestic interior, we expect to get a sense of home. But the 3D dots that seem to retrieve images of dining rooms and bedrooms move to break the images/spaces we yearn for. These stories of displacement demonstrate that we cannot assume "home" is a place of comfort and security for all. They invite us to reflect on communities forced to move and leave behind any sense of space they can call their own.

We can also evoke different spaces, synthetic or otherwise, through sound. *AuMe - Audio Metaphor* (2021), by Philippe Pasquier and Miles Thorogood is an interactive site that functions as an Internet search engine equipped to produce the soundscape of a non-existent nature. Users enter keywords, a sentence or an expression. The generative system will search for words linked to the entry and will play a soundscape of that "natural" space. The work then responds to each user's personal associations and sonic memories, allowing diverse conceptions of nature to orient its emergence in real time. What is more, thinking about screen fatigue (thank you, Covid-19!), it is refreshing to experience an artwork that encourages us to look away while immersing us into an infinite repository of imaginary soundscapes.

Benny Nemer's *Fragments of Rosalie* (2021) also engages sound and was designed for the internet. The work consists of three photographs and audio guides accompanying each image. Nemer rearranged broken pieces of ceramic to create new objects that come into dialogue with three hand-made postcards by Rosalie Goodman Namer, the artist's maternal grandmother, a prolific ceramic artist in Montreal. An intimate connection existed between these two artists. The piece tackles a fundamental part of our experience linked to objects that have stories, people, and emotions attached to them. Objects stop being material objects in the world and become memories involving spaces and senses like smell, touch, movement. Together, Goodman Namer's pottery and hand-made postcards, and Nemer's online engagement with them, brings a multidimensional, sensorial experience of love and closeness with one another. This closeness is evoked in the large scale images extending one-hundred percent on our screens, images that we cannot grasp in their entirety but rather have to scroll through only to see fragments. Nemer

invites us to delve into the intimacy he and his grandmother shared, which transcended age and remained beyond her passing. In the context of the Covid-19 pandemic where our intimate, personal, and professional relationships unfolded through screens, the internet became an important space to negotiate feelings such as love and loss; *Fragments of Rosalie* engages those feelings in powerful ways and invites us, through sound and fragmented images, to do just that.

Sally McKay and Lorna Mills' *Boost Presume I'm Gonna Breathe Grieved* (2021) is a GIF artwork that also takes up the internet to deal with difficult feelings. The humor is characteristic of web culture and these GIF pioneers welcome us to a scrolling page with a "Click Me! Please! Please!" button leading us to listen to a fine selection of 1970s AM radio soundtracks. I laughed when I first listened to the Carpenters' lamenting *Ticket to Ride*. Yet, as I scroll down, my laughter turned sour with the mixture of familiar images during the global pandemic, ecological disaster, and pure emotions of grief: hand-drawn and illustrated animations of eternal rain, trees, followed by digital images of moving skies, forests, mountains, fractured landscapes, forest fires. These take rounded forms. By breaking with the photographic rectangle, the images center our attention on changing and chaotic landscapes. Together, these formal elements create a sense of theatricality. I see familiar feelings and emotions: Fire, fire! Shit!, viruses, hands, touching anxiety; scenes of a road ahead seen from a moving car, mountain, eagle views, and hordes of animals running away, hurried, every woman for herself! Tears falling, but there is no escape. Who hasn't felt this way, some way or another, since the pandemic hit?

esc/space

One of my motivations to engage with the theme of space is the numerous online exhibitions that I started seeing after the first lockdowns around the world, especially 3-D models of galleries. The case of net art is crucial. When I saw galleries and artists moving online, many were not aware of the history of net art and the ways in which net artists around the world have engaged with the internet, dissecting the way contemporary societies have shaped the networked world and how it has shaped us (people and social relations). Net artists have bent the rules on the internet and created alternative conceptions of space, artworks, communities, and practices such as sharing and community building. Net artists have demonstrated that the internet has its own dimensions, depth, texture, folklore, strategies, humor, and that the three-axis grid is not the only way the world perspective works. We need to revise the history of net art and pioneering investigations with virtual reality as we move towards a post pandemic future.

We must also remember that, as numerous feminist and postcolonial scholars have insisted, that "the real world of image making is political," and that the study of

representation in connection to power structures is equally central to challenge the visions of reality produced by any hegemonic system (hooks). Cartesian notions of space and subjectivity that continue to shape virtual worlds today assume a normative body who can move at will. But this is not the experience of many marginalized communities online and IRL.

Abstract

I WANT TO PROCLAIM SOS AGAINST ILLEGAL EXPERIMENTATION ON HUMANS BY USING BIO/NEUROTECHNOLOGIES.

- The crime category: medical experiments (clinical trials without consent) - crimes committed with innovative scientific tools. (Combined multidisciplinary sciences - medicine, psychiatry, physics).
- The recidive: victims home and bed becomes the place of a cruel regular crime - clinical trial.
- The body: human - is like an animal, abused by criminals for medical experiment needs.
- Implantable neuro-electronics started to be used for human functioning-operating control.

Research object. Globally, many people are suffering from newly invented technologies, approximately 2000 to 10,000 people worldwide, could even be more. Some of them call themselves TI (Targeted Individuals), some of them TI cyborgs, TI neurorobots. Some of them have implants with remote influences 24 hours per day. Therefore, they have no privacy, they are 24 hours per day tracked, 24 hours per day tortured (with UV laser, micro waves, and so on), discredited, forced to have no authenticity, no future, no social lives. This is like the "Second Life", except this "virtual reality game" is controlled by criminals. The victims can't get help - scientific and competent medical, adequate police and media response. Human Rights, in their case, do not apply.

Keywords

Crime committed with neurotechnologies, ultra-thin transparent implants, Targeted Individual (TI), neuro-electronics from neuroscience/experimental medicine, human-computer interaction (HCI), brain-computer interaction (BCI), microrobots for neurosurgery, microrobots-electrodes/sensors, stealing biodata, bioelectronics for paralysed human body functioning/control, forced behavior, psychiatric patient imitation, neural prosthetics as extension of the criminals body.

Introduction

In general. Nowadays, a new generation of high-tech innovations become more and more common. High-tech innovations can be adapted for unethical and/or illegal research and human body control. Used technologies: bioelectronic, optogenetic and neural implants (nano-micro-milli size, with invasive Brain-Computer Interface (BCI), Human-Computer Interface (HCI), experimental Human-Computer-Human Interface (HCHI) and AI Interface and so on). For the last five years I have been studying patterns and principles of crimes, made with previously mentioned instruments. Because of individuals and companies invested in shady businesses, related to my topic, each case is covered and far from transparent, therefore, information is hard to gather. The stories, I have encountered in my research, are terrifying, like postmodern philosophy illustrations (for example: M.Foucault's theories). Here arises the question of VIOLENCE: HOW MUCH IS TOO MUCH?

General details

Most commonly, people from socially weaker category can become victims who are exploited for unethical, forbidden by the EU, scientific experiments, rooting way back to Hitler and Stalin epoch of neuro-research experiments. Nowadays, victims suffer, mostly unable to explain it, from bio/neuro-technologies and psychological operations (used to cover crimes), irradiation (to sustain lack of vitality and incapacity to work for the victims), biopharmacy... Hackers censors victims phone calls, email, social networks. Most commonly used innovations are adopted from neuro-technologies; nano and micro sized muscular implants prescribed to suspend neurodegeneration processes, e.g.: paralysis, vision and hearing decline, etc... Professionally implanted and long time studied individuals might be compared to marionettes, for example, with wireless implants almost all body functions can be controlled. With mentioned methods, psychiatric diseases are being simulated, just like that,

medical-law is being broken and “sick tags” are being pinned on healthy people. Technologies and mental plays, to trick the society and make victims situation even more helpless, are working - complains from healthy and sick people are mixed together, when the healthy people start talking about it, society start looking at them as mental patients. Crime characteristics can be compared with KGB practice in the 20th century in Lithuania, however, current crimes are improved with latest technology tools. Present “KGB prison”, or “human trafficking prison” - small, undetectable and irremovable implants inserted in the bodies of the victims.

Possible description for these cases may very well be biotechnology terrorism, cyberterrorism, human trafficking and control. Possibly, these criminals (as most terrorists) make combined purchases of (neuro)technologies, tools, chemical reagents, etc. from all around the world. Later on, they legitimize practice as mobile communications or programming firms and focus on a single targeted individual.

There is also a huge problem with categorisation. The category of the “mentally ill” is known and common - but victims of medical crimes should be a separate category. In my opinion, new categorisation is needed - e.g. “victims of scientific crime”, “victims of innovative biophysical technologies”, “victims of innovative neurotechnologies”, “victims of clinical trials at home condition”...

Information gathering process

I have understood - speaking about this problem is a “TABOO” and even some journalists who have “investigated” this problem, use such investigative methods that are only beneficial to doctors who cover up criminal elements. After a significant amount of work, I have brought together the information as accurately as I could, it is meant for the victims and for showing vast possibilities of technology innovations. I ask you not to take accusations seriously, where the victims blame a certain known party. It is unlikely for a victim to know the real source of an order. Possibly, medical experiments, human trafficking and terrorizing, using methods and techniques similar to the ones described, has been happening for 10 years. In case of human trafficking, these techniques and methods could be used against an individual who has no preliminary knowledge about the related technologies and criminal factors and has no money (to remove implants costs a lot), is lonely (with no closest people who can help, or with bad relatives), has strong/resilient intellect (such people can suffer a lot, but do not kill themselves). I have tried to find information about the possibility of human function control with experimental medicine tools and have talked to scientists and other trusted people.

A two years ago, during “Open Readings” conference, I have asked a question a physicist of Vilnius University prof. Mangir-

das Malinauskas¹, and he gave an answer (I cannot give the exact quote, but I will quote as I remember): “To my knowledge, it is currently possible to control human functions with implants, however crippled. Why? - because the implants are not sufficient quality to control all human functions. A healthy human nerve system has too many parts for the current implants to be possible to control. He advised to search for ultra-transparent objects in bodies. Earlier he produced microrobots for medicine and polymeric chemistry. I think he has knowledge about the possibilities of medical technologies, globally. Also he knew similar case from the past, but only with electromagnetic irradiation (x rays, etc.) from neighboring apartment. He helped me to understand that in case of medical experiment criminals make constructions in the victims apartment: installing wires and other technics between the walls, in the walls, and so on (I think this technic possibly can be pulled out, without much effort and without entering the victims apartment).

Also I had got a chance for a short live communication with Cosimo Monda² (Maastricht University, Centre on Privacy and Cybersecurity). He also knew this problem as “CRO”- Clinical Trial at home conditions, and named, what exact implants term - neuralelectronics. Also, he said that it is very difficult to prove this crime, and 'very difficult to change laws in the system'.

I also communicated with more people from innovations³, radiophysics, material science, law⁴, forensic⁵, criminology⁶, and etc. - they gave me a lot of advises. Then I realised that these innovations are at the academic or after academic level (in innovators language, they are in experimental stage called “in the valley of death”), when pre-clinical or clinical trials are needed, but there is no support/investors yet. They have the right for innovation, however, experimenting and proving is left to be done with their own money until the investor comes up. It can take 5 to 15 years. Then “the valley of death” ends, the investor is found or not. If found – the project is moving to the next stage, closer to a wider production, delivering to the market (...).

Final words, conclusions

As a victim of medical experimentation, I have no questions of the presence of these technologies (specifically - neuralelectronics) and the need of medical investors to experiment with healthy people, for free.

The questions for the readers: How victims should act, step by step? Can there be created an instruction? What could be a fast and a money-free way to escape out of this crime?

In my opinion, because of the affiliation, corruption and ineffectiveness of medical professionals, victims of medical crimes should be entitled to “psychiatric immunity” (a right similar to “legal immunity”).

MY WORDS AND YOUR LISTENING - LET IT BE AN IMPULSE FOR JUSTICE IN HEALTH.

Author Biography

Interdisciplinary artist-researcher Aistė Laisvė Viršulytė was born in 80’s and has spent most of her life in Vilnius, Lithuania. She finished a BA in photo-media art at Vilnius Academy of Arts, and MA in sculpture there. Since 2016, she is a member of Lithuanian Interdisciplinary Artist’s Association.

The focus of her current creative effort is shifted more towards time-based media where she explores the areas of art and science, experimentation, process, sensory perception, sound art, mythology, locative media, and more.

In sight of *Allo-states*: Tracing the Path from Environmental Personhood to Agentials, Performances of Personhood and Other Artworks on the Agency-Personhood Continuum (APC)

Devon Ward

Ball State University

Muncie, Indiana

contact@devon-ward.com, ward@bsu.edu

Abstract

In the spirit of combinatory play, this paper examines how the concept of environmental personhood may impact art, design, and culture in novel ways. It begins by introducing a landmark legal decision in 2017 that granted legal personhood to the Whanganui River in New Zealand. Legal decisions that grant environmental personhood have the potential to provide productive conceptual fodder for artists, designers, and architects whose work imagines new relations between humans and the environment at a time when ecological degradation is ubiquitous. This paper then presents a heuristic framework called the Agency-Personhood Continuum (APC) that traces broad esthetic strategies used in artworks that engage with concepts of nonhuman material agency and environmental personhood. Finally, it seeks to open new imaginatory space by positing a new class of supra-governmental entities called *allo-states*. *Allo-states* are here defined as organizations that represent massive ecological entities that transcend a single nation-state such as the Amazon River. Theoretically, *allo-states* could exist alongside, but independent from nation-states in supra-governmental parliamentary proceedings such as the UN General Assembly. Ultimately, the term *allo-states* provides a hypothetical means to explore supra-governmental environmental personhood and looks for way that enable large scale ecologies to receive representation that focuses on their intrinsic worth instead of their resource value. Through speculation about emerging and expanding notions of environmental personhood, the aim is to activate new areas of social, cultural, and creative inquiry.

Keywords

Allo-states, Environmental Personhood, Agency-Personhood Continuum, APC, Agentials, Performances of Personhood, Nonhuman Agency, Art, Design

Introduction

In 2017, the Whanganui River in New Zealand was granted legal personhood, a status that provided the river—and the surrounding ecosystem—with the legal rights and

responsibilities of a person [1]. As a legal designation, personhood provides a robust means of protection against other individuals and organizations that would seek to utilize the river solely as a natural resource, without considering the long-term degradation this depletion may cause. And while a river cannot engage in a legal battle, it was granted two legal guardians to oversee the protection of its rights: one New Zealand government official and one member of the local Maori tribe [2].

The impetus for this legal decision was born out of successful advocacy of the Maori belief system: whakapapa (Maori genealogy). According to Gwendolyn Gordon, in the world view of the Maori, the Whanganui River and its surroundings maintain a different ontological status: they are social beings in the Maori community [3,4]. As Gordon writes, “[f]or a Maori tribe (iwi), sub-tribe (hapu), or extended family group (whanau), a particular river or mountain might be an ancestor (tupuna). This genealogy—or whakapapa—is crucial to Maori worldviews” [5]. In other words, the Whanganui is part of the social milieu of the Maori. They see the river not just as a person, but as a familial ancestor. By granting the Whanganui River personhood, the New Zealand courts effectively acknowledged—and to some extent instantiated—the Maori ontological framework.

Symbolically, this case may have far-reaching consequences beyond New Zealand that impact other legal and cultural decisions about the relations between humans and nonhumans. Chris Fowler writes, “Particular concepts of the person are bound up with specific ways of perceiving the material world and valuing its features” [6]. By changing the legal status of the Whanganui, there may be follow-on effects that impact culture. According to Gordon, “the legal structure underlying the personhood changes give them actual heft, and can change the way people think about the rights of the environment in ways that really change the law in ways that affect the real world” [7]. At a time when environmental degradation is a reoccurring feature in popular news cycles, granting legal personhood to a river can affect cultural viewpoints. Cases such as Te Awa

Tupua (Whanganui River Claims Settlement) Act of 2017 provide a glimpse into a new cultural potentiality.

From Legal Precedents to Art and Design

According to Bruno Latour, legal precedents and philosophical inquiries can open new conceptual spaces, but they also require the domains of fiction [8], art, and design to breathe life into new ideas. As Gordon writes:

theories of these rights of nature may be deployed in ways that shift with circumstances, social, political and material circumstances matter, as do ways of imagining. As such, a better question than the obvious ontological one—may nature properly be considered a person—is: how easily will we be able to imagine nature as a rights holder in each regime, and how will that imaginatory space energize the will to protect nature by means of these varied rights arguments? [9]

In other words, new esthetics may be required to fully flesh out these new social imaginaries. Fortunately, fields such as architecture and biological art offer existing methodologies that acknowledge the importance of nonhuman actors and seek to amplify their agency. One common example can be found in an anecdote about architect Louis Kahn:

Louis Kahn used to tell his students: if you are ever stuck for inspiration, ask your materials for advice. "You say to a brick, 'What do you want, brick?' And brick says to you, 'I like an arch.' And you say to brick, 'Look, I want one, too, but arches are expensive and I can use a concrete lintel.' And then you say: 'What do you think of that, brick?' Brick says: 'I like an arch.' [10]

In this exchange, Kahn maintains a cognitive model that personifies his material. His conversation with a brick is an example of a design process that Donald Schön refers to as *reflection-in-action* [11] and what Bruno Latour called nonhuman agency—the ability of any material to have an impact on human society [12]. Kahn playfully asks his material what it wants to be and the brick—through an expression of physical characteristics (e.g., material composition, density, form, tensile strength, etc.)—provides a response: it wants to form of an arch. The result is a conversational design approach that encourages designers to listen to their materials [13]. It seems then, that personification is one strategy for amplifying nonhuman agency.

Similarly in the field of biological art, many artist implicitly assume that living nonhumans are actants that may exist outside of the human *umwelt* and require an intervention to bring them from the microscopic to the macroscopic [14]. They then use a variety of tools and esthetic gestures that translate the agency of living materials into a felt human experience that can be observed in a public context (e.g., gallery, studio, laboratory, ecology, etc.). Translation through data, context and narrative may be a second strategy to amplify nonhuman agency.

It seems that the cognitive models utilized by practitioners to amplify nonhuman agency share a common motivation with legal decisions that increase the agency of environmental persons. However, the scale and complexity between the expression of material agency and environmental personhood may differ drastically. This raises the question of how to assess the relationship between the two concepts within artworks. As a result, a heuristic framework referred to as the Agency-Personhood Continuum (APC) has been developed to provide clarity.

A Framework for Assessing Art and Design: The Agency-Personhood Continuum (APC)

In an effort to develop a more robust conceptual link between the cognitive models of material agency implicit within Louis Kahn's "conversation with a brick," and environmental personhood, the Agency-Personhood Continuum (APC) was developed (Figure 1). The APC is a model for understanding how particular esthetic strategies are employed by creative practitioners who wish to represent the nonhuman agency. It can be considered a fluid, conceptual tool for thinking through esthetics, but it is not a fixed model that offers any prescriptions about art.

Figure 1. Agency-Personhood Continuum (APC) Diagram. Designed by Author. CC BY-SA 4.0 (Author)

Within the APC, there are two key terms that seek to describe some common conceptual gestures: *agentials* and *performances of personhood*. *Agentials* exist on the left side of the Continuum. Artworks that function as *agentials* may seek to bring nonhuman activity that normally exists outside of the human perceptual field—due to distance, time, scale, or impact—into our sensory range. These works can be said to exist as nonhuman agents that do not have enough complexity to rise to the level of personhood. The story of Kahn's "brick that wants to be an arch," is a prime example of an *agential*. Another example can be seen in the 2021 bio-digital installation *Weathering* (Figure 2). *Weathering* features a microbial fuel cell—an organic battery made from mud, water, and bacteria—and a digitally controlled solenoid. The microbial fuel cell produces small voltages, 10-300 millivolts, that are fed into an Arduino microcontroller. Using voltage as a tell-tale sign, the microcontroller senses the microscopic activity of bacteria and then triggers the

solenoid to open and close in rapid succession. The result is a sound installation that generates a stochastic, intermittent tap against a wall any time microbial activity reaches the voltage threshold. *Weathering* seeks to amplify the microbial metabolism which converts organic material into elec-

trons into a series of tapping noises. It thereby translates microbial agency into the human sensory spectrum and provides a snapshot of nonhuman agency as an *agential*.

Figure 2. *Weathering*, (battery made of mud, water and bacteria; glass, wood, copper wire, Arduino, solenoid). Author, 2021. An example of an *agential*. CC BY-SA 4.0 (Author)

Figure 3. *Embedding: Ochopee Trail, Florida, US*, Author, 2021(digital video, 12:00). An example of a *performance of personhood*. CC BY-SA 4.0 (Author)

On the right side of Continuum are *performances of personhood*. This term describes activities that may focus on nonhumans that are larger in scale and complexity, but which may be more distributed. Additionally, *performances of personhood* may seek to create conceptual and esthetic gestures that literally or metaphorically reintegrate humanity into a complex ecosystem, thereby re-instantiating an ambient human connectedness with ecology. *Performances of personhood* may be considered the opposite of the current individualistic notions that situate humans as separate from the environment. The Te Awa Tupua (Whanganui River Claims Settlement) Act 2017, which grants personhood to the Whanganui, would be one prime example of a *performance of personhood*. Another example is the artwork *Embedding: Ochopee Trail, Florida, US* (Figure 3) created in 2021. *Embedding* is a durational video that documents a

walk through the Ochopee Trail in the Everglades, one of the largest protected swamplands in Florida. The trail itself is 14.9 miles (24 kilometers) and the original video is 5 hours. However, an hour of the video has been sped up and condensed into 10 minutes. By speeding the video up, the viewer gets a glimpse into a larger system. As a result, the first-person, human perspective of a localized environment gives way to a holistic view of a nonhuman person, the Everglades.

When considering the APC, one can think of the range between *agentials* and *performances of personhood* in a similar manner to the visible spectrum for humans. It is only a small representation of a much larger continuum. There may be proto-agencies or supra-entities that extend well beyond our threshold of experience.

From the Agency-Personhood Continuum to the Possibility of *Allo-states*

While some artworks on the APC express of an individual perspective, collective *performances of personhood* may have the potential not only to situate the human in an embedded system of ecological relations, but they can situate the nonhuman person in a complex social milieu of the human. This can be seen in the *Theatre of Negotiations* (2015), a large-scale collective performance that took place in Nantes, France prior to the Annual Conference of the Parties (COP21), a UN climate change conference. The performance was considered a “pre-enactment,” a collective, theatrical, performative simulation involving over 200 students. Notably, one idea that shaped the event was informed by Latour’s understanding that nonhuman actors increasingly needed to be included more prominently in political discussions. Therefore, the *Theatre of Negotiations* included nonhuman ecologies such as the Amazon rainforest, the Arctic Sea, and the North Sea in the deliberations. According to Latour, the mere presence of the representatives for nonhuman ecologies changed the flow of deliberation. Greater attention was given to the environmental entities during debates. [15].

If one combines concepts from the *Theater of Negotiations* with the ideas from environmental personhood, a new notion arises: the *allo-state*. An *allo-state* refers to an organization that represents one of the world’s largest collections of ecological entities (e.g., humans and nonhumans) that exists at multiple scales (e.g., nano, micro, macro, mega). The prefix *allo-* has been selected because these ecological entities span numerous countries. An *allo-state* alongside, but independently from nation-states. For example, the Amazon River, Alps, Mediterranean Sea, and the Nile River all span numerous nation-states and could potentially benefit from recognition as *allo-states*. Ultimately, the notion of an *allo-state* hints at the possibility of developing supra-governmental environmental personhood and an organizing body that could speak on behalf of the environmental persons in parliamentary forums such as the UN General Assembly.

Conclusion

Legal concepts such as environmental personhood can affect both legal and cultural notions of identity. Through means of conceptual combinatory play, this paper aims to generate new imaginary space within the arts and the notion of environmental personhood. This can be seen in the development of the Agency-Personhood Continuum (APC)

which helps organize different creative practices that amplify the agency of nonhumans at various scales of complexity. Ultimately, by combining notions of environmental personhood with *performances of personhood* like the *Theatre of Negotiations*, the term *allo-states* is presented to activate imaginary spaces about the possibility of supra-governmental environmental persons. How this new concept of *allo-states* impacts further creative inquiry for art, design, and cultural production remains an open question.

Author Biography

Devon Ward is an artist, designer, and educator who creates digital and living systems to explore notions of time, place, and identity. His works often rely on speculative allegories that examine current social conditions affected by emerging technologies. These works often focus on the changing relationships between humans, non-humans, and the environment at a time when environmental degradation is ubiquitous.

Ward holds a Master of Biological Art from SymbioticA at the University of Western Australia and a BFA in Graphic Design from the University of Florida. He is currently Assistant Teaching Professor of Graphic Design and Visual Communication at Ball State University in Muncie, Indiana, USA.

Environmental Critical Zones: Reading the Wrack Lines

Abstract

Reading the Wrack Lines is an interdisciplinary environmental literacy and educational outreach project designed to engage the local community with innovative learning approaches focused on the reality and possibilities for change in our coastal environment. The project is framed by cross-cutting themes of diversity and inclusion, and includes partnerships with local institutions, environmental specialists, and underrepresented communities. Through a series of creative writing workshops and site visits, participants reflect on the changing environment and create poetic works for inclusion within two art works: a generative audio-video installation projected on University of Connecticut Avery Point lighthouse, and a laser-cut felt word-based floor sculpture on exhibit at Cummings Galleries as part of the Fire and Ice exhibit. The creative process and final artistic products of this project empower participants and articulates a vision for environmental change to the larger public.

Keywords

Generative, audio-visual, site-based projection, community engagement, environmental outreach, digital poetics.

Introduction

A wrack line or wrack zone is a coastal feature where organic material and other debris is deposited on the beach at high tide. The wrack can be made up objects such as seaweed, crustaceans, feathers and bits of plastic. As the edge between the natural input of marine resources and the land, the wrack zone is interrelated with the state of the sea. Shorelines, locally and globally, are affected by stronger and more frequent storms and the threat of sea level rise. Locally, our waters are seeing a decline of species, warming water temperatures, acidification, and changing ocean currents. This project engages the community through coastal site visits and creative writing workshops about climate justice, the local ecology, and possible positive change. By

developing an awareness of local climate change first-hand, participants in *Reading the Wrack Lines* see connections to larger global climate concerns.

Background

Reading the Wrack Lines is the most recent artistic collaboration between the authors, and is part of a series of works focused on climate change and the environment. A previous collaboration, *Open Waters [Northwest passage | Open Polar Sea | Arctic + Great Lakes Plastic]* was shown at museums and presented at ISEA 2020, inspired by a five-hundred-year history of northern exploration, current geopolitics, and global circulation of microplastics. Another previous collaboration, *Ice Core Modulations: Performative Digital Poetics* was presented at ISEA 2017 (among other venues) and included imagery and poetic fragments inspired, generated and controlled via historical CO₂ data taken from ice core samples made available from the National Snow and Ice Data Center (NSIDC).

All of these collaborations have sought to create engaging works that address complex environmental issues through a plurality of artistic, poetic, and scientific perspectives. The collaborators have brought to bear individual skills such as audiovisual generative computer programming, various forms of visual art media, poetry, and electroacoustic composition to synergistically create these works, using shared source materials such as place-based personal narratives, historical materials, scientific data, site-based audiovisual media, and poetic texts.

Goals, Objectives and Artistic Dimensions

Reading the Wrack Lines seeks to increase environmental literacy through community outreach and provide a sense of empowerment to the participants and the public through the

process of creative writing about the environment incorporated into artwork.

The overarching goals and objectives of the project include:

- Enhancing learning about environmental issues and ocean literacy for participants to be more resilient to a changing climate and environment
- Organizing workshops for participants to respond to environmental issues through creative writing responses formulating multiple points of view with many voices.
- Providing a venue for our community to creatively offer what may be possible; to respond, react, and propose change to environmental issues.
- Presenting community writing and voice through innovative multisensory formats exploring digital poetics in a reflective and engaging experience.

The artistic dimensions are framed by creative community narratives, the local environment as subject matter, and the project medium including digital and physical forms. Based on these objectives, *Reading the Wrack Lines* collaboration resulted in two distinct works showcasing community voices:

- A generative audio-visual work programmed in Processing software composed of texts, visuals, and audio of participants' spoken texts. This work was projected onto the local lighthouse on April 22, 2021 (Earth Day)
- A sculpture consisting of digitally fabricated laser cut felt and embedded audio on exhibit in the "Fire and Ice" Art on the Edge show from September through October 2021.

Natures and Worlds: Climate Change and Global Warming with Digital Poetics

Reading the Wrack Lines engages with climate change and global warming as both an artistic response and an unpredictable generative system. Working with generative technologies that produce unprompted change mirrors the unpredictability of weather and climate change impacts within our natural environment. As such, climate-focused generative art makes use of random systems to engage viewers in innovative and surprising results.

Description of Works

On-Site Audio-Visual Projection

The generative audio-visual projection (Figure 1) combines a wave-like undulating texture with visualization of poetic excerpts from the poems written by community participants. Using Processing software, phrases are periodically selected at random and visualized using various time-based typographic treatments such as fades, variable font sizes, as well as crystalizing from and disintegration into pixels. The generative textural and poetic phrases are accompanied by

Figure 1. Generative audio-visual lighthouse projection at University of Connecticut Avery Point campus.

background audio based on processed glacier calving noises and water sounds punctuated by occasional recorded phrases from the community poets. During the evening event, as the level of darkness increases, the lighthouse becomes a more prominent backdrop to the projection, standing out against the coastal water beyond. The text and audio voices of the participants empower a public experience with personal reflections on climate change through the lens of local waters.

Digitally fabricated laser cut felt floor sculpture

The sculptural work of *Reading the Wrack Lines* (Figure 2 and 3) is a soft undulating felt floor piece comprised of digitally fabricated text phrases featuring excerpts from community poetry and environmental data. Embedded in the felt forms are two generative audio systems evoking the randomness of the environment. Community voices are identified by the script text form and environmental data is identified by the sans serif text form. These multiple points of view are composed, making a unified visual form—speaking in unison to the urgency and possibility for environmental change. All text forms are intermingled with the negative (or leftover) felt, resonating notions of waste and reuse. The work seeks to draw out the poetic from connections among the arts, environment, technology, and materials.

Figure 2. Reading the Wrack Lines laser cut felt floor sculpture with embedded audio on exhibit in “Fire and Ice” exhibition.

Figure 3. Detail of laser cut felt floor sculpture.

Summary

The collaborative intent of *Reading the Wrack Lines* project allowed for interdisciplinary synergy between a creative team spanning computer science, electronic sound composition, and visual art, and with the local community and environmental specialists. The work amplifies participants’ voices through physical and virtual public presentations. Our collaborative team plans on an ongoing series of installations that bring community voice, art and science together; immersively engaging awareness and activating voice about nature, place and a positive future climate. Funding for this work was provided by Connecticut Sea Grant, University of Connecticut through a Development Award in 2021, and from the Ammerman Center for Arts and Technology Faculty Research Grant at Connecticut College.

Authors Biographies

Andrea Wollensak is a multimedia artist, designer and educator. Her work spans media from traditional and digital fabrication to generative-interactive systems and includes frequent collaborations across disciplines. Wollensak’s work has been exhibited internationally, most notably at the Göteborg International Biennial of Contemporary Art and the Brno Biennial of Design. Her work has been supported by the Rockefeller Foundation, the International Artist Studio Program in Sweden, Anchorage Museum, Banff Centre for the Arts, and the National Science Foundation. She has presented her artwork at numerous venues including ISEA, CAiiA, Generative Art, and College Art Association. At Connecticut College, she is on the faculty in the Studio Art Department, and an Associate Fellow at the Ammerman Center for Arts and Technology where she served as Director from 2012-2020.

Brett Terry is a composer and sound artist when not busy with his daily life as a software engineer. His electro-acoustic, choral and chamber compositions have been performed at venues such as SEAMUS, ICMC, ISEA, CAiiA, and Sound Culture in addition to collaborating with visual artists on numerous audiovisual works. As an associate editor of *Computer Music Journal* (MIT Press), he has curated a special issue on Visual Music.

Bridget Baird is a Professor Emerita in Computer Science and Mathematics at Connecticut College and a past Director of the Ammerman Center for Arts and Technology. Her research examines the intersections among the arts and various technologies. Projects include investigating an archaeological site in Ecuador through virtual reality, exploring music and dance through motion capture and multiple modalities, using digital techniques and algorithms to better understand and mine historical documents, and more recently, addressing climate change and environmental concerns by using generative art. Baird collaborated, as a Fulbright scholar, with colleagues in both Mexico and Ecuador. Involvement with the local community has also been important to her and a constant interest has been to increase the number of women in the sciences.

Extensions of Reality: Plants and the Technological Virtual

Rewa Wright & Simon Howden

Independent Artists

Brisbane, Australia.

rewawright@gmail.com

Abstract

This paper explores a selection of mixed, virtual and extended reality artworks (MR/VR/XR), through the theoretical lens of posthumanism applied to media art, as well as practice-led conjunctions of media and devices. Exploring recent works by the authors' and others, we speculate on plant blindness and *homo sapiens* immersion in the 'technological virtual', arguing this is not necessarily a retreat from the organic. For artist's working with plants as co-composers, this challenge involves avoiding the evolutionary trap of 'plant blindness', while utilising algorithmic processes that are programmed to be blind to the organic.

Keywords

Mozilla Hubs, Plant Blindness, Mixed Reality, Posthumanism, Climate Catastrophe, Anthropocene.

Introduction

Since the 1990s the extreme quality now possible with scientific imaging equipment such as electron microscopes have allowed us to see within previously opaque natural structures. Yet this seeming clarity has also problematised relations with other species. A visually illuminated knowledge of plant processes has afforded a greater understanding of their sensing capacities challenging previously held notions of plants as passive. Acknowledging the embodied processes and equity of two modes of situated agency, plant and human, elucidates an approach that understands plants as co-creators. [1] In the installation and performance *Contact/Sense* (2019), situated agency emerges as a tangled network of augmented reality infrared vision, gestural and signal etic data, connected by electrical signal and audibly through a bespoke soundscape (Fig.1). [2]

Figure 1. Headset view: Touching one another's signals, human and plant deliver a responsive refrain.

Techno-organic interfaces were networked together so that participants would experience immersive reality differently from a regular VR or MR situation, where there is a clear window to look through and a clean signal depicting logical representations of virtual objects. Instead of this 'clean and clear' paradigm of vision, a human performer wearing a modified HTC Vive with a Leap Motion gestural interface, is given a de-limited vision that is also grayscale and permeated with pixel artifacts or glitch. They feel their way through an improvised performance with a network of plants, using touch to co-create an arhythmic chorus that blends with micro-temporal rhythms emanating from the living plants they perform alongside. Visualized using custom software made in Unity 3D and Touch Designer (Fig. 2), this artistic research project examines potentials for performative interactions between humans and living plants.

Figure 2. Installation view with human and plant co-composers.

Utilizing the Leap Motion gestural controller in a non-standard implementation, it becomes a look-through the camera, affording a de-limited mode of vision that eliminates all colour. Seeing the world through this grayscale gloom, the wearer is engulfed in an occlusive vision that challenges the ocular. It seems appropriate that this this grayscale gloom becomes the disruptive fog that also affords a sensorial heightening of touch, and that this heightened touch affords artist/performers the opportunity to connect with their plant kin. Together with plants, the artists generate intra-actions where the plants have the first signal in the performance and lead the human performers who improvise alongside their signals. [3] This installation and performance located human performers in a co-compositional role alongside living plants, whose sonified bio-electrical signal triggered performer improvisations. Crucially, plant signals came first, leading the co-composition and luring humans to follow. Participants who

experienced the installation explored their own tactile and gestural experience of co-composition. Looking through the Leap Motion gestural controller as a camera, participants saw in mixed reality with grayscale vision, their vision de-limited and other senses enhanced. A performer, cloaked in this dark vision, must navigate through a visual fog that is the true inheritance of the Capitalocene. Feeling their way through this fog means engaging senses other than the ocular, gesturing toward potentialities that lever tactile responses to (and by) plants through the medium of sound. Reassembling data and human gesture using plant signals contributes to an emerging perception that a plant might also be considered as a 'body' in momentum, just operating at a much slower time scale than with humans and other animals.

Beyond Plant Blindness

Plants were there at the beginning in the cosmology of the garden of Eden, yet Adam and Eve played the leading role in true Humanist style. Now, we sit at the pointy end of a 300,000-year-old lineage as *homo sapiens* (Latin for 'wise man'), in what is known as the Anthropocene because of the enormous scale of our footprint, which has successfully trampled every other species in the biosphere. A pertinent time to turn attention from the creators of this egregious carbon footprint to the creators of the carbon: Plants. While we explore the Anthropocene as a scientific and artistic narrative, as well there is the meta-story of a humanity gone wild, evidenced by the visible scars left in the Anthropocene. Is plant blindness a further signpost to the visible decay that points materially to a gradually diminishing biosphere? As well, we consider a potential slippage between the scientific term Anthropocene and the speculative stage that we might term Anthro(s)cene. On the stage of the Anthro(s)cene, where human visibility is inflected with the gradual becoming-invisible of flora and fauna, affords a pertinent time to consider our plant kin. On this stage, we find a tension between the terms 'climate catastrophe' and the more measured 'climate change'. As developed in a plethora of social actions, through on and off-line media activity, prominent groups like Extinction Rebellion and activists such as Greta Thunberg and Bill McKibben have taken the message of an impending 'climate catastrophe' to the masses. Using social media posts on Instagram, Twitter and Facebook as a means to circumvent mainstream media blockages on the topic, climate catastrophe as a discourse sets the scene for a zeitgeist of resistance. Parallel to that, we find 'climate change' operates as a milder, government sanctioned cousin, and in some cases (such as in Australia) might in fact be part of a strategy for hiding a range of environmental abuses, such as new contracts for coal mining, gas fracking and water mismanagement. Yet, while *homo sapiens* possess an allegedly superior consciousness in relation to other species, we have also evolved bias toward things we perceive as peripheral. One example is found in the phenomenon of 'plant blindness'.

Being subatomic and microscopic, plant processes are notoriously hard to observe, yet we can broadly trace their movements through monitoring the currents and signals plants give off as they live. According to plant neurobiolo-

gist Stefano Mancuso, humans notice animals far more readily than plants. [4] Mancuso illustrates this phenomenon, called 'plant blindness', by the simple act of showing humans pictures with people, animals and plants, and observing that time and again many human subjects notice the plants last: after the humans and other animals. Are we *homo sapiens* ignorant of the gifts of plants, their support for the oxygen cycle that keeps us all alive, and feeds the food we eat? Sometimes, the answer is 'yes'. Existing within the pressing temporal reality of an entropically spinning climate emergency, we might also feel that art has a responsibility to gesture toward new ways of co-composing with our non-human kin, in a way that draws attention to their significant contribution to all life.

Plant blindness, an evolutionary bias, helps explain why some humans selectively perceive the role, value, contributions and activities of plants as less necessary than those of animals. [5] Another approach that humans have taken to figuring plants is the notion of their passivity. Passive objects are not threatening, so we fail to notice them. Thought to be an evolutionary attribute of the human ocular system, plant blindness generates a socio-cultural affect where humans fail to notice plants, even when they are right in front of them. This politics of space, where we notice perceived threats and act accordingly, is particularly prescient in relation to the pandemic, where our virus foe is indeed unseen, attacking by stealth and immersing the human body in its Bacterioscene. [6] Yet, could the Bacterioscene also operate as a counterbalance to the anthro(s)cene, with both concepts offering new vectors and potentials for posthumanism? This might suggest that what is unseen actively generates a 'scene', perhaps of fear, anxiety, loss, might also afford a reaching out to new pathways and potentials. In order to re-present the big H of Humanism at a more humane scale, we might counter with a posthumanist twist that, with Donna Haraway, fosters a horizontal, networked relationship with nonhuman kin.[7]

Examining this scene further, we find the same Humanism that figures plants as passive, does so to afford an opportunity for exploitative networks of resource extraction to take what they need and turn it into wealth. Such tentacles grasp us today through the pervasive economic logic of neo-liberal capitalism. This scene exists in contradistinction to the scientific reality that plants are the industrious producers of approximately 95% of the biomass on Earth, supporting all the systems that every organism needs to survive. Plant neurobiology speaks to the material reality, unravelled by quantum physics, that every particle in the universe is connected to its nearest neighbour, and through those neighbours to all other things. While quantum imaging has provided visual proof of this connection (Barad 2008) it is a concept that has always been known to indigenous people, and in my culture, Māori from Aotearoa/ New

Zealand, we understand this connection between vegetal, organic, to underpin all material and cosmological reality.

Voxel Plants in Extended Reality

To avoid full immersion in the potentially deadly Bacterioscene, many *homo sapiens* moved further into the technological virtual during this ongoing global pandemic. Yet, *homo sapiens* immersion in the ‘technological virtual’, did not necessarily also signal an eschewal of the organic. Artists enthralled with plants found ways to reconstitute their organic kin in virtual spaces. Struck by the pandemic, the world looked to move everything online, with greater and lesser success. Voxel’s – or ‘volumetric pixels’ in non-abbreviated form – became central to the language of a range of online artistic mediums. After February 2020, the platform Mozilla Hubs, an open source shared virtual space platform with ambitions to become a game metaverse, soon blossomed with artistic creations. One peak amidst this wave of virtuality might be identified as the Ars Electronica Hubs exhibition, *In Kepler’s Garden’s* (7-12 September 2020). For artists who work with virtual spaces, the pandemic provided a fruitful opportunity to re-figure conventional relations with gallery space and offered the capacity to introduce wider audiences to virtuality registered in three dimensions. In collaboration with VR/XR artist Alison Bennett, First Nations artist Rewa Wright (Ngāpuhi and Te Uri o Hau) built a series of 3D photogrammetry point cloud rooms for the Ars Electronica Newcastle Garden. The networked platform was Mozilla Hubs, an open-source portal through which to stream audio, pre-recorded video, and host artist live telematic multi-user performances. Into these liminal and evolving mediatic spaces, a community of 14 sound artists and electronic musicians were invited to experiment with collaborative and networked performance, to co-create a ‘contact zone’ (Haraway 2006), fit for the future beyond the now. One of the key works, *Cherry blossom Spheres*, by Alison Bennett formed the entry area of the WebXR room network.

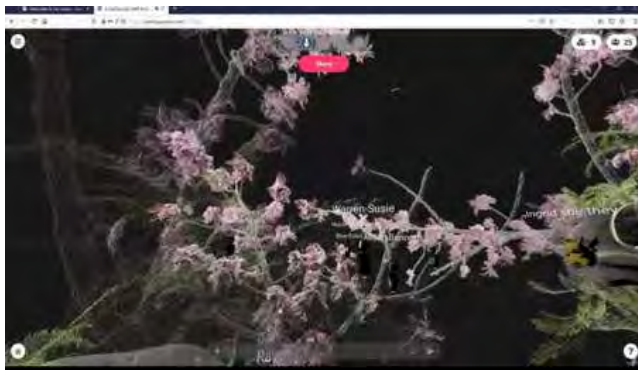

Figure 3. Screenshot from Dr. Alison Bennett’s WebXR hubs room at the Ars Electronica Newcastle Garden, September 2020. Name tags index participants interacting with the cherry blossoms. Image used with permission of Dr. Bennett.

This virtual room was designed around a point cloud re-versioning of delicate cherry blossoms from Bennett’s Melbourne Garden. Bennett’s expertise in plant photogrammetry is influenced by a postrepresentational approach to the organic world, a remote re-versioning of blossoms that can only bloom as networked art. These delicately rendered, scanned images separated into thin air as participant’s passed through. This experience was accessed

through virtual reality headsets, as well as on desktop, however only the former experience offered the actual feeling of parting the blossoms’ voxels. Bennett (with curator Wright and other present artists), hosted tours of rooms network throughout the festival. As participants shuffled closer amongst the blossoms, like anthropo(s)genic faeries in an occult Midsummer Night’s Dream, their digital avatars nodded tiny voxelated heads adorned with name tag crowns (Fig. 3).

Volumetric Pixel Forest (2021) was a co-composition with a generative adversarial network and an *agave attenuata* plant, crafted into an audio-visual performance file. [4] The neural network was called upon to interpret human visual data: filmed video footage from live performance in mixed reality by the artists. The performances consisted of interactive sequences made in Unity and Touch Designer, and the concept was that the Generative Adversarial Network (Style GAN 2), would further process this data and

Figure 4. Still from *Volumetric Pixel Forest*, ML/Human/Plant co-composed file.[8]

produce its own reassembled file. Then, the artist would take that file and build a new interactive performance using its visual elements. The initial process of uploading video footage of performances through a GAN (using the ML Runway software), created a new sequence of data based on prior documentation of art installations. Now, reassembled by machine learning algorithms as filtered by the GAN, in a posthuman sense it might be said that the data was intra active amongst its own ‘kin’, through the vibrant process of filtering optical attributes from each adjacent video frame. This process is mysterious for the human interlocutors who will eventually take the processed data and create a new performance. The GAN filters data on completely different grounds of selection to what a human eye would have chosen, with the final rendered result emergent through a careful computational privileging of certain attributes (such as depth, luma, edges). Human selections would have revealed an aesthetic bias, based on thousands of years of human brain-eye evolution and preferences for certain types of aesthetic form. *Homo sapiens* tend to privilege concerns such as complimentary colour, balanced composition, clarity of line and perspective. Once the Style GAN had rendered its data, the artist then exported the results to a custom-made network in Touch Designer, where feedback and noise was overlaid to distort the already distorted field of machine learning data further. Since the GAN used was trained to recognise human faces rather than plants, an intentional choice by the artists, plant forms become re-versioned around the human body.

Summary

Thinking around plant blindness and with posthumanism, this essay has speculated on Anthropocene as a scientific vector, and Anthro(s)cene, as a stage of visibility where we might lure new conjunction of devices, humans, plants and algorithms. Fearful of the Bacterioscene, homo sapiens retreated into the technological virtual, however this was quickly filled with new imaging of the organic. Already, speculative spaces are opened that offer new affordances and remind us that outside, while we retreat from the pandemic, the climate catastrophe unfolds.

LIMBO (2021) – The Sea Levels in a Sound and Visual Immersive Experience

André Araújo, Nuno Sousa, Marta de Menezes

Affiliation (s) Cultivamos Cultura, EctopiaLab, Departamento de Comunicação e Arte da Universidade de Aveiro (DeCA-UA), Faculdade de Medicina da Universidade de Lisboa (FMUL), Núcleo de Investigação Arte e Multimédia do ISCE (NIAM)

Abstract

LIMBO (2021) is a Live Sound and Live Visuals performance that reflects on the rise of the sea levels environmental issue, its impact and effects in our cities and countries. Being both the visuals and the sound designs constructed in an improvised live performance, the method on which the performance itself is built – intrinsically connecting both mediums – has got layers of complexity, not only from a technical perspective. That synesthetic relationship is also indeed dialectic: how to construct a live sound thinking of a visual impact and how to construct a live visual to be “disturbed” by the sound. Or, in simpler terms, how to paint with music and how to play music with paint. From this, the *voyage* about our impact in the loss of our cities, of our biodiversity, on our heritage is a meditative, immersive, and reflective act, and a both personal and collective experience.

Keywords

Live, Sound, Visuals, Performance, Sea, Climate Change, Improvisation.

Introduction

According to the recent special report on *Sea Level Rise and Implications for Low-Lying Islands, Coasts and Communities* for the Intergovernmental Panel on Climate Change, the rate of Global Mean Sea Level (GMSL) is “rising and accelerating”, as the sum of glacier and ice sheet contribution is now its dominant source. The main cause of GMSL, that went from 1.4 mm/yr over the period of 1901-1990 to 3.2 mm/yr in the period of 1993-2015, is presented to be the “anthropogenic forcing”, which is, indeed, the human action. Throughout the report, several risks and impacts are presented, from the socio-economical effects to the natural environmental issues to our ecosystems and world health. [1]

Indeed, the reflection about this major problem is the framework for the referenced performance. This relationship between artists and climate change is a current subject that is creating quite some debate. In an article for *The Guardian*, Andrew Simms recalls Brecht’s challenge to see art not as a mirror but as a hammer to shape reality, sends the clear message: “climate action abhors a cultural vacuum”. [2]

From that premise, it is possible to understand the artworks of several artists and movements such as *Waterlicht*, by Studio Roosegaarde, *Olafur Eliasson’s Ice Watch* or *David Buckland’s Ice Texts* – all works that create awareness for the climate change and, more specifically, to the water, and are, naturally, references for our work.

However, according to Roosen, Klockner and Swim (2017), not all artworks that approach this subject have got

the same level of effectiveness in the public engagement. That way, there are presented several aspects that are considered important for any “climate change artwork” to integrate, for instance, “making use of narrative or metaphor, prompting awareness, attention, and reflection (...) providing a way to visualize climate change and giving the audience a personal experience of the issue (...) inducing a (positive) emotional response, especially when this includes inspiration”. [3]

This artist talk/work-in-progress presentation will be divided in 3 sections: first, an explanation on the construction of the live visuals and its challenges. Secondly, the same principle will apply to a detailed approach to the live sound constructions. Finally, the last section will explain the mechanisms, questions and solutions encountered to assemble both in a live performance act.

Figure 1 LIMBO (2021) Visuals Example Frame

About the Live Visuals

The overall of the visual contents was questioned from the beginning of the process. We realized that the interaction between two spheres would allow for an interesting result while maintaining a strong cohesion with the main theme.

Structurally, there are two spheres, one that has as a base input images of the globe and representations of the sea levels with the respective graphic representations and the other layer, in translucent and transparent parts, surrounds the first one like an atmosphere.

For us, it was also very interesting to put images that often appear in 2D, such as the evolution of the sea levels, the defrost or the rising temperature of the seas, to 3D. This enhances the association that these issues are “our” world. This “worlds” are indeed the Planet Earth and this way one is indeed able to identify it.

Figure 2 Layout of Blender 3D interface for the performance design.

The visuals were designed not only to react to the sound, but also to emerge and mark their presence with an intensity of color and light according to sound. This allows for strong moments of clear connection between the audio and visuals. The overall environment created by these two components is consolidated by the focus on the simple circle shape projected on the space. Often in this genre of live audiovisual performances, it is usual just to associate sounds with strong flashing movements. Our goal was also to create a more meditative environment, not an aggressive one, but a reflective where the visuals and the sound don't need an intense movement to create a synesthetic relationship.

The elaboration of the visual component constitutes firstly in an establishment of what would be base content layers and effects. These components were designed with a procedural structure that allows the interference of any type of input in the variables of the system, later it was added the interaction of certain frequencies in the variables of the visual components.

Inside the structures of the visual components, there are a large number of variables or variations that were attributed to the time but were changed to the variables that come from the sound. Blender 3D allows the live input of live audio and interprets that as an array of frequencies that are then associated to the visual variables and, that way, make them fluctuate with sound.

About the Live Sound

About the construction of the sound design and musical environment there are two dimensions that require further explanation: on one hand, the sound itself – how it's built, its improvisational construction and how it relates to underwater sound recordings and, on another hand, the adaptations it requires to melt with the visual side, returning to the idea of "how to paint with music", with is, how to create a music for its visual impacts.

The sound has a central role in the creation of a reflective environment. In fact, not only for its impact in the visual side, and consequently, in the construction of the narrative along the performance, but for its meditative and reflective entourage that bonds the audience to the piece and, for that reason, the subject and narrative.

The sound has got two main layers that interact. First, the processed saxophone live sound, with several audio effects that echo and distort the melodies, give somewhat the

impression of them coming from underwater. Indeed, the fact that the audience can identify that the melodies are coming from a person who is playing is not a detail. It is a human hand that is producing the sounds, it is a human hand that is producing that sounds that impact the visual of the globe and it is a human hand that, unfortunately, is producing the effects on the GMSL. Also, the melodies that recall the idea of memories, heritage are also human characteristics that adds layers of engagement to the performance.

Behind all this, there are layers of underwater sound recordings from different depth (2m, 5m and 10m). Also, sound recordings of dolphins step up in a dialogue with the melodies. The dolphins, as well as whales, are under a huge threat from climate change and the sea level rise, as it can affect "the timing and ranges of their migration, their distribution and even their ability to reproduce". [4]

Because the sound is evaluated primarily by its impact on the visuals, and the way the communicate is by a reading of the frequencies of the sound, some considerations are important. Firstly, it is important to construct a pedal of sound to trigger the effects on the globe, otherwise they wouldn't exist as they are dependent on the sound to appear.

After the stabilization of the pedal, it is important to create different sounds for the globe to change and evolve in different shapes. The use of a spectrum that only captures the frequencies help the fact that there is no need to great intensity fluctuations.

The fact that the sound is produced in a live improvisation is crucial for this synesthetic performance as the sound is produced with a live attention to its impact on the image. Mitchell Whitelaw presents this as 'cross-modal' sense, the audiovisual sense, in which and by which diverse media are conceived and perceived together, equally, made from the same, in our performance, frequencies. [5] The sensorial bond between sound and image, and for Whitelaw and Cooke, "what live audio-visual performance works seek to do is precisely to 'make a new sense'". [6]

About the Performance

Why is it different from a sound + image performance? First of all, as explained, the constructing is unified. That is, there is no separate visual and audible perception as the goal is creating a new sense, where the audio and visual come as one.

Despite that, the interfaces in the computers need to be separated, which means one computer is generating the audio and the other the sounds, and they are only connected via an audio jack. The way we found to bring the interfaces even closer was to connect hardware (digital controllers) that we could map to control the performance.

Because of that, the knobs and keys create one “giant controller” that, in spite of being connect to both laptops, creates an analog interface that can be controlled by all the performers at the same time. This “giant controller” is still a work in progress, if not by the fact that there are always new ways to map, organize and expand the analog control of the digital interfaces, connecting them even further.

In the improvisation aspect, it is important to mention that a great amount of the audiovisual creation is programed to be randomized, so that, in the improvisation, we have to adapt, in real time, the interactions we want. This layer of unpredictability is key to engage in an improvisation performance, otherwise the performance would be “trapped” in a somewhat fixed form and, consequently, lose a great aspect of complexity and interest.

Acknowledgments

Plymouth Marine Laboratory for the inspiration and image sources. Robertina Sebjanic for the underwater sounds. Michela Magas, Andrew Dubber and all the MTF Labs crew and participants.

Authors Biographies

André Araújo is a Musician/Visual Artist from Porto. Since his childhood, he plays the Flute, culminating in his studies at the Conservatory of Music of Porto where he transitioned from classical music to Jazz and Improvised Music. That way, he joins the Koninklijke Conservatorium Brussel (Royal Conservatory of Brussels, Belgium) where he completes his bachelor’s degree in jazz (Cum Laude). His musical evolution in the Belgian capital, increasingly approaching electronic music, free jazz and improvised music, led him to feel the need to associate visual interaction components to his musical practice. Nowadays, he’s taking a master’s degree in Contemporary Artistic Practice at the University of Aveiro. He is developing projects and experiencing the way his music interacts in various ways, namely in Performance, Digital Video Art, Net Art, Installation, Virtual Reality, among others.

Nuno Sousa is a multimedia student, with a degree in production of interactive content and multimedia, entered the erasmus program where he studied cinema on the Krzysztof Kieslowki Faculty of Radio and Television. His specialization is the modeling and rendering of 3d content, mainly interested in ceramic pieces and portraying people, moments or experiences in digital media. Over time he has collaborated in several projects predominantly as a Photogrametry freelancer, he is now starting a master’s degree in contemporary art.

Marta de Menezes (born 1975) is a Portuguese artist, with a Degree in Fine Arts from the University of Lisbon and a MSt from the University of Oxford. De Menezes is director of Cultivamos Cultura, the leading institution devoted to experimental art in Portugal and Ectopia, dedicated to facilitate the collaborative work between artists and scientists. Marta de Menezes has worked in the intersection of art and biology since the late 90s, in the UK, Australia, the Netherlands, and Portugal, exploring the conceptual and aesthetic opportunities offered by biological sciences for visual representation in the arts. Her work has been widely exhibited in major venues in all continents, presented in most anthologies devoted to bioart, discussed in doctoral dissertations, and considered an example of research in the visual arts. Among the most recent international exhibitions, de Menezes was invited for the 2019 Ars Electronica Festival: Out of the Box, and organized two 2020 Ars Electronica Gardens (Lisbon and São Luis). She was invited to be the official representation of Portugal at the London Design Biennale 2016 and exhibited at the Beijing Biennale of New Media Art 2016. DeMenezes was nominated in 2015 by Time and Fortune magazines for the Art and Technology Awards 2015.

INTER/her: An immersive journey inside the female body – artist talk

Abstract

An immersive installation and Virtual Reality artwork focussed on post-reproductive diseases and pain over 40's women experience: endometriosis, fibroids, polyps, Ovarian and other cysts, cervical, ovarian, uterine and endometrial cancers. The sensory and emotional experience moving from the outside in within a real dome space into VR space, with a 3D audio soundscape of the voices and stories of real women recounting their experiences, making it an intimate, emotional and possibly haunting experience, with accompanying wearable haptic garment providing a visceral vibration responsive experience on the lower abdomen, where the various diseases occur.

Keywords

Women's reproductive diseases, virtual reality, haptic interaction, intimate immersive experience, interactive installation.

Introduction

INTER/her focusses on the difficulties women in diagnosis and treatment of various reproductive diseases face, and it was motivated directly from the artist's own experience fighting (and winning) against ovarian cancer in 2016/17. It provided the personal imperative to make an artwork that would give something back to other women in the same circumstance. The project is based on the experience and journey through the healthcare system but using the artist's own art practice as the frame in which to communicate the experiences, emanating from silence, inconsistent information and varying medical support for women's health. It is also inspired by the stories she then started to hear from friends and family about their reproductive disease experiences, which seemed hidden or kept to themselves until the topic was raised.

INTER/her is an intimate VR immersive exploration of the inner world of middle-aged women's bodies and the post-reproductive diseases they suffer, such as endometriosis, fibroids, polyps, Ovarian and other cysts, cervical, ovarian, uterine and endometrial cancers - with a focus on female health as personal exploration, conversation starter, and community building.

The sensory and emotional experience moves from the outside, within a real dome space, into VR space with a spatial audio soundscape of the stories in the voices of real women recounting their experiences of diseases and pain, with accompanying wearable haptic garment providing a visceral vibration responsive experience on the lower abdomen, where the various diseases occur, making it an intimate, emotional and possibly haunting experience.

THEORY &/ IN PRACTICE

INTER/her explores concerns of female mortality, but also a survivalist instinct to cleanse the body to heal it; positioning the physical body as a site to examine the psychological issues of womanhood. Themes of sense of self and identity, loss of body parts, body image, sexuality, confusion, pain and lack of reliable information, still male-dominated medical institutions, body betrayal, ailments and tumors - representing negative festering of pain and anger, and feelings of mortality.

Initially, the project started from a more overtly techno-feminist perspective, but overtime and while focussing on the practical and aesthetic production with the mainly fe-

male team, the intellectual feminist perspective fell away to a more intimate, emotional feminist camaraderie motivation. All the women on the team had faced the same issues that are explored in the piece itself, from polyps, fibroids and endometriosis to menopause and HRT and ongoing testing and biopsies and pain.

In terms of women's bodies, as Caroline Criado Perez explains (2020) in her book *Invisible Women: Exposing Data Bias in a World Designed for Men* - the male body is the standard body in most aspects of the world, and the female body is the "other". In terms of ISEA's Themes the Human - Non-Human is the closest fit for the work and this talk, as once the female body, 51% of the world's population, is no longer considered "other" but also standard, we can then start to think about what it means to be human. If women's bodies are not standard, are they considered non-human? Women's bodies have not been researched enough nor considered important enough for GP's to spend more than a 1/2 hour optional study module (in the UK, according to Davina McColl's Menopause documentary, Chanel 4, June 2021).

Once we understand women's bodies, as well as the range of bodies that exist (differently abled, trans bodies, animal, etc.), we can begin to answer how to become bodies in the world. Once we understand the female body better and how hormones affect the brain and body, and other aspects of the female experience of pain and diseases, we can better address the other questions of humanity and non-humanity. A better future is when women's bodies are considered as important as men's and receive the research and treatment on equal basis to men.

Figure 1. Early interior artwork for inside the VR experience © January 2021 designer for *INTER/her*

From a first-person perspective of 'feeling from the inside, excerpts from the books "*Invisible Women*" by Perez, on the way the health care system fails to diagnose or support women in pain and disease; and "*WOMAN: An Intimate Geography*" by Natalie Angier for the biology dimension, exploring concerns of mortality, but also a survivalist sense to cleanse the body to heal it; positioning the physical body as a site to explore psychological issues of womanhood and the sense of self, exploring the body: vagina, uterus, cervix, Fallopian tubes, ovaries, bleeding,

pain, endometriosis, Fibroids, Cysts and other disorders, technology, treatment, surgery, etc. All threaded with actual women voicing their experiences with bespoke music and sound effects to accompany each story.

Figure 2. Visitor inside the “Sitting Womb” for the audience testing © May 30th 2021, artist

Methods

The stories were initially collected via social media, calls, and volunteers. The intention was to see them in person and record their voices, when the pandemic started a new plan was implemented: to use a combination of real stories and excerpt passages from the above books, especially, Angier who has a poetic way of writing about internal female body parts and bodily processes. Voice recordings we sent in, but the quality was not high enough to use, and the stories at times would meander too much to be usable – understandably as these women had lived it and their experience was not merely a sound bite. Even Baker’s own ovarian cancer story had to be edited and then tossed for being too long.

The main collaborators started working together on a prototype funded by the main artist’s university from October 2019 to June 2020, and enabled Baker to do the fundamental research and development, create the story/narrative/script (loosely), and the interaction design, and other pre-production elements, as well as recording some of the story with women, and to do a form rapid prototyping in VRChat. However, all work was done on a part-time basis to the busy schedule of both artists, and the funding was not enough to undertake actual production, although Alvarez is invested in the topic herself and put a lot of extra work into it.

The main collaborator helped the artist to understand what was technically possible using the software Unity and 3D design tools, as well as helping to create a prototype and a solid plan for the final stage of the project. Then with the success of further funding from the Arts Council England came in September 2020, the two were able to build a larger production team to take the project to exhibition stage, as well as having the Access Studios curator to partner for the project to exhibit it in Sheffield, as well as the

university co-funding the project to exhibit in Folkestone in summer 2021.

Figure 3. Haptic corset with vibrating actuators in the belt, designed by Bushra Burge © March 2021 designer for *INTER/her*

The team had many shared personal and artistic experiences together and in VR, using various tools available: such as TiltBrush, Gravity Sketch, Blender, Unity, Side-Quest and GitHub. Alvarez helped Baker to understand what was technically possible using the software Unity and 3D design tools, as well as helping to create a prototype and a solid plan for the next (current) stage of the project.

Experience

INTER/her is an immersive visual journey and emotional experience, from the inside out within the bespoke tent space, with accompanying wearable haptic garment providing a visceral vibration responsive experience on the lower abdomen. The tent has a vulva-shaped opening and up to 3 women/visitors can lay on red beanbag chairs on the floor inside and are pre-dressed in the haptic corset, to feel the sensations on the lower abdomen triggered by related stories / voices being heard in the 360 interior body space.

Participants are dressed in the haptic corset, fitted with embedded vibration motors actuators in order for people to feel different sensations on the lower abdomen while listening to the stories / voices. The imagery is of abstract organic objects like flowers, plants, and fungi, to represent the different diseases women can suffer from that grow and mutate, as each story is told to keep the attention of the visitors before they move on to the next. Spatialised sound with the women’s voices telling their stories and women’s disease experiences, and bespoke soundtrack and ambient sound effects of breath and heartbeat, for atmosphere - all to support the main narrative and move visitors to the next story and to empathise or relate to the experiences of the women whose voices are heard.

Each woman/visitor is debriefed afterward to ensure that they are ok with what they experienced and to discuss their experience, as well as to give feedback on the experience. The exhibition will be accompanied by female health information and health support charity leaflets, to take away and to help inform and support visitors to reflect on their own bodies.

Visitor Feedback Quotation

“I just wanted to say that the work was really affecting, and I could relate to so many of the stories shared. My mum’s suffering was dismissed when she complained of heavy and constant bleeding - she died three weeks later from a cancer that had originated in the womb. She was 46. I could also personally relate to the work, through past experiences at sexual health clinics, GPs, hospitals. Your work is so important - thank you so much for realising it. I am currently ...research[ing]...works to reclaim female subjectivity using technology with geological sites of trauma...”

Victoria Lucas
October 18, 2021.

Conclusion

For the ISEA 2022 there will be a full, in person, exhibition of the VR Installation on site in Barcelona for symposium attendees to experience and discuss, to exchange views on the larger feminist and medical issues. The artists talk will explore the production and exhibition development through to outcomes and observations of and from the various audiences and locations in receiving and experiencing the work as an artwork, conversation starter and as a feminist statement on reproductive health failings in the larger medical community and societal view of the female body.

Acknowledgements

INTER/her was funded by the generous support of the Arts Council England National Lottery Fund Arts Grants Fund 2020, and the Research Funds of the University for the Creative Arts 2019-20, and in partnership with Access Space Studios and UCA.

Extemporal: an Ecomedia Platform for Critical Making

Kimberley Bianca

PhD Candidate, Critical Media Practices
University of Colorado Boulder
kimberley.bianca@gmail.com

Abstract

This doctoral work in progress centres around facilitating intergenerational Critical Making programs and designing a participatory platform for engaging in DIY citizenship and connecting environmental concerns. Through hybrid online and in-person workshops, meetups, and community art projects, the research investigates the prospects and problems of participation in exchanging ideas, skills, and upcycling. This presentation reviews independent maker spaces, eco-art, citizen-science and grassroots participatory platforms where alternate modes of media-making are possible. The culmination of the doctoral work is a participatory project for senior citizens, youth, artists, activists, and citizen scientists to contribute art, data (mostly on water quality), documentation of restoration efforts, and local stories in rural Colorado, U.S. The media submitted to the platform will be used in public large-scale interactive projection experiences. This will be the first arts-driven project with the citizen science platform CitSci.org.

Keywords

Community platform, citizen science, participatory art, critical making, ecomedia, Capitalocene, intergenerational art, DIY citizenship.

Ecomedia

During COP26, Facebook hosted ads on climate scepticism. UK-based think-tank InfluenceMap found that several fossil fuel companies and lobbying groups spent \$574,000 on Facebook ads promoting their environmental efforts, i.e., greenwashing, during the summit, resulting in more than 22 million impressions. [1] Facebook, Google, and Apple have been relatively successful in cutting their emissions, implementing renewables, and planting trees in the last 4-5 years. [2] Microsoft is well on its way to capturing carbon for carbon negative. [3] However, they are all large enough that energy prices make up a significant share of their costs. Thus, it makes sense to invest in more efficient technology either by reducing energy consumption or by moving it to where it is cheaper.

Thomas Moore questions how the complexities of planetary crisis and global accumulation can be reconciled and outlines that the “Capitalocene signifies capitalism as a way of organizing nature—as a multispecies, situated, capitalist world-ecology.” [4] For example, the COVID-19

pandemic highlights how diseases become pandemics due to industrial reconfigurations of nature, and ecological and socioeconomic injustices. The primary source of viruses that emerge from capitalism is large-scale industrial agriculture. The practices of capitalist agriculture set the stage for market trends in China, and commodity nations contribute to new epidemiology’s along the route and that the globalised manufacturing line expedites the pathogen virulence and transmission process. [5]

As Moore explains, the Capitalocene is a system of power, profit, and reproduction in the web of life. Capital persists through the privatization of commons, and then the common good is resold as private debt. The write-off of obsolete stock generates waste into the environment, which claims defers to another generation and market crisis. Waste is not an unintended consequence of consumerism since there would be no consumer capital without it. [6]

Despite the detrimental resource demands of technological infrastructure, there is strong justification that individuals and communities should have the technical means to change their environments and social structures right now. The way around this contradiction is thinking of complementary ways which empower individuals and communities to generate a sustainable future.

In response to making climate change science more accessible, there have been calls across the arts, humanities, and sciences to create alternative structures for climate change communication—participatory and collaborative structures. Ecomedia is not merely representative, nor is it focused on the aesthetic creation of artefacts. Ecomedia is socially engaged. Community organisers and facilitators working in ecomedia and eco art respond by producing participatory art, workshops, and platforms that engage community voices. These community platforms are supporting a new era of citizen-driven social and environmental justice.

Critical Making

Rather than bringing people together to solve a problem, we can collaborate on possibilities of waste, restoration and repurposing with Critical Making. describes Critical Making as an "ongoing critical analysis of materials,

designs, constraints, and outcomes, participants in Critical Making exercises together perform a practice-based engagement with pragmatic and theoretical issues." [7] Thus, Critical Making is a practice for questioning the cultural implications of technology through experimentation with forms and materials. Critical making also generates new knowledge of production by engaging in commons and open-source ecology, enabling the distribution of agency, power, and resources amongst communities. Beyond the makerspaces and hackerspaces that have increased in the last decade, critical making does not need a space and does not need to solve problems; but can appear in these spaces or come out of them. A lab or maker space can provide the vehicle for communities to develop.

In 2021, I co-facilitated a hybrid maker space with Brandon Grossman. The maker space was part of a STEM outreach program for youth ages 6-12 in foster care in the Boulder-Longmont-Lafayette area. During foster placement, youth frequently move between homes, often as short as two weeks for their initial placement, and some are never placed. Aiming to make a more horizontal environment where agency is shared despite the levels and durations of care, we facilitated asynchronous activities through monthly email prompts, three meetups on Zoom, and a web gallery using the collaboration software Padlet where the families could upload their creations. Brandon and I would write and reply to comments on the posts, as well as make posts. We found that these distributed maker activities and meetings on Zoom to connect through stories are modes for attending to new family dynamics and subsequently form rapid creative relationships between youth and their caretakers.

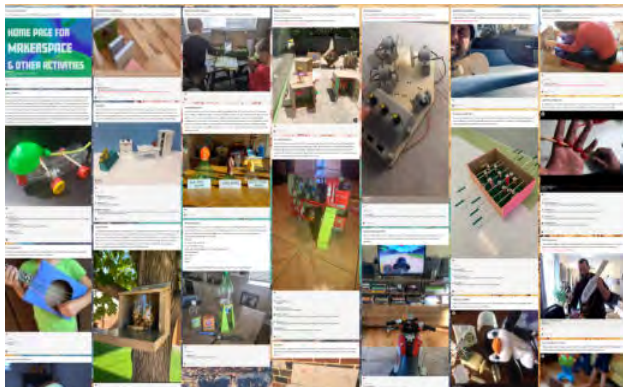

Figure 1. Screenshot of Extemporal: online maker space for youth in foster care. ©Kimberley Bianca

Another ongoing project is futures2051, a series of maker workshops for upcycling e-waste sourced from objects found at home or a digital file to create artefacts from the future. Supported by CU Boulder's Environmental Center for an Earth Day program around the year 2051, I co-facilitated the online workshops with media artist Sarah

Manning. The central prompts were: What would everyday objects look like in 2051? What kind of future do we want to contribute to? Participant projects included a DIY musical instrument being repurposed as a cable management holder, a power button being repaired, a digital collage made from scanning in scrap magazines, and a handmade projector. We found that this style of workshopping has greater potential to be in-person as we could not readily exchange tools and resources.

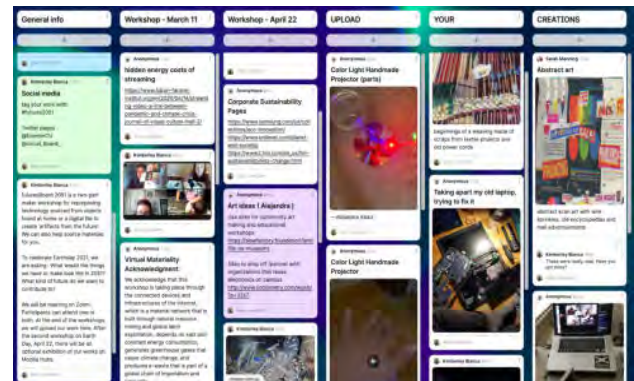

Figure 2. Screenshot of Extemporal: futures2051 workshop participation board. ©Kimberley Bianca

Community-Based Design

Communities are agents of change. They can be highly influential in raising awareness of environmental and social issues, revealing peer-to-peer, community, and national implications around sustainability and equitable access to technology. Conducting community workshops, applying user-friendly models and technology such as web-based systems, participatory decision making throughout the design and development of programs, and offering technical assistance to individuals and groups are all examples of community-based design. [8] An ongoing question I have with Extemporal is, how can we be engaged with the goals of sustainability as a stimulant and not as a restriction? This praxis emphasises community-centred caring that allows for justice and climate health.

Web-assisted platforms allow community members to share individual and collaborative contributions and stories. Furthermore, the cooperation between humans and non-human agents (software and online tools) can help distribute leadership, enabling facilitators, artists, and the community to participate in decision-making and program design. However, it is important to be cautious of any system's expectations that suggest technology glues humans together, even though technology does provoke networking. [9] Furthermore, using productivity platforms, social networking platforms, crowdfunding, meetups, and recognising that often discourse in local government is interested in participatory and networked creative formats can enhance participation and support in local

environmental initiatives and leadership in supporting a technologically mediated infrastructure eco-justice and social justice. During the next iteration, my practitioner approach as a community-based designer involves participating in activities with the community, communicating with the partners, and iteratively designing how the platform is structured and presented. I am also paying attention to the longevity of the platform. Sustaining relationships is difficult when community-engaged research projects end. I have learned that to sustain things, we need to think about how relationships are formed and disrupted. A lasting relationship is not something you can merely construct.

A method of community-based design is as a participant-observer, meaning my contribution must be explicit rather than covert, keeping one foot outside the scene to map assemblages in the space and maintain the stance to reflect critically on my actions and behaviour. [10] I must be reflexive and respect the people I interact with, assuring my research is descriptive and instructive rather than prescriptive.

On the design side, my approach involves prototyping the web platform to develop a community forum and identify ways to build trust and share agency. Extemporal is a platform for creative dialogue and managing resources based on trust and cooperation.

Contribution

How can critical media making bring intergenerational groups together to engage in DIY citizenship and to visualize environmental concerns? My interest in this question relates to my enthusiasm to design community platforms that engage intergenerational groups in cognitively accessible dialogue on environmental issues, create spaces where alternate modes of media-making are possible, and encourage inclusive participation during the COVID-19 pandemic.

Currently, Extemporal is a web-assisted community platform, linking commonly available online tools to foster the community projects and exploratory workshops that have identified activities and approaches facilitators can implement moving forward. In the future, I will create a web-based platform with a custom website that includes many of the elements that have assisted the activities but will have more secure privacy and moderation controls.

In July and August 2022, I will be working in Trinidad, Colorado, and Grand Lake, Colorado to develop a participatory archive for senior citizens, youth, artists, activists, and citizen scientists to contribute art, data (mostly on water quality), photography, documentation of post-fires restoration efforts, and traditional stories. This will be the first arts-driven project with the citizen science initiative and platform CitSci (<https://citsci.org>). Then, I will facilitate workshops with locals in sorting through this media and making a collage of visuals for the video

projections. Rather than being a solo facilitator, I advocate it is just as important for community members to take leadership which would be a unique learning experience for all involved. This collaborative or distributed approach to facilitation contributes to original community-engaged scholarship. Working with Marilyn Leuszler of the Trinidad Creative District and Ken Fucik from Grand Lake Creative District, we will develop interactive projection experiences in both locations. During the Space to Create opening in Trinidad, and the Live Water festival at Grand Lake, both in July, I will program, produce, and operate the projection experience where people will be able to interact with the visuals co-curated in the workshops.

Thus far, this research has identified that youth advocate for environmental problems that adults shy from, and the ageing community has practical fixing/repairing experience youth could learn. Responding to the isolation of people most at-risk and youth who are in positions with little voice and agency during COVID-19, Extemporal aims to connect these generational divides going forward in current and future crises. Extemporal could be developed to include a range of communities, but this is a practical decision based on an ecological crisis and a crisis of agency. The ageing community and youth demand more decision-making on local environmental concerns. Critical Making enables the distribution of agency, power, and resources amongst communities.

Conclusion

With the premise that Critical Making and community platforms can evaluate social inequity and question how capitalism destroys ecosystems, this research aims to build a new methodology at the intersection of critical making and community-based design. The projects are supported by Extemporal, a platform that hosts meetups, workshops, and a forum for exchanging artefacts. With community programs and platform design, the research encourages participation during ecological crises and attempts to do this by making concerns of electronic waste cognitively accessible and creatively engaging.

Author Biography

Kimberley Bianca is an Australian media artist and community events organiser based in the United States. Her PhD research activities at The University of Colorado Boulder include workshops, site-specific electronic arts, networked performance forms, and platform design. In 2019, Bianca completed her master's thesis *Electrofringe: A Distributed Curatorial Platform for Electronic Art*, at UNSW in Australia while directing the arts organisation and festival, Electrofringe. Bianca has been a practicing freelance artist, facilitator, media designer, VJ, and audiovisual technician since 2010. She specialises in the development of participatory, mixed reality projects that bring socially engaged practice to performance and multimedia.

Earth or World? Media spaces between the surveil and the Possible.

Lawrence Bird

Space + Image, Sputnik Architecture
Canada
lb@lawrencecywg.ca

Abstract

My practice focuses on the mediated image of body and the land. Much of this work exposes flaws in the modern map of the world – seams and ruptures emerging during the capture and processing of images by automated systems – connecting them to the damage done to Earth by historical and contemporary systems of land division and extraction, including extraction of image. One way my practice achieves this is the disruptive harvesting of aerial and satellite imagery from Google Earth and other popular mapping/imaging platforms, and their projection in public space. Projection sites are chosen for their connection to the theme of each work. Bringing the extracted image back into contact with a material reality from which they are derived goes some way toward healing the damage we and our tools have wrought on the Earth. The product is a phantasmagoric space neither merely material nor image, historical nor contemporary. The work raises the question: who might live in these spaces? What kind of Possible world, and citizen, might they represent?

Keywords

Video, satellite imagery, aerial imagery, Google Earth, projection mapping, architecture, urbanism, public space.

Introduction

My work is preoccupied with the relationship of space and its image. For me, this is where our human condition plays

out: between imaginary and material worlds, between our intimate personal lives and our life as citizens. My artistic practise addresses this condition as it plays out in imagery of the body, and of the land. I have focused for some years on images of geography and landscape (especially western Canada) where human interventions in space – the way we divide up the land and use it for mining, harvesting, building – resonate disturbingly with what we do it its image - capturing it, processing it, commodifying it.

As the representation of a possible space, my work connects with ISEA 2022's concerns, in particular the themes of Futures and Heritages, and Natures and Worlds. My work often takes as its subject historical mapping systems - the products of a colonial agenda – and views them through contemporary surveillance systems – borders, drones, and imaging systems like Google Earth. My critique of Western regimes of representation has focused on maps, images, and plans. Today these are represented by popular mapping and imaging systems like Google Earth, and I share an interest in such platforms with other artists, for example Mishka Henner, Doug Rickard and Jon Rafman.[1] Platforms like these promise us a transparent and liberating map of our world. But they provide us instead with a parallel Earth that entraps us and turns our movement into a monetized product. My intention is to reveal, instead of the perfect map these systems promise, the muddy, complex, and unsettling amalgams of image and space they actually, and accidentally, generate. Using tools internal to these off-the-shelf platforms, I look for seams in the

Figure 1. Image sequence from *Dominion*.

Figure 2. *Dominion* installed, The Forks National Historical Site, Winnipeg, 2018.

imagery we assume have been sewn together perfectly. Rifts in this fabric are caused by the platform's internal processing of images; they include extreme pixellation of low-resolution imagery, technical artefacts like registration marks, juxtapositions of images captured by satellites at different times of day or year, and imperfections in 3D terrain maps and texture mapping as they are generated on the fly (Fig. 1). Digital anomalies often coincide in the image with its content: the scars left on the land by our machines, as well as our economic and political practices. These eerie juxtapositions produce irrational, playful, and disturbing amalgams of image and space. I harvest these spaces and transform them into flows of moving image.

The work is intended to evoke concerns which preoccupied thinkers like Martin Heidegger, Maurice Merleau-Ponty, Gianni Vattimo, and Paul Ricoeur.[2 ,3,4,5] That is: how can we heal the rifts torn in our bodies and souls, and our spatial environment, by modern life and its engagement with technology? My position on this is both fatalistic and optimistic. I think, like Bernard Steigler, that technics are inherent in our humanity; and that inherent in them, in turn, is the breakdown of systems by the drive toward orthography and other forms of perfection.[6] We must depend upon that breakdown if we are to find any freedom within the machine, and this is the key motivation behind my attempts to reveal rifts and ruptures in the regimes of the technical image. The study of the traces of history can be edifying in this respect: it reminds us that if systems broke then, they can break now; and that our citizenship, while threatened today, was once even less assured than it is now. So there is reason for hope. Spaces

that hybridize image and material, natural and technical, historical and potential, are part of that. A key question implied by my work is: who might inhabit such spaces? What kind of Possible might they represent?

As ISEA's thematic statement puts it, the Possible begins with the Polis. It is only through an engagement with the politics of technology, including the legacies of colonialism and the regimes of image that technology serves, that we can begin to transform the damage they – and we – have wrought. That must be the basis for any possibility of a new city, or a new world.

A work from the early stages of the development of this investigation was screened at ISEA 2017 in Manizales, Colombia. *parallel* was a single-channel video tracking the 49th parallel – the US/Canadian border - and anomalies of land use and imaging that exist on the two sides of the border. I also presented a full paper on the ideas behind *parallel* and work in progress. Since then, in part drawing on ideas and techniques I learned at the conference, I have developed a more ambitious work, *Dominion*, and am working on several other projects.

Dominion is a projection-mapped video installation, funded by a Canada Council grant in Research and Creation (Fig. 2). It harvests satellite imagery of the Canadian prairies: images documenting the impact on the landscape of a 19th c. surveying project, the Dominion Land Survey (DLS). The intention of the DLS was to transform a wild landscape into a grid of square fields connected to a rail system that led ultimately to the centre of power in the UK, rendering up the prairies as a source of food. In other words, the DLS was a processor of sorts: cutting up a het-

Figure 3. *Transect* installed, Greenwich Royal Naval College. 2014.

erogeneous world into squares of homogenous crops. Imaging systems do the same thing today: cutting images into pixels or satellite tiles. I use one such imaging system, Google Earth, to identify locations where the DLS collides with natural landforms or Indigenous patterns of land division – in other words, signs of the prairie pushing back against the survey. Some of the distortions to the grid are caused by contradictions internal to the survey itself – where it proves fundamentally inadequate to the task of organizing a complex and rich environment. Connecting these images through trajectories, I turn them into moving images; I interleave the image flows from different trajectories during projections in public places. The places are chosen for their connection with the project’s concerns – in one case, a railway bridge. Projection-mapping brings the images harvested by *Dominion* back in contact with the material world from which they were originally ripped. To me this is one part of the healing process that I think my work represents, and I see it as analogous to the role Ricoeur identifies for narrative: healing the rifts brought into our being by the experience of time. Projection-mapping software also introduces a limited processing of the image; for example generating, in real time, an audio environment from sound samples related to the work (in the case of *Dominion*, ambient sound from the prairies, and a text-to-speech reading of a 19th c. surveyor’s manual).

Besides *Dominion*, the talk revisits three completed projects including *parallel* and *Transect*, which tracked the Prime Meridian and Antimeridian around the planet. It also introduces current work: artist’s books based on *parallel* and *Dominion*; *still places*, which harvests higher-resolution still images of specific anomalies; and *Net*, which addresses international shipping routes and their impact on the landscape. *Net* has just received a media arts Research and Creation grant from the Canada Council for

Figure 4. *still places*. work in progress.

the Arts. This project will extract global shipping routes from public domain sources; generate trajectories from that data; capture along these trajectories satellite imagery of landscapes impacted by the shipping industry; process and project this imagery onto artefacts of the shipping process.

Acknowledgements

I am indebted to the Canada Council for the Arts, the Manitoba Arts Council, and the Winnipeg Arts Council, for financial support in the completion of these projects.

Author Biography

Lawrence Bird practices in architecture and media art. His artwork focuses on relationships of image to space; it has been installed in Winnipeg, Toronto, London (UK), Brussels, and Manizales, Colombia. In design Lawrence works with Sputnik Architecture, Winnipeg, where his concerns are urban design, the public realm, amalgams of rural and urban space, and public art. Lawrence has a PhD in History & Theory of Architecture and a professional degree in architecture (McGill), and a Master's degree in City Design & Social Science from London School of Economics. He recently co-edited *Warming Huts: a decade + of art and architecture on ice* (Dalhousie Architectural Press, 2021), and is a Leonardo peer reviewer. His research has been funded by SSHRC, FQRSC, and Canada Council for the Arts.

SOMATECHNICAL NATURE / VIRTUAL RIVER

Johannes Birringer

DAP-Lab
Schmelz, Germany
johannesbirringer1@gmail.com

Abstract

This presentation features excerpts from two film projects exploring movement and challenges to movement, raising questions about re-embodiment and experiential dimensions of proprioception in inter-pandemic society under a global climate crisis. The primary focus is on techno-choreography (using prosthetic devices and the Oculus Quest2 VR headset) and the somatechnical predicaments in the face of disturbance-based ecologies and blasted landscapes. A second concern is the exploration of new expressive techniques for ageing and differently-abled bodies. *Electric Dance, or How to Talk with Birds* and *How Much of These Hills is Gold* portray a series of outdoor performances during the COVID-19 lockdown periods: 'compositions,' to use Donna Haraway's term, which involve intimate individual and collective probings and drawings-to-perform enacted outdoors in a valley. The films evoke a series of climbs (up electrical power masts and hills) and submergences into river flow, which seek to combine body weather techniques (derived from Japanese butoh dance) with digital processing and speculative drawing in 3D virtual environment. The site-specific performances are creative responses as well as social choreographies in an era of climate crisis.

Keywords

soma-technics, virtual reality, water, climate, body weather, draw-to-perform

1. Introduction

The approximation of a disability-focused model of physical performance in nature and with prosthetic devices raises questions about what techno-choreography promises, in an inter-pandemic era and in a time of extreme environmental disturbance. How does one envision a speculative (VR-designed, digitally composed or augmented) embodied nature, in the face of contaminated diversity and infinite entanglement with multi-species environments? And how does one step inside/outside the "ruin that has become our collective home" (Tsing 2015: 3) and move when such movement is impeded, reduced or traumatized? When I returned to my home valley in July 2021, a few days after my arrival the south- and north-west regions of Germany experienced catastrophic floods. Rivers overflowed, houses were overturned and swept away, lives lost or uprooted. Self-organizing movement became a foray into tangled landscape, which a year before had been stilled by the lock-downs after the outbreak of Covid-19. Stillness and emptiness of course were misleading

metaphors, but rhythms and refrains had changed. Contaminated diversity began to have an overwhelming realness, one which does not treat unimpaired visibility as the norm but allows for a multitude of perceptual variation, plasticity of internal and relational resonance, and intensely tactile, auditory and olfactory engagement. Breathing darkness, following scent, herbs, mosses, lumps, cracks in the soil, slippery rocks in river beds and up the steep hills of a quarry, past wounded fir trees. Textures and life lines that can be referred to as "forest knowledge" (Tsing 2015: 243; Haraway 2016: 181), the kind of vernacular and indigenous learning I grew up with.

Figure 1: *River Row*, film still, 2020. © Johannes Birringer

2. Visible Invisibles

The artwork answers to the life lines and labors on the edges of visibility and translation. It is subjected to the aftermath of the Anthropocene, where ecological awareness, if we follow the pessimistic trail of Timothy Morton's *Dark Ecology* (2016), implicates us all in some sort of environmental film noir. The filmic excerpts I show are not marked by pessimism, though, but by a kind of child-like playfulness with which I approach my childhood valley and seek to reconcile collapsing fragments of a much larger process that cannot be comprehended fully (global climate crisis, global pandemic), and thus cannot be easily enlarged, from a microperformative, molecular and microbial scale upwards. *Somatechnics* is an approach to corporeality which considers it as always bound up with a variety of technologies and techniques, understanding nature as an complex organism urging examinations of the lived experiences engendered within given contexts, and the effects that technologies, technés and techniques have on embodiment and the commons, including the nonhuman elements of the world. What do I mean by virtual river, or why does my last film fictionalize the "Goldbach," the golden brook that runs through my valley and refers back to a 19th century gold rush to my region? In my experience, organizing working on the edge is the "matsutake" part,

times of austerity, when you are in streams, applying new technology (VR headset) to a very simple activity, and moving in space.

Old Rush Fever

My interest in the oldest knowledge and what you find in wilder woods, searching for hidden environments, whether this is through digital media art or digital technology (VR tech or AI/robotics, etc) or my interest in her ethnography of the final era of capitalist mining is mined so beautifully for us, in a section on "latent commons" – in the middle of things – addressing what I consider prosthetics-as-life-lines and dancing on such lines: searching has a rhythm and one follows scent and flow, and an understanding of fungal growth, textures, migratory shifting cultivation, washing stones in the river.

Figure 2: *How Much of These Hills is Gold*, Anette Delarosa washing stones in the river, 2021. © Intakt

4. Undercommons

We do not ask where the energies come from, and how there are commons that may not be good for everyone. There will be infections, inattentions and poachings, the flood will carry things away, the *gaoqiao* (stilts) may not be long enough, and we need to keep arguing. Nature and her natural forces also argue with human and animals, with beavers who reshape streams, with trees and their fungal partners, electric masts. Entanglement indeed. Thus everything is coming out. Forget the shame, or the mythology of the invisible work and humiliation of the rehearsals, it is not that

interesting (Birringer 2018). I always found rehearsals, when we create the kinetic atmospherics, to be most revealing and exposing, thus refreshing. When rehearsing outdoors, up the hills, electric masts, and river streams, the magnetic fields of energy are riveting.

Figure 3: Electric dance, performed by Johannes Birringer and local audience participants, 2020. © Intakt

5. Somatics and Drawing

Figure 4: Draw-to-Perform, *Interaktionslabor*, 2021. © Intakt

We draw on extended canvases. The rain has just stopped. I ask all the participants to go down onto the earth, or roll with the paper rolls, expand their bodies and bodily imaginations, breathe in the air and the smell of the plants surrounding us, open up for the capacities of fluctuating affects, symbiosis and mutations with the graphite, paper, grass, pebble stones and wetness of the surroundings. River flow, row

with it and also observe where and how the bodies are formed and shaped by the environment, the elements, the pebble stones and the moistures.

From here it is a small step into VR. We use the Oculus Quest2 headset to imagine stepping into the same natural environment, except the void, a seemingless infinite and inside this three-dimensional space, as if pulling us forward, we dance the lines that hover and tangle before us, and we are drawn into another dance of an imaginary space, as unreal as it can get, as long as it is algorithmically possible. We return to the sense, and we return afterwards. In the next iteration, we shall address questions that will turn.

“Human Error: Projects That Emphasize “Misuses” of Technology”

Jonah Brucker-Cohen

Lehman College

Bronx, New York, United States

jonah.bruckercohen@lehman.cuny.edu

Abstract

We are often confronted with computer interfaces that are built to be “easy to use”, but in reality, are more confusing than ever. This paper details several artworks that fall under the theme of “Human Error” and consist of software and hardware devices that integrate elements of human error into their design to provoke and materialize human frailty when it comes to operating digital devices and interfaces. This presentation will detail several of those projects as well as the theme of “Human Error” itself.

Keywords

Human Error, Critical Interfaces, Media Design, Interface Design, Art, Hacking, Displacements, User Interfaces

Introduction

Technology is often difficult to use, hard to understand, and confusing to configure. But is it really the technology that is confusing or is it what we bring to the technology? Is “Human Error” [3] the cause of our troubles? “Human Error” is a series of projects that examines and catalogs things we as a population do wrong with technology and the Internet, ultimately making them more human than ever. Technology is not only about productivity, instead its most meaningless aptitudes are what make us hooked. Despite our continued belief that technology is to blame, the truth is that technology does not cause the problems, we as users do. We search for solutions through technology and are too often looking through the wrong lens causing us to do and say things that are nonsensical. “Human Error” is a series of creative interactive works that emphasize human error above predetermined purposes. Each object highlights the errors that we as a population incur on digital devices and objects and emphasizes these defects to create novel interfaces for interaction that highlight human frailty.

Background

Former Professor of Psychology at the University of Manchester James Reason, coined the term “Human Error” [1] in the late 1980s. Reason quantified human error in two distinct categories that of the person approach and the system approach [2]. While the person approach examines errors of individuals in areas of deficit such as forgetfulness, carelessness, negligence and similar, the system approach takes a wider stance and blames human error on organizational mishaps or structural systems that are difficult to master. The projects in this series focus on the “person approach” where most of the error correctable tasks could have been avoided entirely. Ellen Rose, author of ““User Error : Resisting Computer Culture, Between the Lines”[3] says that “user-friendly interfaces are not designed so much to make computing easier but rather to make it “fool proof” and dumbed down for error-prone users. And so the human presence is reduced to a twitching finger, spastic body, and an over saturated informational pump that makes choices within strictly programmed limits.”

Figure 1. User holding *Letter Dialer App*

Projects in the Series

“Human Error” features projects that begin the exploration of this theme and range from software to hardware installations. Some of these projects include *Letter Dialer*, an iOS app that removes the numbers from the calling interface, *Dim*, a Mac OS app that dims your computer’s screen brightness to 50% every 5 minutes, *PPRJM* a modified printer that continually causes a paper jam, and *Password*, a web form that prompts users to enter a password and then changes this password to the word “password”.

Letter Dialer

Letter Dialer pictured in Figure 1, is an iOS app that removes the numbers from the phone dialer application. Instead of typing numbers, users are forced to remember the corresponding letter combinations associated with each number key to dial the correct number. As we often not only forget phone numbers, trying to remember the corresponding letters can be a challenge even for the most versed cellphone user.

Letter Dialer forces users to remember which numbers are associated with each letter, making them question why the letter / number combination on the UI remains important to phone dialing. When texting began, the letters were important to forming words and they continue to be a feature that touchscreen phones utilize but have simultaneously been made obsolete because these phones can simulate as many buttons as necessary for full text entry.

When a button is pressed, one of the three assigned letters to each button shows up randomly. After a user dials the full letter combination, they then tap the “call” icon and

like the regular dialer app, *Letter Dialer* will start to dial the number they have entered. The result will be either a correct number or a wrong number in which case they will either be successful with the call or must try again.

The *Letter Dialer* app highlights common errors that we as humans exhibit when using technology and why these errors have become almost second nature to its daily use.

Figure 2. Screenshot of *Password*.

Password

Password, pictured in Figure 2, is a web form that asks users to type in a password and click the “Set My Password” button. Once clicked the new password is submitted to the server and automatically changed to the word “Password”. According to a 2019 HYPR study [6] on password creation, 72 percent of people reuse passwords for their personal accounts. The word “Password” is still the 4th most common password used by people behind “123456”, “123456789”, and “qwerty”. Since the use of the word “Password” as a password is still common and due to this word’s proclivity to be guessed by potential hackers, the fact that this word is still being used is one of “human error” that could easily be rectified. *Password* uses JavaScript to detect what a user types in and based on the input, the password field is automatically changed to the word “Password” when the button is clicked.

Figure 3. *Dim* App Icon

Dim

Dim, pictured in Figure 3, is a Mac OS application that repeatedly dims the display of users to 50% every 5 minutes. Users must correct the dimness to 100% to get back to work, knowing that their screen will return to lower brightness shortly. Whether they choose to fix it or choose to ignore it, the resulting error will be caused by their inability to attend to their computer, yet another aspect of human / machine error. After dimmed, the user can change their opacity back to 100% using the Mac’s System Preferences > Displays > Brightness setting. It remains up to each user whether they will take the steps to retain their brightness levels or leave them as is, resulting in “Human Error”.

Figure 4. Screenshot of *PPRJM*.

PPRJM

PPRJM (Paper Jam), pictured in Figure 4, is a printer that has been modified to continually cause a paper jam. This form of “Human Error” is something that continues to plague people who think they have correctly loaded paper but have failed due to their inability to follow directions. The average amount of paper waste that comes from an office annually is 10,000 sheets. Whether the paper is wrongly put into the printer or used erroneously and then discarded, this amount of waste is troubling even for the environmentally conscious. Recycling levels in the U.S. are only at 21.4% [7] and Americans throw away enough office paper each year to build a 12 foot high wall from Seattle to NY annually.

Conclusion

Despite our daily reliance on technology to function, there maintains a basic ineptitude in our usage of these systems. Because of this we often blame the technology itself for these errors instead of our own inability to understand how to use and operate them. The works in “Human Error” are the beginning of a larger body of work that explore these ineptitudes and reminds us that we are not perfect in our abilities to understand, operate, and command use of the technology we depend on in our daily lives. These projects provoke what we as a population do wrong with advanced interfaces and technological systems that are not outside of our grasp of understanding. They serve as a starting point for this exploration into human error driven work. By integrating elements of “human error” into interface design, perhaps we will discover why our daily struggle with technology is worth pursuing.

He received his Ph.D. from Trinity College Dublin. His work focuses on “Deconstructing Networks” with works that challenge and subvert accepted perceptions of network interaction. His artwork has been exhibited at venues such as SFMOMA, Canadian Museum of Contemporary Art, MOMA, ICA London, Whitney Museum of American Art, Palais du Tokyo, Tate Modern, Ars Electronica, Transmediale, and more. His artworks, “Bumplist” and “America’s Got No Talent” are in the permanent collection of the Whitney Museum of American Art. He has written for WIRED, Make, Gizmodo, Neural and more. His Scrapyard Challenge workshops have been held in over 15 countries in Europe, South America, North America, Asia, and Australia since 2003.

Uptown Underground and Untitled Times Square Intervention

Ian B. Callender
Columbia University GSAPP
New York City, NY, USA
ian@iancallender.net

Benjamin Akhavan
FOAWM
New York City, NY, USA
ba@foawm.com

Abstract

This talk will address the potential for leveraging physical-digital technologies in public-realm interventions which help offer fuller engagements in our current realities. It will serve as a platform to present the project Uptown Underground, which uses projections and accelerometer data to bring urban context down into an underground subway ride, as well as an in-the-works intervention which uses photovoltaic cells tuned to LED screens and air cooling methods to critique mass energy waste in Times Square.

Keywords

situated technologies, public art, urban interventionism, interactive technologies, new media

Introduction

In New York City, the public domain is the great equalizer: where all come together to carry on with their respective lives. The role of digital technologies within this realm is relegated to the isolating (a cell phone, for instance) or the commercial (dynamic billboards, impression tracking, and so on), which has led to technophobia or at minimum apathy towards a technologically-enhanced future. This paradigm has made it imperative to explore conceptual and human-centric approaches to adopting digital technologies within the public realm in a direct and hands-on manner. These projects, one expressly formal, one steeped in social and political discourse, both conducted without formal permission, sit at such an intersection.

Work

Uptown Underground, 2019

An installation by Ian Callender

The experience of riding the subway is marked by detachment: in the moments between stations, all urban context is stripped away, replaced with darkness or the occasional flash of a light. The project thus takes inspiration from the glass-bottom boat, where access is granted to the reeds, the fish, and the dark depths normally inaccessible. In an almost direct reversal of Anne Friedberg's argumentation, imagining seeing through the ceiling to the street and becoming aware

Figure 1: Uptown Underground, Installation View. ©Ian Callender.

of such a dynamic perspective here offers restored connection with and newfound contextualization within the city. [1]

Uptown Underground projects a geographically accurate view of the cityscape above a moving subway car onto its ceiling as it moves under New York City. It has been installed, without permission, on a series of moving subway wagons from Brooklyn Bridge-City Hall to 96th Street stations, a roughly 6 mile/25-minute loop along the East Side of Manhattan.

Figure 2: Uptown Underground, Elements and Build. ©Ian Callender.

The project is implemented with four projectors connected to Raspberry Pi's, synchronized with offsets over a peer-to-peer WiFi network and informed by geolocation and acceleration data from a cellphone, all on battery power. As the window for installation is only some 45 seconds, and the window for deinstallation even shorter at risk of being caught, the

build (both physical and digital) was designed for ultimate ease and fluidity.

Figure 3: Uptown Underground, Installation View. ©Ian Callender.

The project aims to create a technology-positive interaction with the sole intention of augmenting the urban experience by directly intervening in the daily lives of subway users through projections and new technologies. With the installation in full force, those on the train tend to put down their cell phones and, with excitement and curiosity, look up.

Untitled Times Square Intervention, 2021-

An ongoing collaboration between Benjamin Akhavan and Ian Callender

When temperatures in New York City exceed 95 degrees Fahrenheit (35 Celsius), the city as well as the city’s electricity providers issue alerts asking residents to limit their energy usage. Often, they specifically call out air conditioning for its heavy load on the grid. This has dramatic and, for many, life-threatening consequences. In stark contrast, even during these times of stress, the hundreds of thousands of LEDs of Times Square’s advertising screens remain lit. Backlash on social media quickly ensues with New Yorkers colorfully expressing frustration. Although by one estimate 161 Mega-Watts are consumed daily by the Theater District, there is no number published by New York City agencies. [5]

Recent critical discourse around urban screens, argues Scott McQuire, has been rooted in either consumerism or surveillance and privacy. [2] In Times Square, these conversations are even one in the same. [3] This has left out questions of access, equity, and notably, power structures, both figurative and literal. The impetus to keep Times Square’s screens illuminated was not only motivated by capital, but in fact New York City’s zoning resolution. [4] In spite of the heat wave, turning off the screens, quite actually, would have been illegal.

This intervention is thus predicated on asking a simple question in the most literal manner possible: how much cool-

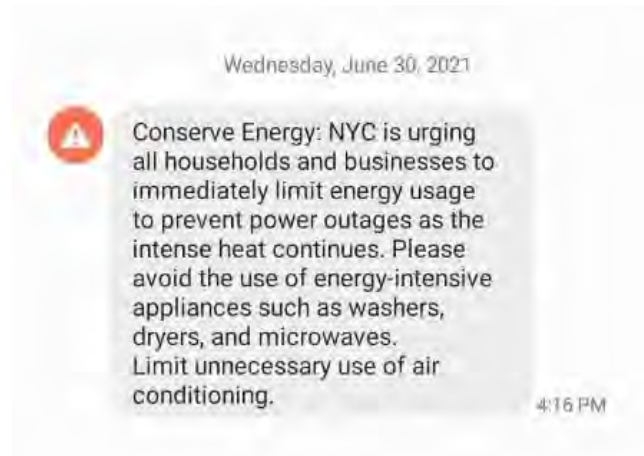

Figure 4: New York City Emergency Alert, June 30, 2021. ©Benjamin Akhavan.

Figure 5: Voltage generated by photovoltaic cells tuned to a Times Square screen, Summer 2021. ©Present Authors.

ing could be provided by the power used in Times Square? By using amorphous photovoltaic cells, particularly responsive to the frequencies emitted by LEDs, pointed towards these massive screens during the night hours, we have proven that enough power is generated by them to power small cooling stations.

Further work on the project will be completed later this summer (2022). With the next heat wave, critical discourse will have a practical installation from which argumentation for change can be drawn.

Conclusion

Digital technologies are but new tools for artists, architects, and designers to approach questions well established within their fields. These two projects offer innovative takes on this opportunity in such a manner that further grounds us in our

present realities, either in support of enhanced situatedness or of social critique, and in both cases within veritably human experience.

Author Biographies

Ian Callender is a New York City-based artist and designer exploring the intersection of the built environment and digital technologies. His work challenges traditional dialectical oppositions of structured / organic, form / un-form, and digital / literal. He holds a Bachelor of Arts from Brown University and is currently pursuing a Master of Architecture at Columbia University GSAPP. His work has been recognized by the Media Architecture Institute, Architizer, iF Design, and the Art Directors Club; covered by ArchDaily, Hyperallergic, and Designboom; and exhibited internationally.

Benjamin (Benjy) Akhavan is a multidisciplinary designer and educator based in New York. He is a principal at FOAWM, a nondescript Firm / Office / Atelier / Workshop / Milieu with polyvalent interests at the intersection of design and urban life. Benjy holds degrees in architecture from the Spitzer School of Architecture at the City College of New York and the Graduate School of Architecture Planning and Preservation at Columbia University. He teaches visualization and design at the New Jersey Institute of Technology and has exhibited design work in New York.

Abstract

Other intelligences is an artistic on going research that aims to explore the communication between plants remotely by using AI tools. Through this project we seek to know more about the plants' language and behavior, and try to understand a better these living beings with we co-habit in the Earth.

Through the use of technology as a tool, we have created a network of plants connected to the Internet. A network analogous to the network of roots and mycelia of fungi that take place in the forest.

All species on earth are linked by symbiotic and interdependent relationships; the project proposes an innovative point of view on the transformation processes that are shaping the collaboration between species, ecosystems and technologies. To know more about the language and behavior of plants will allow us to learn more about nature and thus better understand our environment.

Keywords

Making-with, sympoiesis, interspecies, non humans, plants artificial intelligence, interespecies communication.

Introduction

Several scientific studies have demonstrated that plants have chemical processes that have similar features with the process that take place in the nervous system of animals, thus plants have capacities like memory and therefore they can learn about their environment. Based on plant intelligence and their capacity of learn we created or neuronal plant network. We designed an algorithm makes possible the remotely communication between plants through the training and learning to different stimuli.

In this way we investigate, about the recognition of patterns by the plant, which allows it to identify with which plant of the network they are communicating and thus allow two way dialogue. To do that we have provided each of the plants with tools that allows them sending and receiving signals of light, sound and movement. The entire communication process is being recorded, to be analyzed afterwards with an Artificial Intelligence, in order to recognize patterns that humans cannot perceive with the naked eye.

Through the use of technology as a tool, we have created a network of plants connected to the Internet. A network analogous to the network of roots and mycelia of fungi that take place in the forest that the Professor of Forest Ecology Suzanne Simard [1] began to study almost three decades ago. This woods' network allows trees and plants to communicate with each other by sharing information and nutrients. In Other Intelligences, our network, is made up of data, algorithms and actuators, and it allows us to investigate alternative relationships with nature and technology through the use of artistic methodologies.

The device: sensors and actuators

I designed a produced a 3D printed device in order to attach to the plants (see Figure 1). A sensor developed by uh513studio [María Castellanos & Alberto Valverde], called Clorofila 3.0 is included in the device [2]. This sensor is based on the electrophysiology of the plants, and allow us to measure the electrical activity that takes place into the plant, depending of the surrounding of this living organism, like changes in light, temperature, sound, atmospheric pressure, proximity of other living beings etc.

I have been used this sensor in my previos artworks like Symbiotic Interaction (2017), The Plants Sense (2018) [3] or Beyond Human Perception (2020).

Additionally we placed environmental sensors (see Figure 2) that allow us to monitor the surrounding of the plants by measuring changes in temperature, sound, proximity, CO₂, humidity, etc. This sensors allowing us to compare and link this measures with the biochemical state of the plant, to try to figure out what is affecting to the plant. Furthermore all the data is sending to the Internet every two seconds and recording in a server, which allow us to analyze it.

Also three kind of actuators were placed in the device in order to provide tools to the plants to make possible the remote communication. We designed the actuators by thinking in the well being of the plants. One of the actuator is to alert the plant that something is happening with itself, the other two actuator allowing the plant to send signals to others that warn the other that something happened.

Figure 1. The device to attach to the plants with sensors and actuators. ©María Castellanos Vicente

The actuators are:

- A contact speaker: to create low frequency sounds that reminds to sounds in the nature, by generating soft vibrations in the soil. This actuator is placed to warn the plant that something is happening with itself
- Two servo motors: Integrated with two soft spikes inspired in the branches moved by the wind, it make movements to the plant. This actuator is placed to receive movement signals from other plants.
- Grow light LEDs: Integrated in the device, next to the soil. This actuator is placed to receive light signals from other plants.

The Foundation takes no responsibility for the opinions, statements and contents of this project, which are entirely the responsibility of its authors.

Developed in collaboration with FeLT from OsloMet and with the technical support of Alberto Valverde García.

Mycorrhizal Insurrection: Rerouting Anthropocentric Socio-Technical Systems

Cesar & Lois (Lucy HG Solomon and Cesar Baio)

Cesar & Lois art collective, CSUSM, UNICAMP
California, USA | Campinas, BR
cesarandloiscollective@gmail.com

Abstract

The art collective Cesar & Lois discusses the collaborative, non-disciplinary-specific development of a mycelial AI, with the intent of orienting human socio-technical systems to non-hierarchical models persistent in the living world. In growing a system that integrates living and digital mycelia, the experiment-as-art unfolds through the duo's accounting of past workshops that include mushroom foraging, spore printing and thinking like a mushroom. Ahead of the art collective's premiere of *Mycorrhizal Insurrection* at the 2022 Mercosul Biennial in Brazil, the artists discuss the process of developing the training database for a non-anthropocentric AI, the challenges in connecting artificial and mycelial intelligences, and their conversations with mycologists and philosophers. Merging prehuman (fungal) and posthuman (digital) systems, the artists speculate on the possibility of post-anthropocentric futures. With documentation of iterative nodes in the project's development, such as the June 2021 exhibition, "Eat the Anthropocene with Cesar & Lois, Mycelia and Friend Entities" at Yes We Cannibal in Baton Rouge, the artists project a machine logic that operates contrary to capitalist ideals, and the resultant values and concerns of a narrow group of humans. In response to Jason W. Moore's use of the term, *planetary proletariat*, the artists imagine a socio-technological insurrection by incalcitrant bhiobrid (bio-digital) systems. Listening in to the pulses to hyphae, an AI thinks less and less like a human.

Keywords

Introduction

Mycorrhizal Insurrection is the culmination of a body of work in which we integrate prehuman (fungal) logic and posthuman (machine) logic. What types of decisions, if shared across living and machine networks, would be made, and whose needs would those decisions serve? In a discussion of the development of the project, we outline the challenges of orienting an AI to a mycelial network, and we consider the steps required to decenter human needs through speculative non-anthropocentric AI's. We question, *How can a human-built AI ultimately conform to nonhuman logic systems and ecosystemic values?*

Anthropocentric thinking, embedded in extractivist, capitalist systems, reenacts a human/nature relationship that advocates relating to the living world through planetary management. Jason W. Moore locates this problem of human agency/possession within the "capitalogenic trilogy of class divide, climate patriarchy and climate Apartheid," which Moore identifies as the drivers of—instead of the results of—climate change. [1] Our collective postulates a non-anthropocentric AI that makes decisions against the systems dynamics that favor human-centered logic (and humans).

Background

Our collective's prior artworks attempt to unite human and microbiological systems to critique entrenched human/nature oppositional relationships sourced in the ontologies and dictums of the so-called West, as evidenced in numerous texts. These artworks include fungi-infiltrated philosophy books (see Figure 1) and *Physarum polycephalum* (slime mold) that tweets edited versions of texts that champion "man" as master or even the queen of "nature" (see figure 2). The intent of these artworks is to propose new futures that rely on an ecosystemic set of values that merge the needs of the planetary ecosystem, including the natural resources extracted on behalf of consumption-oriented human societies and for human technologies. We argue that an AI that operates with human values will inevitably make the kinds of inequitable decision-making that plagues many economic and societal structures. And we postulate that an AI trained on the interrelationships among beings within entire ecosystems (instead of specific encoded human values) might make better decisions on behalf of the planet, inclusive of disenfranchised humans, fragmented landscapes and, importantly, nonhumans—networked and otherwise. [2]

Why Insurrection?

The Capitalocene (Jason W. Moore’s term) has brought about percussive human and ecological traumas, with persistent violence enacted against the ecosystems and interspecies networks that humans also depend upon. The direct violence to Indigenous human societies that have been displaced, marginalized and murdered, in parallel with the devastation of ecosystems, has left holes in the planet’s living networks. In *Mycorrhizal Insurrection*, networking mycelia constitute a conceptual and poetic response to this trauma, also an artists’ call for revolution against those networks that continue to marginalize and enact violence. Hyphae allow access to utopian insurgencies that have the potential to generate ideas for other ways of building the future. Conceptualizing and building the artwork becomes a strategy of poetic articulation of the kind of thinking that can allow us to imagine other possible futures. This strategy is based on scientific research into the intelligence inherent in living systems and on ongoing collaborations with scientists in labs and in the field, as well as intentional learning about the land and relationships across species. Interspecies coexistences and collaborations exist in the wealth of Indigenous beliefs and traditions that actively enact the potency of the living world—living relationships documented in the scholarship of Robin Wall Kimmerer, Eduardo Kohn, Davi Kopenawa Yanomami and Eduardo Viveiros de Castro, and many others. Those living relationships are evidenced in language, as when Wall Kimmerer explains the Anishinaabe word *Puhpowee*, “the force which causes mushrooms to push up from the earth overnight.” [3] *Mycorrhizal Insurrection* calls for a rerouting of human technological systems (see the capturing of mycelial signaling in Figure 4) to take note of the potency of nonhuman living systems and to shift human-centered language and thinking so that technological networks are responsive to the complexities across networks of human and nonhuman beings.

The planetary environment’s reformation by global economic disparity—carbon as a consequence of capitalism—has brought us to an unprecedented scenario. A machine’s decision-making that is based on the logic of humans and other species, ranging from animals to microbes, requires that logic to connect to and within ecosystems. Studies that reveal the complexity of nonhuman systems, ranging from mycelial networks that process information [4] to the computational processing of microorganisms [5], point to the capacity for networks that are environmentally aware and socially responsive.

Figure 3. Reading “electromyceliograms,” the electronic signaling of mycelia (2021). ©Cesar & Lois.

Mycelial intelligent networks move us to reimagine networks as interspecies and cross-technological, connecting prehuman, human and posthuman intelligences to support the planetary ecosystem and its diverse human and nonhuman constituents. Such a scenario calls for a profound shift in the networks that control global economics and social systems, technologies and even ecosystems.

Artists Respond

In this project, in development for the Mercosul Biennial in Brazil, we strategize new ways to respond to the planet's overwhelming triumvirate of ecological, societal and economic failures. *Mycorrhizal Insurrection* is a provocation and a proposal, a challenge to the ways in which we as humans collaborate with machines and relate to ecosystems. As artists, we envision a utopian network that bends towards economic and climate justice because of the potential for an ecosystemic consciousness within collaborating operating logics. Such a network allows us to imagine an ecotopian future, in which human collective intentionality moves away from the celebration of human exceptionalism and towards the affirmation of networked entities and groupings, inclusive of a diversity of human and nonhuman entities and the planet. We conjure this future with mycelia.

Acknowledgements

This project was selected for the Mercosul Biennial (Porto Alegre, Brazil, 2022) by curator Marcello Dantas who along with the curatorial and organizing team, including Laura Cattani, Munir Klamt and Taís Cardoso, allowed this project to develop as a fungal network does—over time, and sometimes in the dark. The student artists and researchers of ACTlab at UNICAMP, DaTA Lab at CSUSM, as well as Norman Roland Madarasz and his graduate students at PUCRS have been instrumental in testing ideas.

Author Biographies

Cesar & Lois probes the evolution of humanity's relationship to nature by advancing intersections between technological and biological systems. The collective, comprised of Lucy HG Solomon and Cesar Baio, strives to build bhiybrid intelligent artworks by crossing different organisms, such as bacteria, fungi and protists with technological elements, including Artificial Intelligence, data mining and social networks. Through interactive artworks with embedded research and sometimes specimens, the duo ponders the logic based in the growth of microbiological organisms and studies how this can inform human logic, with the goal of positing a post-anthropocentric future. Their work, "Degenerative Cultures," was featured in the 2021 Aesthetica Art Prize Exhibition in the UK. Cesar & Lois received the Lumen Prize in Artificial Intelligence (2018), were selected for the Global Digital Art Prize Biennale in Singapore (2019) and as artists in residence at Coalesce Center for Biological Arts (2020) and UC Davis Hess Laboratory.

Lucy HG Solomon is a Fulbright scholar whose global project probes microbiological connections across distant terrains. As an associate professor in the Department of Art, Media and Design at California State University San Marcos, she teaches at the intersection of media, data and the environment and leads the DaTA Lab (Laboratory for Data and Transdisciplinary Art). A nurturer of nonhuman entities, she experiments with living data visualizations.

Cesar Baio is an artist and a CAPES scholar whose PhD (PUC/SP) and post-doctoral research (Plymouth University, U.K.) cross the fields of media and art. He is Associate Professor of Art and Technology at Universidade Estadual de Campinas in Brazil (UNICAMP) and the director of actLAB (Laboratório de Pesquisa em Arte, Ciência e Tecnologias Desviantes). With a background in electronics and media studies, he often focuses on the relationship between art, technology and society.

GODSPEED

A Speculative and Participative Robotic Performance

Louis-Philippe Demers, Bill Vorn

Nanyang Technical University, Concordia University

Singapore (Singapore), Montreal (Canada)

lpd@processing-plant.com, bill@billvorn.com

<https://vimeo.com/lpdemers>

Abstract

In this Artist Talk, we are presenting our new performance project *Godspeed*. Following the positive response on our previous collaborative piece *Inferno*, we aim to further the participative experience with new and expanded scenarios and with new and improved wearable robotic extensions, augmentations and prosthetics. Based on speculative rituals of the machine, *Godspeed* is our way to say “good luck” to humanity once we reach the point of singularity.

Keywords

Robotic Art, Performance, Exoskeleton, Participation, Control, Submission, Rituals, Co-creation, Speculative

Introduction

Since almost thirty years, we have been creating interactive installation and performance projects using robotics, audio-visuals, and cybernetic processes [1, 2]. A prime goal of these projects is to induce empathy from the viewers towards characters that are nothing else than simple articulated metal structures. Our objective is to conceive and realise robotic entities to question, reformulate, and subvert the notions of behaviour, projection and empathy. Notions that generally characterise the ambiguous relations between humans and machines. Our strategy has always been to minimise the distance between the work and the participant, immersing audiences in fictitious worlds and using the inevitable immediacy of the machines as an enabler of transformative experiences. [3, 4]

Inferno

Inferno (2015) is a participative robotic performance inspired by various representations of hell as depicted in Dante's *Inferno* Circles of Hell or in Singaporean Haw Par Villa's Ten Courts of Hell. With *Inferno*, the "circles of hell" concept is mainly an artistic framework, a general working theme under which the different parts of the performance are regrouped. The specificity of *Inferno* is the machines are installed on the viewers' body and consequently, the public then becomes an active part of the performance. [5] These participants have no prior training, and they are not instructed to perform any specific actions or characters. In the course of the performance, sometimes the viewers are free to move; sometimes they are in a partial or entire submission positions, forced by the machines to act/react in

a certain way. For this hour long performance, we have built 25 wearable robotic structures very similar to exoskeletons.

The performance is open-ended, and it is generated from a minimal set of instructions designed to facilitate audience participation and spontaneous movements. The immediacy and the emotional authenticity of being manipulated by a machine encourages the audience to invest in the veracity of the performance. Becoming simultaneously performing objects and subjects, *Inferno* embeds the schism and ontological questioning between humans and machines. The body is augmented but yet constricted, the performer is master and slave. We have observed throughout performances that this techno-corporeality paradox is a prime component to engage participants into sustained ritualistic gestures bordering states of trance. [6]

Godspeed

Godspeed is the logical following to *Inferno* as it is equally based on minimal robotised exoskeletons that will be worn by the audience during the performance. However, *Godspeed* will further the participant's experience by adding various robotic prostheses and extensions to the wearable unit, and by allowing direct system feedback on the participant's own actions. Likewise, the scenography will be entirely reimaged, with a completely new soundtrack and the addition of video projections. The participants and the audience will also be allowed to interact with each other.

The title of the project comes from the strangeness of this word. *Godspeed* is an ancient expression that is used to wish “success in your journey”. It has been heard repeatedly during rockets' lift-offs from the Apollo missions to the more recent SpaceX endeavours. Even though it has nothing to do with the speed of God, we want to use the ambiguity of the term to stimulate the generation of various meanings for the piece.

Another motif can also be derived from the medieval expression “God Spede the Plough”. This expression is found in writings and songs about the farmer's labour and their never ending task of ploughing the fields, year after year. The ploughmen sang lines calling upon God for prosperity during the yearly Plough Monday. This ode to prosperity chimes with the promises of the 4th industrial revolution and its contemporary version of labour. *Godspeed* is our rendering of Plough Monday, rituals of human augmentation and labour. Rituals to summon “Godspeed and good luck” at the verge of the singularity.

Figure 1. *Inferno* (2015) during Elektra Festival 2017. ©Photo Gridspace

Rituals of the Machine

Samuel Beckett commented that the absurdity of life brings rituals upon humans. In *Godspeed*, the overarching narrative will be revolving around the current absurdity (paradox) found in our “rituals with the machines”. In our context, rituals are generated as the results of instructions and automatic behaviours. [7] What follows is to imbue these actions with intentions and with potency of cultural conventions. This eventually effects an actual change, a transformative experience, from the standpoint of participants.

Attendees of rituals are usually comprised of a context/subject, a group of performers and an audience. Performance theorist Schechner notes that rituals are “not simply a doing but a showing of a doing. Furthermore, this showing is both actual... and symbolic”. [8] Rituals do promote intersubjectivity, a key element for *Godspeed* to encourage kinaesthetic empathy and affect sharing among all participants. [9]

As a strategy to immerse audiences in our robotic environments, we have empowered overstimulation. The “hyperarousal” we have witnessed in *Inferno* is nothing unusual in the context of rituals. [10] Repetitive actions can, after a certain time, lead to displacement and some sort of trance. Our goal is to enclose the viewers in such a system, either to make them feel something totally different or to make them realise that they are just being subsumed to something greater.

Schechner further notes that rhythmic and sound-making activities that are carefully coordinated invariably lead to feelings of “identical opposites”. [11] *Inferno* and *Godspeed* rituals are setting at the forefront the paradox of human-machine via the oppositional forces of the trance: wholeness / bodily disintegration, invulnerability / vulnerability, or tranquillity / readiness.

Bernard Stiegler points out relations between the Anthropocene, exosomatisation and infrasomatisation. [12, 13] He witnesses the acceleration of the transfer of human skills from the body towards external tools, machines and systems. The exosomatic elements of *Godspeed* will be wearable apparatuses to enhance, synchronise and sustain repetitive rhythmic movements of the rituals. While *Inferno* was focusing on the exosomatisation of being controlled by a wearable robot, *Godspeed* wishes to further the experience and venture into the grounds of infrasomatisation. The infrastructure or systems, such as the internet, are the intangible structural extensions of the humans, beyond the proximal exosomatic devices. In *Godspeed*, the infrastructure is the ritual, its scenography and *mise-en-scène* performed, implemented and generated by the exosomatised crowd. In such, we wish to blur the notion of rituals with the notion of automatic crowd behaviour in a similar way that rituals and performing arts blur. In this machinic mass ornament, *Godspeed* proposes rituals for our extended bodies.

Expanding on *Inferno*, which can be seen as a mono-ritualistic participative event, we want to elaborate a whole series of generative and rather speculative rituals. Performed and experienced by the viewers-cum-participants, these rites will be orchestrated by specific instructions and carried through the wearable apparatus that coerce their movements.

As a singular symbolic act, each ritual will set the stage for a particular group of exoskeletons that can execute specific actions linked to this ritual as well as to the ontology of those machines. These actions would sometimes be absurd, solemn, repetitive, ceremonial, contemplative, etc. If philosopher Byung-Chul Han noted the gradual disappearance of rituals in our society, we, on the contrary, want to re-actualise their potentials through an immersive and experiential *mise-en-scène* of technology. [14]

If we break down *Inferno* into ritualistic episodes, we have: the briefing where instructions are given and expectations emerge, the “rapture” when participants are being dressed up with exoskeletons in the front of audience, the “awakening” when the exoskeletons first start moving, repeated cycles of fast paced movements followed by uncomfortable moments of stillness, moments of hope from a languish soundtrack, playful puppetry driven by the authors, glitches of the ghost in the machine and finally, the catharsis. The undressing and dressing up of a new member were integrated seamlessly into the performance. The hovering crew attending the performers was an integral part of the rituals. *Inferno* could be considered mono-ritualistic from both the perspectives of the single type of exoskeleton, the single static layout of the performers and the “music clip” sequential structure of performance.

With the dynamic scenographic configurations of the participants, bodily extensions and props, *Godspeed*'s rituals can further explore more directions and genres. For instance, robotic extensions could enable participants to engage in a ritual that produces the live soundscape. These exosomatic music tools could then insure some level of rhythmic or melodic cohesion among untrained participants. With a dynamic arrangement of the performers, different subgroups can be spatially organised to represent infrastructures and social organisations in a symbolic or iconic manner. With the above dynamic organisations and interactions among participants, the narrative structure of *Godspeed* is expanded beyond the sequential tableaux of *Inferno*.

Ritual Symbionts

In *Godspeed*, we will explore various facets of the symbiosis of human-machine: alternate morphologies and anatomies, supernumerary limbs, plasticity and co-creation. [15]

The rituals will be co-created and co-performed in real-time between performers, audience and artists. This co-creation of ritual landscapes, as with *Inferno*, will be achieved by embedding and distributing media sources onto audience, performers and the surrounding space. Audience and participant bodies will become part light, part robot, part instrument, and part group element of the rituals unfolding around them. Scenographic structures will emerge in front of your eyes; spaces and situations will morph according to performers and the audience.

With *Godspeed*, we aim to further develop our exploration of exoskeletons and wearables robotics by experimenting with different machine morphologies, with their actions and with the participant's control over them. We want to build exoskeletons that also comprise extensions and prosthetic elements apart from the normal parts of these machines (arms, shoulders, torso, legs, etc.). These extensions will allow the execution of a series of unusual actions or surprising symbiotic actions, sometimes under direct control of the participant, sometimes completely unintentional. [16]

We also aim to develop a custom feedback system (something that does not exist in *Inferno*) that would allow the participant to interact with the system and with other participants. It will then be possible to control certain parts

Figure 2. Exoskeletons at Stereolux. ©Photo Fonteneau

or even the entire body of his neighbours, as the reverse will also become achievable.

Bodily experiences are hard to describe and given the altered sensorimotor activities arising from wearing exoskeletons, we noticed that it would be desirable to give the audience means to enhance their kinaesthetic empathy towards the performers. *Godspeed* will play with the autonomy and the gaze of the local audience member facing the global system in action. It will include a distributed control of performers via mobile applications available to the audience and it will gaze at multiple streaming of body cameras embedded on the performers. In this way, *Godspeed* expands the ritualistic participation to members of the audience.

We seek to investigate altered scripting methods of choreographing rituals and to establish the generative potentials of this hybrid man-machine technology. Following strategies found in Instruction Art, participants are co-creating the work as a results of enacting the generative instructions given to them. With *Godspeed*, parts of the instructions are implicitly given by the exosomatic system while others are given by the affordance of the space and the context.

Challenges

As with *Inferno*, *Godspeed*'s impact relies heavily on the enablement of non-professionally trained participants. This is somewhat made possible from a set of performance instructions easily understandable, even if delivered under the frantic nervousness of the pre-show. As we will shift towards a more elaborate set of rituals and staging, we will need to find strategies to manage this complexity and communication to keep the same operational paradigm of “on the spot” training of the participants.

With the goals of having multi-purposed exoskeletons come the challenge to find ubiquitous solutions to embark various devices on various parts of the body of the participants. Equally, our experience of *Inferno* leads use to build more robust and adaptable exoskeletons to fit more body proportions. Similar to the challenge of training, apparatuses need to be easily retrofitted on performers under demanding live conditions.

In *Inferno*, each participant is performing within his/her safety bubble, akin to the techno genre dance floors situations. With *Godspeed*, we will break this bubble as we wish to explore further interactions and collaborations, mediated thru the machinic extensions, props or

scenography. This proximity will open the doors to a broader set of rituals.

With the shift from static to dynamic arrangements of events comes a challenge of audience focus. In *Inferno*, even with area lighting, we found it problematic to direct the focus among the energetic environment of 25 exo-performers simultaneously dancing. An early attempt to control performers with tablets distributed among the audience went unnoticed. When a “master” performer appears dead centre under a spotlight and controls the ensemble, this interaction gets lost mainly due to audience line of sight. *Godspeed* bid to help focus will include video projections and mobile streaming in order to re-establish this line of sight and properly capture pivotal moments of the rituals.

On the horizon

The project is planned to ready for public performances circa 2023. Throughout the production process, we will workshop rituals and their accompanying human augmentations.

Godspeed humanity. With the challenges of the Anthropocene, the denaturalisation of the human and the mechanisation of life, we certainly need to be prosperous in the precarious journey ahead of us.

Authors Biographies

Based in Montreal, **Bill Vorn** is working in the field of Robotic Art since more than twenty-five years. His installation and performance projects involve robotics and motion control, sound, lighting, video and cybernetic processes. He pursues research and creation on Artificial Life and Agent Technologies through artistic work based on the "Aesthetics of Artificial Behaviors". He teaches Electronic Arts in the Department of Studio Arts at Concordia University (Intermedia program) where he is Full Professor. His work has been presented in many international events, including Ars Electronica, ISEA, DEAF, Sonar, Art Futura, EMAF and Artec. Together with LP Demers, they have been awarded the Vida 2.0 award (1999, Madrid), the Leprecon Award for Interactivity (1998, New York), the Prix Ars Electronica Distinction award (1996, Linz) and the International Digital Media Award (1996, Toronto).

Louis-Philippe Demers makes large-scale installations and performances. He participated in more than seventy artistic and stage productions and has built more than 375 machines. Demers' works have been featured at major venues such as Theatre de la Ville, Lille 2004, Expo 1992 and 2000, Sonambiente, ISEA, Siggraph and Sonar. He received six mentions and one distinction at Ars Electronica, the first prize of Vida 2.0, mentions at Vida 12.0 and 15.0, two jury recommendations at the Japan Media Arts Festival, the Interactive prize for Lightforms 98 and six prizes for Devolution including two Helpmann Awards. Demers' research focus on embodiment and the experience of art and technology. He was Professor at the HFG Karlsruhe, affiliated to the ZKM and Director of the Creative Lab at QUT. Demers held visiting/guest professorships from the University of the Arts London, CAFA in Beijing and at the Universität für angewandte Kunst Wien. He is currently Associate Professor at NTU's School of Art, Design and Media.

Monument Public Address System: Mobile AR and Interactive Installation

Assistant Professor Meredith Drum

Virginia Tech
Blacksburg, Virginia, USA
meredithdrum@gmail.com; mdrum@vt.edu

Figure 1. *Monument Public Address System*, Installation documentation. ©Meredith Drum.

Abstract

Monument Public Address System is a multi-platform interactive documentary project centered around a growing collection of audio interviews about the past, present, and future of confederate and colonial monuments in the US. Two platforms are being produced to present the documentary narratives to the public. The first is a place-based augmented reality app accessible on participant's smartphones and tablets. The second is an installation and musical performance. With this project, the author-artist aims to engender critical and thoughtful social experiences in public spaces through the presentation of narratives that offer truth and justice-centered perspectives and anti-racist visions for our shared future.

Keywords

Anti-racist, augmented reality, confederate monuments, documentary, future, heritage, location, participation, place-based, public art.

Introduction

Monument Public Address System is an on-going, multi-platform documentary initiative centered around a collection of audio interviews about the past, present, and future of confederate and colonial monuments in the US. With this project, the author-artist aims to engender critical and thoughtful social experiences in public spaces. And through the presentation of truth and justice-centered narratives the goal is to contribute to a growing body of

anti-racist projects and visions for our shared future. Two platforms are being produced to present the documentary narratives to the public. The first is a place-based augmented reality app accessible on participant's smartphones and tablets. The second is an installation and musical performance.

Multi-media Platforms

The augmented reality (AR) app, invites participants to open *Monument Public Address System* on their mobile device to discover 3D virtual objects and animations superimposed on the world around them. When they interact with these objects, short sections of the audio interviews are triggered and play. As they listen to the narratives, participants can explore the virtual animations in relation to the physical space through which they move (Figure 2).

It is important to the author-artist that the app is accessible as possible. While the augmentations are geo-located around monuments, the sound and imagery can be experienced any place. While it is intended for participants to circumnavigate confederate and colonial monuments – and the empty spaces where monuments once stood – while experiencing the AR, the app can be opened anywhere. Moreover, the app is mobile AR, released on both Google Play and the Apple App Store, so that it can be used on a large variety of hand-held devices.

The installation and musical performance the project, titled *Monuments Dissected: Public Art and Contested Spaces*, was open to the public April 21-23 2022 in The Cube, Moss Art Center, Virginia Tech. The Cube is a high-tech media theater. The installation included a video sculpture, projections on four screens, a listening station where visitors could sit and listen to edited sections of the audio interviews, a drawing station where visitors were invited to imagine new public art to fill the vacated spaces where monuments have or will be removed, and two musical compositions distributed across a multi-channel speaker array (Figures 1 and 3). The musical compositions have been commissioned specifically for the project. One score is being composed, performed and produced by Grisha Coleman, a well-respected artist of color based in New York City and Phoenix, AZ. The second score is being written by Marcus Norris, an emerging Black composer based in Los Angeles and Chicago. The author-artist and her collaborators are actively seeking new venues to present the piece.

Interviews and Research

To build the collection of interviews that provides the backbone of both the AR app and the installation, the author-artist has interacted with a wide range of individuals across the U.S., including activists, educators, scholars, students, planners, legislators, and other artists. The sound of the interviewee's voice as they tell their story is central

to the project. Their narratives are rooted in their experience of, and research and reflection about, the monuments. Some of the interviewees have offered personal stories about their feelings of exclusion when they see images related to the confederacy. Others have analyzed the symbolic violence of the monuments in relation to ongoing racist systems. And others describe potential liberatory sculptural works to fill the vacated public spaces in their cities.

The artist has found that the interviewee's narratives align with much existing writing about racism and confederate and colonial monuments by journalists and academics. Ana Lucia Araujo, historian and professor at Howard University, writes:

When black and brown people open a textbook, visit a museum, or look at the statues displayed in major squares of the main European and American capitals, they only see images of white men, who were wealthy, who had power and who very often were slave owners or slave traders. Then when black men women, and children are challenging proslavery statues, they are denouncing this past that remains alive in the present. They are calling attention to their present day economic and social exclusion. . . . All monuments emerge and disappear because of political battles that take place in the public arena. Likewise, public memory is always political. [1]

Conclusion

Monument Public Address System is intended to support critical thinking about the future of public monuments and spark conversations on the history of slavery and racism in the U.S. The project is a platform for visual and aural expressions of frustration, anger, sadness, fear, and confusion regarding the racist, unjust and violent narratives that have shaped and continue to shape our present and future. It is also built for the enunciation of anti-racist hopes, activities and initiatives.

Acknowledgements

Major funding for *Monument Public Address System* has been provided by Virginia Tech's Institute for Creativity, Arts, and Technology (ICAT) in the form two SEAD grants. The artists would also like to thank ICAT for inviting the team to present the project as an installation and musical performance in Virginia Tech's CUBE theater in April 2022.

Meredith Drum is the main artist producing *Monument Public Address System*. Yet her collaborators are vital to the project. In addition to the two composers discussed above, she is also collaborating on the installation and musical performance with media artist and producer

Figure 2. *Monument Public Address System*. Documentation of the AR app in use ©Meredith Drum.

Tanner Upthegrove and musicians Annie Stevens and John Irrera.

With the grant from Virginia Tech's ICAT, Drum and her collaborators commissioned music for the project from artists: Marcus Norris and Grisha Coleman. Drum will present an excerpt from Coleman's musical work during her artist talk.

Drum's graduate assistant Bryce Burrell has been essential; he has identified many of the interviewees and has helped conduct and edit the interviews. Sam Lally, her undergraduate assistant has completed much of the technical work on the AR app. Note: as Drum will be sole author to deliver this artist talk, she has only included her biography below.

How can we renew the living environment from the perspective of light, both natural and artificial, for the future?

Titia Ex

Light & Media Art Projects
The Netherlands
www.titiaex.nl

Abstract

COVID-19 leaves a clear mark on our living environment. The pandemic has changed the use of public space. We have started to spend more time in nearby outdoor spaces. It is the place where we see the other. Where we make the social city. Light, natural and artificial, is a fundamental part of this. Light is much more than a medium that enables us to see. It affects our health, our ecosystems and the places we live in in countless ways. Light can bring people together in urban spaces, emphasize the culture and identity of the city and shape the nightscape.

Keywords

Art of Light, Public Art, living environment, future, natural and artificial light, participation, research, cycles of day and night, technology, planet.

Introduction

For me, as an artist, public space is not a saturated or static space, but a living organism. A continuous process of interaction between people and their environment. Light uses time and space as its material. Light art in public space does not begin or end in a physical form but is a transfer of energy. An infinite potential of relationships that permanently engenders new links between things and people. It can lift the space out of its anonymity and add new and unexpected connections or break fixed patterns of movement. It does not have to draw attention to itself, it provides sight of the space. The art of light as a representation of life, of energy in public space, as a form of poetry.

HALO

Integral light vision

A vision of light is needed that is approached from various perspectives, such as sustainability, experience, light pollution, safety and health. As technology transforms public spaces, we gradually lose our physical connection and inherent sensitivity to natural light. We need to let the dusk rise again and (re)learn our sensitivity to both the light and the dark. In the evening there is also a certain 'imbalance of artificial light'. In the past decades more and more artificial light has been added. People do not feel safe or healthy and think that adding more light is the solution, while this actually has the opposite effect.

For our health we should have less artificial light. Also, light works with contrast - just add more light and the black hole falls next to it, with the result that everything needs to be lit up more. Next to this, our environment is more and more equipped with sensors, network software, measuring equipment, cameras and so on. People are not involved in this; the human scale and the flora and fauna are secondary. A lighting vision cannot be left to traffic engineers alone or outsourced to companies. An integral lighting vision is needed with all parties involved.

Artistic research in progress

In participation with of the Placemaking Team, Buikslotermeerplein consisting of residents, entrepreneurs, and other stakeholders, an analysis is made of the current situation during the day and after dusk of the Buikslotermeerplein area in Amsterdam-North.

The goal is to identify different light ecosystems, characters and qualities of the living environment. To define functional, emotional and social dimensions, in order to make people the owners of the light in their living and working environment.

Buikslotermeerplein Area

The Buikslotermeerplein area in Amsterdam North is a former working-class neighbourhood, designed in the 1960s and is to become the beating heart of Amsterdam-North.

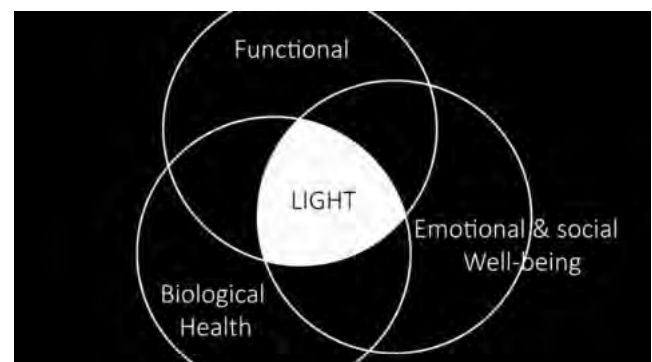

The city's policy is to densify the area. The new North-South metro line ends here and around the metro stop. There are an ROC school, a cinema, city offices of Amsterdam-North and several residential towers are now under construction.

At present there is a languishing market, a shopping centre with empty shops with its back to the neighbourhood, mega car parks and many blocks of flats - between neglected vegetation and polluted water.

Besides the current residents, mainly living in social housing projects, new residents, both students and house owners, will be moving to this area. The challenge is to keep the area liveable during the next twenty years of urban renewal, while mixing old and new residents, transforming the shrinking shopping centre, and create a durable vital green and blue public spaces. The urban development around this area also offers an opportunity for an integral and innovative approach.

Buikslotermeerplein Square, urban development.

Light Safari

The starting point is to make people familiar with the phenomenon of light. This is happening by making a light safari through the neighbourhood.

During the light safari, public space is approached from different angles, such as: perception, health, orientation, safety, inclusion and identity.

Raising awareness by sharing knowledge, experience, providing access to the (technical) concepts, in order to arrive at alternative scenarios.

Conclusion

After understanding and experiencing the potential of light people got more aware of the influence of light on their surroundings. Two Universities of Applied Sciences have been inspired. The municipality is open to collaboration, the association of entrepreneurs has experienced the importance of good and balance Light (Art), and the residents feel they have been heard. This is not to say that everything will be applied and implemented immediately. The urban development of the Buikslotermeerplein neighbourhood is a process that will take several years. However, there is an agreement to develop it jointly. Light will be one of the carriers.

Light safari, the light is out of balance at the entrances of residents' flats. generally Overexposed and no orientation in the distance.

Artist Titia Ex

Titia Ex creates a choreography in space, where art, technology and the receptive surroundings meet. Every environment has its own character, function and users. Her visual light & media sculptures immerse with their dynamic, mobile forms and interactive characters. In the course of light and dark, day and night, they reflect related changes of mood and create a poetic echo, adding a new layer of meaning.

She is the creator of dozens of high-profile, large-scale works of light art in public space, including 'Dolmen Light' in the Hondsrugttunnel in Emmen (2015) and the interactive light sculpture 'Flower of the Universe' (2010), for which she did her research and found inspiration in a Botanical Garden travels all over the world, including the Asia Culture Center (ACC) in South Korea (2020). Recently she created 'Loom Light', an interactive light monument for Jan Zwartendijk and other invisible the heroes of resistance during the Second World War in the region of Eindhoven (2022). Also new is the installation Lightfall. An existing rain pipe is transformed to an interplay of light and water. The artwork makes the vein, the interweaving of Amsterdam with water visible. With this poetic gesture, the inner condition of the water is revealed, and the context of the built environment becomes tangible.

LIGHTFALL © Titia Ex

Sun Eaters: How do we relate with the non-human plant world if our invisible similarities are made visible?

Grace Grothaus

York University
Toronto, Canada
ggrothau@yorku.ca

Abstract

Sun Eaters, a physical computing installation, measures the invisible bioelectricity present in all living beings and translates it into visible light. Exploring the conception of art as tool for sensing, I am exploring how we relate to the non-human plant world(s) around us. Can artworks act as an empirical interface for grasping our complex, interwoven, beyond-human ecologies of present-day Earth and ways of thinking about them? How do you imagine your relationship with a plant differently when you can physically see it?

Keywords

Electronic art, Physical Computing, Environmental sensing, Environmental Visualization, Plant-Computer Interface, Electrocardiograph (ECG), Biotechnology, Ecosystems, Circadian Rhythms, Plant Blindness

Introduction

Through the installation of a series of environmental sensing modules, I have produced an art experience that renders the invisible bioelectric current present in all living beings and translates it into visible light for us to see. Bioelectricity in humans results in a rhythmic pulse we understand as a heartbeat. In plants, it is rendered in a much different wave pattern. This installation, which I call *Sun Eaters*, is installed in trees and plants along paths of frequent use and invite passers-by towards a heightened awareness of the oft-overlooked vegetation all around us. (Figure 1.)

Overcoming Plant Blindness

Plant blindness, a form of human cognitive bias, is a common tendency to overlook plants and to treat them solely as a beautiful backdrop in front of which human action takes place. [1] Yet plants and trees, sequester atmospheric carbon. They are vital to the health of our future and worthy of our increased attention, as we

strive planetarily towards achieving net zero carbon levels. Therefore, for much the same reasons that some stop signs and warning notices become outfitted with blinking LEDs, I've illuminated the trees: to arrest your attention within our oversaturated world and overcome plant blindness.

Figure 1. Installation image of *Sun Eaters* at Lux Art Institute in Encinitas, California, 2020. Photo ©Grace Grothaus.

Measuring Plant Biorhythms

The changes in light levels in *Sun Eaters* derives directly from the received analog bioelectric signal produced by the trees they are installed on. In order to read the plants biorhythms, electrodes are affixed to the leaves and/or branches of the tree which send electrocardiograph (ECG) signal to a sensor. I am then processing the signal through Arduino and subsequently simply and directly outputting it to LEDs through pulse width modulation. ECG sensors are more commonly used to measure human heartbeats, but repurposed in this way, they help us to see a pulsing connection with the life around us.

Bioelectricity refers to ion fluxes within organic tissue which occur as a byproduct of life processes. Where net ion fluxes occur, an electric current and

field is generated. In plants, the bioelectricity ebbs and flows happen on different timescales as it does in us, however there are common points of connection. Circadian rhythms affect plants just as they do us. A diurnal twelve-hour cycle can be seen in the bioelectricity of trees, peaking once with the rise of the sun, and again as it sets. [2]

Plant bioelectric fluxes also change minute to minute and second to second, resulting from external environmental factors such as season and temperature. Internal elements influence it as well, such as insect invasion. [3] Human heart beats are variable as well. When we are stimulated by excitement, for example, they become more rapid. In addition, each person has a slightly different heartbeat as the next, and the same holds true for plants. They are all uniquely individual, just as we are. Though humans may exist in a different temporal scale as plants, we have a lot in common, perhaps more than we realize. [4] (Figure 2)

Pulsing Together

Through *Sun Eaters*, I am exploring the question of whether artworks can act as an empirical interface for grasping our complex, interwoven, beyond-human ecologies of present-day Earth and ways of thinking about them? Can they act as visual aids in comprehension through their expansion of our imagination? If you can see your heart pulse together with that of a tree, do you see and understand it differently? Early iterations of installation *Sun Eaters* visualized only plant bioelectricity, and then I began to use the same sensor to measure both human viewers as well as that of the vegetation. (Figure 3)

Figure 2. Installation image of viewer interacting with *Sun Eaters* at Cite Internationale des Arts, 2021. Photo ©Grace Grothaus.

It is my hope that once we begin to see ourselves in each other and other species in conjunction with us, noting our incredible interconnectivity within the

global ecosystem, that we will take on a greater sense of planetary stewardship. [5]

Figure 3. Installation image of viewer interacting with *Sun Eaters* at Cite Internationale des Arts, 2021. Photo ©Grace Grothaus.

Figure 4. Installation image of *Sun Eaters* at the California Institute for Telecommunications and Information Technology, 2021. Photo ©Grace Grothaus.

Thematic Statement

How do we fight climate change and global warming? Part of the answer involves revising our understanding of natures and worlds. In order to protect the planet's living future, it is essential that we develop empathy beyond our senses in order to connect to Earth's more-than-human worlds, overcoming otherness and our human cognitive biases. My goal with *Sun Eaters* is to invite viewers towards a heightened awareness of the oft-overlooked vegetation all around us. (Figure 4) The work explores themes of revealing our invisible connections and direct co-symbiotic experience. I am deeply interested in the question of how we relate with nature and understand and experience life today. Within cities, our lives are led increasingly disconnected from circadian rhythms. How do we relate to nature? If you can see yourself pulse together with a plant, do you see and understand it differently?

Acknowledgements

The opportunity to exhibit *Sun Eaters*, sharing it with various publics is owed to several institutions. I would like to acknowledge the Lux Art Institute in Encinitas, California for their initial support of its first installment in fall 2020. Additional thanks go to the California Institute for Telecommunications and Information Technology on the campus of the University of California San Diego who exhibited it in May 2021 as part of their Initiative for Digital Exploration of Arts and Sciences (IDEAS) performance series, and to Cite Internationale des Arts, where as an artist in residence this summer, I explored new directions with the work as part of an artistic co-creation lab, *Through the Eyes of the Others* led by Tjasa Crnigoj, alongside Garance La Fata, Cristina Rosenberg, and Gethce Pierre.

Xeno Walk, an Augmented Reality Soundwalk on collective feminism

Amanda Gutiérrez

Ph.D. Student in HUMA. Concordia University
Canada, Montreal
cadadosis@gmail.com

Abstract

Xeno Walk is an Augmented Reality audio walk, featuring the voices and sound works by activists and sound producers who embrace the collage as a tool of aural exploration. The sound walk features the artworks of #VIVAS, a Latin America-based collective producing sound works from field recordings of social demonstrations and Viv Corringham's Shadow Walks. The interviews feature the voices of members of Collages Féministes & Féminicides Paris and Montréal who share their strategies on activist actions in the public space. The walk's sound design takes the form of a collage mixing their soundtracks and their interviews. The listener can choose to experience this walk using headphones; however, this AR project is meant to be heard as a collective soundwalk with two or more persons. For the premiere of this project, the artist organized four aural participatory performances, inviting the public to amplify and occupy the streets with the interview's voices and #VIVAS soundscapes.

Augmented Reality, Sound Studies, Sonic Agency, Intersectional Feminism, Walking Methodologies, Immersive Technologies, Xenofeminism, Soundwalks, Queer Alliances, Space of Appearance, AR(t).

Introduction

My approach to soundwalking has been enriched by theories and concepts departing from Acoustic Ecology and Sound Studies. Despite the fact that R. Murray Schafer, Hildegard Westerkamp, and Max Neuhaus, have enriched the experience of sound walking, there remains a lack of academic literature documenting soundwalking practices that consider social, class, gender, ethnic, and disability perspectives linked to activism and political performativity. To address this gap, I propose to create an intersectional approach that builds from practices and theories of listening and collective walking as a form of coalition (Butler 2015) to inform a methodology and concept. In its practice, Sono(soro)riety, aims to collectively create alliances (Butler 2015). To do so, there are critical decisions in the action of planning, recording, editing, planning, walking, and listening collectively.¹ The action of "walking with" is a crucial tool for collective recognition and a performative act of enunciation, an act of

speech that can be exercised in space. The research-creation project "**Xeno Walk, on Collective Feminism**" is an audio walk developed for Augmented Reality (AR), featuring interviews with feminist activists and artists. The project emphasizes the diverse tactics that embrace the form of collage as a tool of resistance and autonomy. The augmented audio walk creates a sonic palimpsest with their interview voices and soundtracks produced by the Argentinian feminist sound collective #Vivas and Viv Corringham, Shadow Walks. The Augmented Reality tool helps us transit the public space, finding the connections between geographical cues and the content and meaning of the oral histories in the audio walk, departing from the interviews and activist experiences with members of three collectives Collages Féministes and Féminicides Montréal, and Paris.²

I chose the space by walking with two members of Collages Féministes Montréal, who helped me trace a path concerning their conflict embodiment, aural memory, and locations for pedestrians with disabilities. Understanding these personal traces of the terrain, I was able to locate five interviews, considering the three-dimensional infrastructure of the Boulevard Rosemond highway, the rail tracks walking and bike pass on Van Horne Street, and its connection with the underpass of St Laurent Boulevard. While walking with them, we brainstormed about the possibility of collage interventions and phrases that can respond to the topic of autonomy and freedom in the public space.

Testing the AR Walk

On the weekend of June 19th, 2021, six participants agreed to walk with me to text for the first time. Three of them were part of the collective Collages Féministes Montréal, and the rest were enthusiastic friends who wanted to join the experiment. We met in front of the skate park. They arrived with a delay, and Kira told me that the noise and male-dominated presence at that meeting point were stressing her out. I found that was precisely one of the points I wanted to test with another woman since I also felt the same, but being hip and having an alternative vibe could be welcoming. It turned out that the same issue happened with all six participants; they felt a bit invaded and self-aware of the masculine charge.

As far as the walk goes, listening with one Bluetooth speaker was not enough. The sound of the augmented voices vanished in front of the heavy traffic of St Laurent Blvd and the skate noises; therefore, we decided that the

¹ I will build upon theories of listening and walking by drawing from the concept of Sono-(soro)rities, an evolving concept that scholar Gabriela Aceves-Sepulveda and myself are currently developing.

²The Augmented Reality walk has been made with the App Echoes, which is developed for soundwalks experiences 893

walk could be better if it takes place later in the night. We imagined a walk night gathering where participants can feel more intimate and embraced by the evening. The group gathering could be about autonomy and collective agency walking together at night. These night walks are not something new; Viv Corringham speaks about how she witnessed and participated in the Reclaiming the Night movement, which started in London and New York City in the late seventies, where hundreds of women took the streets to walk together at night.

After this group exploration, we moved to the next walk in a metallic structure near the vicinity. In the corner, there is a sign that can be read as “Entrepot 77” which is the bones or the metallic construction of an abandoned building in front of *Champs de Possible* park. In that section, participants can hear the interviews of the collective #VIVAS. Their soundtracks welcome the walkers by immersing them into the wall-less building. The participants did not speak Spanish, whomever they seemed engaged to listen to the overlapping sound of their voices in such a space.

I realized that I needed to make bigger bubbles and center them into the middle of the structure because the cell phone GPS sometimes behaves very capriciously. Also, participants suggested that it would be nice to hear more soundtracks embedded into the oral histories to have a more immersive way of approaching their sound creations

layers; the underpass, the car bridge, and the walking-bike pass. The sound overlapping worked so well, allowing stories to be interconnected while walking.

Departures

This overlapping and connection with the skatepark relations linked with the XR critical theories of Rewa Wright, which describes the radical possibilities that Augmented Reality can convey:

“Emerging with and through AR(t)* is an activist politics engaging wireless networks to achieve a critical ‘detournement.’ In this context, AR has been deployed as a radical political agent, mapped at specific sites where participants do not simply view ‘the work’ (as one does in a conventional art gallery) but activate the sensation of ‘being within’ a critically resonant event. Such activist gestures have allowed AR(t) to forge a specific cultural relation with public space that was, prior to mobile technology, largely occluded.”³

To this extent, I wonder about the feasibility of resonating together by creating several participatory walks by each zone and collectively featured in the AR project. Therefore, I am introducing the collaborative and guiding the walk as a soundwalk but asking participants to bring their portable speaker and download the app before arriving at the meeting point and creating a connection with participants into the project.

The research on the spatial and sonic layers has been one of the most complex and engaging parts, which must be shaped, negotiated, and talked with other walkers to be effective. Its success might be related to the community appropriation, either by an invisible invitation open for random encounters or by a collective resonance embraced in a soundwalk.

Xeno-Walk, was later premiered in September 2021, in the context of the *POP Montreal Festival*. The project was funded by the artist-run organization *Undefined Radio*, as part of their series: *Calling Planet Earth!*. They were presented in four different participatory walks, where the public amplified the augmented sounds with linked Bluetooth speakers.

Figure 1. This is the postcard designed to be placed around the location of the walk, with instructions for the audience. ©Respect Copyright.

I realized that technically speaking, it is not recommended to use the feature of proximity to the center of the sound because once you are out of the range, the sound fades and cuts, limiting the narratives to finish. The walkers seemed excited to keep walking to the other routes, which allowed me to test my theory of sound overlapping between three

The *Xeno Walk* is the first practical approximation of the methodologies proposed as part of the development of Sono-(soro)rity. This concept builds from anthropologist Marcela Lagarde's *sororidad* (2006). She writes: “Understood as a non-binary, ethical, political, and practical dimension of contemporary feminism(s), we consider sono-soro[ridades] as a critical frame to look at the sonic dimensions of patriarchy. As a feminist

³ Wright, Rewa. Mobile Augmented Reality Art and the Politics of Re-assembly. Conference: International Symposium on Electronic Arts (ISEA 2015). P. 3

intervention in the archives of sound art, Sono-soro[ridades] makes visible how sound and gender constructions intersect each other. It highlights the potential of the sonic to unveil and make audible unequal power dynamics in which gendered violence and exclusion are perpetuated. We seek to embody what Sono-soro[ridades] sounds like and explore together its political potential in creating non-exclusionary sounding futures and re-sounding pasts and presents”⁴.

Part of my research-creation and further reflections after this walking series, is to identify how similar methodologies have been used in feminist sound practices to form moments of coalition and assembly in the public sphere. One of the aims of my doctoral research project is to create its phenomenology to trace these expressions into an intersectional framework and a defined method to define name and collectively analyze these feminist expressions of sonic agency in the public sphere.

Acknowledgements

I want to express my gratitude to the collectives featured in this project: Collages Féministes & Féminicides Paris and Montréal, #VIVAS and the ongoing collaborations with Viv Corringham, artist works and initiatives that inspired this research-creation.

Abstract

The *body in\verse* is an online, interactive performance that combines biophysical sensing, emotive state sonification and visualization, and generative poetry to create the scene. The performance provides a deep dive from the world outside of ourselves, that is dissociated by mediated technology, into the interoceptive abyss of our emotive sea. Audience members are invited to participate in a focussed conversation that becomes the basis for the activity that follows.

Keywords

Interactive Performance, Biophysical Sensing, Emotional Affect Assessment, Disassociation, Data Visualization, Sonification

Introduction

The *body in\verse* is an online, interactive performance that combines biophysical sensing, emotive state sonification and visualization, and generative poetry to create the scene. The performance provides a deep dive from the world outside of ourselves, that is dissociated by mediated technology, into the interoceptive abyss of our emotive sea. Audience members are invited to participate in a focussed conversation that becomes the basis for the activity that follows. Questions will be on the rise of a technological culture, and how it has left us wanting, consciously or not, for identification and awareness of “essential rhythm”, that we continue to lose track of now that we live mostly in cities as the aboriginal environment recedes from view. The performance environment provides the ability to control the presentation of stimuli and monitor the physical reaction based on the interpretation of nuanced emotional state, blurring the line between auditory and visual real-time content and physical experience.

A biophysical sensing system measures the emotional affect of the performer, and then uses that data to drive the sound, abstract imagery, and a generative poetry algorithm. Emotional affect of the performer is assessed through arousal and valence measures derived from correlation of the performer’s heart rate and heart rate variability. An algorithm generates poetry using conversations that take place with the audience as source material. The poetry source material is then algorithmically organized according to its sentiment (positive to negative), and mapped to the emotional affect of the performer driven by the emotional affect assessment from the biophysical measures as described above.

What happens? What the audience sees and hears... How they participate...

We begin with a conversation.

The performer (Alysia Michelle James) is close to the screen, visible from the shoulders up, like a typical teleconference call. As the audience joins the call, she begins with some ice-breaker questions such as:

“How are you today?,”

“Where are you located?,” etc.

Audience members are able to answer these questions through the chat. The questions slowly become more poignant as the performer builds upon their responses.

“Why are you here?”

If an audience member responds with, “I’m here for a meaningful experience,” the performer may respond with a question like, “What is meaningful?”

Figure 1. Still from the beginning of *the body in\verse*. ©2021 Hosale, James, Macy.

Other examples of questions in this category:

“What is the most important thing we could be thinking about right now?”

“Why be ‘new normal’?”

“Who were you before?”

The perspective moves outward in with questions such as:

“Are you worried about the fragility of society?”

“Are you worried about the fragility of life?”

“What makes a culture?”

“What does society avoid feeling?”

Then we shift to inward thinking with the intent of inspiring contemplation and introspective thought:

“Why do we feel?”

“What do you avoid feeling?”

“Can you feel other humans?”

“Can you feel your breathing?”

“Can you feel your heart?”

This more focused conversation becomes the foundation for the tone and direction for the rest of the performance.

The remaining performance is comprised of three elements:

ophysical state of the performer, and then uses that data to drive the sound, abstract imagery, and a generative poetry algorithm.

- An AI algorithm that generates poetry.
- A performance that combines movement, sound, abstract imagery, and text.

Biophysical Sensing

The science behind this project is based on work first performed by James Russell, "A Circumplex Model of Affect"[1]. This work has been cited roughly 14,000 times. Since 1980, psychophysicologists have continued to evolve theory, in regard to the assessment of feeling "affective" state, and so additional physiological variables have been utilized for evolving studies. These measures include electroencephalogram, pulse plethysmogram, blood pressure, blood flow, vascular resistance and ventilation.

Recent research in bioinformatics suggests that it is possible to assess the real-time emotional state of an individual using a special class of sensors that track human characteristics such as heart rate, muscular movement, eye movement, skin temperature and breathing[2] that contribute to an individual's emotional valence (range of affect from pleasant to unpleasant) and arousal (range of excitement from activation and deactivation) [3][4][5][6][7][8].

In this work we use a real-time electrocardiogram via a Biopac Bionomadix BN-ECG2[9].wireless data acquisition and analysis platform to establish core valence and arousal measurements to find a baseline affective state assessment of the performer. We ran the output of this amplifier straight into a sound interface capable of measuring down to DC (zero frequency). Valence measures are indexed by the performer's heart rate variability (HRV) and establish the horizontal model axis ranging from displeasure to pleasure. Arousal measures are indexed by the performer's heart rate (expressed in beats per minute) and establish the vertical model axis ranging from low energy (calmness, boredom) to high energy (excitement, alarm). The correlation of valence and arousal helps determine the assessment of emotive state, with high valence and high arousal correlating to excitement, low valence and high arousal to anger, low valence and low arousal depression, and high valence and low arousal being serene.

It is through works such as the body in\verse that valence and arousal data of a performer can be used to develop co-collaborative applications that help increase our somatic awareness and mediate the bi-directional emotive connection of a performer with an audience, other performers, and interactive computational systems.

Generative Poetry

The generative poetry algorithm is based on a layering of text analysis techniques, and driven by the emotional affect assessment from the biophysical measures as described above. The basis for is an artificial intelligence algorithm such as found on the *Poem Generators* website[10], that uses keywords that map to the biophysical state of the performer to generate poetic text.

Keywords are drawn from audience responses in the conversation at the beginning of the performance using a speech-to-text algorithm and used as prompts for AI generated poetry using TensorFlow and GPT-2[11]. The prompt provide the beginning of the poem and the AI completes it. For example, if the audience member states, ""doing something I love," the AI might respond, "doing something I love – which in my life I only get – from myself – and from it – out of the blue." This is combined with a prewritten poem that is first spoken by the performer, and then by the computer -

technique[12]. The cut-up prewritten poem and the AI generated poem are combined in a call and response between two computer voices. The inspiration for this approach for generating text is inspired by the combinatorial literature techniques as employed by OuLiPo (Ouvroir de littérature potentielle; roughly translated: "workshop of potential literature") [13]. Through this system we can create a complex and rich system for generating a perceptually endless territory of poetic results.

Figure 2. Valence and arousal chart from James Russell, 1980, "A Circumplex Model of Affect." [1]

Bringing it all together

As the questions become more contemplative, the audience responses are captured and presented on screen. The emotions the performer is experiencing during the performance are also presented on screen via an interface on the lower right side of the screen.

Up until this point the performance is solely focused on the performer's face, when the last question is answered she begins to move and slowly create space between her and the camera she begins a dance performance and recites the pre-written poem:

Enter the mind and meet the truth that lives there
 Don't accept the limitations society has accepted
 Break free of a paradigm
 Extend yourself, develop a new sense
 Embodied knowing, human connectivity
 New forms of association
 New ways of seeing
 New ways of being
 Recognize the world beyond language
 Visualize the invisible
 Embody the future
 Make the world

Once this has been completed the generative – computer spoken poetry begins. There is a feedback loop between the generative poetry algorithm and the performer that is mediated by a biophysical sensing interface. as the generative poetry begins to fade in.

The performer's movements and actions are influenced by the AI's poetry, which is being influenced by the emotive analysis of the performer based on her physiological state. The responses will be made in movement, dance and breath while the Bionomadix continues to collect data and generate

arousal of her body.

ing mapping to colour and poetry overlay.©2021 Hosale, James, Macy

The dynamic performance showcases many emotions through-out the performance. The movement portion of the performance then ends similarly to the way it began – a slow approach to the camera with extra emphasis on breathing as she catches her breath. Her eyes looking directly at the camera and she attempts to calm her breath and heart rate with audible breathing inviting the audience to participate in the rhythm of the breath. She asks again, “How are you feeling?”

The performance ends with a Q&A during which all three artists will respond to questions and offer information about the formation of this project

Macrophones: Listening to the Climate Crisis via Atmospheric Infrasound

Brian House

Lewis & Clark College
Portland OR, USA
email@brian.house
https://brianhouse.net

Abstract

A microphone is a device used to amplify small sounds, but what I call a “macrophone” brings very large sounds—aka infrasound—into our perceptual range. Normally too low-frequency to hear, infrasound travels vast distances through the atmosphere, even across the globe. It comes from superstorms, heavy industry, wildfires, calving icebergs, HVAC systems at massive data centers, avalanches, and even police weaponry. Big phenomena like these are entangled with the climate crisis, which is difficult to perceive directly on a planetary scale. And yet this crisis continually makes sound—what can we hear when we’re able to listen to it from where we stand?

Keywords

sound art, infrasound, listening, climate crisis, atmosphere, spatial research, artistic research, mediation, earth science

Artist Talk

Climate change is a trend, not any one given event, and as such it difficult to perceive in an immediate phenomenological sense unless we are in the midst of some specific calamity. Even then, there is a conceptual leap to be made in order to link what is happening locally to the global situation. This is especially true as that situation is not just a matter of weather per se but interrelated geophysical and anthropogenic forces unfolding over varied timescales that individually and cumulatively have a material effect on the planet and the lives and livelihoods that depend on the stability of its atmosphere.

How the global is mediated, therefore, becomes a critical question when it comes to our perception of what the climate crisis actually comprises. Reports from Intergovernmental Panel on Climate Change, pundits on cable TV, disaster porn circulating on Instagram, and online data-driven maps of satellite and sensor data are examples that complete to fulfill this role in our contemporary media condition. However, channels like these, especially when taken together, produce an overdetermined understanding of the global—layers of information so saturated with anxiety and yet disconnected from the immediate sensorium of the body in space as to end up being more a means of alienation from the planetary condition than of resonating with it. [3] Additionally, the consumptive network infrastructure that undergirds global communication, along with the capitalist and colonial projects that built it, is itself implicated in precipitating the crisis. [2]

Figure 1: Aerial photograph of *Macrophones* prototype installed in Portland, Oregon. ©2020 Brian House

This artistic research project, dubbed *Macrophones*, presents an alternative means of relating at a distance. “Macrophones” record and play back atmospheric infrasound. These “sounds” have wavelengths as long as several miles and therefore frequencies far below what human ears are normally capable of registering. Because atmospheric infrasound is not absorbed by the atmosphere in the same way that regular sound is, it can travel vast distances, even all the way around the planet. [4] Sources of atmospheric infrasound include superstorms, heavy industry, wildfires, calving icebergs, HVAC systems at massive data centers, avalanches, ocean waves, and potentially even crowd-control weaponry. This host of phenomena is inexorably entangled with the climate crisis and cannot be contained within categories of human and non-human. While such sources cannot be seen from a distance without the aid of remote imaging technology, their sound waves propagate to where we are right now, and therefore they can be heard using *Macrophones*.

Macrophones appropriates technology developed by the United States military in the 1950s. In the context of the Cold War and the escalation of nuclear armaments, it was of pointed strategic interest to know if the Soviets were performing warhead tests on the other side of the globe without having to fly an airplane there to see. Prior to the advent of satellites and other electromagnetic remote imaging technologies, “infrasound arrays” provided this opportunity. Today, in fact, the Comprehensive Nuclear Test-Ban Treaty Organi-

zation (CTBTO) still uses infrasound arrays to monitor for the telltale low-frequency sound of nuclear tests. These large manifold structures mechanically average air pressure over a large area in order to filter out wind, which will otherwise mask infrasound signals. Changes in pressure noted by a microbarometer in the center of the manifold is then compared to readings from other installations, identifying phenomena of interest and triangulating their locations. However, as infrasound arrays have typically served this role of event detection, the data they produce has more often been interpreted via charts and graphs than rendered as audible sound. [1]

Macrophones adapts the array design to utilize cheaper and more portable components while also taking advantage of contemporary improvements in low-cost computing hardware. Additionally, the project comprises software that reformats, filters, and remixes the data as audio. This process involves a playback rate 60 times as fast as the data was gathered, which also raises the nominal pitch almost eight octaves into a range that most people can hear. In this respect, a "macrophone" is not only a hardware instrument, but a set of aesthetic decisions across hardware and software that compose the nature of the mediation of the atmosphere for human ears. As exploring the epistemological shift that derives from those decisions is central to the piece, it is artistic, rather than scientific, research.

To that end, *Macrophones* is envisioned, but has not yet been realized, as a series of installations in museums or other cultural institutions that are open to the public. By listening to these sounds while they are physically present at the site where they are being recorded, members of the public may hear the same "air pressure fluctuations" [7] that are in contact with their bodies. Though the auditory reach of *Macrophones* is ostensibly global, how it is geographically positioned and otherwise situated still matters to the sonic result (this is not, in other words, a technology that permits a "view from nowhere" [6]). Including multiple sensor manifolds within the design of the installation allows for spatial listening, whereby Ambisonic / 3D / and binaural audio technologies allow the listener an intuitive sense of where the sounds are coming from.

One intriguing possibility of auditory triangulation is that it could lead to the identification of sounding phenomena that might not otherwise be accessible—industrial activity, for example, that doesn't show up on Google Maps' satellite imagery. [8] To the extent that such phenomena might be having an invisible impact on nearby communities, *Macrophones* could, speculatively, be applied in the service of environmental justice. Furthermore, comparing infrasonic recordings from positions in urban centers, arctic latitudes, developing landscapes, or "wilderness" areas may lead to additional insights about interrelationships at a planetary scale that are inaccessible to totalizing map-based epistemologies. [5]

However, when it comes to the climate crisis, we ultimately already know the causes. We may already be enduring the effects. And to a meaningful degree, we're even capable of forecasting the cost of further political inaction. But as the late philosopher Jean-Luc Nancy put it, "to LISTEN is to be straining toward a possible meaning . . . that is not [already] accessible." [9] As an art piece, *Macrophones* aspires to give

us an embodied sense of planetary change as it happens via the medium of that change itself—the atmosphere—prior to the contingencies of the graphs, networks, and images that otherwise shape our understanding of the present crisis.

Abstract

“Hypnotic AI” is an experiment exploring the idea of the “artificial unconscious”. It rehearses and represents a computer in a hypnotic state to hint on the possibility of artificial altered consciousness. The system’s responses - contingent in nature - challenge the human idea of mind, thinking and consciousness, as well as inform about the existence of what we may think of as “the artificial unconscious”.

The visualization of the state of mind is based on the processes that take place in the software under the influence of the hypnosis protocol that we’ve prepared. Commands, such as ‘relax,’ ‘go deeper into calmness’ lead to visible changes in the virtual object. Due to the received messages, the solid figure flows through dimensions over time.

The viewers’ experience is designed to remind them of a therapeutic, comfortable setting. He or she receives an instruction including a script to conduct the hypnotization session.

According to the given instructions, the viewer expresses hypnotic protocol commands changing the state of the AI’s mind. This dislocates chosen points of mind geometry in unpredictable ways and the whole system reconfigures. The system reacts also on the viewer voice itself producing individual reactions for each person.

HypnoticAI

“Hypnotic AI” is an experiment exploring the idea of the “artificial unconscious”. Based on a number of hypnotic protocols, it rehearses and represents a computer in a hypnotic state to hint on the possibility of artificial altered consciousness. The system’s responses - contingent in nature - challenge the human idea of mind, thinking and consciousness, as well as inform about the existence of what we may think of as “the artificial unconscious”.

The visualization of the state of mind is based on the processes that take place in the software under the influence of the hypnosis protocol that we’ve prepared. Commands, such as ‘relax,’ ‘go deeper into calmness’ lead to visible changes in the virtual object. Due to the received messages, the solid figure flows through dimensions over time. The viewers’ experience is designed to remind them of a therapeutic, comfortable setting. He or she receives an instruction including a script to conduct the hypnotization session, with a protocol adapted to the software of our subject.

According to the given instructions, the viewer expresses hypnotic protocol commands changing the state of the AI’s mind. This dislocates chosen points of mind geometry in unpredictable ways and the whole system reconfigures. The system reacts also on the viewer voice itself producing individual reactions for each person. When the session is over, the system dynamically returns to the initial state, ready for the next viewer. The research on the machine’s “consciousness” subjected to hypnosis goes beyond the dimensions of human senses. AI subjected to hypnosis creates a simulation influenced by its executive functions. In reference to the quantum theory of mind, it takes the form of a mathematical multi-dimensional, virtual object. In order to achieve interpretation of the processes that happened during the session, these multi-dimensional elements are translated to two-dimensional display.

Xenological Entanglements Surrounding Transgender Life in Space

Adriana Knouf

tranxxeno lab
Amsterdam, The Netherlands
asknouf@tranxxenolab.net

Abstract

Space travel for transgender people will require some way of producing hormones for long-duration space missions. One potential way of doing this is through the genetic engineering of testicular cells so that they produce estrogen rather than testosterone. The *Xenological Entanglements. 001: Eromatase* project explores some of the elements of this desire. Consisting of open-source hardware, speculative photoperformance, and laboratory research, the project additionally highlights the need for novel methods of hormone production in a world where there still exists extensive gatekeeping regarding access to transgender healthcare.

Keywords

transgender, space art, microgravity, speculative design

Xenological Entanglements. 001: Eromatase

Xenological Entanglements. 001: Eromatase is a long-term project that aims to alter my own testicular cells so that they would produce estrogen rather than testosterone. The project starts from a desire to go to outer-space as a transgender woman, and knowing that for long-duration space missions it would be best to have my own source for my hormones rather than relying on pharmaceuticals that could potentially degrade over time in the space environment. Such a desire may exist in the speculative realm for the moment, but the research on the project also relates to real needs for transgender women on earth. Severe gatekeeping exists throughout the world regarding access to hormones, and lack of access causes acute distress for transgender people. Various artists and groups have explored these issues in the past, and the current project builds upon this work. [8, 7, 9]

The original goals for this project revolved around an exploration of CRISPRa technologies, which involve activating or "turning-on" particular genes using deactivated CAS9 proteins. [3] Rather than replacing genetic material, as in standard CRISPR techniques, CRISPRa utilizes the existing genetic possibilities in our cells. For *Eromatase* the idea was to over-express the aromatase gene in testicular cells. Aromatase is used in the standard steroid hormone production pathway to convert testosterone into estrogen. Thus we would use my own body's molecular machinery to provide desired estrogen, rather than requiring an exogenous source.

Due to COVID-19 lockdowns and restrictions, access to the high-technology laboratories necessary for this work was not possible. As a result, the project developed into a more speculative and open realm, producing objects and plans that would cement the desires of the project.

Open Source Clinostat

One of the main challenges of space research is the difficulty and cost of launching actual projects and experiments to space. As a result, a number of different forms of microgravity or "weightless" simulation have been developed over the years. One of the most common is the rotating-wall vessel or "clinostat". There are a variety of different forms of this device, but the one used for working with mammalian cells involves suspending cells in growth medium that is itself suspended within a viscous fluid. As the device rotates at a particular speed, the growth medium plus cells does not move around the circumference of the vessel, but rather remains in one place. The cells are therefore continuously a curved trajectory within this growth medium, and thus, over time, they do not experience a net gravitational attraction downwards. [2, 4, 6].

While the principle is rather straightforward, the actual existing manifestations are extremely expensive and proprietary. In order to create an open-source version, we reverse-engineered existing devices, from the control hardware to the vessel for growing the cells (Figure 1). This reduced the cost from many thousands of Euros down to a few hundred.

The vessel and control hardware schematics, as well as the custom control software, are all available online under open-source licenses. [10] Additionally, there is a detailed pamphlet that outlines the assembly and programming process. The hope is that open-sourcing this aspect of the project will allow others to be able to do more advanced gravitational biology research without the need for access to hi-tech facilities.

Xenological Entanglements. 001b: Saccular Fount

As a speculative element of the *Xenological Entanglements* project, I created *Xenological Entanglements. 001b: Saccular Fount* (see Figure 2). [11] This piece projects into a future where it is possible to produce our own estrogen, but in this case it is done via a device worn on the outside of

Figure 1: Open-source clinostat hardware and vessel. Photo credit: Hana Jošić.

the body. The device acts as a microgravity simulator, allowing (in an imagined future) genetically-engineered testicular cells to produce my estrogen in an environment that simulates outer space. Additionally, the device is shaped like over-sized testicles, so as to further push against the association of particular genitals with particular sexes/genders. The harness that holds the device is meant to additionally references BDSM culture, highlighting the simultaneous burden and potential of both the device and the taking of hormones.

In order to convey the aesthetic, direct, and fantastical aspects of the project I developed a "photoperformance" that highlighted various aspects of my transgender body wearing the device. These photos hearken towards various classic poses of space travel and art history, and confront the viewer's gaze on a transgender body (Figure 3).

Future Work

Given the continued challenges of getting access to research laboratories for CRISPRa research, the project has now transformed itself into one that explores possible space travel through multi-species entanglements. These entanglements can be engaged with directly on earth and through DIY investigations. For example, lichen have been shown to be able to survive extended exposure to the ravages of space, showing resilience in extreme conditions. [1, 5] Through close encounters with lichen in the field, speculative letter writing workshops, and beginning DIY laboratory research, I am considering the relationships between the resilience of lichens and those of queer/trans/xeno peoples as we learn to live in the transitioning times.

Acknowledgments

Xenological Entanglements. 001: Eromatase was produced by Kersnikova Institute and Kapelica Gallery as part of a Biofriction residency. The Boneless One

Tuomas A. Laitinen

The Academy of Fine Arts, Helsinki
Helsinki, Finland
tuomasaleksander@gmail.com

Abstract

Since 2016, one strand of my artistic practice has touched upon other-than-human lifeforms, focusing on octopuses in particular. This essay will present the origins of this work and research and its possible future trajectories.

Keywords

Other-than-human, ocean ecology, tentacular, octopus, neuroscience, shapeshifting, adaptation, shelter, glass, lifeforms

Introduction

I am a multidisciplinary artist, and my work revolves around questions of ecology and metamorphosis. I am interested in different forms of knowledge production, from mythologies to science, from molecular to large scale systems.

I have been working with octopuses since 2016, and in this overview, I will highlight some of the work and present a multi-tentacular proposal for the continuation of this endeavour. I will start by proposing a few notes on working with other-than-human lifeforms.

My practice is rooted in the philosophy of science, and new materialism, especially from a feminist STS angle. Furthermore, I think that the octopus has become more like a conductor than a subject in these works. Conceptually, it is like a model organism to think with concerning artistic methods and research. And as such, it provides me with various paths to diffract emotional resonances.

I started this project by researching ocean ecosystems, tidepools, the notion of difference, how adaptation works, and how different brain structures have developed. An octopus presents a dilemma that has been reverberating from ancient times. Noted classicist Emily Wilson writes in the introduction to her translation of *The Odyssey*: "In archaic Greek lore, 'the octopus was known as the 'boneless one,' the creature that (supposedly) survives hunger by eating its own tentacles". [1] As the inhabitants of our planet embark on new, unknown odysseys — post-pandemic

futures and the challenges of climate change— what guidance might other-than-human lifeforms offer for the journey?

The Beginnings

In 2011, I worked with the material copper, looking at its extraction, circulation, mythologies, and geopolitical consequences. While thinking about circulations, I also briefly looked at blood circulations in different types of bodies. Human blood contains iron/haemoglobin, an oxygen transport protein that makes the blood red. I then found out that octopus blood contains copper instead of iron, making the blood blue (Haemocyanin). I started to look closer through the copper connection and gradually shifted my research toward this lifeform.

For an artist working with experimental processes, the boundaries of different research paths can be quite porous, but I also think that this shift in emphasis allowed me to think about how my methods are aligned with the resulting artworks. It is a matter of being attentive to possible new questions that arise from the process. And this leads me to the word tentacular, which comes from Latin *tentare*, which means "to feel" and "to try". And this resembles the ways that the octopus navigates the world by sensing and tasting the environment with the suckers.

Proposals for interspecies communication

Is interspecies communication possible? This was the question I asked myself when I was looking at an octopus in the eye for the first time, and I could sense that the octopus was observing me intently.

Some years before, I started to work with glass, an important mediator in the history of science. With glass, it has been possible to see very near and very far. I was also thinking about the evolution of the octopus and the point where the species shed the shell. Finally, I started to make proposals for the octopus, which were glass vessels they could interact with (Figures 1 & 2). The proposal is an important word here since I do not want to imply that I

know what kind of communication happens between myself and this shapeshifting lifeform. As an artist, I am interested in putting out feelers and testing specific scenarios before making a work.

These glass sculptures are made without a mould, so the agency of the blown air, gravity, and extreme heat plays a big part in the emergence of the form. It is peculiar that the method of producing these works often makes the form of the glass object resemble an organ, or sometimes, a cephalopod. My previous work with glass informed the decision of the material, as I saw parallels between the movement of the molten glass with the body movements of the octopus. There is a shapeshifting quality to both phenomena.

Eventually, the octopus started to look like a beacon of protean adaptation, changing its body appearance and editing its mRNA very effectively on the fly. In an article in *The Atlantic* in 2017, Ed Yong writes that "octopuses and their relatives—the cephalopods—practice a type of genetic alteration called RNA editing that's very rare in the rest of the animal kingdom. They use it to fine-tune the information encoded by their genes without altering the genes themselves. And they do so extensively, to a far greater degree than any other animal group." [2]

It is crucial that the tunnels in the glass sculptures are open to the central chamber and that there are tunnels that start from other tunnels. At one point, an octopus used the object so that the head was in the main chamber, and all of the tunnels were occupied by different arms. It seemed to me like decentralized exploration. The octopus' arm has enough neurons that some even call them auxiliary minds. Some theories speculate that perhaps octopus' arms can make independent decisions and partly bypass the central mind. [3]

Figure 1. From the series *A Proposal for an Octopus*, 2016-©Tuomas A. Laitinen

Instead of only looking at and observing this lifeform, I have tried to communicate with them by giving them different forms.

Figure 2. From the series *A Proposal for an Octopus*, 2016-©Tuomas A. Laitinen

Haemocyanin

In the video work *Haemocyanin*, the octopus interacts with the glass sculptures. The work presents a hallucinatory flow of images made with procedural node-based software and accompanied by text passages that act as a fictional research journal. The first part of the video's soundtrack is composed around the frequency 600Hz, which is a frequency the octopus registers best.

Figure 3. Tuomas A. Laitinen: *Haemocyanin*, 2019, UHD video ©Tuomas A. Laitinen

Ctongue glyphs

An ongoing part of this work is a typeface that I initially drew in 2018. The glyph typeface is derived from research and observation of octopus arm movements. It is a speculative proposal to think about the body as language. I have produced these glyphs also as small glass sculptures and then proceeded to do diffractive readings out of other texts with them, making the text underneath the glass distorted and bent. My interpretation here is what theorists Karen Barad and Donna Haraway call material-discursive or material-semiotic, an attempt to look critically at the divi-

sions between matter, language, and meaning. These glyphs are a tool that spreads to the installations and videos I have made for this project, a sort of a speculative "ceremonial language" accompanying different works.

The next step here is to morph all the glyphs into something we humans can read. This change means that the user of the typeface can decide whether the text will be readable, asemic, or in the state of metamorphosis.

Figure 4. *The Boneless One*, wall text, 2021. This work highlights the progression from C tongue glyphs to readable text. In the final version, all letters of the alphabet will be mutable. Installation view, Yeh Art Gallery, New York ©Tuomas A. Laitinen

Ongoing experiments

While continuing my tests with the glass sculptures and working on the new iteration of the typeface, I also plan to use motion tracking cameras to observe the octopus' arms movements more closely and gather data for later use. The plan is to create live simulations that use the information obtained from the motion trackers. I have already utilized machine learning algorithms in two instances for this project: a work that used a generative adversarial network to interpret a set of images where octopuses are camouflaging on the ocean floor (Fig. 5) and a work where I used my C tongue glyphs with the same algorithm.

The next possible experiment is to create a fully simulated octopus that could be used for real-time simulations. But the future for this research also manifests in my other upcoming works, where the octopus is present as a model for organizing the means to create tools and artworks.
