ISEA2022 Barcelona Opening Ceremony

Josep A. Planell Estany

President of the Universitat Oberta de Catalunya

Barcelona

10 June 2022

After ten years away from Europe, Barcelona is now hosting the 27th International Symposium on Electronic Arts, ISEA2022.

None of us here today will fail to see the importance, the recognition and the responsibility this carries.

For one thing, it's **a tribute to the reputation of both Barcelona and its creative, artistic, scientific, technological and institutional nexus.**

It's an ecosystem whose fertility comes from its variety, fullness, multidisciplinary and compatibility; an ecosystem that has accumulated experiences and successes and has now reached a state of maturity.

No longer is it an emerging power, it's part of a driving force for the economy, industry and the arts.

Behind this Barcelona-based ISEA there are professionals, organizations and networks keenly committed to creativity and innovation.

Their unique and distinctive character and their talent, diversity and strength can be seen in their respective histories and projects.

And for another thing, in Barcelona there is determined ambition to join and play an active part in our future world – designed here and now.

This is why, as pointed out by Cristina de Middel, winner of Spain's National

Photography Prize in 2017 and guest speaker for the UOC's inaugural lecture the following year, *"it's hugely important now to encourage people to question things, more than it is to offer answers"*.¹ We know the future isn't a programmed destination, rather it's a place that we all must co-create.

In this sense, the dozens of activities, exhibitions and talks populating the ISEA2022 Barcelona programme offer us a map of this future that we are already starting to build.

With our hybrid, all-encompassing format, we have sought to decentralize our locations in and outside the city, above all aiming to involve every area of

knowledge, to encourage contact between artists, scientists, engineers and theoreticians, and to discuss, present and share prototypes, devices, art and ideas.

This is why, for the UOC, it is an honour and a privilege to be an organizer of this event.

First: because we want to remain at the cutting edge of research in the knowledge society and in digital transformation; this means interconnecting academia with public and private entities, enhancing teaching, research and innovation.

Because, if we want our university to be useful to citizens, if we want to make

ISEA2022 BARCELONA

impacts that are relevant for society, if we want to count and be counted **we must be part of the change, we must deliver digital literacy for our citizens, we must commit ourselves to open and shared knowledge, we must contribute to the designing of our future.**

Second: because – like ISEA – we treasure our legacy: an academic community made up of a critical mass of teaching staff and researchers who work at the intersections of the arts, science and technology; an interdisciplinarity that – to be useful both internally and externally, to the university and to society – must be steered to support teaching, to strengthen research and innovation, to encourage knowledge transfer and to increase the social impact. And third: because our involvement here gives continuity to greater works. Everything we will learn, discuss and discover over the coming days can only make sense as part of a continuum. Without the intense preparations, there would be no symposium. Without having anything to show for it afterwards, our work would be in vain. In short, ISEA is and **must be a link in the chain holding together our strategic and transformative outlook.** Each time this international symposium has been held anew, it has enriched us with networks, knowledge, infrastructure and policies. It will also do so this time. We also want to do this.

This is why we have initiatives such as Hac Te, the art, science and technology hub created by numerous people here among us, which aims to provide a strong root for this ecosystem, upon which it can develop structure and stability.

This holding of ISEA2022 Barcelona is a materialization of the work of Hac Te and demonstrates its potential. It will do so over the coming days, offering many different activities in this symposium. And it will do so in the aftermath of ISEA2022 Barcelona, taking over to let the conversation continue.

We do this and will continue do this maintaining the bearing that Carme Pinós, recent winner of Spain's National Architecture Award, summed up in four points: ***"Respect each other. Encourage debate and participate. Listen and ask questions. Believe that we have responsibilities and we can contribute."***²

Right now, technology and innovation are inseparable from our culture and creative industries. And ISEA2022 Barcelona presents us with a spur, a window of opportunity for exchanges, collaborations and learning. ■

Joan Soler-Adillon, Enric Mor

Universitat Oberta de Catalunya

It was in the summer of 2017, as the last details were being added to ISEA2017 in Manizales (Colombia), when we began to receive emails encouraging us to present a candidacy to organize an edition of the symposium in Barcelona. Our city had been taken into account for years due to the quantity and quality of the professionals that work in its digital arts scene: they include collectives and artists (some of whom have won major awards) as well as internationally renowned festivals, centres of artistic production, universities with their research groups and researchers, and the outstanding artistic and cultural centres in a broad-based relationship between art, science, technology and society.

We initially believed that an undertaking of this nature would involve too many resources and that although it was an extremely interesting idea, we needed to find better reasons with greater potential if we were to carry it out successfully. So we began to think about the idea that perhaps ISEA itself could be the perfect excuse to help bring about some changes and transformations in the city. In fact, both the resources and the parties involved in the network were already receptive to an initiative like this one, aimed at channelling and creating the structural qualitative transition that many prominent members of the community in Barcelona had been demanding for a long time. We then began to think on a larger

scale, aware of the potential and vitality of a city that is particularly creative and open to the world, and we realized the tremendous wealth of the art, science, technology and society ecosystem in our immediate surroundings, which despite its broad base and heterogeneous nature, and its location and distribution in multiple places and venues, continued to enjoy remarkable levels of energy and motivation.

Any multidisciplinary and heterogeneous space tends to be difficult to administer and digest, especially in a world of isolated factions, sectors and immovable identities. That is what it means to place oneself outside the mainstream, beyond

disciplines, beyond boundaries and beyond the realms of what is possible. The possible and the impossible - daring to imagine other possibilities as a horizon of change that unfolds and organizes the world. The possible as an opening and a movement from which to leave the pre-established, pre-conceived and pre-designed behind, and place oneself in the future and its creative uncertainty. It was obvious that "the possible" should be the main theme of the ISEA Symposium that we wanted to organize in Barcelona - halfway between realistic pragmatism and futuristic speculation with ramifications of truth, moving beyond the placid distance of utopias and the eternal frustration of revolutions.

ISEA2022 BARCELONA

That was the situation when, with the institutional partnership of the Universitat Oberta de Catalunya (UOC) and the support of Barcelona City Council, we presented our candidacy for ISEA2021 in Durban, South Africa, in mid-June 2018. ISEA 2018 Symposium was a major transformational experience due to the wide variety of contributions and perspectives that we were able to experience in a few intense days in Africa. We knew then that if everything went according to plan and we were selected, we would have to announce our venue in Gwangju, Korea, in 2019 and take centre stage in Montreal in 2020. And that was how it turned out - we were selected by the ISEA International Board, and brought the event back to Europe after an absence of more than 10 years. We had to go to Korea to present our proposal based on the theme of "Possibles", which was, by then, more structured thanks to our collaboration with a network of institutions which understood from the very beginning the opportunity and the need for involvement in a transformational event like the ISEA.

What we did not know at that time is that at the end of that same year, 2019, the world would change completely as a result of the coronavirus pandemic - a pandemic that is still ongoing at a global level today, and which continues to wreak havoc as its variants evolve and spread across the world. Under those circumstances it was impossible for ISEA2020 Montreal to take

place in a face-to-face format, and this was a contributory factor to how, despite the dates being changed in the hope of an improvement of the global health situation, in the end practically everything had to take place online. Similarly, in view of the outlook, we had to postpone the face-to-face edition planned in Barcelona for 2021 until 2022. In 2021 we held an entirely online preparatory event that we were able to schedule within the framework of the Barcelona Science Biennial. It would have been perfect to be able to hold the ISEA Symposium at the same time as the Science Biennial, and link the two events in the way we had initially proposed with the backing of the City Council, but at that time it would have been extremely reckless to bring to Barcelona participants from the over 40 countries that usually contribute to this event.

We created the institutional architecture of our Barcelona edition surrounded by all the uncertainty associated with major events in these new circumstances. From the outset it was our aim to combine the academic, education and research spheres with the cultural and civic artistic context, and with the technological-industrial environment. The UOC, as the organizing and promoting university, gradually added partners with the support of the Catalan Ministry of Science and Universities, and Barcelona City Council's

Pau Alsina, Director of ISEA2022 Barcelona

Irma Vilà, Vice-director of ISEA2022 Barcelona

Institute of Culture. The first to join were the Centre de Cultura Contemporània de Barcelona, and the Santa Mònica Arts Centre respectively hosting the conference sessions and one of the main exhibition venues. A decisive contribution was made by the Government of Catalonia's Ministry of Culture and the Ramón Llull Institute, which also led the way in the event's internationalization by organizing two editions of the Ars Electronica Garden in the city, together

with the expertise of the New Art Foundation and its outstanding digital art collection, which was also presented at the four venues of the ISEA exhibitions.

Barcelona City Council's support made it possible to extend ISEA across the entire city. More than 40 institutions were involved in the programme including Canòdrom democratic digital cultural centre and La Capella exhibition centre, highlighting the decentralized and broad-

ISEA2022 BARCELONA

based nature of the event. In turn, the Government of Catalonia's support made it possible to produce the main ISEA exhibition in Arts Santa Mònica with the highest levels of quality, arising from the selection of the more than 500 ideas that arrived in the wake of the open call for artistic projects. The support of the Government of Catalonia was also crucial in extending the programme to 10 more cities and towns (Girona, Lleida, Mataró, L'Hospitalet de Llobregat, Amposta, Tarragona, Vic, Balaguer, Reus and Berga), establishing links with centres and programmes across Catalonia. In addition to the above, there is the Sant Pau Art Nouveau Site, with a magnificent exhibition of works of art from the ISEA open call and from the New Art Foundation Collection, as well as a selection of artworks from the platform Niio.art. The objective was to merge local and international communities, contributing to the creation of collaboration and exchange networks between the various parties involved. We also aimed to make everything accessible to the public and citizens in general, both in Barcelona and elsewhere in Catalonia, who were invited to participate in a wide range of activities spread throughout the area.

ISEA2022 Barcelona was then defined as an international, interinstitutional, intersectoral and intergenerational event with a clear multidisciplinary and transformational vocation, creating a structural foundation in the city (and the other participating towns)

with the creation of projects including Hac Te, Barcelona's Art, Science and Technology hub that brings together more than a dozen institutions committed to the development of art, science, technology and society, including universities such as the UOC, UPC (Universitat Politècnica de Catalunya) and UPF (Pompeu Fabra University), research centres such as the BSC, ICFO and BIST, festivals such as SÓNAR, production centres including HANGAR and museums including MNAC, collectors such as NAF, business groups including Tech Barcelona and events such as the FIRA trade fair. This is in addition to the Spanish RED ACTS network created by the Daniel and Nina Carasso Foundation, with the UOC, Hac Te, CCCB, Hangar in Barcelona, Tabakalera in San Sebastián, and the UPV (Universitat Politècnica de València) and the CCC in Valencia, among other projects promoted within the framework created by the event and which are currently ongoing, such as the update of the art, science, technology and society White Paper undertaken by the FECYT (Spanish Foundation for Science and Technology). The synergies arising between all the different initiatives mentioned above which are in progress in Spain, as well as the clear connection with the programmes that are being undertaken at a European level, such as the S+T+ARTS programme and the recent New European Bauhaus programme, herald a positive outcome in terms of the structural impact of the major initiatives.

And so now we find ourselves in 2022 with the pandemic brought substantially under control, and emerging from a global health situation that was a major concern in its early years, while at the same time suddenly having to deal with another unexpected war in Europe; the Russian invasion of Ukraine upset global mobility even further, increased uncertainty, and led to changes in the organization of events with the consequent international travel involved. The changes that have taken place during these intense years of fusion between the virtual and the face-to-face realms, with forced physical distancing and unavoidable online proximity have yet to be assimilated. Indeed, we have been unable to include participants from all the countries that had their proposals accepted for our event.

Nevertheless, despite all the difficulties that have arisen, we obtained a magnificent response from the international community, with 1,019 proposals submitted for evaluation by the 268 international experts in the ISEA scientific committee and the joint artistic jury in Barcelona. It was a complete success given the circumstances, for which we can only extend our warmest thanks to all those who took part in the evaluation process. In turn, the ISEA organizational team, which had over 40 members, had to coordinate, in record time, all the teams of both the scientific and artistic committee and of the over 50 institutions in the 11 towns and cities taking part.

In addition to the traditional ISEA conference and main exhibition, we have added partnerships, activities and venues to

ISEA2022 BARCELONA

create an ISEA that is spread throughout the city and across Catalonia, and firmly committed to involving the various agents and audiences interested, citizens and society in general. As a result, and counting all those attending each of the events taking place in all the venues, there have been 45,447 attendees, of whom 743 were accredited and participated in some of the events taking place in more than 40 venues, 11 towns and cities, 4 exhibitions with more than 80 artworks, 4 keynote lectures, 140 research presentations, 45 institutional presentations, 40 artist talks, 23 screenings, 18 posters and demos, 16 round table discussions, 13 workshops, 13 performances, 1 specialized meeting on

media art archives, 1 founding meeting of the Spanish ACTS network, in addition to 2 mappings and a drone show for the general public, which took place in the city of Barcelona for the first time.

ISEA2022 Barcelona involved an exceptional exhibition containing more than 80 artworks at the intersection of art, science and technology. The artworks exhibited were the result of the selection from the ISEA open call related to the theme of "Possibles", as well as the resolution of the open call for the production grants awarded: all of them were selected in a review and selection process by the international committee

and artistic jury, and the teams of curators at each venue. Pieces from the electronic art collection of the New Art Foundation were also selected based on the event's main theme, with the aim of establishing a fruitful dialogue with the long and fertile history of interrelationships between art, science, technology and society. The 80 artistic pieces, the 13 performances and the 23 screenings that were on display during ISEA make a total of 116 items, which are documented in this catalogue, and which highlight the diversity of the projects that were exhibited during the event and in the subsequent months when the 4 associated exhibitions and events took place.

The Santa Mònica Arts Centre hosted the main exhibition at ISEA2022 Barcelona, entitled "The Irruption", which featured a selection of pieces that came from the open public call for entries, making up "a set of pieces and projects that, from different positions, investigate the environmental, climate and social crisis and the possibilities of art (always limited and partial) to re-politicize the imaginations, traumas, fears and urgencies that challenge and instigate us to irrupt otherwise, under response(-able) conditions from within the environmental and socio-economic collapse into which planet Earth has been plunged". The exhibition was open for three months, and was designed as an

invitation for all those attending to trace multiple narratives, either individually or accompanied by the group of collaborators who activated the pieces with their narrative itineraries and mutant visits. "La Irrupción" clearly resonates with the experiences related to the pandemic and the consequent associated collapses, and presents the isolated imbalances of normality as a manifestation of a continuum of accumulated phenomena that are an expression of the planet's exhaustion and of the potential that has yet to open up.

For two months the La Capella exhibition hall hosted the exhibition entitled "What is possible and what is not", which linked local artists selected through the ISEA call with local artists from the call by Barcelona Producció which defines the programming of the venue. "What is possible and what is not" thereby presented a crisis in the possibilities that lie within technological breakthroughs, but which conceal important limitations and conditioning factors. The same capacity of technologies to make possible what was previously impossible to imagine also prepares us to collide with its boundaries. In turn, the ability of science to explore those boundaries shows us that what is possible is always a horizon that can be moved - an opening to the imagination that has yet to be developed.

ISEA2022 BARCELONA

This fascination with "Possibles", which presents what is real and unfinished in front of us, gave its name to the third exhibition organized in Barcelona which took place in the Sant Pau Art Nouveau Site, where a mixture of 17 pieces from the NAF collection, 5 pieces selected by the Art Jury of the ISEA open call and 6 works chosen by the Nio.Art platform were on display. In the venue's imaginative art nouveau setting, the exhibition of art, science and technology explored these other "Possibles" behind climate change and global warming, behind robotics and biotechnologies, within algorithms, artificial intelligence and data science, in quantum worlds, endeavouring to understand what matter is, up there above our heads in outer space and the multiverse. Beyond seeing ourselves trapped in a world of pre-designed possibles, the exhibition included ideas from all over the planet and from all areas of experience and knowledge, opening up to contingency, the future and the uncertainty of futures that are already open or which will be opened up in our present.

Finally, last but not least, the Cal Massó art centre in Reus hosted the exhibition entitled "Beep Collection: Origins", which used different perspectives to present some of the founding works in this pioneering collection, consisting of pieces considered essential in the history and development of electronic art which the collection has been rescuing and restoring, in order to highlight

the legacy of the pioneering creators who are now part of the history of contemporary art. The "Origins" exhibition also constructed a timeframe which sought to bring us closer to our evolution as a species and to the unstoppable development of life in its broadest sense, with works of art that explore identity and appearance, memories and recall, intelligence and the perception of reality and of the human body, and even material and cosmic environments. It provided a multidisciplinary perspective that in our complex historical and current framework, whether it is virtual or face-to-face, local or international, and with the other towns and cities in Catalonia (Girona, Lleida, Mataró, L'Hospitalet de Llobregat, Amposta, Tarragona, Vic, Balaguer and Berga), extended the universe of possibilities left behind by ISEA.

As we said at the beginning of the text on the origins of the 27th edition of the International Symposium on Electronic Art, the Possible was born in the polis, in the city, through dialogue, discussion and debate, and it is political by definition, as it shapes our reality. The political realm is made up of feelings, the ability to move and be moved in our openness to the world, in our network of intensities of the experience and adventures of the encounter. Encounters are made up of

relationships that account for every political dimension of our existence. After these difficult years of the pandemic, with their multiple ecosystemic upheavals, and the consequent isolation and social distancing, our aim was to use this policy of emotions to bring together the community of communities which is the multidisciplinary sphere that is recognized in ISEA. To create long-awaited embraces between local and international agents, individuals and groups, between virtual closeness and

face-to-face distances, between possibles and impossibles yet to be experienced in the multiple spaces for meeting, relationships, exchanges and complicity which we have been able to create, so that the composition of knowledge that gives name to our emotions can experience a resurgence, like a Phoenix in the firmament of the Possible. ■

ISEA, International Symposium on Electronic Art

ISEA is one of the most important annual events worldwide dedicated to the crossroads where art, design, science, technology and society meet.

The event has been held over 26 times all over the world, and after more than 10 years since it last graced European soil, it finally touched down in [Barcelona](#) during 2022. With it came an enthusiastic international and local community reunited to develop this interdisciplinary field.

ISEA2022 BARCELONA

ISEA2022 BARCELONA has reinforced the role of the city as a leader in research and scientific output and cultural and artistic creativity in both a national and international context.

What makes ISEA unique is that it is not so much an academic conference as a conference-based event that offers a wide array of activities, which surprise visitors with newly conceived formats in every edition. At the symposium you are sure to find exhibitions, workshops, open-air projects, round tables, artist talks, school initiatives and a variety of other activities, all with the involvement of different organisations and communities from the city of Barcelona.

ISEA, International Symposium on Electronic Art

Conference

ISEA2022 BARCELONA invited the participants to contribute to the growing debate on our world of "Possibles", the Symposium's central theme, in multiple formats including more than 140 papers presentations by experts, 45 institutional presentations, 40 talks by artists, 20 screenings, 18 posters and demos, 16 round table discussions, 16 workshops and 13 performances, all from the open call launched a year before, which received 1,100 proposals.

The **CCCB** has been the main venue for an international community of experts in art, science and technology who addressed topical issues including the creative capacity of artificial intelligence, the possibilities of immersive experiences, the imaginary of biotechnology in the arts, the challenges surrounding climate change, and new ways of addressing education, as

well as our cultural legacy. In addition, it has been the space for four keynote speeches by leading figures in their respective fields: Olga Goriunova, Joan Fontcuberta, Christl Baur and Ricard Solé.

Also, **MACBA** has hosted the **Second Summit on New Media Art Archiving**, among other activities such as artist talks or a performance. More related activities have been programmed in other venues such as Canòdrom, that hosted four panels from the call.

ISEA, International Symposium on Electronic Art

Extended Program

With the aim of bringing the intersections between Art, Science and Technology closer to the public, ISEA2022 has created the ISEA Extended Program, in Barcelona and other 10 cities (Girona, Lleida, Mataró, L'Hospitalet de Llobregat, Amposta, Tarragona, Vic, Balaguer, Reus and Berga), which has included more than 50 activities along the Catalan territory.

ISEA Extended Program made possible exhibitions, workshops, outdoor projects, panels, artists talks or school initiatives where visual arts venues, design schools, museums and art centers, art factories, festivals and high schools were involved.

The night of June 15, ISEA2022 Barcelona offered the first drone show in Barcelona, by Flock Drone Art Barcelona, open to the public.

ISEA, International Symposium on Electronic Art

Exhibition

ISEA2022 BARCELONA had brought together a marvellous and extensive display of pieces located at the convergence between art, science and technology, with more than 80 works including immersive installations, interactive and on-line works, sound art, animations, mapping and a drone show.

This exhibition has been a dialogue between works by international authors and around twenty Catalan artists, and pieces from the open call had been interspersed with other digital art collections.

LA IRRUPCIÓ

Santa Mònica, Barcelona
From June 9 to August 21

The main exhibition has featured 32 works: 23 pieces from the ISEA2022 Barcelona public call selected in conjunction with Santa Mònica, 2 pieces donated by the NewArtFoundation and 7 works acting as itineraries for the exhibition. The Irruption has presented works by leading international and local artists including Robertina Šebjanič, Lauren Lee McCarthy, Eric Berger, Joan Soler-Adillon and Andy Gracie.

POSSIBLES

Recinte Modernista de Sant Pau, Barcelona
From June 9 to 30

It included five outstanding works from the ISEA2022 Barcelona call by Thierry Fournier, Monika Fleischmann and Wolfgang Strauss, Paul Thomas, Keith Armstrong and Linda Dement, Paul Brown and Carmine Gentile, and it has been completed by Alex Posada (winner of one of the ISEA2022 Barcelona grants) and twenty digital works by the NewArtFoundation.

WHAT IS POSSIBLE AND WHAT IS NOT

La Capella, Barcelona
From June 9 to August 28

A dialogue between works by five local artists (Josep Manuel Berenguer, Anna Carreras, Mónica Rikić, Roc Parés and Yolanda Uriz) from ISEA2022 Barcelona's call, and works by artists from Barcelona Producció (Anna Pascó, Ariadna Parreu, Mario Santamaría and Estampa).

2nd SUMMIT ON NEW MEDIA ART ARCHIVING EXHIBITION

Online exhibition composed of 8 artworks related to archives or archival practices as well as data visualisation of archives.

BEEPCollection: ORIGINS

Cal Massó, Reus
From May 26 to July 23

An ambitious selection of new projects and foundational works of international electronic art by leading artists including Joan Fontcuberta, Marcel·lí Antúnez and Rafael Lozano-Hemmer.

Dynamic Paintings: Real-Time Interactive Artworks in Web

Ergun Akleman, Anusha Shanker, Yinan Xiong, Ani Barseghyan, Motahareh Fard

Department of Visualization, Department of Computer Science and Engineering,

Texas A&M University, College Station, Texas, USA

ergun@tamu.edu, akshankar@tamu.edu, yvonnexiong1114@gmail.com, anibarseghyan@tamu.edu, motah.fard@tamu.edu

Abstract

In this work, we present an approach to creating dynamic paintings that can be re-rendered interactively in real-time on the web. Using this approach, any existing painting can be turned into an interactive web-based dynamic artwork. Our interactive system provides most global illumination effects such as reflection, refraction, shadow, and subsurface scattering by processing images. In our system, the scene is defined only by a set of images. These include (1) A shape image, (2) two diffuse images, (3) one background image, (4) one foreground image, and (5) one transparency image. A shape image is either a normal map or height. Two diffuse images are usually hand-painted. They are interpolated using illumination information. The transparency image is used to define the transparent and reflective regions that can reflect the foreground image and refract the background image, both of which are also hand-drawn. This framework that mainly uses hand-drawn images provides qualitatively convincing painterly global illumination effects such as reflection and refraction. We also include parameters to provide additional artistic controls. For instance, using our piece-wise linear Fresnel function it is possible to control the ratio of reflection and refraction. This system is a result of a long line of research contributions. On the other hand, the art-directed Fresnel function that provides physically plausible compositing of reflection and refraction with artistic control is completely new. The art-directed warping equations that provide qualitatively convincing refraction and reflection effects with linearized artistic control are also new. You can try our web-based system for real-time interactive dynamic paintings at <http://mock3d.tamu.edu/>.

Keywords

Dynamic Paintings, Interactive Paintings, Web-Based Artistic Interfaces

Introduction and Motivation

Non-photorealistic rendering (NPR) has emerged as a sub-field of computer graphics during 1990s to produce computer generated images that invoke the appearance of being created "by hand" [26, 10] by emulating broad artistic styles such as outlines and silhouettes [13], technical illustrations [11], pen and ink drawings [7, 20], impressionist [16] and cubist paintings [21, 25, 22], Chinese painting [3, 17], charcoals [19, 8], and stippling [18]; as well as artistic tools and mediums such as brush strokes [28, 30, 12, 15], watercolor [5]. Convolutional

Neural Networks has turned out to be effective for style transfer [9, 24].

In recent years, there has also been growing interest to turn specific paintings into dynamic computer-generated images with moving lights and cameras. These paintings can have non-realistic components. For instance, Murphy developed a non-photorealistic approach for matching shapes and colors of the artwork of Disney background painter Eyvind Earle who uses non-realistic shadows [23]. "Atelier des Lumières" group developed large-scale video projections of many of Vincent van Gogh's well-known works [6]. Liu created a 3D version of a Jiangnan water country painting by the contemporary Chinese artist Yang Ming-Yi as the primary visual reference [17]. Justice created dynamic time-lapse animations based on some of the works of Edgar Payne, using Barycentric shading as the core of his procedure [14] (see Figure 1a). Subramanian obtained painterly reflection, refraction, and caustics with a classical wine and glass still life painting [27] (see Figure 1a). Clifford created time-lapse animations of two of Anne Garney's paintings for different times of the day [4].

Problem Definition

The main problem with these methods is that they are still based on the standard computer graphics pipeline. There is still need for a modeling and animation software such as Maya or Blender even if proxy geometry is simple. Moreover, there is also need for a shader software such as Arnold or Renderman even for expressive depiction. In this work, we propose a completely different pipeline. All information from shapes to materials is provided by images. Shapes are defined either by normal maps or depth maps. Shading parameters are also provided by a set of control images. Using these images we can obtain physically plausible local and global illumination with complete style control. There already exist solutions to obtain diffuse reflection, shadows, reflection, and refraction with a set of images [31, 29, 1, 2]. An example that shows how to diffuse rendering is computed is shown in Figure 2. More examples of illustrations or paintings that are obtained interactively in real-time using our web-based system are shown in Figures 3, 4, 5, 11, and ???. The interface of our system is shown in Figures 8, and 9.

In this work, we describe physically plausible yet stylistically expressive transparency. A real transparent layer must

(a) Three frames from a time-lapse animation of an Edgar Payne Painting for different times of a day [14].

(b) Three frames from an animation of Vine & Glass painting that demonstrate reflection, refraction and caustics [27].

(c) Three frames from time-lapse animation of Anne Garney's "Fusion At Playa del Carmen" for different times of the day [4].

Figure 1: *Examples of previous works of dynamic paintings with dynamically changing shadows, reflections, and refractions using moving light sources. These images are not created in real-time. Although the methods allowed to create of such non-photorealistic results with complete control, the process is still based on a standard computer graphics pipeline that requires modeling and animation software to run the shader to obtain animations. These animations, therefore, still took a significant amount of time to render. In this work, by using a completely different pipeline, we can obtain real-time rendering with dynamically changing shadows, reflections, and refractions using moving light sources.*

Figure 2: An example demonstrating the pipeline for diffuse rendering. I_0 and I_1 are the control images, Ω_0 and Ω_1 , are weight images that satisfy the partition of unity. Here, we compute Ω_0 from a shape image just using image processing. $I = I_0\Omega_0 + I_1\Omega_1$ is the final rendering obtained by taking a weighted average of the two control images.

Figure 3: Interactively created illustrations based on “Self-Portrait in Spherical Mirror”, a lithograph by Dutch artist M. C. Escher.

refract the background image and reflect the foreground image. Moreover, reflection and refraction must be combined by using the Fresnel equation, which provides a weighted average of reflection and refraction based on the incident angle. The inclusion of such a physically plausible transparency operation in digital compositing is very useful for the post-processing stage. Instead of re-rendering the whole scene, artists can simply control the Fresnel function to obtain desired effects. Such control can significantly improve the efficiency of the image synthesis process by moving some of the effects in 3D rendering to post-processing through digital compositing. It can also provide 2D artists to design physically plausible painterly refraction and reflection effects during image manipulation.

Art-Directed Fresnel Function

One of the key parts of our approach is an art-directed Fresnel function that can allow the physically plausible combination of reflections and refractions. Figure 6 demonstrates that it is

possible to control results using a single slider with two parameters. The first parameter controls the incident angle position where we want to obtain total refraction and the second parameter control the incident angle position where we want an equal mix. An additional control allows changing Fresnel from total refraction to total reflection as shown in Figure 7.

Our Fresnel function starts with a piecewise linear approximation of the real-Fresnel function. This particular sequence is provided for a single index of refraction. We allow users to change the incident angle positions (i.e. $\sin\theta$) of two control points of this piecewise linear function, which turned out to be sufficient to obtain visually convincing Fresnel effects. The top row in Figure 6 shows painterly compositing effects. The middle row directly shows Fresnel control using a black background and white environment map, in which full black means full refraction and full white means full reflection. In this case, the bottle is simply a normal map image. Gray is a weighted average of reflection and refraction. The last row shows actual Fresnel functions, in which grey areas are not reached to be used.

Linearized Reflections & Refractions

We replace standard reflection and refraction effects with linearized transformations for art-directed intuitive control. These linearized transformations provide warping effects that are visually similar to 3D realistic rendering since they indirectly correspond to underlying physical phenomena of reflection and refraction.

Mock-3D Objects

We also replace transparent 3D objects with transparent images that to provide partial 3D information, which we call “mock-3D objects”. These images can be inserted into any digital paint system without any significant structural change. We visually demonstrate that it is possible to obtain qualita-

Figure 4: Interactively created paintings based on “Autoportrait”, an oil painting by Pablo Picasso in 1907. All images are created using a normal map.

Figure 5: Interactively created paintings based on “Portrait of woman (Dora Maar)”, an oil painting by Pablo Picasso in 1942. The two images in the left are created using a depth map, therefore, we obtain shadows also.

tively convincing reflection and refraction effects with a minimal amount of 3D information, such as normal as a vector field and thickness [31]. This 3D information, moreover, does not have to be complete or consistent for obtaining convincing composites. The images that provide 3D information can directly be obtained through 3D rendering by harvesting normal and thickness information. More important for 2D artists, they can be directly sketched or painted based on artists’ intentions.

Conclusion

Our approach provides the ability for 2D artists to efficiently include refraction and refraction into their artworks and allow intuitive artistic control over visual results (See Figure 10). Using this approach, artists can create artificial, but still believable, versions of the original images as well as original artwork that can be dynamically manipulated. Our system is available for any artist to create dynamic artwork. The link to our web-based software is mock3d.tamu.edu. The system is developed using java-script and WebGL. The interfaces of our system for normal maps and depth maps are shown in Figures 8, and 9.

Abstract

Sarah Everard, a 33-year-old woman who went missing and got tragically murdered during her walk home, sparked an international conversation about women's safety in early 2021. It is one thing to discuss such a tragic and unfortunately common occurrence, yet it is even more harrowing to experience it for yourself. *A Walk Alone* is a virtual reality experience that simulates what it feels like for women to walk alone at night. The experience is centered around a linear story involving the user in first person point-of-view navigating a night-city environment with eerie sound design, immersive visuals, and dim street lighting.

Keywords

Virtual Reality, Empathy, Immersive Experience, Presence, Embodiment, Women Empowerment, Sexual Assault and Violence, Embodied Experience.

Introduction

Immersive technologies including virtual and augmented reality have shown great potential in art, education, healthcare and other areas. The VR environment brings a black box for traditional, digital and virtual artists who want to bring new dimension to their creations [1]. It supports visualizing abstract concepts and interacting with the three-dimensional virtual representation. It allows individuals to interact with each other in collaborative virtual environments, as well as visit and interact with events that are unavailable or unfeasible due to distance, time, cost or safety factors [2].

General characteristics of VR experience include immersion, presence, and embodiment [3]. First, immersion is a perception of being physically present in a virtual environment. This is the technical capability of the immersive system to deliver a convincing experience by interacting with the virtual environment [4]. Another characteristic of VR experience is presence. Presence refers to the feeling of being physically located in a different environment. In contrast to immersion, presence is considered as a subjective experience [5]. The last aspect of VR experience is the sense of embodiment. Even though many VR environments often simulate events that may not be experienced in the physical world, a user feels the ownership of the body in the virtual environment [6]. That supports the concepts of immersion and presence as well.

Because of the main characteristics of VR experience, artists, storytellers explore VR as a communication method to provide compelling narratives or to address social issues. Chris Milk in his TED talk said that VR is "the empathy machine." VR could be utilized to make people understand other people's situations and help people such as refugees, the homeless, and people with physical and mental disabilities [7].

This concept inspired us to create a VR project entitled, *A Walk Alone*. It provides an immersive experience that the audience feels like to walk alone at night as a woman. This project was inspired by current events regarding the kidnapping and the murder of Sara Everard who went missing during her walk home from her friend's apartment in South London. This paper presents the background, the design process, and the preliminary user feedback from public demonstration events.

Background

In this section, we examine how VR could be used to evoke empathy in various areas by reviewing prior works.

Empathy Generation in Virtual Reality

Empathy is an ability that encompasses diverse psychological processes related to sharing and understanding the internal mental steps of other beings [8]. Empathy consists of the ability to view the world from another person's point of view combined with an emotional reaction to that perspective, including feelings and concerns for other people [9]. It is important because a higher level of empathy creates more socially appropriate behavior and better social adjustment [10, 11].

According to Davis [9], empathy is a multi-faceted positive characteristic consisting of both cognitive and affective components. Affective aspects of empathy include experiencing another feeling and having an appropriate emotional response to another person's situation [12]. Cognitive aspects of empathy include understanding another person's perspective and being able to judge and understand the intention of others. Nicovich et al. [13] presents that empathy and presence are associated with interactivity.

There are many artworks and research projects utilized VR as a vehicle for evoking empathy in many social justice related issues. *Cloud Over Sidra* [14] is a 360 VR video, sponsored by the United Nations. It is about the story of Sidra, a 12-year-old Syrian girl in a refugee camp in Jordan. It aims to raise awareness of Syrian refugees. Ahn et al. [15] found that VR is helpful in terms of taking the perspective of animals. It led participants to experience more embodiment with the environment and a greater connection between the self and nature. Since the 1990s, there have been disability simulations to evoke awareness of disability and reduce implicit bias towards people with disabilities. Chu et al. [16] created a 360 VR application, *Colors for All* to raise awareness of the challenging daily lives of color blindness people. It consists of three daily scenarios (driving, shopping, and cooking) that present different color-blind conditions to the user. This project allows normal color vision people to experience different types of color blindness and its impact on their everyday lives. They found that immersive video can be a powerful tool for helping users experience outside of

their daily lives and evoke empathetic feelings to other people's experiences. Kalyanaraman et al. [17] reported that their schizophrenia virtual simulation induced greater empathy and more positive perceptions toward people suffering from schizophrenia than the control group with the written empathy-set condition.

A Walk Alone: Design Development

Concept

During ideation, concept sketches were exhausted to explore various environment atmospheres, lighting scenarios, and set design (see Figure 1). The sketches served as studies for different color palettes, potential urban city locations, and general storylines. Initially, it was important to showcase a gradual change in the users' field of view significantly to employ a sense of isolation and vulnerability. By the end of the simulation, darkness would completely envelope the user to stimulate psychological distress. Concept sketches also informed user interface design within virtual reality to further immerse the viewer into the narrative; no assistive interfaces, like mini maps or objective markers, were used. Instead, intentionally positioned lighting and diegetic mobile notification guides became the only tools used to assist the user in navigation. A blueprint of the entire virtual world was created before laying out set design in Unreal. After initial development of the environment, the blueprint was reduced in size and complexity based on time constraints. The environment elevation was flattened, omitting all dead-ends, stairs, and complex street compositions. The final map followed linear navigation to denote any misdirection the user may experience without maps or objective markers. The final environment spanned the size of one city block, populated by buildings and urban assets that would restrict the user's journey to one path. For example, blocking the street with construction forces the user to go walk towards a dimly lit alleyway.

Design Research

Before developing *A Walk Alone*, we tried to understand what virtual reality elements can evoke empathy and elevate the impact of such a sensitive topic. Our aesthetic research included existing games and simulations that fit

within the horror genre of both virtual reality and games in general. *Phasmophobia* is a fictional horror game that has gained popularity for its powerful psychological stimulation in both regular gameplay and the virtual reality version of the game [18]. A great contributor to emotional stimulation it elicits is its detailed sound design. The user is swept up in a believable auditory experience that involves location-based sound as well as a variety of different sound effects. Other horror games like *Slender: The Arrival*, *Amnesia: The Dark Descent*, and *Outlast* [19, 20, 21] played an important role in inspiring our audio and visual design; even though these games are not set in virtual reality and contain fictional elements, our main takeaway consisted of dimly lit environments and eerie sound design to elicit emotional unease from the viewer. The limited lighting in each of these four games allows the game designers to restrict the path and vision of the users. By only lighting key sections of our environment, we deliberately guide our users through the city street environment of *A Walk Alone*. In addition, strategically placed construction assets and roadblocks further limit the user's path.

Outside of psychological stimulation, we also looked at references of movement within virtual reality. Since our concept is based heavily on simulating the act of walking, it was important to research the different methods of locomotion in virtual reality, especially with regards to motion sickness. Our aim was to minimize locomotion discomfort while still mirroring the feeling of walking alone at night in real life. We looked at the locomotion within the game *Onward* [22], which utilizes the trackpad to move the user in the virtual reality space. The user can change the course of their movement by pointing their hand in the direction they are heading, while pressing down on the trackpad. Since the user is not moving in real life, this method may trigger motion sickness. A way to combat this is to restrict the field of view of the user when they are walking, or to use smooth and slow motion. We also reviewed *Vindicta* [23], which offered a more creative solution for user locomotion. In order to move forward, the user has to swing their arms in a "walking" motion while holding both controllers. The faster you swing your arms, the faster you'll walk in the game. Even though this method requires natural physical movement that can control the user's walking speed, we felt it would be too distracting of a motion. We decided to use trackpad touch as our method for locomotion. To combat motion sickness, we maintained slow and controlled locomotion movement paired with a dimly lit environment that restricts the user's peripheral vision.

Figure 1. Sketches of an urban city street environment developed in the early stages of ideation to determine lighting, color, set design and overall mood.

Asset Creation

To reduce the viewer's field of vision and stimulate psychological distress, the virtual environment of *A Walk Alone* is dimly lit and claustrophobic in nature. The main objective of the simulation consisted of triggering feelings of isolation and vulnerability by prompting the user to navigate through sparsely lit darkness (see Figure 2). To enhance user immersion and mimic the reality of the scenario, intentionally positioned lighting and diegetic mobile notification guides serve as the only navigation tools available to assist the user.

Figure 2. Screenshots from *A Walk Alone* simulation highlighting different scenes, like walking through alleyways and a park, in first person point of view.

Environment Design

Since the simulation is set in an urban city at night, the environment includes a comprehensive collection of 3-dimensional assets like dumpsters, construction signs, trashcans, windows with AC units, doors, parking meters, construction barriers, containers, and streetlamps...etc. The 3-dimensional models were created in Maya while Substance Painter was used for surfacing and texturing. For efficiency, the models were built to specific poly-counts, then were distributed into the master scene in Maya. Time constraints limited asset production to only include the most valuable objects in the environment. Thus, park environment assets and the user’s car were outsourced from Unreal Engine’s Marketplace. The remaining assets that were modeled in-house were textured with gritty, street-like materials and graffiti to make the space seem true to an urban city environment (see Figure 3).

Figure 3. Examples of gritty, urban 3D Assets like construction signs, containers and street objects scattered in the environment of *A Walk Alone* simulation.

The assets were combined with procedurally generated buildings to create a populated, diverse, and immersive experience for the user to navigate through. Different door and window models were imported into Houdini in order to procedurally generate different window and door layouts for each building (See Figure 4). Using this method permits the generation of buildings that appear different, even though most of the buildings are made up of the same base models.

Figure 4. Windows selected in blue showcase unique display patterns procedurally generated in Houdini.

Other notable 3-dimensional assets include a replica of the real life “missing persons” poster of Sarah Everard, the woman whose tragedy reignited an international conversation about women’s safety in early 2021. Though Sarah went missing on her walk home from her friend’s apartment in South London, women across the globe saw themselves in her shoes. Scattering the posters throughout the environment connects the game’s narrative to its social inspiration and encourages users to reflect on their experiences in-game with the real-life dangers women face in society today (see Figure 5).

Figure 5. Two versions of the Sarah Everard missing person poster 3D assets with varying tears and textures.

Sound Design

Sound plays a vital role in supplementing our visual-heavy simulation to re-enforce an eerie mood. Sound effects that were collected from open-source websites, like PacDV.com and Freesound.org, include footsteps, city traffic, bottles and cans jangling, glass breaking, soft crickets and dogs barking in the distance, police car sirens, and heavy breathing. The sound experience begins with quiet street ambience and construction noise that slowly fades into jolting sound

effects to ramp up the user's anxiety. The sound effects begin to accumulate over time and overstimulate the user from all directions. Once the user leaves the park, they are struck with a sudden lack of sound. The viewer is left with an uncomfortable silence and an emphasis on their own breathing at the end of the simulation.

Since sound design plays an important role in the simulation, a spatial sound design map was created to plot the auditory experience. Whenever the user enters the trigger boxes that are set up in Unreal, area-specific sounds are played. On the other hand, looped sounds are constantly playing in the simulation, but can only be heard within a specific radius near the sound (See Figure 6).

Figure 6. The spatial sound map highlights trigger boxes (dashed yellow rectangles), area-specific sound effects (yellow rectangles), and looped sounds (white rectangles) strategically positioned in the simulation.

Information Design

To assist the user with navigating the space, it was vital to involve guides that connect the user personally to the narrative. The user is prompted to explore the virtual space through mobile notifications that act as a diegetic user interface guide throughout the entire simulation. Using area triggers in Unreal, each notification pops-up in front of the user depending on where they are in the scene. Text messages from the user's "best friend" direct the user to complete tasks, like walking around the construction site to get to their car, which ultimately guide the user from the start to finish. Mobile alerts like "low battery" or "signal lost" amplify the fear factor intended to be conveyed to the user and act as narrative triggers that increase anxiety (see Figure 7).

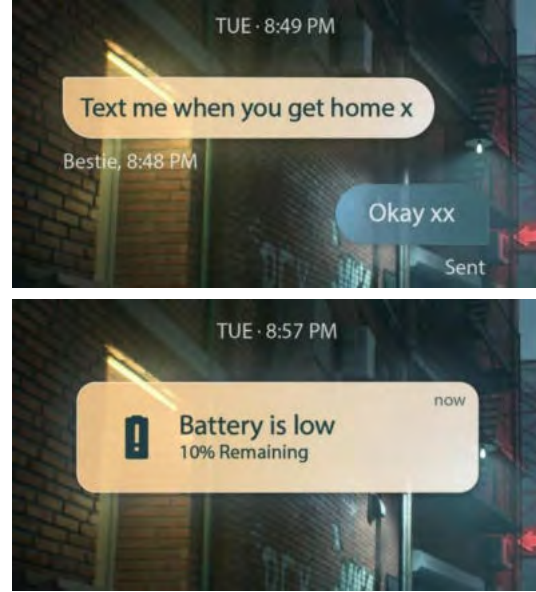

Figure 7. Two mockups of mobile notifications acting as diegetic guides during the simulation of *A Walk Alone*.

The experience starts with an introductory trigger warning and ends with real life statistics that shed a light on how many women are affected by sexual assault and the precautions they must take when walking alone in public. Since the user's field of vision gets darker towards the end of the experience, the simulation fades to black once the user reaches their car then finally transitions into a blank screen showing statistical data in a visually appealing manner.

Public Demonstration

The results from the public demonstration were majorly positive. Of the 16 participants, 10 identified as male. Based on a pre-study question, 62.6% of our users claimed to be knowledgeable or very knowledgeable of the dangers women face when walking alone at night. After experiencing *A Walk Alone*, that percentage increased to 83.1%.

Most participants stated that the most effective and educational portion of the experience were the statistics at the end. However, one user felt as though the message could be communicated more effectively if more graphic scenarios played out during the experience, like simulating an assault happening to the user if they don't get to the car in time. This gives us an idea that those statistics could have been incorporated into the game more interactively, which could increase the effectiveness of teaching users of the dangers women face when walking alone at night. Other users stated that the sounds were most effective since the auditory immersion made them more aware of the environment or gave them a general sense of fear. The remaining users stated that not being able to walk faster or knowing that your phone died sparked increased anxiety. The participants' engagement with the visuals, sounds, and notifications is a great indicator that they were engrossed in the story, both emotionally and psychologically. One user stated that "walking along the path as slow as possible along with hearing my surrounding made me very uncomfortable very quickly." 81.3% of the participants claimed they were fully immersed in the narrative and environment and felt vulnerable during the simulation.

Regarding being good allies, roughly 55% of our users stated that they are careful or very careful of their presence and actions around women who are alone at night. That

leaves the remaining percentage of our users as being not careful, somewhat careful, or neutral in said situation. With overwhelmingly positive results, all our users stated they are likely or very likely to take actions to ensure a woman near them feels safe when walking alone at night after experiencing *A Walk Alone*.

After a few revisions to lighting and adding more road-blocks, we successfully orchestrated an experience where most of our users navigated our simulation smoothly. Almost 69% of our users responded that it was easy or very easy to navigate the scene to find their way to the car. One user stated that “The actual walk was most effective in putting me in the mindset of walking alone and the potential dangers that are associated with it”.

In addition to the majorly positive feedback we received, some users had constructive suggestions to improve the overall experience. A few participants felt like they were walking too slow, while on the other hand, some users enjoyed that feature because it triggered anxiety. A few participants felt motion-sickness in spite of the slow navigation. Others had technical comments about leaving the text notifications and statistics on screen for a longer duration of time for better readability. While one user stated that “It was chilling to hear what was behind you without seeing it”, another user felt like not seeing the objects triggering the sound effects made it difficult to attach certain sounds to the environment”. Suggestions like seeing shadows, having characters walking around or standing in odd places, and adding jump scares give us an idea that some participants would also like to be visually stimulated to feel more fear and anxiety, instead of merely through sound design. Users describing the experience as “rather terrifying”, “uncomfortable”, and “realistic” proves that *A Walk Alone* is making an impact regarding this issue. It also demonstrates that we need to continue to discuss and confront the dangers women still face on a daily basis.

The Tapestry: Past and Possibility in the History of Magic

Peter Anders Ph.D.

Figure 1 Night view of the Tapestry.

Abstract

This paper presents the Tapestry, a mapping of the history of magic. It describes a system that lets users create *lifelines* and map them using GoogleEarth. Each lifeline, or *thread*, is laid over the globe, showing the trace of the person's historical travels, locations, and activities. By successively laying these threads over one another, users can see points of intersection, suggesting historic interactions and influence. It is hoped that such graphic presentation and users' pattern recognition will lead to discovery of previously unsuspected influences in magic's historical development.

Keywords

Magic, Western Esotericism, mapping, history, database, GoogleEarth, Wikipedia, information architecture, lifelines

This paper presents the Tapestry, a mapping of the history of magic. There is a growing literature on the subject of magic and Western Esotericism. Since the early 1990s universities have developed programs and departments for their study. However defining magic is itself a challenge. Is it a tradition, or a practice? What are its characteristics, and how do they differ over time, or from one culture to the next?

Another challenge is the irony of rationally exploring a subject that defies conventional explanation. Indeed magic

has a troublesome reputation, dismissed as blasphemy by formal religion, and quackery by material science. [1] Yet magic historically has anticipated many contemporary sciences. It presently is used to help understand cognition and consciousness. It persists to this day in most world cultures and deserves serious inquiry. [2] [3]

This paper will demonstrate a system that lets users create timelines of individuals involved magic and map them geographically using GoogleEarth. [4] (Fig. 1) Each timeline, or thread, lies on the globe, showing the trace of a person's historical travels, activities, and locations. By successively laying these threads over one another, users can see points of intersection – suggestions of interaction. At the smallest scale one can visit individual sites and see their activities. At the largest scale one can see movement and migration of different magical traditions over time. It is hoped that such graphic presentation will lead to discovery of previously unsuspected influences on magic's historical development.

Regarding Magic

Magic, as used here, refers to the full range of its cognate practices. It covers conjuring, stage magic, legerdemaine, alchemy, astrology, divination, hermeticism, ceremonial or ritual magic, psychical abilities, geomancy, spiritualism, some religious practices, and a host of other activities

At present the Tapestry database records over 3000 persons, societies, movements, and other entities. Data is entered into an Excel spreadsheet with horizontal rows denoting events in a life. There are presently over 18,000 horizontal rows of data in the set. Vertical columns call out details of each event: names, dates of birth and death, date of the event, location, citation of sources, historical role, influences, and notes on activity.

The project used mapping software GoogleEarth Pro 7.3.4.8248 running on Mac OS X 10.12.6. Colored nodes represent life events mapped onto the Earth. A colored lifeline connects these nodes sequentially from beginning to end. Lifelines between nodes are straight, rarely following actually traveled routes. This means that their intersection *at places other than nodes* are not necessarily meaningful. The color of lines and nodes represents the historical roles of the entity. These roles include conjurors, witches, stage magicians, spiritualists, esoteric societies, psychical researchers, religious leaders, and several other categories.

An Example: John Dee

The process of creating a lifeline may best be demonstrated by an example. For this we will use the lifeline of John Dee, the advisor and wizard of Queen Elizabeth I. [10] Dee, an occultist and polymath, was also a scholar, mathematician, alchemist, ceremonial magician, and astrologer. He had a large influence on magic of his time, and echoes of his work remain today in the practice of Enochian or Angel Magic.

Following research into his life, the data was entered in a Google Earth folder for the 16th century, in a subfolder named 'John Dee 1527 CE'. Events in Dee's life show up on the 3D globe as red-colored nodes – red being the color assigned to occultists. Each node links to a brief note describing the event, year and location. Clicking on a node opens its note. (Fig. 3)

For example clicking on the first node of his lifeline reveals Dee's years of birth and death, a brief summary of his roles in magic, as well as his place of birth. It also links to the Wikipedia source used to make the lifeline. In the current version of the project Dee's lifeline has twenty-four event nodes linked sequentially with a red line. Point #24 records his death in Mortlake, England in 1608 CE.

The Tapestry

Each of the project's roughly 3000 entities – individuals, societies, and events – has its own lifeline, or thread, in a larger pattern called the Tapestry. They are organized in centuries ranging from 4000 BCE to the present. Within each century folder is a list of entities ranked by the year of their birth. Within each entity's folder is a list of event nodes. (Fig. 4) One can edit the list as new information is

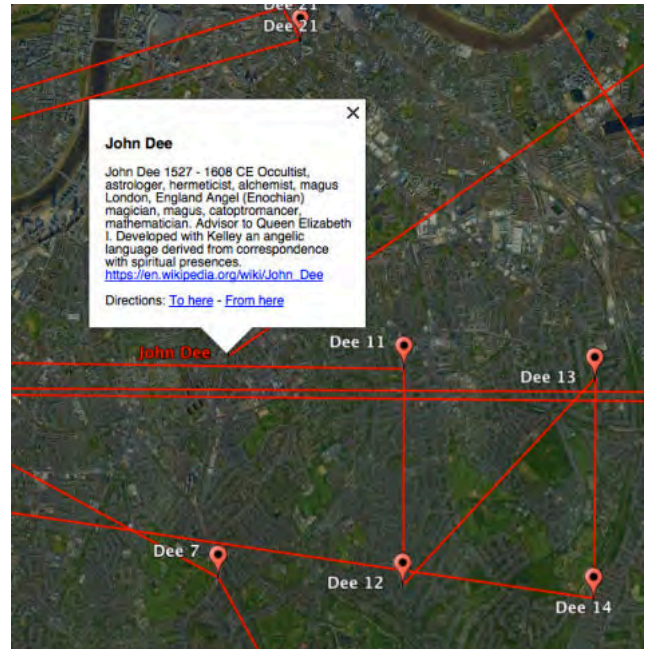

Figure 3 Detail of Dee lifeline showing note.

Figure 4 Detail of Dee folder showing nodes of his lifeline.

uncovered. Also one can turn on lifelines and nodes on the globe, or turn them off at will.

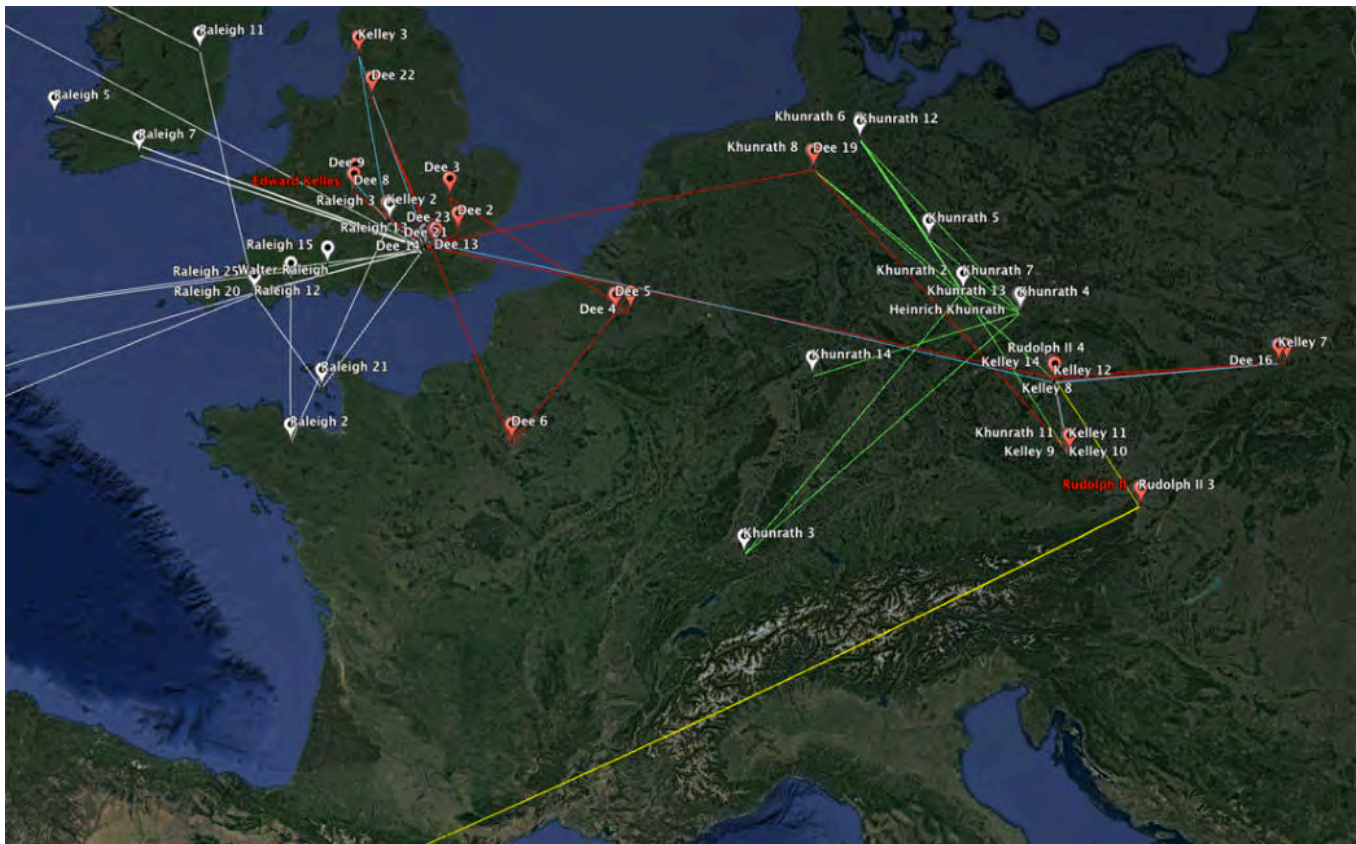

Figure 5 Lifelines of John Dee, Edward Kelley, Rudolph II, Heinrich Khunrath, and Walter Raleigh.

Overlaps of people's lifelines imply that they were simultaneously in the same place. And, if so, they may have had meaningful interaction. Unless this interaction is specifically stated in the supporting literature such an exchange would remain speculative. But it is at least marked by the intersection for future study that could confirm the influence of one person on the other.

This feature of the Tapestry is distinct from literary sources in that possibilities of interaction emerge from the patterns of the threads. One could use it to discover alternate narratives of magical history based on possible influences.

Synchronicity and Possibility

Let's return to our example of John Dee's life to see how these overlaps and possible interactions play out. (Fig. 5) Viewing the lifelines of John Dee (red lifeline) and Edward Kelley (blue lifeline) we can see that they overlie each other from 1582 to 1587, reaching from Mortlake, England to Třeboň, Czechia. [11] In 1582 Dee retained Kelley as an assistant for his alchemical work at Mortlake. Kelley also served as Dee's sryer, using a crystal to communicate with angels. Dee recorded these conversations.

Owing to court politics Dee was forced to seek patronage beyond England, so he and Kelley left Mortlake for Poland. Shortly thereafter they sought patronage from the Holy Roman Emperor Rudolph II (yellow lifeline) in Pra-

gue in what is now Czechia. The emperor's lifeline extends from Austria to Spain and back, ending in Prague. [12]

In the meantime Dee and Kelley continued their correspondence with angels in the hope of providing sacred counsel to monarchs. But they struggled, finances were running out and Rudolph was not interested. Finally Dee and Kelley fell out, spectacularly, and Dee returned to England. Kelley stayed, working as an alchemist in Rudolph's laboratories.

On his return from Prague, Dee met Heinrich Khunrath (green lifeline) in Bremen in 1588. [13] Khunrath, a fellow alchemist, sought work and Dee recommended he visit Kelley at Rudolph II's laboratories. From there Khunrath went on to Prague while Dee returned to London. It is possible that in the later years of his life that Dee may have taught alchemy to Sir Walter Raleigh, a fellow alumnus of Queen Elizabeth's court (white lifeline). [14] Raleigh was being held in London Tower for an illegal naval attack on Spain. Before his death there he took up alchemy. Dee may have offered his tutelage as, by then, he was destitute and near death himself.

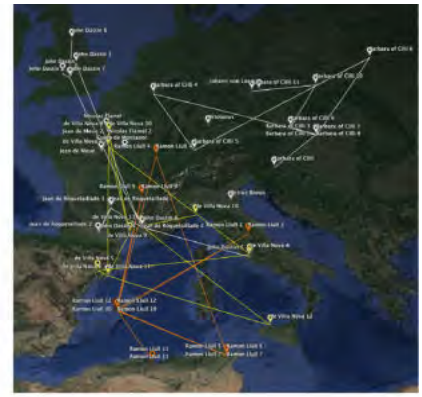

This brief history links four lives that intersected with Dee's own. The literature records three of these interactions, the fourth is inferred from Dee and Raleigh's lifelines in London. That intersection *suggests the possibility* of these two persons' meeting, which could be borne out in further investigation. Another method of finding intersections is to sort the Excel database for locations and dates.

1100s

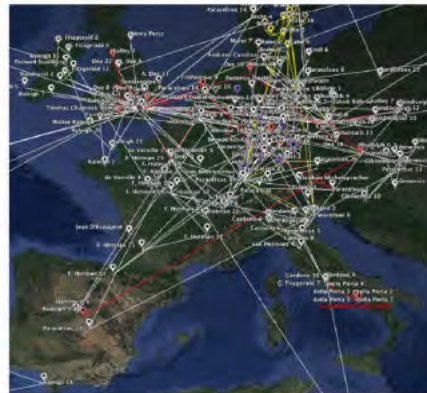

1200s

1300s

1400s

1500s

1600s

Figure 6 Overlapping lifelines indicating the growth and spread of alchemy in Europe between the 1100s and 1700s.

This helps if the graphics get dense and complicated – as in large cities with many intersecting lifelines.

Magical Networks and Trends

As one of the 16th century’s most famous magicians Dee certainly had more connections than the four cited here. Each of the four’s lifelines intersect with others before and

after their encounter with Dee. In turn each of those intersect other sets of lifelines. Connecting these secondary and tertiary intersections would outline a network of Dee’s influence.

The Tapestry can also show how a magical practice can change over time. For instance by comparing alchemists lifelines over several centuries, one can trace the spread of alchemy within Europe and beyond. (Fig. 6)

When all of a century’s lifelines are visible one can see the spread of magical practices. The leap of Western magic to the Americas in the 12th and 13th centuries follows closely on the New World’s exploration and settlement. This connection only strengthens as it approaches our own day. Importantly the 19th century appears to be saturated with magical practice, spanning Europe and North America. (Fig. 7)

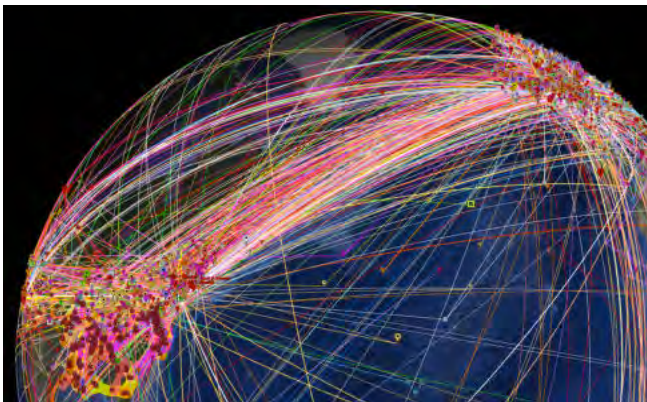

Figure 7 Lifelines showing the spread of magical practice from Europe to North America in the 19th Century.

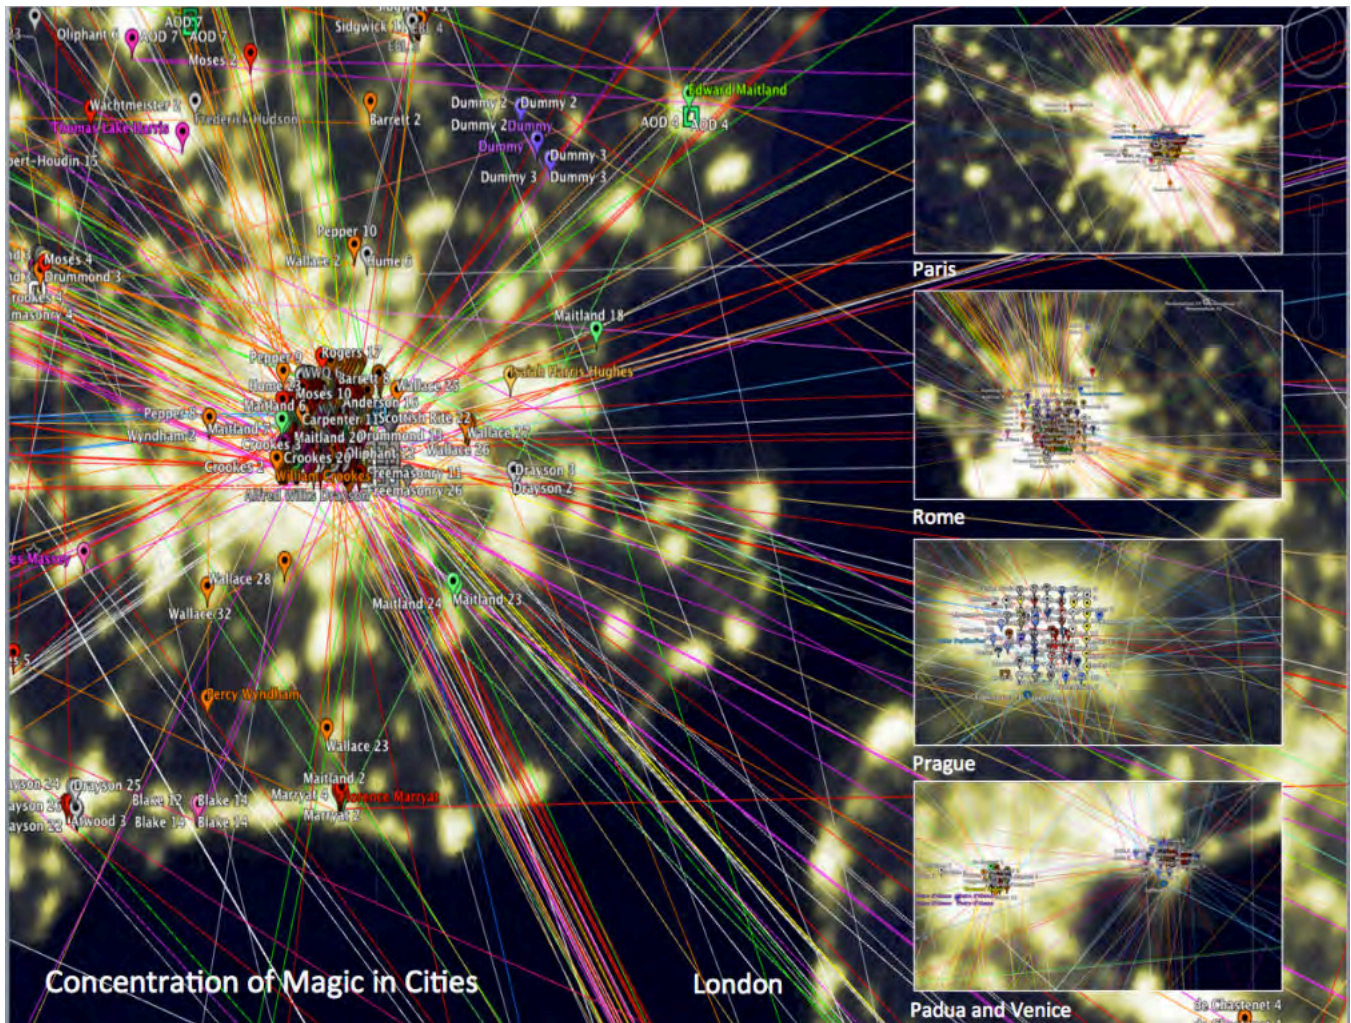

Figure 8 Lifelines showing density of magical activities in cities. ‘Starry’ background is image of the cities at night.

This magical density appears at smaller scales as well. Unlike a conventional map, the GoogleEarth globe can be viewed at various magnifications, allowing users to ‘zoom in’ on cities and settlements. Cities are important centers for magical activity, possibly because of their own density, diverse population, proximity to like-minded colleagues, and universities with libraries. London for example seethed with magical activity in the 19th and 20th century. So did Paris and to a lesser extent other major cities. (Fig. 8)

Correspondence vs. Interaction

The Tapestry is presently limited in scope and content. Its scope focuses on individuals’ action in a place and time. It suggests that interaction is only likely if two entities are *physically present* in a place and time. But proximity doesn’t guarantee interaction.

Riding in a crowded elevator or subway doesn’t usually lead to conversations with fellow passengers. Conversely distance in time or space doesn’t mean lack of in-

fluence. Letters, books, and other media have overcome time and distance for centuries. Because of their durability authors can talk with us from centuries before. For these reasons, the Tapestry can only suggest the possibility of *physical* interaction. There is no presentation in the Tapestry for media and literature’s role in linking individuals and influence. We hope to account for this in future iterations of the project.

Source Limitations

Originally the Tapestry was to be a comprehensive overview of the world’s magical history. In its present state, it accounts for barely a fraction of it. The Tapestry’s database is based almost entirely on information taken from the internet, and especially from Wikipedia. At the beginning this was the most expeditious resource because of its accessibility and acknowledged reliability. However, despite finding magical practices throughout the world, we found the predominance of material was from Western and especially Anglophone countries.

Protest and Aesthetics in The Metainterface Spectacle

Christian Ulrik Andersen, Søren Bro Pold

Dept. of Digital Design and Information Studies, Aarhus University

Aarhus, Denmark

cua@cc.au.dk, pold@cavi.au.dk

Abstract

The article asks how political agency play out in contemporary uses of the interface. It, firstly, stipulates that the interface is a ‘spectacle’, belonging to a longer history of media spectacles, mass organization, politics and aesthetics. Secondly, that contemporary interfaces are metainterfaces, depending on a new organization of the masses characterized by mass profiling. Finally, it analyses how this play out in examples from art and cultural practices, and speculates on what political protest and revolution is in light of the interface.

Keywords

Digital art, interface criticism, media aesthetics, media spectacle, political protest.

Introduction

A spectacle is commonly understood as something that visually attracts our attention – typically a mediated experience. It is an object of desire that naturally lends itself to not only pleasure, but also manipulation. Media spectacles have therefore always been a central part of Marxist cultural criticism, ranging from Walter Benjamin, Siegfried Kracauer, Theodor Adorno, Max Horkheimer to Guy Débord, and beyond; and they have always been a contested zone for political struggle – for propaganda as well as for activism and situationist happenings. In this tradition of cultural critique, a spectacle presents an organization of the masses, but also a way for the individual to experience one-self as part of the masses. This can be used for populist manipulation, but potentially also opens up for critical reflection on the mediated organization of the masses. In other words, the media spectacle is historically tied to relations of power and control; of control of the masses, but also of the individual to see and understand one’s one position in the masses and thereby assume individual agency.

Try to think of the user interface as a contemporary spectacle that organizes and controls the masses, and also of the user’s possibilities to experience this organization, and the possible agencies that relate to this. Arguably, the organization of the masses is a complex question. The interface spectacle is not only visually organized, as in traditional cinema and mass media, but belongs to a tradition of statistics that has roots in urban mass control as well as in advertisement – a tradition of data and profiling. As we have described elsewhere, the contemporary user interface must be seen as a ‘metainterface’: an interface that both seals off and gives access to a larger network of interfaces that exchange data;

typically to profile the user and deliver customized experiences. It is an interface that is general (in everything), and abstract (nowhere in particular), and which is often associated with the proliferation of platforms, apps, cloud computing, and other phenomena. [1]

In this article we want to discuss the contemporary interface spectacle through examples of organization of the masses in a networked computational reality. More specifically, we ask: how does political agency play out in the contemporary metainterface spectacle? This question takes us beyond the use of seemingly innocent apps for divertissement, and into the question of how the spectacle is used politically – how its representations and collections of data are used for populist propaganda, as well as for critical scrutiny and other forms of agencies. This is not least relevant in light of political developments as displayed on Capitol Hill in January 2021, or in global nation politics where e.g., Russia has been accused of collecting data and profiling users in order to influence the outcome of elections. How does the metainterface serve such populist spectacles, and what potential forms of critical agencies may rise in this? In search for possible answers, we discuss the so-called twitter-revolutions in light of more recent events and uses of social media; in particular the artistic performance *HEWILLNOTDIVIDE.US*. The work is one of the most high-profile political artworks of recent years, and we analyze how its protest against the Trump presidency, and the responses to this carried out by the Alternative Right movement, brings the relation between aesthetics and politics to the fore. Finally, we also compare the ‘ideal’ twitter-revolution to other perceptions of the revolution as presented in Amira Hanafi’s work *A Dictionary of the Revolution*; a work that presents a quite different interpretation of the Egyptian revolution than its often-acclaimed association with social media.

The media spectacle

Before we enter more deeply into analysis, we want to begin by briefly touch upon the nature of the spectacle. Historically, the spectacle, as a view on and of the masses, involves a particular political agency related to the increased urbanization and rise of the masses following industrialization, as seen for instance in George-Eugène Haussmann’s transformation of Paris into boulevards with views to see, be seen, and be controlled. In Haussmann’s 19th Century Paris the boulevards did not only provide new urban experiences of strolling, Paris was also a city mapped out and controlled from above, and a city that was designed to control the masses (related to Paris’ history of upheaval of the masses).

With modern urban development also came different forms of spatial and mediated spectacles, such as arcades (to see and be seen), as well as zoological gardens and also aquariums that somehow compensates for the boundless scale of urban development and growth of the masses. [2] It is likely that the interface at hand (the facial filter app, the social media interface and its overview of connections and likes, the feature and estimation list of the Uber app, etc.) can be seen as following this urban tradition and need for a human scale miniature perspective in face of a limitless (global) world of planetary scale. However, what interests us in particular is the *mediated* spectacle, which also, historically, ties the organization of the masses, and the individual's perspective on this, to populism, propaganda and political agency in capitalist societies.

In particular the cinematic spectacle lends itself to political propaganda and control of the masses, as noted by the German cultural and film critic Siegfried Kracauer. Kracauer who writes, for instance, about Leni Riefenstahl's infamous *Triumph des Willens*: "Triumph of the Will is undoubtedly the film of the Reich's Party Convention; however, the Convention itself had also been staged to produce Triumph of the Will, for the purpose of resurrecting the ecstasy of the people through it." As such, it is a film "symbolizing the readiness of the masses to be shaped and used at will by their leaders" – "a show simulating German reality and of German reality maneuvered into a show." [3]

Although lending itself to propaganda and the anesthetization of the German people, the spectacle is far more complex than mere manipulation. In Kracauer's understanding, the spectacle (as what he calls "a mass ornament") is also an aesthetic reflection of capitalism's production process, the assembly line, and statistical control. All of these characteristics of a modern mass society are generally abstract or invisible and can only be recognized by the individual as an indirect experience; or, staged aesthetically as a mass ornament, for instance in the stadium spectacles of synchronized gymnasts: "The production process runs its secret course in public. Everyone does his or her task on the conveyor belt, performing a partial function without grasping the totality. Like the pattern in the stadium, the organization stands above the masses, a monstrous figure whose creator withdraws it from the eyes of its bearers, and barely even observes it himself." [4]

The loss of perspective embodies the desires of the worshippers: the experience of a common project that binds people together (as he writes, "The bearer of the ornaments is the *mass* and not the people," [5] but the stadium spectacles offer a reflection of the compulsive actions of a new mass, and a way to experience this as a mass ornament – in which the withdrawal of perspective and the hiding of an origin can even be a sublime experience. In this way, the mass ornament exists above the level of the individual, but nevertheless offers the individual a perspective on the mass. Although, it was this enchantment that fascism and Nazism misused in perverse ways and took advantage of in their propaganda, its effects are not uniform. [6] [7] Its social significance cannot simply be compared to that of a roman theatre, staged by the ruling power, as Kracauer notes; as he highlights how the mass indulges in sensations comparable to a godless cult. [8] In fact, it is such sensations that help the individual reflect the rationale of industrial production;

that makes the ornament 'real': a reflection in how reality is produced.

The metainterface spectacle is as complex as the mass ornament. Following Kracauer's line of thinking, we may assume that the mass ornamentation of customized media reflects a new moment in cultural production – the moment of a "metainterface industry" with ties to former cultural industries. [9] Just as in the 1920s and 30s, we may also assume that mass ornamentation make way for propaganda, but also realist (media) reflection. However, the mechanisms of both propaganda and realism function substantially differently than in the mass ornament of cinema or stadium spectacles: interfaces see us differently, and we see ourselves differently in them.

In the metainterface everybody takes and sees the same snapshot of the Eiffel Tower (as a compulsive action of the mass), but unlike former mass spectacles, nobody is seeing *the mass perspective*. The spectator of the new mass ornament, the user, is limited to responding emotionally to the feed (by sharing what is on one's mind, or liking what is on the minds of others) – there is, in other words, no one to see 'the figure' (in Kracauer's terminology). If the mass ornament (the spectacle) is the aesthetic mirroring of the ruling economic system and its inner rationale, there is nobody to see this; there is no sensation of this. As a particular datafied perspective, one might even question whether the mass itself can be the bearer of ornaments? [10]

The metadata protest

If the user is limited to an emotional response to a feed of snapshots that all look the same, and there is no one to see the figure of the mass, where does this leave the politics of the metainterface spectacle? How is politics aestheticized in the metainterface spectacle? And, how does aesthetics become politics? In order to extend reflections on the metainterface spectacle into such questions, we want to analyze and discuss contemporary examples of how the metainterface enters the fabric of political and social activism and protest.

The wider public experience of how interfaces and social desires come together first became evident with the so-called 'twitter revolutions' – the mobilization of a mass using social media. These include a number of protests taking place in the early 2010s, broadly covering diverse settings and political agendas, including, for instance, The Arab Spring (2010-12), the Gezi Park protests in Istanbul (2013), the 15-M Movement at Plaça del Sol in Madrid (2011-15), and various others. Arguably, these protests did not just take place on social media; they were events taking place in parks and at squares, and they involved people with feelings of indignation (as the movement in Spain labelled itself, "los indignados"). However, as a common characteristic, the use of the hashtag ("#jan25" (marking the beginning of the protest on Tahir Square in Cairo), "#spanishrevolution", etc.), demonstrated how the interface was integrated into the social and political tissue of the protests. Judging from phenomena such as #MeToo, #BlackLivesMatter, #UmbrellaMovement and more, this has been the case for much political activism and many protest movements ever since.

Put briefly, using a hashtag signifies one's identity with a discourse across media platforms and contexts. At the same

time, the hashtag is not merely a word, or key word, that embodies a protest movement and its social or political desires, it is also used by the individual platform as metadata to organize the feed on, say, Twitter (where the use originates). As most social media users will know, the # symbol ('hash') automatically turns the following keyword ('tag') into a link to a real-time feed of all posts with the given hashtag, and it also allows users to search within the platform for particular keywords. In other words, using a popular hashtag is a way to generate visibility to one's individual post; and often, the real-time feed turns into a particular kind of conversation of exclamations, opinions, information, images, videos, memes, etc. where users express themselves in relation to the hashtag of the protest (in this case); including, at times, also interfering with opposite or provoking opinions. Even plain advertisement or spam, which has an air of being machine-generated and out of context, often appears in the feed. In this environment, the protest is always on(line) as a feed, tailored 'just for you' as a list of exclamations, and a multiplicity of individual voices where an advertisement can appear as close as a friend combatant. In other words, it is a diverse cultural practice that involve both human and machine agencies.

Vis-à-vis the hashtag-protest as a form of mediated spectacle (a metainterface spectacle), it is well-worth questioning the construction of a mass perspective, and how one sees oneself as part of the mass. Obviously, tying microblog posts on racism, sexism, austerity, oppression together with hashtags, potentially generates a common discourse that may mobilize a mass across spaces. The #BlackLivesMatter, for instance, is not intrinsic to one platform or particular events in the United States, but travels across different individual and cultural contexts (for instance, although #BlackLivesMatter originates in a particular American context, it is also adopted by protesters in Denmark as a general label for protests relating to racism, Danish immigration policies, the Palestinian situation). [11] In this sense, it has both a "multiplicity", and a "narrative power," as noted by Anna Nacher in her study of the feminist Black Protests in Poland in 2016. [12] However, adding an informational layer (of metadata) to real events that are tied to complex political, societal, or other problems also *virtualizes* the protest, and reduces the resolution and diffraction of the incident in order to make it computable information. As Matthew Fuller has claimed, the interface (as a control mechanism, distributed throughout the system, across different processes or executions – and a tool that allows a user to manipulate, but never change these processes) is an extension of 'virtuality' into a technical system. Virtuality is, as he quotes N. Katherine Hayles, "the cultural perception that material objects are interpenetrated by information patterns." [13] In other words, what we claim here is that the protest's narrative ability, its ability travel across spaces and contexts, follow a particular cultural logic: that of 'virtuality'. Or, put differently, in order to make the protest travel across spaces and contexts on the platform, one needs to see them as informational, as metadata; one needs to perceive their virtuality, their 'interfacial' character.

When 'tagged', the protests (including their documentation of oppression, and their social and political desires) not only become a narrative of resistance, they also become part of a 'statistical spectacle'. The metadata of the hash symbol

is then also part of a much larger spectacle in which the collection of data takes part in the organization of the masses. The main principle of organization is 'the feed', an instrumentalist modelling of the protest (its events, its actions, its participants, its relations, etc.) as data. The objective of the feed is to generate visibility to what the protesters are likely to respond to affectively, to be adaptable to know 'the mood' of the protest. As a spectacle that organizes the mass and allows the individual to experience oneself as part of the mass, it is no longer about seeing the mass and oneself as part of the mass, but about knowing the mass, and knowing what one likes, detests, etc. as part of the mass. With this, the protest is not just made up of a mass gathered in a space, but it *becomes* the feed and subject to the platforms' instrumentalist modellings; subject to what Ned Rossiter and Geert Lovink in the analysis of the protests of the early 2010s have called "bursts of 'social media' activity", or "communication peaks, which fade away after the initial excitement". [14] And, the instrumentalist and pragmatic production of such peaks and bursts in moods is always withdrawn, without clear origin, one merely 'feels' it.

It is however also tempting to compare this kind of personalized spectacle to how the metainterface articulates processes of subjectivation; and how the spectacle reflects, more generally, a rationale of production in a neoliberal economy – a mass perspective that reflects capitalist production, but withdraws from our attention (as Kracauer's writes, "The production process runs its secret course in public" [15]). Although the hashtag relation and the sharing and liking of moods and sentiments of a protest seemingly unites a group of people in a common cause, one might ask if the metainterface (and the lack of a mass ornament) does not also contribute to a more individualized perspective on political change? In the individualized feed that invites to affective 'mood' responses (in the form of likes and shares), the protest risks becoming without consequences, and merely expressing our individual experiences of subjugation or disruption and our affective responses to this; it risks becoming incapable of constituting a different world.

HEWILLNOTDIVIDE.US – capture the flag

Speculating on how the metainterface spectacle relates to more general articulations of the subject and the mass in a neoliberal economy, the lack of a mass perspective potentially also leads to a displacement of a common class analysis and consciousness. Shia LaBeouf, Nastja Säde Rönkkö, and Luke Turner art project *HEWILLNOTDIVIDE.US* (or, particularly the responses to it from alternative right networks) serves as an illustrative example of this.

In 2017 the three artists initiated the project *HEWILLNOTDIVIDE.US* – a live streamed durational work that ran between Jan 20 2017 and January 20. 2021 (i.e., the entire duration of Donald Trump's presidency in the United States). The work consisted of a mural outside the Museum of the Moving Image in New York, with the words "he will not divide us". Underneath the artists had mounted a camera (a live stream feed), into which the public was invited to chant "he will not divide us". In this way, the work, according to the artists, "acted as a show of resistance and insistence, opposition and optimism, guided by the spirit of each individual participant and the community." [16]

The work follows a series of works (#*IAMSORRY* (2014), #*FOLLOWMYHEART* (2015), #*INTRODUCTIONS* (2015), #*ALLMYMOVIES* (2015), #*TOUCHMYSOUL* (2015), #*TAKEMEANYWHERE* (2016), #*ANDINTHEEND* (2016), #*ALONETOGETHER* (2017)), all including live participatory performance, and with clear reference to network culture and social media (in the hashtag). As such their work make reference to a number of political movements, also trying to unite a mass using network culture and social media, and articulating what Anna Nacher has called a “weak opposition” whose efficiency lies in its “ability to reclaim and mobilize the narrative power of hashtags.” [17] Such weakness should not necessarily be interpreted as similar to the incapability of forming alternative futures, as in Rossiter and Lovink’s analysis of the Twitter revolutions as characterized by ‘weak ties’. The weakness is also a form of resistance: as a rejection of a heroic understanding of protest (as a ‘militaristic machismo’) it points to a process of caring and social maintenance, and a wider common transformation. As Nacher points out, she strongly disagrees with perceiving digital activism as a failed promise: “What failed was rather a kind of novelty allure and media-hype generated by the early, enthusiastic analyses. Perceiving digital activism in general as a failed and corrupted enterprise may lead to throwing the baby out with the bathwater.” [17] Consequently, one could say, that what failed was the Twitter marketing of Twitter revolutions.

Our intention here is not to judge the ‘weak opposition’ of LaBeouf, Rönkkö, and Turner’s work, but to point to the unexpected spectacle it led to. Already on 10 February 2017, only three weeks after its installation, the Museum of the Moving Image abandoned the project. As stated by the museum in their press release, “the installation created a serious and ongoing public safety hazard.” [18] A few days into the performance, multiple threads on the performance were running at 4chan, Tynychat, and Discord, including ones that organized pro-Trump and pro-alt-right performances – such as showing a sign “Make America Great Again” in front of the camera, changing the name of the museum to Museum of KEK (a misspelling of LOL, used on 4chan, and also the Egyptian God of chaos), advertising the site as a prostitution meetup on Craigslist, and more. This, naturally, resulted in various confrontations between the pro- and anti-Trump protesters, culminating in the arrest of Shia LaBeouf for shoving a man who addressed the camera with a “Hitler did nothing wrong” sign. [19]

After its removal from the Museum of the Moving Image, the installation was set up at El Rey Theater, Albuquerque (and later also at Foundation for Art and Creative Technology in Liverpool, le lieu unique in Nantes, and Muzeum Sztuki in Łódź), but the Internet trolls had already turned the performance into a viral meme. Eventually (on March 8, 2017), the artists replaced the installation with a livestream of a flag with the words “HE WILL NOT DIVIDE US”, filmed from below, and containing only the sky, not to give away its location.[20] This initiated an insane game of ‘capture the flag’ by the Alt-Right online community. [21] They, for instance, detected the airplanes appearing in the sky behind the flag, and compared their condensation trails to flight radar information. They also discovered a tweet from LeBeouf, and used this information to rigorously map the potential position of the flag. After locating a small town in

Tennessee, one of the participants drove around the town honking his horn until the sound was picked up in the stream. Eventually, they were able to take down the flag and replace it with a red Trump cap. [22]

The interventions by the Alt-Right community mirrors the event-centered elements of the art work itself, and may be seen as contributing to what Rossiter and Lovink in their analysis of the protests of the early 2010s called “carnivalist ruptures of the everyday life”, and “revolts without consequences.” [23] However, it also adds further dimensions.

Notably, the campaigns of the Alt-Right community are driven by particular network cultural practices; a particular version of what Olga Goriunova has labelled “new media idiocy”, which, for instance would account for the production of memes as well as the collective forensics of ‘capturing the flag’: “Idiocy is a kind of individuation that produces, [...] objects and behaviours, subjectivities, as well as collective performances.” And, this process of individuation has become “a very successful way to concretize a collective movement: to be heard politically; to concretize an object of achieving media attention; to individuate the human and to experience her individuation through expression, and so on.” [24]

Furthermore, there is evidently a strong organization behind not only this campaign, but also other Alt-Right campaigns – residing on message and image boards such as 4chan and 8chan, and more recently on Discord and Telegram, but possibly also with institutional ties to e.g., the Trump administration. [25] Rossiter and Lovink, in fact, already described the potential political agency of organized networks (or, ‘orgnets’) in their critique of the 2010s protest movements

“The orgnet concept (short for organized networks) is clear and simple: instead of further exploiting the weak ties of the dominant social networking sites, orgnets emphasize intensive collaborations within a limited group of engaged users. The internet’s potential should not be limited to corporate platforms that are out to resell our private data in exchange for free use.” [26]

What Lovink and Rossiter here highlight, is that in order to contrast the lightweight nature of political activism on social media (which basically makes the hashtag protest another contribution to the mood-driven platform economy), one needs intensive collaboration and organization. The presence of this in phenomena like the ‘capture the flag’ campaign, or the other organized interventions by the Alt-Right presents an alternative to the weak ties of social networking platforms. Clearly, the message and image boards present another organizational tool to the protest movement; a tool that goes beyond hashtags, shares and likes.

The organized network of a game also resonates with contemporary theory of participatory, computational or rewired propaganda; and how propaganda has changed from a ‘top-down’ model of one (leader) communicating to the many (the masses), into a model of one communicating to a smaller group of ‘followers’ that also include fake identities, which then communicate to the masses. [27] [28] It is tempting to draw lines between this organization of politics and how Riefenstahl’s staging of the Nürnberg party days represents “an inextricable mixture of a show simulating German

reality and of German reality maneuvered into a show.” [29] The Alt-Right protesters’ media spectacle is produced by the media along the media’s own agency as an “aestheticizing of political life,” which Walter Benjamin, at the time, also saw as “the logical outcome of fascism.” [30]

Or, put differently, for the individual participants, hiding behind their interfaces, one may still question in what ways they are themselves bearers of the mass ornament? The idiocy of the memetic carnival protest also seems to limit their perspective and prevent the participants to see the figure of the mass, so to speak; and, again, limit them to their individual experiences without constituting what Mark Fisher calls “a *we* that is both the agent of struggle and what is struggled for”; or as he continues: “Subjugated group consciousness is first of all a consciousness of the (cultural, political, existential) machineries which produce subjugation – the machineries which normalise the dominant group and create a sense of inferiority in the subjugated.” [31]

Being able to see how the mass perspective is constructed might be a sense of its innate machineries; a productive class consciousness-raising. Seeing just oneself, on the other hand might potentially lead to a “class resentment without class consciousness or class analysis,” as put by Wendy Brown, who continues: “This resentment is displaced onto discourses of injustice other than class but, like all resentments, retains the real or imagined holdings of its reviled subject.” [32] This is presumably the kinds cynicism captured in expressions such as “Hitler did nothing wrong” (as shown on the sign that triggered Shia LaBeouf).

A Dictionary of the Revolution

If the metainterface articulates a datafied and instrumentalist organization of the mass in which one only sees one self, where does it leave the grand narratives of refusals, protests and revolutions?

In one interpretation, the metainterface spectacle and the mood-driven ‘feed’ with its disparate voices and exclamations, make way for the articulation of subjugation with no class analysis and consciousness of the machineries that produce subjugation (including those of the metainterface itself); of knowing and sharing the feeling, but not knowing and sharing the consciousness of what produces it. The protest risks becoming weak, merely a shared mood – bursts of social media activity driven by the platforms’ mood algorithms. With some level of organization, the sinister parts of such feelings and moods of the class can even turn the lived reality into a (racist, sexist, etc.) carnival show or game of idiocy; an aestheticization of politics with no shared vision of an alternative future (other than that of the white male supremacist).

In another interpretation, the weakness expresses a different kind of organization (as pointed to by Nacher). The metadata, the mood algorithm and the feed does not just produce a weak organization of the mass as a shared feeling, it also produces everyday narratives of subjugation; narratives that reject the understanding of the protest as a heroic revolt of change, and instead highlights the importance of common transformations in the everyday that lies in caring and other affective actions of social maintenance in our relation to the other. As a final example of a spectacle that further highlights such aspects of the protest, but operates through a

different interface, we want to analyse the work *A Dictionary of the Revolution* (2014-17) by the Egyptian-American artist Amira Hanafi. [33]

The (online) dictionary consists of 125 texts related to the word ‘revolution’, made by circa 200 individuals, interviewed by Hanafi. The work was initiated a few years after the Egyptian revolution in 2011, which led to the abdication of the country’s longtime ruler Hosni Mubarak, the democratic election of Mohamed Morsi from the Muslim Brotherhood in 2012, the protests against Morsi, and the military coup and inauguration of the current president, Abdel Fattah El-Sisi in 2014. In other words, it is a dictionary narrated by people who have lived through a complex political situation. Looking into the dictionary you therefore see the many different individual voices and understandings of words associated with the revolution (Brotherhood, the Army, elections, hope, etc.); what the words mean to people, and how they relate to the Egyptian situation, and in what ways the Egyptian revolution was revolutionary. ‘Revolution’ is described as a word “with no meaning”, or “whose meaning we don’t understand.” Rather, it has an affective meaning and purpose: “We build on it and we hold on to it, only because we don’t want to spoil the moment [...] the beauty of the moment for Egyptians who went out in the streets.” In this way, the work is a mapping of the affective relationship between the order of the revolution and the order of language, and of how the order of language is constantly negotiated by the voices of the people in the space and time that appears when a ruling power is overthrown.

Another example is the word ‘tamarod’ which means ‘rebellion’ in Arabic, but which also refers to a person who breaks with tradition, and takes an unconventional approach. After the election of Morsi, it became a label for the resistance movement against Morsi, and after July 3 where the military and El-Sisi deposed Morsi, “we found out that Tamarod was a lie like everything else, and that Intelligence created it. But that doesn’t negate that the people themselves protected Tamarod, because Tamarod isn’t its individual members. I mean, the members of Tamarod didn’t make twenty-two million.” In this way, the dictionary is a reflection of the metamorphosis of language and the complex processes of signification: “As they say, language is a living thing.”

The entry ‘ideal girl’ addresses how gender and power are related in conservative religious societies, but also points to the violence and oppressions of revolutions. Women, and in particular younger women, are notoriously harassed by military and the police who submit them to humiliating undressing and ‘virginity tests’, obviously with the purpose of creating control:

“At the end of the day, they saw her as a woman, with a certain form. Based on something that she has no control over, that she can’t change—the form in which God created her biologically. Based on that form, she can be marked by any stain that you can imagine: she can be insulted, she can be exploited, the whole situation can be exploited and the most terrible charges thrown at her and everyone around her. The whole idea is that... is that God made you a girl, so you must endure. Don’t participate in anything, don’t go out, stay afraid all the time that

someone will expose you because of your body and because you were created a girl.”

Bodies, genders, humans, and society are weaved together by language, power, revolt and a failed revolution. Obviously, the media and media technologies also play a significant role in this weaving. In the entry “the Media” it reads: “The media broadcasts all the vocabulary in the world. Someone says a word, but it's the media that says it to the people, and the people interpret it. I myself didn't know a lot of words. They teach us to talk.” The revolution is also an act of language, or of mediation, where the media industry diffuses its vocabulary, but also defines it – for better, or for worse. As mentioned above, the Egyptian revolution is often labelled as a ‘Twitter revolution’, but social media and hashtags do not seem to play a significant role in the dictionary. Although it is mentioned how cameras are “broadcasting directly from the street”, the principal reference is television. In this sense, the perception of the Egyptian revolution as a Twitter-revolution is also a construction, and perhaps even a branding of the (at the time) new social media platforms as ‘democratic’. Academic critique of social media and its role in the revolts, too, may be seen as a successful part of this.

In this sense, the work points to other ties than the weak ties of the hashtags. The linguistic keywords of the revolution are not just algorithmically trending on Twitter or other social media platforms; they are real words undergoing far more composite processes of signification. Considering the role of the media, they are not just subject to moods of what people like and share, propagated in feeds on a platform; feeds that display a stream of exclamations and disparate voices that all seem to be talking about the same thing, but rarely together. Rather, the meaning of key words, and what comes to be a key word, is subject to relations of power and control (as in the case of ‘tamarod’) in which the control of broadcast media is still important. And, perhaps more importantly in the work, it is subject to 200 different individual voices linked together (in a hypertext). The 160 key words in the vocabulary appear in a beautiful diagram created by an algorithm, reading and interpreting the texts, identifying the key words, and suggesting relations between them. How the algorithm works remains unclear, but the voices all belong to anonymous individuals who raise different opinions, giving the words different meaning, and making them ambiguous. Rather than the algorithmically framed and individualized perspective on a discourse (with low equivocation, and where everybody sees, feels, understands the same), it seeks to present a perspective on the entire discourse, how it changes over time, and how people relate to it in different ways: how they discuss the revolution in language, and language as a revolution.

As a spectacle *A Dictionary of the Revolution* is very far from turning a social reality into a show. As an interface it makes the words of the dictionary multivocal and gives the mass a voice in which one can see oneself as part of the revolution and the mass, and for outsiders to see this. It points to the linguistic, social and media technological dimensions of the revolution as a spectacle (of how it organizes the mass, and how one sees oneself in this). The dictionary provides evidence of the revolution, and of how revolutions become meaningful. Reading and exploring the diagram

creates a sense of how the revolution – far from being a Twitter-revolution – manifests itself through its ambiguities; the doubts, the linguistic ambivalences, counter revolutions, and even the diagram itself as a care-full knowledge resource on which to build revolutions to come.

Conclusions

We have tried to demonstrate how the appearance of a metainterface – an interface that is always present (sensing us, available in our pockets, etc.), but is no-where in particular (abstract and in the cloud), and where global platform providers make up a foundation for all other interfaces – lays the ground for a new media spectacle: a new organization of the masses, and a new moment for political agencies.

The metainterface differs substantially from other media, in that the spectacle is always also statistical; resting in the assumption that perspective is computable (and non-visual), and with this a particular instrumentalist hiding of the perspective. In other words, the individual users behind their interfaces cannot see the workings of the machinery that produces the feeds, the likes, the shares, and the mood-driven collective. In the metainterface spectacle, political, social, or other confrontations therefore easily become confrontations of ‘truths’ – one statistical cinema confronted with another; one user’s feed confronted with another’s. Hence, we believe that a better understanding of the metainterface spectacle is important, in that it allows for new understandings of how contemporary politics and political activism is intrinsically related to the functioning of the interface. In other words, is it possible to understand, say, the Black Protest (Czarny Protest), held nation-wide in Poland in October 2016, or the events on Capitol Hill in the United States in January 2021, without also understanding how they were organized on message and image boards, and how they were distributed (and disrupted) on social media platforms?

Through the analysis of a particular incident (*HEWILLNOTDIVIDE.US*, the performance’ conflicts with the Alt-Right communities, and the following organized ‘capture the flag’), we have attempted to demonstrate both similarities and differences in the contemporary political media spectacles. Political confrontations and protests are increasingly dependent on layers of information patterning – of software that can interpret the hashtags and the likes, and provoke consciousness-raising awareness at the level of the individual spectator of the live feed and participant of the hashtag protest, and form a mood-driven community at the basis of this. The material of the protest is always also informational (hashtag-able, share-able, copy-able, etc.), eventually giving the protest a ‘virtual’ and ‘carnivalist’ characteristic. However, this has (like social media in general) undergone a paradigmatic shift from being a global organization of information networks to a more local organization of information networks, and with this it also lends itself to certain orgnets’ maneuvering of reality into a show; a show of idiocy, memes, and trolls that simulates a contemporary (in this case American) reality.

Albeit more briefly, we have also tried to tie this kind of political activism to a process of neo-liberal individuation, and to question political agency in the metainterface industry. The individualized perspective of the metainterface may create a sense of affective community coherence (a *we* that

shares the same feeling), but one may question whether it is capable of creating a consciousness of the larger apparatus that produces and normalizes the subjugation (a *we* with a class consciousness)? Whether change is individualized and collective ties weak, or whether the collective is capable of envisioning the constitution of a different reality?

Can the masses be granted rights, and not just expression, in the metainterface spectacle (to paraphrase Walter Benjamin)? In the perspective of German critique of the media spectacle, this would demand the possibility to reflect the larger apparatus that produces the mass perspective. As a final example of a care-full reflection of the larger apparatus that produces both oppression and revolution, we have included Amira Hanafi's *A Dictionary of the Revolution*. It is a work that presents a different spectacle of the revolution than the often-acclaimed spectacle of democratizing social media (and its failures). The work suggests a different interface spectacle in which one can navigate the discourse as metadata, but where the bodies and voices of the revolution are never reduced to information patterns. It suggests that diagramming the revolution as a discourse is a way of providing evidence of how oppressions and revolts play out – of their many cultural, technical, legal and other executions. As such, it functions as an instrument of knowledge that can help us observe the features, patterns and correlations of a discourse. It presents a secular perspective on the masses of the revolution in which the revolutionary subjects (the participants) articulate their shared experience of a revolution, perceive themselves as part of the revolutionary mass, and begin their analysis of the complex apparatus that produced the (failed) revolution: a 'class awareness' of what people say and experience.

Although Hanafi's work does not directly claim the use of a large dataset, metadata and complex natural language processing (as does corporate and state intelligence in their 'interfacial' perception of the revolution as informational events), the question of the algorithmic architecture and how machine agency constructs knowledge and power can be seen as crucial in granting the users and masses rights, and point to further studies of the metainterface spectacle. A critical metainterface spectacle might well demand that the various tools for data analytics should no longer be restricted to corporate platforms or the NSA, but reclaimed by political and social organizations. However, the cultural and social engagement with the algorithmic architecture and an instrumentalist perspective should not be carried out in a carefree manner. Diagramming, data analytics, and also dictionaries, and other techniques (as carried out across corporate, literary, political, activist platforms), and the significant differences in the ways they deal with evidences, data, subjects, bodies, affects, language, discourse, and more, are examples of how the metainterface spectacle has become a new aesthetic and political battlefield.

Decolonizing the imaginary through the tactical use of machinimas

Abstract

This essay starts from a reading of Decolonizing the virtual: Future Knowledges and the Extrahuman in Africa, a collection of essays published in the Journal of African Studies in March 2021, responses, and commentaries to the Abiola lecture delivered by Achille Mbembe in 2016 in the context of #Rhodesmustfall and the new light given by this movement to the question of decolonizing knowledge.[1] During this lecture, Mbembe states that Africans are better able to leap into the digital because there is a similarity between the plasticity of pre-colonial knowledge and the plasticity of digital virtuality. I therefore sought to know if this hypothesis could be verified: is the digital, through immersive works, video games and machinimas¹, a good way to document, archive, represent and promote oral tradition and ancestral knowledge? And it is then that I discovered the text of Lia Beatriz Teixeira Torraca published in April 2021 on the Aesthetic look of affect which analyses the machinima as being a medium allowing to change the point of view, to proceed to a displacement, to a reterritorialization while simultaneously presenting multiple worlds and spaces, often invisibilized.[2]

Keywords

Decolonizing, Imaginary, Ancestral, Knowledge, Machinima, Deterritorialization, Reterritorialization, Games, Indigenous, Pluriversalism

Introduction: New perspectives on knowledge decolonisation in the digital era

This text is an exploration of the different possibilities offered by digital technology to enter into discussion and allow for exchanges of knowledge and skills between ancestral techniques and knowledge and digital creations, by illustrating my remarks with different examples of works and games mixing ancestry, speculative fiction and digital creations, and by focusing on the experiences of machinima workshops conducted during the Art & Games World Tour, which, in Togo and Kenya, have made it possible to experiment with the mixing of imaginary worlds and the sharing of knowledge, and to archive an oral culture that has been invisibilized by colonization and Christianity. This approach resonates with movements such as ancestro-futurism and techno-shamanism in Brazil and

with indigenous futurism which, relying on speculative fiction, imagine futures free of colonization. [3] [4]

I will begin by returning to the notions of decolonization of knowledge and the idea of pluriversality discussed by Mbembe in Abiola, and then analyse the various arguments supporting his remarks on the possible parallel between pre-colonial knowledge and the virtuality of the digital and by extension with the virtual universes of video games.

If I have chosen to approach video game creation from a decolonial angle in the Art & Games Global South World, it is because the global gaming market is still dominated by Europe, the United States and Japan, and to speak of the art and games decolonization is to promote works conceived on the periphery of this global and globalizing culture and to be able to immerse oneself in other types of representations, conceived and expressed in other languages, allowing one to evolve in other cities and landscapes and through other stories and cosmogonies. It is to accompany and promote the emergence of a market of contents from the Global South. This is a recent phenomenon, linked to the rise of mobile phone and the Internet, which, as Mbembe points out, allows the younger generations to express themselves and have access to the media like never before. In the field of video games, the market is no longer solely a market of subcontracting or localization of games produced in the West. Many independent studios are emerging in Asia, Latin America and Africa and are producing content for the local market as well as for the global market.

It is thus that new voices emerge by reappropriating the narrative on themselves in order to no longer be an exotic context but rather the own enunciation of their representation. It is also to seek to decolonize the imaginary by the co-construction of narrations born of the meeting between oral tradition, endogenous knowledge, and virtual universes of video games.

Necessary dialog between knowledges

As Victoria Bernal reminds us, when Achille Mbembe speaks at Abiola, he does so in the very particular context of the post #Rhodesmustfall movement, the South African student uprising for a decolonization of knowledge, which will give a new dimension to the notion of decolonisation, based on "Pan Africanism, black consciousness and black radical feminism. » as defined by Abdul Kayum Ahmed. [5] [6]

¹ Machinimas are films made from video game engines.

In this context, Mbembe begins by recalling the pitfalls of decolonization, at the risk of Africanisation, a criticism formulated by Frantz Fanon in the aftermath of decolonisation when power was transferred from the colonists to an African middle class society of which he was suspicious, and at the risk of an identity withdrawal, while it is important to teach African languages and to express oneself and create in African languages, decolonization, according to him, does not consist of debunking universalist knowledge and replacing it with other, more particularistic knowledge, but rather of thinking in terms of pluriversalism.[7] [8]

A concept brought by Enrique Dussel, and Anibal Quijano to demonstrate that modernity developed concomitantly with colonialism by destroying ancestral cultures and knowledge. [9] [10] Pluriversalism can only be achieved by "recognizing this asymmetry of knowledge". This openness and dialogue can therefore only take place if there is a recognition of the different epistemicides to which the cultures of the countries of the South have been subjected as shown by Boaventura de Sousa Santos by silencing languages, traditions, vernacular knowledge or by reappropriating them without paying them homage, or by invisibilizing them or demonizing them. [11] "In Brazil, 3000 languages were spoken before colonization, today only 188 languages are remaining" affirms Ricardo Ruiz in an online interview. Francis Nyamnjoh indeed shows why it is difficult to create a dialogue between the so-called traditional knowledge and scientific knowledge if such knowledge is denigrated as witchcraft or primitivism. [12] On the contrary, it is better to consider these knowledges as techniques.

Figure 1 The online Game Contos de Ifa uma aventura brasileira

This is what Ricardo Ruiz, the designer of the online game *Contos de Ifa*², explains about its game that blends ancestrality and digital technologies to introduce people to the tradition of the Orishas, the nature spirits of the Candomblé³ religion, which was brought to Latin America by slaves from West Africa.

² Contos de Ifã - Uma aventura afro-brasileira. <http://contosdeifa.com>

³ A religion that developed in the 19th century in Brazil brought by slaves from West Africa.

⁴ Oshun in the pantheon of spirits, deities of the Ifa Yoruba oral culture represent the river and is the guardian of the Osun River in Nigeria. She is the goddess of femininity and fertility.

"Women, before the witch hunt that deprived them of their relationship to nature and sources of knowledge, knew techniques. The same is true for the Orisha tradition, it is about techniques. Let's say you are initiated into Oshun⁴, then I would have to know all the instruments, the plants, the smells, the colors, the drumbeat and the predictions that we have for Oshun. If you are blessed by Oshun, it means that you come from a river. Practitioners of this religion extract the energy from the river using these combined objects and dance it into your body, and then that energy takes your body and dances for a while and then goes away. For this Orisha, we have this knife, this plate, these are all the different variables and then you have the process, you cut the chicken, you sing a song, first we sing for the earth because the earth is going to receive the blood, which as a technique, carries the energy of life, so you have to play for the earth, you bring the life of an animal that you are going to eat, you bring it back to the earth, and at the same time you are opening up a way to speak to the earth... »

Figure 2 Ritual to Osu and Jemandja by the Nigerian Performer © Isabelle Arvers

Beyond this necessary recognition, Aghi Bahi specifies that this dialogue between knowledge must be thought of not as a juxtaposition but rather as a reciprocal exchange where each opens up to the other. [13] This pre-colonial knowledge and techniques must be studied and come to resonate with scientific knowledge, without which traditional knowledge finds itself on the "periphery of the periphery", considers Paulin Hountondji. "Peripheral to metropolitan science, institutional research in Africa in turn leads to a secondary peripheralisation of endogenous bodies of knowledge, relegating them to the periphery of the periphery. » [14]

An approach followed by Roy Ascott, Tania Fraga and Maria Luysa Frago in 1997, in their meeting with the Kuikuros, a tribe located in the North of the State of Mato

Grosso, in the National Park on the Xingu river in Brazil, not having been evangelized and having kept intact their shamanic beliefs in a multidimensional world. Roy Ascott, who was working on the idea of Shamantics⁵ and double consciousness, wanted to immerse himself in the knowledge of the Kuikorus, who live permanently between three worlds: the earth, the sky and the underworld, as told by Maria Luysa Fragoso in an online interview. Roy Ascott will then write about the parallels between the shamanic double consciousness and the possibilities offered by cybernetics and immersive or networked works to act at a distance and be able to perceive several worlds. Roy Ascott suggests, "Cyberception and the double gaze. It is as if, through our bio-telematics art, we are weaving what I would call a "shamantic" web, combining the sense of shamanic and semantic, the navigation of consciousness and the construction of meaning." [15]

For this encounter to take place, it requires an elimination of the hierarchy of knowledge and also passes through the notion of co-learning to which another text by Achille Mbembe on the decolonization of knowledge and the question of the archive refers: "In order to set our institutions firmly on the path of future knowledges, we need to reinvent a classroom without walls in which we are all co-learners; a university that is capable of convening various publics in new forms of assemblies that become points of convergence of and platforms for the redistribution of different kinds of knowledges." [16]

As Katrien Type reminds us, Achille Mbembe relies here on the work of Jane Guyer on Ecuadorian societies in which knowledge is not the business of a few, nor of an elite, possessing alone the keys to an inaccessible knowledge, but based on an exchange of knowledge and techniques. [17] Knowledge should no longer be the business of a small elite, but that of all, as was the case in Burundi before colonization, where knowledge was not only held and promulgated by griots or priests but was held by all, in a collective manner. "In Burundi, mythical and historical traditions were never the prerogative of specialists compared to the griots of West Africa or the abiru⁶ of neighbouring Rwanda. Each Burundian was, to every degree, the custodian of the ancestral heritage that was transmitted, from generation to generation, during vigils where the talent of each person was free to express itself." [18]

This necessary dialogue between these different modes of knowledge, in which digital technology is redefining the contours of access to knowledge, requires a paradigm shift. Science and human thought are no longer the only sources of knowledge; it is now possible to think with Eduardo Kohn of knowledge "beyond the human. » [19] This implies to recognise as Jeremy Narby that nature thinks, that animals think, and that non-humans can teach us tech-

niques and knowledge, by making a change of perspective, referring here to Eduardo Viveiros de Castro. [20] [21]

This leads us to reconsider shamanism or pre-colonial modes of communication as techniques and modes of knowledge and learning, in the same way as scientific knowledge, considered until now as the only source of knowledge. When I ask Daniela Fernandez, author of the ITA game about the legends of her people the Guarani, indigenous people of Northern Argentina, to explain her working process, she answers in an online interview:

"Personally, I have been lucky enough to be in the physical spaces they inhabited, in the Paraguay River, in Chaco and Formosa, but I am also lucky enough to dream of other worlds and have access to other types of images outside of the plausible, which serve as inspiration when I create. To a skeptic, these dreams would be influenced by the stories I heard as a child, but to a believer, these dreams are influenced by my ancestors. »

Figure 3: ITA a video game designed by Daniela Fernandez about her indigenous ancestors the Guarani © Daniela Fernandez

Plasticity of pre-colonial knowledges and plasticity of the virtual

As Eleonore Hellio, a member of the artistic duo the Kongo Astronauts in Kinshasa, pointed out to me in an online conversation, "In Congo we live with the second world all the time." This ability to think the real and the virtual simultaneously, in the sense that Pierre Lévy understands it, i.e., as being in the process of being real, thus as another mode of the real, according to Mbembe, allows Africans to embrace the virtuality of the digital in an innate way. [22] Therefore he puts forward the idea that Africa is better prepared to make a leap into the digital because there

⁵ Shamantic is the contraction of shamanism and semantics. A research that Roy Ascott led by making a parallel between the double shamanic conscience and the parallel worlds of cybernetics by trying to make a fusion between shamanic knowledge and scientific knowledge.

⁶ Royal ritualists in Rwanda

are enormous similarities between the plasticity of pre-colonial knowledge and the plasticity of the virtual.

This question intrigues me because in the context of the elaboration of a decolonial geography of art and video games, I was led to exhibit digital works and video games conceived by a new generation of indigenous artists and game designers in Asia and Latin America, and then during my stay in Togo and Kenya I was able to collaborate with traditional storytellers to conceive films from virtual video game universes, thus mixing ancestry, oral tradition and virtual environments.

Mbembe adds that "in old African traditions" people "were constantly in search of a supplement to their human hood," sometimes adding "attributes or properties taken from the worlds of animals, plants, and various objects."

Africans, however, are not the only ones to have retained this pre-colonial knowledge within themselves and the ability to communicate with other beings or non-humans. The indigenous peoples of Latin America as we have seen previously or, for example, of Asia also have a capacity to apprehend different modalities of apprehension of reality. In Indonesia, but also in Taiwan, the spirits of nature, trees, mountains, water, are constantly invoked, objects are charged and have the power to mediate with spirits or spectral beings.

As Amry Anton, from the Serlok Bantaran community in Bandung, Indonesia, who is responsible for cleaning rivers of plastic, told me in July 2019, "the spirits are constantly around us, if we don't see them it's because there are so many of them that if we saw them we wouldn't be able to move freely in space."

Co-learning pedagogy in machinima workshops

The daily presence of spirits also appeared to me in Brazil when I gave a machinima workshop in 2016 as part of my residency at Ruralscapes in Sao Jose de Barreiro, invited by the artists Rachel Rosalen and Rafael Marcheti. A residency in Santa Tereza farm in the heart of the mountains, on the border of the states of Mina Gerais, Sao Paulo and Rio, whose aim was to put in relation traditional knowledge and techniques with electronic or digital technologies. During this residency, the machinima workshops - making films from video game engines - aimed to use video games as a means of emancipation for these young future farmers. After playing and discovering many independent games, I found myself confronted with the apparent blockage of young people to tell or write stories. I came back the next day and asked them to take me to the streets of their village, Sao Jose de Barreiro, to show me the places that were important to them and to explain why. In each place, we

took pictures and interviewed them on the microphone. Two stories about spirits emerged.

The first *Matadouro*⁷ is the story of a matador, killed by a cow, whose spirit comes back to haunt the walls of the village houses. The second, *Espiritos*⁸, takes place in the house of a poet who died at home, but was found much later by his neighbours, whose spirit remains in the house. In ten years of workshops, I had never had spirit stories from children or teenagers whose imaginations are rather influenced by mainstream TV shows or video games, mostly from the US or Europe. It was also the first time in the history of these workshops that we mixed two modalities of reality: photographs of the village of Sao Jose de Barreiro, the abandoned slaughterhouse, cows, streets, and vegetation, with avatars and 3D objects. Another important aspect of this experience is that the use of the virtual worlds of the video games allowed us to communicate, without being able to use the spoken language to be able to exchange between us, but we understood ourselves with these young people thanks to the mediation of the visual universes of the video games.

Figure 4: *Matadouro* a machinima mixing real photographs and 3D avatars © Isabelle Arvers

In this workshop experience, there was also a co-learning and exchange of skills and knowledge: I learned from the children, new working methods and I learned about local beliefs and myths, while teaching them how to use game engines to be able to represent reality, and I was able to see their daily lives through their eyes.

These first few examples show, first of all, that there are many similarities between pre-colonial knowledge and digital virtuality, but also that there is a propensity in this exchange to abolish hierarchies between knowledge and between learners and facilitators. A change in the pedagogical relationship that allows a teacher who learns from his students and the learners to emancipate themselves in Jacques Rancière words, because they already have all the knowledge in themselves, it is just a matter of getting it out. [23]

⁷ *Matadouro*, machinima directed by teenagers in Sao Jose do Barreiro in Brasil during a workshop held by Isabelle Arvers

⁸ *Espiritos*, machinima directed by teenagers in Sao Jose do Barreiro in Brasil during a workshop held by Isabelle Arvers

In addition to being better able to apprehend several levels of reality as seen previously in the South, Mbembe adds that Africans are also used to decentering themselves from human by conferring mediumnic powers on objects, which predisposes them to embrace the mobile culture of entertainment.

Mathematics, cybernetics and ancestral knowledges

Katrin Pye illustrates Mbembe's remarks by giving examples of objects that can be assimilated to computers, either because they are charged with power and give access to other worlds and allow the acquisition of knowledge, or because the elements of which they are composed, the cowry shells, can be assimilated to pixels, as if they allowed to see other images, other representations, and realities. This is the case with the Lukasa, the memory objects of the Luba that record stories and can be compared physically and spiritually to "memory cards". [24] The similarity between the Lukasa and the computer also brings to mind the Khipu, the first analogical computer of the Incas, made of strings and knots, allowing the calculation and forecasting of the future, thanks to the observation and analysis of the constellations of stars by the ancestors. Constanza Pina, a Chilean artist based in Mexico City, learned the Khipu data coding system through workshops and created a sound installation mixing ancestral knowledge and electronic circuits.

An analogy between ancestral knowledge, mathematics and cybernetics can be found in Ron Eglash's work on fractals in Adinkras, the art of the Ashanti people in Ghana. In Adinkra, each symbol tells a story, a proverb or refers to beliefs. Their forms also have a mathematical meaning, "especially in the ways that they use logarithmic curves to represent organic growth." [25] Ron Eglash, in his text on the positive perception of race in design, shows that beyond denouncing the racist biases that exist in artificial intelligence and on the Internet, it is necessary to decolonize algorithms by calling upon ancestral knowledge and their modes of visual representation to derive mathematical formulas, which are also used in cybernetics. [26]

A way to turn to the visual, spiritual, and mathematical representations of the ancestral world to remove the bias of our understanding of the present and enrich it. An approach that we find in the work of Tania Fraga who organized the expedition for Roy Ascott to meet the Kuikoros in 1997. Her life and her work were deeply modified by her meeting with the Kuikoros and the observation of the vegetal forms and natural life. "It was the 10 days that changed my life. I lived with them. The Kuikoros. They did not have contact with missionaries (only 50 years of contact, very few spoke Portuguese) and kept their shamanic beliefs intact. That was the reason I chose them." In a beautiful text written during her stay with the Kuikoros, Tania Fraga describes a multidimensional world with shimmering colours, during which she cannot stop swimming.

"I became impregnated with their hypnotic sound. The natives painted our bodies with fragrant black resin and reddish oil transforming us into the Surucucú, the serpent. We lost the notion of time we had up to a few days before, and we began to discern another time, multidimensional, non-linear and very complex, swinging smoothly as if it were flowing around the variations of a strange attractor." [27]

Following this experience, Tania Fraga conceived works such as 'Xamantic Web', 'Xamantic Journey' (1999), a work in VRML (Virtual Reality Modeling Language) that explores the similarities between the shamanic journey and wanderings in virtual spaces and takes up the multi-dimensional and non-linear aspect of the Kuikoros' perception of the world in a telematics work allowing multiple modalities of online presence and exchange; or The Epicurus Garden, (2014) a generative Garden of Eden, presented as an immersive installation, whose forms unfold according to brain waves captured through a neural interface. Designed from growth algorithms, the plants, mushrooms, and flowers unfold in a very organic and fractal way according to the waves emitted by the viewers' brain.

Fraga is also inspired by logarithmic spirals and other symbols to generate her images, she adds, "Yes, the logarithmic spiral and others, they are all connected with growth and I am fascinated with them. I use them in my work, not only on shapes but in trajectories, in relations (for example, colour variations), in variations in general." told Tania Fraga in an online interview.

Figure 05: Epicurus Garden Virtual Reality worlds. Source Tania Fraga

These different examples of artistic reinterpretations of ancestral knowledge and techniques permitted by the virtuality of the digital allow to illustrate Mbembe's remarks while insisting on the fact that these remarks are not only linked to Africans but to all the peoples who have remained in contact with and listening to ancestral knowledge and whose new generations are more likely to make a leap into the digital.

Decolonizing our imaginary

However, the stakes are high because the massive use of digital technologies transforms our way of thinking, our imagination but also our way of being and seeing the world and this imagination is a space to be decolonized. Accordingly, to Mbembe, "The biggest impact of the mobile phone-and of digital technologies more broadly-has been at the level of the imaginary. The interaction between humans and screens has intensified, and with it, the experience of life and the world as cinema-the cinematic nature of life. [1]

An idea that is at the origin of my curatorial work on the relationship between art and video games. In the mid-1990s, when I was talking to teenagers, they told me they dreamed in video games and explained to me that they loved video games so much, that they would prefer games to replace television and even that they would like to live inside games. That's how I realized that games were shaping our imaginary as tales used to do and that if games could shape our imaginary, they were also a way to manipulate our minds and to spread a certain morality, ethics, certain representations of the world. And that's why, from my first exhibitions, I focused on promoting diversity in terms of aesthetics and game plays in video games by showing the other side of video games, the artistic, experimental, political games.

Since 2005, I also started to promote the use of video games as a medium in machinimas, a cinematographic technique and new genre that consists in hijacking video games to make films, in order to bring a distanced critique towards a simulacrum world in the sense of Guy Debord. [28]

Using the virtual worlds of video games and diverting them to tell stories or use them as a means of expression allows us to manipulate the images that without this critical distance manipulate us by shaping our ways of thinking and seeing the world. For if, to use Mbembe's words, technologies plunge us into a cinematic vision of reality, my working hypothesis is that it is most opportune to divert these technologies to think critically and reappropriate them tactically. Since 2009, I have been organizing and leading machinima workshops during which people learn how to use video games or virtual universes to produce films and thus transform an object of mass consumption into a means of expression.

With the virtual storytelling workshops, conducted in close collaboration with traditional storytellers during my stays in Togo and Kenya, I am now working on the mix between oral tradition and virtual universes. Hijacking these virtual universes allows us to encounter knowledge that tends to be forgotten by most of the new generations, while their imaginations are filled with images that come from elsewhere.

It is therefore necessary to take distance in order to make a reflexive critique, in the sense that Rama Thiaw, a Sen-

galese director and author of the documentary *The Revolution won't be televised*, understands it when she presents the feminist workshops, the "Artistic Sabbars"⁹, that she has organized in Dakar with creative women. She thinks of these workshops as "reflexive" workshops, that is, workshops where the women are the "I" of their enunciation, and speak for themselves, from their point of view. [29]

It is therefore this question of the point of view from which it is possible to reappropriate the narrative that I wish to address with the practice of machinimas. The machinima can indeed be understood as a counter-gaming practice that consists in diverting video games from their initial function, which is to play, to use them in a tactical manner in order to operate a shift of perspective and to take back the initiative of the narrative and to speak from a point of view that has often had little access to the media.

For as Francis Nyamnjoh rejoices, new technologies allow younger generations to have access to media and speech "to claim, express themselves, and procure social capital in spaces and places not previously accessible to them, and on issues generally considered the prerogative of their parents or the ruling elite." [30]

In the machinima's workshops, I use this technique of designing films from video game engines to make visible forgotten knowledge buried under centuries of colonialism by collaborating with storytellers to put stories, legends, but especially pre-colonial knowledge into images. This leads the participants to tactically use images that were intended for another use. In this I join the tactical media movement which consists in using social networks, blogs, podcasts, machinimas to document, make visible and disseminate these words and knowledge to new generations.

Figure 06: L'aigle et le Vautour a machinima directed by the Togolese storyteller Charlotte Boane in Lomé, Togo, 2020

Conclusion

By transforming the player into the director and author of her/his own narrative, machinimas allow for a displacement, a reterritorialization as Lia Beatriz Teixeira Torraca

⁹ For more information about these workshops see: <https://www.au-senegal.com/sabbar-artistiques-feminins-de-dakar.15647.html>

indicates in her magnificent text on The aesthetic look of affect, "The machinima represents in effect the possibility of erasing the distance between the one who watches or plays and the one who expresses himself and can then become a producer of content and director of his own story... A new way of constructing the reality of spaces that are invisibilized or communicated in narratives that are not those that occupy and usurp these spaces, those that construct the spaces of war, of the post-war period, of the intervals of escape from conflict. « [2]

In addition to allowing for the juxtaposition of multiple types of reality by integrating photographs, live action, and voices with virtual environments, they also have the ability to alter the viewer's relationship to the image by giving them the ability to become narrators and authors of their own narrative. The player acts and performs his character and speaks from his point of view: "Machinima is the chance to create a common space of communication mediated by affect, an alternative medium to affect and be affected by a resizing of spaces and the participation of the user/spectator/agent. It is the reconfiguration of perception and the imaginary, conjugating two spaces and multiple realities produced by the user/spectator/agent." [2]

Acknowledgements

I would like to thank Patricia Gouveia (FBaul, ITI, LARSyS) for her guidance and Liz, B. Teixeira Torraca for her kindness and cooperation. I also would like to thank Daniela Fernandez, Ricardo Ruiz, Tania Fraga and Maria, L. Frago for our exchanges.

Author Biography

Isabelle Arvers, PHD Candidate, LARSyS, Interactive Technologies Institute (ITI), Faculdade de Belas-Artes, Universidade de Lisboa (FBAUL), Portugal, is a French artist and curator whose research focuses on the interaction between art and video games. For the past twenty years, she has been investigating the artistic, ethical, and critical implications of digital gaming. Her work explores the creative potential of hacking video games through machinima.

As a curator, she focuses on video games as a new language for artists. She curated several shows and festivals around the world, including Jibambe na Tec (Nairobi, AF, 2020), Tecnofeminismo (Bogota, AF, 2019), Art Games World Tour exhibit (Buenos Aires, 2019), Interspecies Imaginaries (Overkill, 2019), Machinima in Mash Up (Vancouver Art Gallery, 2016), UCLA Gamelab Festival (Hammer Museum, Los Angeles 2015, 2017), Evolution of Gaming (Vancouver, 2014), Game Heroes (Alcazar, Marseille, 2011), Playing Real (Gamerz, 2007), Mind Control (Banana RAM Ancona, Italy, 2004), Node Runner (Paris, 2004) Playtime (Villette Numérique, 2002).

From 2013 to 2016, she worked on art and research projects and curated and produced six antiAtlas of Borders exhibitions around the mutations of the borders in the 21st century, including The Art of Bordering at MAXXI in Roma and Coding and decoding borders in Brussels. She was also in charge of the End of the Map exhibition in the fall 2015 in Paris about alternative, subversive and emotional cartography.

As a tribute to Nathalie Magnan, her association Kareron produced in 2018 TRANS//BORDER, Nathalie Magnan's teachings, a series of events about eco-sexuality, cyber feminism, alternative media and situated knowledge. Kareron is actually producing UKI a Sci-fi Alt reality cinema by Shu Lea Cheang.

In 2019, she embarked on an Art and Games World Tour in non western countries to promote the notion of diversity of gender, sexuality and geographic origin, focusing on queer, feminist, and decolonial practices. In 2020, Arvers started a PHD on Art & Games decolonization at Fine Arts Faculty in Lisbon, Portugal, under the direction of Patricia Gouveia.

A comparative study of practice-based research and research-creation in media art: Comparing two doctoral studies in Australia and Canada

Sojung Bahng, Stephanie McKnight (Stéfy), Jon McCormack

Media Production and Design, Carleton University (Ottawa, Canada)

SensiLab, Monash University (Melbourne, Australia)

sojung_bahng@carleton.ca, stefy.mcknight@carleton.ca, jon.mccormack@monash.edu

Abstract

This paper examines the differences and similarities between practice-based research (PBR) and research-creation (RC) in media art. As case studies, two PhD research projects — one from Australia (Sojung Bahng, PBR) and the other from Canada (Stéphanie McKnight, RC) — are compared. The comparative analysis demonstrates that critical reflection and phenomenological awareness through creative practice are crucial in generating knowledge in both PBR and RC. Simultaneously, this study shows that research methods and approaches between PBR and RC differ due to different academic and socio-cultural factors. PBR's main aim is to generate knowledge through practice in a broader sense, whereas RC, with its conceptual roots in fine arts, emphasizes social and community-based engagement.

Keywords

Practice-based Research, Research-Creation, Media Practice, Cinematic Virtual Reality, Surveillance Studies

Introduction

This paper critically examines and compares the methodologies of practice-based research (PBR) and research-creation (RC) in media and fine arts from a multicultural perspective to further understand how these methodologies intersect and differentiate in global academic settings. In the 1980s, interest in PBR grew among creative disciplines in Australia and the United Kingdom [1]. The so-called "Canadian" approach, known as *research-creation*, is the use of practice-based methods in artistic research [2]. In Canada, scholars often define research-creation as a form of PBR, or even PBR in itself, and these methodologies are often mistaken as interchangeable. Indeed, this is because both PBR and RC emphasize generating new knowledge through creative practice and art-making.

For example, many scholars in Canada, such as Natalie Loveless [2], Erin Manning [3] and Owen Chapman & Kim Sawchuck [4], have outlined a direct link between PBR and RC, arguing that RC is a progression and development of PBR, or a Canadian "version" of PBR. For them, "research-creation" is a creative practice that is localized in Canada, therefore, carries its own name, beyond international terms such as "practice as research", arts-based research, practice-led research and so on [4]. We argue, however, although these concepts have shared values and identity, they are not identical or interchangeable ideas or approaches. They need to be analyzed through a localized, geographical, and multicultural lens. By comparing, contrasting, and analyzing both PBR and RC alongside each other, we can further understand the history of both these methodologies - how they intersect, and differentiate.

This paper describes the differences and similarities between PBR and RC in terms of their knowledge contribution to artistic and creative practice in media and fine arts. As case studies, this paper analyzes two doctoral dissertations completed in 2020, one from Australia (Sojung Bahng, PBR) and the other from Canada (Stéphanie McKnight, RC). This analysis is unique and important because it situates two different dissertations alongside each other, and complicates their development, circulation, and assessment of both projects. Bahng used virtual reality (VR) as an artistic and cinematic medium to explore the concept of reflexivity and created three VR projects as part of the research process [5]. McKnight draws on methods of fine art and RC to investigate the issue of contemporary surveillance and colonialism in Canada [6].

Both artist-researchers critically reflected on their socio-cultural identities through their individual media practices, showing that reflective practices are essential for both PBR and RC projects. Although both researchers employed creative practices as part of their research processes, their methods and approaches for contributing academic knowledge are somewhat different. Bahng used the artistic investigation to explore her research questions around reflexivity and empathy in VR. On the other hand, McKnight explored their fine art practice as knowledge production for the field of surveillance studies. Bahng's approach reflects PBR's emphasis on extending knowledge through the process of media practice in general. McKnight's approach draws from the terminology of research-creation, which emphasizes the importance of creation in itself, showing the significance of artistic practice within the context of academic knowledge.

Our study shows that academic research which embraces creative media practice differs depending on the socio-cultural and institutional contexts, and that these cannot be easily simplified into one concept or approach. However, the research also demonstrates PBR and RC are reciprocal, and that both critical and phenomenological awareness are essential in contributing to knowledge in media art.

Related work

Many scholars utilize creative methodologies for academic and research. This may be called art as research [7], art-based research [8], practice-led research (PLR) [9], PBR [1, 10], and RC [2, 3, 4]. However, there is some variation in the definitions of these types of research, where concepts are used differently depending on disciplines, cultural background, geography, research questions, and institutions. However, we are focusing our analysis on PBR in Australia and RC in Canada, specifically in relation to media and fine art disciplines, because these methodologies are often seen as parallel, regardless of locality.

Practice-based research in Australia

PBR is generally understood as a mode of academic investigation and inquiry that pursues knowledge through practice [1,10]. PBR is differentiated from practice-led research (PLR). If the artefact or creative outcome is the basis for the knowledge contribution, the research can be considered PBR. In PLR, the study's main aim is to generate new understandings of the practice itself. Thus, the creative artefact is not necessarily considered as knowledge production [9,10].

The tradition of PBR in technology is related to the first polytechnic founded in London in 1880 [1]; the program was central to developing knowledge in practice but not contextualized as PBR. PBR in creative arts disciplines has grown rapidly in Australia since it was implemented in 1984 at the University of Technology, Sydney (UTS). Ernest Edmonds and Linda Candy, pioneers of the PBR program at Creativity & Cognition (C&C) Studios at UTS, defined PBR as "An original investigation undertaken in order to gain new knowledge partly by means of practice and the outcomes of that practice" [1]. This definition of PBR emphasizes the originality of creative outcomes and artefacts as knowledge production. For a practice-based doctoral submission, PBR normally requires the inclusion of creative artifacts (or artworks) as well as a written dissertation that contextualizes the creative outcome academically [1,10].

SensiLab, established in 2016 by computer artist Jon McCormack at Monash University in Australia, has suggested a new model for PBR in media art and creative technologies. SensiLab was created within the Faculty of Information Technology, but influenced by existing models used in creative disciplines in the Faculty of Art, Design & Architecture (MADA). SensiLab's program expanded the practice of PBR beyond the creative arts to include research in creative technologies, visualization, artificial intelligence, human-computer interaction, interactive media, games, simulation, cultural heritage, and information systems [11]. SensiLab acknowledges the value of tacit and implicit knowledge as an embodied phenomenological knowledge [12, 13]. For its doctoral program, SensiLab adopted an approach to PBR similar to that of C&C at UTS. The SensiLab PBR examination process requires an artefact with a public exhibition accompanied by a written exegesis¹. The length of the exegesis is approximately half the length of a traditional written doctoral thesis dissertation [11].

In general, PBR in Australia has developed by emphasizing the value of the process of knowledge production and embodied tacit knowledge in both creative arts and technologies. These movements can be considered fundamental academic efforts that include phenomenological approaches and methods: those that put forward the importance of

¹ The practice-based PhD research is examined on a written exegesis of around 30,000 to 50,000 words.

suspension of judgement, bodily awareness and subjective reflection [14] as a primary method of knowledge production.

Research-creation in Canada

The Social Sciences and Humanities Research Council (SSHRC) in Canada define RC as "an approach to research that combines creative and academic research practices, and supports the development of knowledge and innovation through artistic expression, scholarly investigation, and experimentation" [15]. However, many artist-scholars in Canada have redefined and expanded the concept of RC as a uniquely innovative research methodology. The idea of RC also has been developed as a tool to explore critical social engagement in artistic and experimental ways.

RC is rooted in practices of fine arts but borrows inspiration from multiple disciplines. RC is an interdisciplinary practice that brings together a constellation of theory, practice, and events [3, 4]. Artist-scholar Stéphanie McKnight has argued that the methodology of RC allows artists who work in academia the skills, tools, and support needed to generate research through the production of artworks and cultural texts [6,16]. In RC projects, research, knowledge, and production work reciprocally to form new ways of thinking of old and new ideas [2].

For research-creationists Owen Chapman and Kim Sawchuck, the process of RC is embedded in academic institutions, and thus draws on some traditional modes of research inquiry [4,17]. However, this is only one component of a series of ways that RC functions. RC projects can be incomplete, and may produce new knowledge throughout its creative process, and even beyond it. This is not to say that RC projects cannot be treated and exhibited like "autonomous artworks" [18], or translations of knowledge; however, the process of creation and manipulation of research and knowledge at all stages of creation is the primary mode of inquiry and knowledge production for RC.

Furthermore, RC arguably privileges feminist and activism methodologies [2, 3]. Many research-creationists draw knowledge from intersectional practices such as community-based research and socially engaged work. They speak to community members, install exhibitions, and think while creating, reading, performing, sketching, publishing, and failing [17, 19]. RC gives space for unsettling, uncomfortable, and productive failure [16, 19]. In short, research-creationists seek to produce artistic and innovative research that will change the way audiences, scholars, artists and viewers move throughout society and space.

Two PhD Case Studies

Cinematic VR as a reflexive tool by Sojung Bahng

Sojung Bahng's Practice-based PhD research, conducted at SensiLab at Monash University in Australia, explores the reflexive dimensions of cinematic virtual reality (VR) within intersubjective contexts. Through conceptual and practical explorations of VR storytelling, Bahng developed new cinematic practices applied to VR and expanded the contextual understanding of reflexivity and empathy. Her practice-based research developed three cinematic VR projects: *Floating Walk* (360° video), *Anonymous* (interactive mobile VR) and *Sleeping Eyes* (interactive navigable VR). Each creative work applied reflexive elements in qualitatively different ways, exploring the potential of cinematic VR for eliciting embodied reflection. The projects are responses to both personal and societal alienation, disconnection and isolation.

Figure 1. – A still from *Floating Walk*: the image shows the artist standing in front of a wall of passports from different countries carrying a 360° camera.

Background

Based on the developments of virtual reality (VR) technologies, many artists and filmmakers have attempted to create moving image works that provoke empathetic engagement in virtual characters or stories [20]. Bahng argued that immersive engagement without critical or reflexive awareness has the potential danger of objectifying others' pain or emotionally identifying with others' difficult situations without critically thinking about the social and historical issues around them [21]. Based on this perspective, she examined VR as a reflexive storytelling tool inspired by the reflexive

mode of documentary filmmaking [22] and Bertolt Brecht's epic theater [23]. Bahng further noted that VR has a fundamentally reflexive nature due to the limitations of immersive engagement; thus, she explores these limitations as reflexive elements for VR storytelling to encourage audiences to actively fill in the gaps between their physical sensations and virtual perceptions.

Research Objective and Method

The research objective of Bahng's dissertation was to explore cinematic VR as a reflexive tool beyond empathy. She investigated her research objective through her creative projects by critically examining how reflexive storytelling is effectively used to promote self-reflection in socio-cultural contexts. Her research questions concerned the methods and techniques that can be used for reflexive VR storytelling.

Bahng's research covered multiple disciplines, including film and media studies, HCI, visual art, and philosophy. She drew upon a practice-based research methodology specifically in artistic practice, but utilized a variety of research techniques and methods: autobiographical, autoethnographical, interview-based, and collaborative. As the research progressed, Bahng critically reflected on her creative works and applied what she had learned from one project to the next. The works informed and iteratively developed the framework presented in the exegesis, and this refinement informed the development of each subsequent work.

Thesis Structure

Bahng's exegesis is divided into two main parts: theory (Part I) and practice (Part II). In Part I, Bahng proposes a conceptual framework for reflexive storytelling design in cinematic VR. For example, she reframes VR as a reflexive tool by using theoretical backgrounds such as Buddhist philosophy, Brechtian aesthetics and phenomenology. She also introduces embodied spatial montage as a cinematic concept that is extended to the spatial dimension and the participatory situations of VR storytelling. In Part II, she uses the proposed conceptual framework and theoretical analysis of Part I to describe her three cinematic VR projects. She explains each project's background and overview and then describes the process of making the project. She also addresses the audience study and discussed the reflexive dimensions based on the findings from the audience interview. In the concluding section, Bahng discusses her overall research process by reflecting on this body of creative work and connecting the practical, studio investigation with the theoretical framework. She responds to the research questions and offers reflective analysis of the practice-based research.

Research Contribution

Bahng's research embraces both conceptual and creative knowledge, exploiting diverse technical possibilities. Through three distinct creative projects, Bahng reframes and develops a novel form of VR storytelling for self and social reflection. Together, the three projects provide insight into our understanding of VR as a cinematic, artistic medium and

as a means of promoting self and social reflection, specifically regarding socio-cultural issues such as alienation, disconnection and isolation.

Each project emphasizes its own distinctive contribution. *Floating Walk* reveals the potential of 360° video for autobiographical self-expression and as an autoethnographic tool that promotes reflexive thoughts about immigrants' identity issues. *Anonymous* contributes design factors and technical implementations for using VR to elicit self-reflection on loneliness and death. *Sleeping Eyes* demonstrates how phenomenological and participatory engagement in VR storytelling can elicit critical awareness of narcolepsy and social ignorance. Collectively, the body of creative research provides knowledge about reflexive modes of immersive storytelling while considering the various technical, design and narrative elements available to cinematic VR.

***Colder Now: Surveillance as Contemporary Colonialism* by Stéphanie McKnight**

McKnight's doctoral research-creation project, conducted at the graduate program in cultural studies in Queen's University, investigates surveillance and colonialism in Canada through media art practice and exhibition. As a representative outcome, her doctoral RC exhibition titled *Colder Now*, was exhibited at the Art and Media Lab in the Isabel Bader Centre for the Performing Arts on October 23rd to November 3rd 2017. Drawing from the methodology of RC, *Colder Now* juxtaposed surveillance studies, colonial studies, and media art technologies to ask how does surveillance and policing contribute to contemporary colonialism in so-called Canada post-9/11.

Figure2. *The triangle of trust* (2017) by Stéphanie McKnight

Colder Now's anchor piece *the triangle of trust* is one example of the ways that McKnight uses media, collaboration, installation, and surveillance studies theory to question their white settler relationship to Canada and its colonial histories. *the triangle of trust* is a neon replica of the

Canada Security Intelligence Service (CSIS) headquarters on unceded and unsundered Algonquin territory (also known as Ottawa, Ontario), known for investigating "activities suspected of constituting threats to the security of Canada and to report on these to the government of Canada" (Government of Canada). This sculpture centers CSIS as a primary institution of surveillance and intelligence gathering. *the triangle of trust* replicates the aesthetic of CSIS, including the colour blue, which is referenced in several Google Images of the establishment. The line drawing was inspired by a screenshot taken of the CSIS building found on Google Maps.

Background

As an exhibition, *Colder Now* critiques the invasive and unclear intent of Canada's Anti-terror Act (Bill C-51). Canada introduced its first "Anti-terrorism Act" (Bill C-36) and "Public Safety Act" (Bill C-42) in 2001, as a response to 9/11 [24]. CSIS is one of the primary institutions governing these policies. Bill C-36 was heavily contested and protested because of its racially motivated tendencies (2012). Furthermore, Bill C-36 has affected Indigenous Peoples in so-called Canada, especially Indigenous activists who may participate in activities of resistance and political dissent (Adese, 2009). Bill C-51 and its successor Bill C-59 are arguably no different. They include similar languages that attempt to define terrorism in extremely broad terms. Regardless of the original intent of these bills, and whether or not citizens agree they are necessary for security purposes, they actively produce normal (white) and abnormal bodies (non-white). In these contexts, Indigenous resistance that challenges colonial and settler practices in Canada are labelled as unpatriotic, dangerous, criminal, and a national threat [25].

Research Objective and Method

the triangle of trust captures the architectural design of the CSIS headquarters by illuminating a line drawing of the building. The glass tubing and florescent blue tints intentionally replicate the glass exterior of CSIS. Painted with a sea of windows, the CSIS headquarter insists that it is a transparent and visible institution. Though as several scholars have argued, windows and glass façades don't actually equate visibility [25, 26]. Despite CSIS's desire to render its interior visible, viewers gaze is subject to several factors including security personnel, trespassing, limited gaze. As such, *the triangle of trust* complicates CSIS's desire to be transparent in its processes of security through its architecture by replicating its glass façade, but also illustrating limited architectural information through a simple line drawing. Despite this transparency, there is still a lack of transparency relating to their governing bills, such as Bill C-51.

Using these fine-arts-based methods, McKnight's research objective was to explore the ways RC is integrated with surveillance studies and McKnight's white settlerhood. By questioning the visibility and the institution who is governed by policies such as Bill C-51 through the creation of

art, audiences can engage with the dialogues in ways that complicate their relationship to the research questions at hand.

Thesis Structure

McKnight's dissertation takes the form of a portfolio project. In the Cultural Studies program at Queen's University, a portfolio dissertation is defined as, "Like a monograph thesis, the portfolio thesis comprises a coherent research project based in academic literature, but the body of original work consists of multiple components that function as standalone elements and may be diverse in format, voice, medium, method, and address" [27]. McKnight's portfolio project consisted of seven individual standalone articles that addressed the research question, how does surveillance contribute to contemporary colonialism in so-called "Canada post-9/11"? Funded by the Social Sciences of Humanities Research Council in Canada (SSHRC), McKnight's dissertation unsettled traditional methods of knowledge dissemination at Queen's University, by centering interdisciplinary and novel ways of publishing their dissertation. More interesting than the articles embedded in McKnight's final dissertation package, was the inclusion of a visual essay titled *Working, Watching, Working: a methodology for a white settler surveillance artist scholar* – a journal and sketchbooks of ideas, drafts, photographs, and notes taken during the processes of creation. In this visual essay, we have access to their processes of thinking, critical reflection, failure, and the moments where their ideas have changed to better reflect their identity and posed research questions. As mentioned above, RC happens at all stages of the research process. McKnight's visual essay demonstrates this. The articles are a form of appendix to the visual essay and *Colder Now* exhibition to fulfil the traditional colonial and neoliberal expectations of Canadian Universities. The institutional expectation and rule that art cannot function as research and knowledge, in its own right.

Research Contribution

Not only does McKnight's creative dissertation project and exhibition *Colder Now* rethink and reveal contemporary colonialism through methodologies of art-making and interdisciplinarity, but it also reimagines new ways of integrating RC as a doctoral methodology in Canadian Universities. It does this by inviting portfolio projects as an option to exhibit and publish a creative dissertation. *Colder Now*, and specifically *the triangle of trust*, interrogates Canada's security, surveillance, and policing strategy through the production of art. Through their art-making, McKnight reveals the invasive and violent colonialism still plaguing Turtle Island. The artworks are in themselves artefacts of social justice and self-reflexivity, as well as producers of new knowledges in their own right. The new knowledges that these pieces contribute to the social sciences and humanities, especially surveillance studies, is their ability to use surveillance the visual as methodology itself. McKnight's work function creeps' surveillance policies,

anti-terror legislation, and white settler colonial ideations to critique the settler state against itself.

Finding and Discussion

Bahng and McKnight both use media and fine art practices to generate academic and scholarly knowledge in PhD doctoral studies. However, their research approaches and methods are different. Most noticeably, Bahng's PhD dissertation format is considered an exegesis in Australia, and it follows a relatively conventional format for PhD research that includes an introduction, theoretical background, creative practice and overall reflection and conclusion. However, McKnight's portfolio project combines several art projects that include the written contextualization of each work.

In a similar context, Bahng's creative practice informed the development of her next project through critical reflection and audience observation or interview. Her three creative projects are deeply interconnected, and her design process was iterative. However, each of McKnight's artworks has a separate emphasis and importance in terms of knowledge production, even though the three projects embrace a broader umbrella of ideas. Each of McKnight's pieces can work alone or alongside each other.

Bahng's study used explicit research questions that were addressed through practice. To answer the questions, she used a combination of different research methods combining autoethnography, ethnography, interviewing, collaboration, and more. In contrast, McKnight's research questions were unfixed, and their inquires did not aim to find specific answers. The artworks themselves became producers of knowledge; thus, the thesis and questions were unstatic and constantly changing. McKnight raises questions to investigate the way creative practice can produce new knowledges in surveillance studies, but they allow the audience to find answers or ask other questions. McKnight's research methods and questions are designed to provoke discourse or elicit critical inquires.

The differences in the research approaches and methods are not surprising because Bahng and McKnight's research topics and purposes are different. However, the noticeable difference between the two PhD projects is deeply related to the dissimilar traditions between PBR and RC. As discussed previously, PBR in media art in Australia has developed within interdisciplinary art and technology disciplines. Because Bahng's research was conducted at SensiLab, her dissertation format partially embraces a technoscience academic style and approach. However, as a SSHRC funded project, McKnight's research approaches are oriented toward the humanities and fine arts. They explore RC as an art practice to produce new knowledge for specific cultural, social and political events. Furthermore, McKnight suggests a new portfolio model for RC as a doctoral methodology for Canadian Universities. The trials of embracing creative

practice for doctoral studies are relatively new, and there is a less established format in Canada. Therefore, McKnight combines the portfolio style dissertation and art exhibition in their PhD research to validate the value of artistic RC for doctoral research methodology more broadly.

Furthermore, it is clear that RC puts greater emphasis on social engagement, social justice and activism as a research practice. However, this does not mean that PBR places no importance on social value or community-based engagement. However, PBR's main aim is to generate knowledge through practice in broader research questions and themes; thus, PBR approaches are not necessarily limited within the frame of social intervention. As mentioned earlier, many artist-scholars use PBR and RC interchangeably, as though they are the same concept. However, it can be seen that PBR is a broader umbrella concept that values practice and creative artefacts as vehicles for knowledge production. On the other hand, RC has a specific tradition and history stemming from Canadian fine art practices and humanities traditions that facilitate social action through artistic practice.

Despite these differences, Bahng and McKnight emphasize the importance of self-reflexivity and critical reflection as a research method and artistic tool. They demonstrate that subjective knowledge and embodied understanding by practice are important in both PBR and RC. Furthermore, as media and fine art practitioners, both researchers use technology as a critical tool to deconstruct the conventional or old perceptions and provide new ways of explorative mediation to the audience. Simultaneously, they value the collaborative elements in all research or creation processes, demonstrating that many factors beyond a researcher's individual idea (e.g., artistic collaborators, audience members and collaborative technological tools) can produce unexpected but valuable contextual knowledge. Bahng and McKnight both indicate that new media can be used reflectively and critically in media and fine art research practice.

Conclusion and Limitations

This study brings forward the differences and similarities between PBR and RC in doctoral media and fine art research. Two PhD dissertations, one from Australia using PBR (Sojung Bahng) and the other from Canada using RC (Stéphanie McKnight) were described and analyzed as case studies. We found both researchers used media practice to reflect their socio-cultural identities critically and to prompt an audience's critical awareness of and questioning in their socio-cultural contexts. In their studies, media practice was used as a form of knowledge production to demonstrate the significance of embodied knowledge through creative practice. However, we also found the research methods and approaches were significantly different between the two studies. Bahng's PBR study adopted various technical methods and demonstrated that PBR methods can be applied to broader research objectives. McKnight's RC project showed the way RC is positioned within fine art practice and

humanities in Canada and that it prompts social engagement and activism. Comparing only two doctoral studies limits generalizing the characteristics of PBR and RC. Nevertheless, the differences based on the comparative analysis between two studies clearly show the histories and traditions of PBR are different in Australia and Canada, demonstrating that creative research has been interpreted in complex ways, considering socio-cultural backgrounds and institutional or academic heritage and disciplinary lineages.

Abstract

This paper reviews a virtual exhibition titled *reflexive-vr.com*. Initially planned as a public exhibition featuring cinematic VR works by media artist/filmmaker Sojung Bahng, however, due to restrictions imposed by the COVID-19 pandemic, a different curatorial approach was needed in order to reconfigure the original installation plan into an interactive online viewing experience. This reflective analysis explores the design strategies involved in this case and how the viewing experiences associated with the artistic intent of three VR artworks (*Floating Walk*, *Anonymous* and *Sleeping Eyes*) was supported by the exhibition's translation from a gallery-based installation into an online virtual environment. We will address technical specifications, consider curatorial strategy and implications to narrative flow and phenomenological experience, and – while acknowledging present limitations – raise the potential for online exhibition formats to serve as a distinctive presentational mode in their own right for engaging viewers with VR works.

Keywords

Virtual Reality (VR), Viewing experience, Virtual exhibition, Curatorial Design, Mixed Reality, Scenography

Introduction

The coronavirus pandemic has had a significant impact on the cultural sector globally. One response to the disruption caused by COVID-19 to the "normal operations" of museums, galleries and contemporary arts venues has seen cultural organisations turn their attention towards digital channels and platforms in order to maintain their programming activity and engagement with audiences [1]. Since the beginning of 2020, countless exhibitions, including many public exhibitions of Virtual Reality (VR) works that require shared head mount displays (HMDs), were cancelled and some moved to remote online formats due to social distancing requirements [2, 3]. While prestigious film and media art festivals had already begun adopting virtual platforms to showcase VR films or artworks – a notable example being

the Cannes Film Festival and its immersive multiplayer platform, the Museum of Other Realities (MOR) [4] – the forced closure of exhibition venues over the past two years along with restrictive measures introduced upon their reopening has instigated the need for further experimentation into how web-based virtual environments can be designed to support an accessible, inclusive and sustainable exhibition model, post-pandemic.

Definitions of 'virtual reality' vary markedly, including the broad concept of an imaginary or represented reality distinguished from the real world [5, 6, 7]. For the sake of clarity, in this paper, we define VR in direct reference to digital media whose highly personalised viewing experience requires an HMD in order to simulate visual realities. As such, exhibiting VR artworks in the public and social setting provided by galleries and festivals raises a set of challenges to exhibition design and more conventional modes of viewing, as well as curatorial protocols. As artists and curators working with the medium of VR, this situation has become even more compounded due to the implications of the pandemic on cultural engagement and urgent, prompting us to think about the roles that physical environments (e.g., galleries and exhibition venues), embodiment and performativity play in not only framing VR works curatorially, but underpinning the distinctive qualities of their viewing experience.

These observations lead us to ask: In what ways can virtual environments be designed to adequately support the aesthetic experience of VR? Can such digital spaces enhance or even supersede certain features associated with experiencing VR works in the context of physical exhibition? In this paper, we introduce the online VR exhibition, *reflexive-vr.com*, as a means of entertaining some of these associated questions.

reflexive-vr.com is an online exhibition that was initially developed to support the final presentation of cinematic VR artworks produced by Sojung Bahng (first author) as part of her *PhD* research thesis undertaken with SensiLab, an interdisciplinary research lab based at Monash University in Melbourne, Australia¹. Bahng's practice-based research

¹ This PhD project aligns with SensiLab's 'VR as Cultural Practice' research track, supervised by Jon McCormack and Vince Dziekan. This track recognizes that contemporary filmmakers and

visual artists alike are embracing the potential of immersive digital technology – such as Augmented and Virtual Reality – to tell stories in powerful, new and affective ways that mark a

programme was due to culminate with an examination conducted in the format of a public exhibition in June 2020. However, due to the outbreak of COVID-19 experienced in Melbourne at this time, plans for staging this examination exhibition were cancelled to comply with restrictions imposed by the Victorian State government and University, which included enforced "lockdown" and other precautionary hygienic and physical distancing measures. As a consequence, it was not possible to realise the original designs for presenting the works as part of a mixed-reality, gallery-based installation. This imposed a significant challenge to reconceptualise the curatorial strategy as a digital exhibition, and in response, a web-based 3D virtual environment was designed to meet the requirements of examination within a tight timeframe and a modest budget.

Over the rest of this paper, we will review the process of translating the physical exhibition, which was initially conceived to provide the necessary viewing conditions to experience three VR projects (*Floating Walk*, *Anonymous* and *Sleeping Eyes*), into an online 3D virtual environment. We will address key considerations involved as part of the process of reconfiguring the exhibition, its inventory and spatial design or scenography. We will discuss the outcome and reflect upon curatorial considerations, audience engagement and the potential – and limitations – realised from developing the virtual exhibition itself.

VR Exhibition in VR

In the following section, we will briefly introduce two relevant precedents that help contextualise the creative response guiding the development of *reflexive-vr.com*.

Alluded to earlier, the Museum of Other Realities (MOR) is an online, multiplayer interactive VR exhibition platform that prestigious international festivals, including Cannes XR and Tribeca, have used to exhibit VR projects affected by the COVID-19 pandemic [4]. The MOR is run by SteamVR². Audiences can access media using personal headsets, such as the HTC VIVE or Oculus Rift(S), which are enabled to run Steam; however, it is currently not possible to use the MOR with mobile headsets such as Gear VR or Google Cardboard. Upon entering the MOR, audience members can customise their avatars and communicate with others using gestures or sending messages. VR projects are exhibited in a virtual space that resembles a "white cube" gallery. MOR provides a navigable interactive experience

transformational moment in the evolution in the craft of "immersive storytelling". By adopting practice-based methodologies that embrace studio research, practitioner-researchers (media artists, creative technologists, content producers) are challenged to engage deeply and experimentally with immersive image technologies to conceive, develop and undertake projects resulting in creative outcomes (artworks, film screenings, installations) that seek to define the language of these media forms and introduce new

whereby the visitor is able to move through galleries and select the VR work they wish to view by clicking upon the installation artworks or sculptures. While providing a format to experience virtual artworks using HMDs, the design tropes that the MOR calls upon mimic a real-world event and venue.

In comparison, the Festival of International Virtual & Augmented Reality (FIVARS) built its own multiplayer VR exhibition platform to work on the Web [8]. While supporting a fuller range of headsets, all VR projects are rendered in 360° video. Upon entering the FIVARS online exhibition, audience members can choose avatars and interact socially with others via voice or text chat. The festival is composed of a mixture of imaginary spaces and a typical exhibition venue with spherical images standing in for each project. This inventory of videos can be watched on a personal computer or headset. If wearing a headset, audience members can access media content by navigating the spaces using controllers or through gaze interaction. In contrast, the Web version only enables the environment to be navigated by using a keyboard and mouse.

To summarise: Achieving the fullest visual and interactive experience of VR requires a demanding technical set-up. Nonetheless, it is still possible to provide audiences with a cinematic viewing experience by curating online festivals or virtual galleries that serve up readily accessible 360° rendered videos distributed via the Web or mobile headsets. While the MOR offers a navigable-interactive VR experience, it only works with high-performance virtual headsets; whereas, the FIVARS's platform works with the Web and all kinds of headsets but does not support interactive experiences. These comparisons – and the dilemmas they reveal – speak to the current possibilities and limitations of experiencing VR in a domestic setting.

The curated experience provided by MOR and FIVARS translates features immediately associated with physical exhibition (galleries; conference venue) into a virtual facsimile of those spaces. While effective and efficient for the most part, are there other possibilities for reaching audiences online that are more affective, satisfying and speak to the fuller spatial, embodied and performative experience that VR artworks can conjure?

understandings of the narrative and experiential parameters of the medium beyond the cinematic frame to cinematographic space.

² Steam is a video game digital distribution service by Valve. SteamVR, operated by Steam, is the tool for experiencing VR content using HTC VIVE, Oculus Rift or Window Mixed Reality headset.

Reflexive-VR.com

Inventory of the exhibition

As part of the examination requirements associated with Sojung Bahng's practice-based PhD thesis, *Cinematic VR as a reflective tool beyond empathy*, it was expected that the creative outcomes of her studio research be presented in the form of a final exhibition. Ostensibly, the purpose of the exhibition and its adherence to the examination policies outlined by Monash University is predicated upon providing two appointed external examiners with the opportunity to view the body of creative work first-hand. This viewing experience enables them to engage in a first-hand phenomenological way with each VR project – which might be construed as the "primary source" artefacts – along with accompanying archival materials and other supporting documentation.

The inventory of the examination exhibition was comprised of three VR projects produced by Bahng between 2016-2020: *Floating Walk* (360° video), *Anonymous* (interactive mobile VR) and *Sleeping Eyes* (interactive navigable VR). Each project was conceived as a means of exploring the communicative potential of cinematic VR in response to themes of personal and societal alienation, disconnection and isolation. The socio-cultural issues focused upon in these creative works prompt the audience to engage in critical self-reflection and to reconsider how they connect empathetically with others. More specifically, the subject of these projects engaged with immigrant identity (*Floating Walk*), no-relationship society (*Anonymous*), narcolepsy and social ignorance (*Sleeping Eyes*). Brief synopses of each work follow.

Figure 1. – A still from *Floating Walk*

Floating Walk – Gangnam Kangaroo is a 360° autobiographical documentary of a Korean woman living in Australia. She goes on a journey of self-confrontation to the root of her unclear but painful emotion and discovers that historical traumas have affected her identity. A spatial collage of 360° video images represents the artist's journey in Australia and Korea.

Figure 2. – A still from *Anonymous*

Anonymous is an interactive 3D real-time rendered cinematic VR applying gaze interaction. The story concerns the life of an old man living alone and remembering his life. The main character and his environment are abstracted by using cardboard textures. The viewer is able to access the perspective of objects that fill this domestic setting, ultimately finding themselves assuming the role of the man's dead wife, where from the vantage of her portrait hung on the wall, they observe the rituals of his solitary daily life.

Figure 3. – A still from *Sleeping Eyes*

Sleeping Eyes is an interactive cinematic VR piece that tells the story of Sungeun Lee, a South Korean media artist suffering from narcolepsy. The work invites viewers to experience the symptoms and experience of someone with narcolepsy, including uncontrollable sleepiness and physical violence rooted in social ignorance. Non-linear narrative and gamification techniques were applied to make the viewers actively explore a series of surrealistic episodes. Additionally, the viewer makes them aware of their own feelings by utilising a heart-rate sensor to visualise their own stress states while experiencing the artwork.

Initial exhibition plan

As an integral part of Bahng's research programme, each of these works was presented previously in a variety of public exhibition settings and contexts. These occasions provided the opportunity to understand how viewing conditions influence the interpretation of the work by audiences. Insights gained from reflecting on the successes (and otherwise) were drawn upon to inform installation plans for the final examination exhibition.

Floating Walk was exhibited at several venues³. Installation components were limited to a set of rotating chairs with mobile headsets, such as Gear VR or Google Daydream, and stereo headphones. As this project relates the artist's personal stories to historical and collective memories, it was crucial that viewers be encouraged to draw connections between historical events and the artist's family history through the archival information provided. Furthermore, as the work contains a high degree of spatiotemporal information, including various spaces, times, people and audio sources, it was observed that many people struggled to focus simultaneously on the visuals and audio, and thus missing important information about significant parts of the story. Informed by this observation, it was decided that it would be beneficial to display background historical documents, such as family photos, news articles and related books, along with the VR film as part of any future exhibition of *Floating Walk*.

Anonymous was previously exhibited for both a single viewer in an enclosed room, as well as for a larger audience in a public venue⁴. From these experiences, it was gleaned that some viewers tended to reflect more upon the work and their own feelings when in the private set-up than when in the public venue surrounded by people. Thus, for the final examination exhibition, it was determined that creating a staged, ritualistic private set-up in an enclosed room containing cardboard made ceremonial objects related to the work would be most affective to elicit the viewer's curiosity about the work and provide a ceremonial experience for *Anonymous* related to death and loneliness. For example, we planned to create cardboard portraits of the widower and his wife. In front of the portraits, we wanted to put different foods such as fruits, chocolates, nuts and tea on cardboard made plates, as is often used in a small ritual for commemorating dead people in Korea.

Lastly, with regards to *Sleeping Eyes*, VR was used as a medium to represent the symptoms of narcolepsy and provoke fundamental reflections on the boundary between dreams and reality. The story itself is set between locations

representing a high school and a military training ground. Considering the important role that these psychologically charged environments play in the work, we aimed to fabricate a physical structure resembling an army watchtower in the exhibition space. In addition to symbolising an in-between liminal space that resonates with the project's theme, this structure would be treated as the main presentation platform where viewers would be fitted with the headset and heart-rate monitor to interact with the piece.

However, with the onset of COVID-19, it became immediately clear that it would no longer be feasible to convene the examination exhibition as per "normal", let alone realise the curatorial design of the installation as envisaged. Thus, with little other recourse, the strategy for the examination had to be reconsidered, and the staging of the exhibition reconfigured in response to presenting the works exclusively through an online exhibition platform.

Redevelopment of the exhibition

The main objective of the virtual exhibition was to substitute for the physical exhibition as the part of PhD examination process. We designed a Web-based 3D virtual environment working with a tight timeframe of six weeks and a modest budget of \$4000. Technically, the virtual exhibition was implemented using Three.js, a JavaScript library used to create and display animated 3D graphics in a web browser using WebGL. Presently, the current version of the exhibition can be only viewed on a standard computer screen; for instance, the viewer can play a 360° video in the virtual gallery by clicking and dragging with a mouse. As with the FIVARS implementation, the ultimate goal is to turn the exhibition into a fully immersive experience by using VR HMDs to showcase the works within the virtual environment (i.e., VR in VR).

Our aim was not to recreate the planned physical exhibition in a virtual format, but rather to create an explorative, phenomenological and spatial experience that would support and contextualise the set of cinematic VR works being exhibited. In this respect, our chosen approach aligns with the concept of 'time-based scenography' [9]. While originally drawn from a theatrical context, in more contemporary terms, scenography is recognised as a transformative model for curating and designing exhibition-based experiences that cross-pollinate theory and practice. Instead of considering objects and media as discrete from each other, or viewing visual, auditory or other sensory modes separately, time-based scenography seeks to take account of all elements that comprise an exhibition more holistically. As part of our

³ *Floating Walk* was presented at the Melbourne Fringe Festival 2017 and was selected as one of the finalists for the Social Impact Media Awards (SIMA) 2018 in Los Angeles.

⁴ *Anonymous* was shown at Bucheon International Animation Festival (BIAF2019) in Korea, Tbilisi International Animation

Festival (TIAF2019) in Georgia, Torino Short Film Market (TSFM2019) in Italy, and Montreal International Animation Film Festival (ANIMAZE2020) in Canada.

curatorial strategy, we intended to provide an immersive experience along with supplementary documentation related to each VR project. This redevelopment supported main requirements of the exhibition; namely, establishing spatial context, embodied experience and performative viewing.

Figure 4. – First-person views of the online gallery: the gallery entrance. A simple menu (top right in each image) allows quick navigation to rooms in the exhibition already explored.

Design of the virtual environment

In order to support these requirements, we developed a curatorial design approach [10] that treated the virtual exhibition as an opportunity to reconfigure the spatial, embodied and performative aspects associated with the distinctive viewing experiences of each of the three principal VR projects.

In the resulting web-based 3D environment, the exhibition space is divided into four sections. The visitor's journey through these "galleries" is predetermined and follows a linear path. The presentation of each VR work follows a chronological order. The viewer is directed from one gallery space to the next in successive order, and only upon reaching the final room are they able to retrace their steps and re-visit works at their own discretion.

Upon first entering the exhibition, the viewer finds themselves in an anteroom where they are provided with an introductory explanation about the exhibition and its inventory of artworks in the form of a didactic panel. Each artwork is installed in a dedicated gallery, providing the viewer with access to renditions of the VR films (either 360° video or play-through) along with representative images, digital objects and textual descriptions related to the individual project.

Figure 5. – The room of *Floating Walk* with the headset visible on the table.

The 360° VR film, *Floating Walk*, is located in the first gallery. A timeline runs along the side wall of this small cubic space, juxtaposing modern and contemporary South Korean history with the personal history of the artist and her family. Facing opposite, a full wall of passports is displayed from all over the world symbolising a story of immigration. These collected artefacts (photographs, newspaper clippings, passports) can be inspected more closely by the viewer and at their own discretion. These documentary materials provide the viewer with a wealth of historical and personal detail that help contextualise the auto-ethnographic aspects of *Floating Walk*.

In order to view the VR film itself, the viewer activates the 360° video by clicking on a virtual depiction of HMD found amongst assorted items placed on a desk in the centre of the room. Next to the HMD is a pair of headphones, which plays a short, spoken explanation of the work by the artist in a manner similar to a traditional gallery audio guide. By drawing upon familiar and established museological conventions (i.e., the interpretive function of displays of archival resources or audio guides), the viewer is comfortably enabled to navigate the virtual environment in a manner not unlike how they might experience the exhibition in a physical gallery setting.

After watching the video, the visitor will notice that the gallery environment has undergone a subtle change: a cardboard door has appeared in the corner of the room, which reveals a connecting passageway leading onwards to the next gallery in which the second artwork, *Anonymous*, is featured.

Figure 6. – The gallery room for *Anonymous*

This second space is treated in a far less literal than the first. Our design intention was to defamiliarise the viewer by transitioning from a space that resembles a conventional art gallery to a small room made from cardboard. Finding themselves in this enclosure breaks the viewer's expectations. By evoking spatial estrangement [11], we hoped to instill a sense of curiosity that encourages them to explore the virtual space more actively and imaginatively. For starters, the lining of the walls, floor and ceiling appear to be made from a cardboard box. A small shrine is placed in the middle of the room.

This discrete installation serves an important ritualistic purpose, and reprises a performative strategy whereby a constructed model (or "prop") was included in previous public exhibitions of the work. On a small, unassuming table, portraits of the film's main characters (the widower and his wife) are lovingly placed, along with a candle and some food such as fruits, chocolates, nuts and tea. Crucially, this tableau was originally fabricated entirely from cardboard, thereby creating a portal between the physical environment of the exhibition space and the virtual world the viewer discovers themselves performing the ritual as soon as they don a headset and enter the imaginary scene.

Once again, digital renditions of an HMD and headphones resting unobtrusively on a cardboard box cue the protocol established with the viewer with the first work, whereby upon clicking the HMD, the 360° video of *Anonymous* is played. At the conclusion of the video, the visitor is drawn towards a doorway in the corner of the room, which serves as a gateway into the final section of the exhibition.

Unlike the previous transitions between the gallery spaces, this time, the viewer is immediately immersed in a different, alien environment that resembles a meandering, cave-like tunnel. Atmospherically, a sense of unease is reinforced by a surreal soundscape interspersed with distorted voices. The cave symbolises a bridge from the conscious world to the unconscious dream world. After their descent, the viewer emerges into a surprisingly vast, cavernous space where only a single watchtower stands, imposing and silent.

The design of the virtual environment was inspired by the original intention to fabricate a physical platform in which

to situate the viewer as part of the gallery-based exhibition. This construction would have introduced a theatrical dimension to the viewing experience, and transformed the otherwise limited "visual" engagement with the VR film into a fuller multisensory, mixed-reality encounter with the work.

This exhibition-making approach is not uncommon amongst contemporary artists working with VR who incorporate installation-based or spatial design considerations into their practices. Illustratively, artists Jess Johnson and Simon Ward introduced a themed series of spatial elements to create a multi-dimensional setting for their five-part, virtual reality experience, *Terminus* (2017-18). Each "station" plays an important role in what might be considered as a world-building exercise that establishes a relationship between these interior spaces and the virtual world experienced via VR. A similar convergence, this time between real objects and represented spaces, was achieved in a survey exhibition of New Zealand jeweler, Lisa Walker at the Museum of New Zealand Te Papa Tongarewa. The exhibition design featured a range of constructions and objects as well as tools and materials from her workshop displayed along with a 360° video tour of the artist's studio; which serves to contextualise the other is left open to interpretation. For his part, Christian Thompson successfully transported the viewer of '*Bayi Gardiya*' (*Singing Desert*) – his VR commission for the Australian Centre for the Moving Image – into the landscape of his childhood by staging the performative viewing of the work within a simple ring of sand. This simple physical feature complemented the highly immersive, visual and sonic experience by literally and imaginatively connecting the viewer to a creek bed known as The Sixth Mile in Barcaldine, Western Queensland, where the artist grew up.

Returning to *Sleeping Eyes*: When the viewer approaches the watchtower in its reconstructed digital form in the virtual exhibition, they are invited to ascend a ladder. Upon reaching the top, they alight onto a small, restrictive platform containing a classroom desk where a set of drawings created by the film's protagonist (the artist, Sungeun Lee) are scattered across its surface, along with an HMD that invites activation of a 2D play-through video of the VR film.

Figure 7. – The view from up in the watchtower for *Sleeping Eyes*; The HMD and headphones can be seen on Sungeun's desk.

Reflection and Discussion

The need to shift from preexisting plans for physical installation to online exhibition demanded an agile curatorial response. The subsequent manifestation of the virtual environment sought to reconfigure certain presentational as well as more phenomenological considerations related to the experiential qualities associated with each of the three VR artworks.

In the first instance, it proved unfeasible to provide viewers with a full VR experience of the works due to the technical and budgetary constraints of the current version of the online exhibition. Head-mounted displays are synonymous with VR, and the physical encumbrance of wearing one is certainly an embodied aspect of the viewing experience. However, in the current version of the digital exhibition, the three VR films can only be viewed in a web browser as rendered videos (360° and 2D play-through videos). Because there is currently no uniformly adopted platform for sharing VR media, for practical purposes, we found that exported 360°, or 2D play-through video proved to be the safest way to both archive and share content remotely through an online presentation.

Because *Floating Walk* was originally created in 360° video, it is readily viewable online. For its part, *Anonymous* was exported as a 360° video. Original production considerations for this work took into account a seated viewing position and simple gaze interaction; however, the active engagement derived from looking at and interacting with objects was omitted from the 360° version. Additionally, it was determined that producing a 360° video version of *Sleeping Eyes* was not an applicable way to represent the work.

The viewer's interactive engagement within the film is integral to the narrative experience; these interactions include grabbing objects to trigger sounds, gamification elements that require viewers to perform movements such as avoiding lasers and a biofeedback sensor that connects the viewer's heart rate to values that affect audiovisual aesthetics. Complex interactive elements like these cannot be translated into 360° video. Instead, it was determined that a 2D play-through video that provides a first-person simulation experienced by the typical viewer would be more appropriate. The video represents the audiovisual and narrative aspects of the project and demonstrates how these interactions were intended to work. However, this format cannot deliver the actual phenomenological engagement provided by interactive navigable VR with HMDs and controllers.

Despite these technical limitations, the design of online exhibition online forced us to rethink some underlying presentational conventions. In the first instance, as demonstrated by the curatorial design strategy applied to *Floating Walk*, familiar gallery conventions were called upon to make the viewer comfortable with the virtual environment. This strategy supported the viewer's ability to access supplementary

materials related to each of the works and actively explore this content (informative and poetic artefacts, images, and texts). These materials enriched contextual understanding of the works, their genesis and framing stories.

The curatorial design framing the presentation of both *Anonymous* and *Sleeping Eyes* embraced the potential of the virtual exhibition more adventurously. In each of these cases, the VR films are contextualised in ways that would otherwise not be possible in a "real" gallery by creating unrealistic and exaggerated settings for these works to be experienced within. In a sense, instead of incorporating digital media "into" the exhibition, it is the visitor who finds themselves brought "inside" the narrative. These design interventions indicate the potential to interleave different spatial tropes in order to produce a more experiential scenography.

Conclusion

This paper has presented a timely opportunity to take account of the significant implications that the COVID-19 pandemic had upon the way in which we approached the staging of an exhibition of cinematic VR works. This unexpected situation forced us to reflect more directly upon the role of the exhibition, notably the ways that physical environments and embodied performativity contribute to the viewing experience of VR. Ultimately, we found these deliberations to be especially prescient, given that the subject of social isolation found itself represented both in the central themes found in this body of creative work and amplified by presentational issues facing their exhibition and viewing experience.

Finding ourselves in a situation wherein we needed to find a practicable way to present this series of VR projects, we discovered that we were faced with a larger intellectual challenge. This entailed reconceiving the very idea of what constitutes VR exhibition-making. In this regard, time-based scenography inspired us to rise to the challenge – not only those encountered with respect to issues surrounding the staging of the aforementioned examination exhibition – but to seize the curatorial opportunity for treating the exhibition as a means to reimagine the nature of viewing experiences involving 'a multisensory body, moving through multi-channel space and an elapsed time' [9].

Having negotiated this reconfiguration from a physical to virtual means of exhibiting VR works, we inevitably found ourselves reflecting upon what enduring impact the global pandemic might have on the ecosystem of the VR industry in coming years. Faced with the post-pandemic "reopening" of museums, galleries and arts festivals, it is to be expected that it will become increasingly difficult for shared headsets to be used if presenting VR artworks in public settings. In contrast, it is reasonable to anticipate that VR experiences will become more directed towards private consumption at home using personal devices than at present.

These implications raise a host of new opportunities to develop imaginative modes of VR exhibition-making that support rich, situated mixed reality experiences to connect people with place and counteract isolation and disconnected social circumstances.

Acknowledgements

The online exhibition was produced in Australia at SensiLab, Monash University, and developed as a part of Sojung Bahng's practice-based research, supervised by Jon McCormack and Vincent Dziekan. Yingchen Liu worked as a Web-developer to implement the web-based 3D gallery space. Aiden Hatcher helped with designing the historical timeline and texture. This paper was supported by the Media Production and Design program at Carleton University in Canada.

Abstract

This paper explores the impact of invisible and incomprehensible computational processes on human-technology relations via a series of multi-channel video installation art investigations. Historically, gaps in knowledge and understanding have often been filled with mystic and superstitious systems of belief. The spheres of computation, from network technologies to machine-learning, are equally susceptible. I explore how the use of metaphor both anthropomorphises and governs programming and systems design in ways that involve irrational thought systems, such as those associated with mysticism and superstition. This has informed my research in making the iterative networked video installations *Summoning the Nereid Nerdz* (2017) *Access Remote Fervour* (2018) and *Dense Bodies and Unknown Systems* (2021). In a 21st century context where art schools are being cannibalised and dissolved into larger amorphous institutional hybrids whilst, simultaneously, computer engineering faculties are staking claim as the rightful centres for creativity and imagination, this paper posits that historically informed creative research remains a formidable toolkit in understanding this current moment of the connected condition.

Introduction

How is the invisible and the unknown shaped by cultural attitudes? How does data shift between the seen and the unseen? Invisible, in this context, applies to both hard and soft network architectures: the hidden massive structures of server farms for offsite storage and the illegible processes of digital transmission and algorithmic manipulation. In contrast to conceptions of cloud technologies and data storage as being formless, quantised, wireless or ephemeral, I discuss how twenty-first century data architectures are housed and maintained by entirely nineteenth and twentieth century infrastructures, replete with excessive power draws and pollution. Furthermore, in jarring contrast to common conceptions of computing as an emblem of rationalist scientific innovation, many core processes carry out functions and actions that are unknown, invisible, impractical and confusing, as is frequently expressed by programmers employing the black box metaphor. This paradox of the visible and the invisible in network architectures, of form and formlessness, and of rationality and willful ignorance in understanding computational processes was the premise for my research and development of *Summoning the Nereid Nerdz* (2017), *Access Remote Fervour* (2018) and *Dense Bodies and Unknown Systems* (2021). The production and exhibition of which is logged

in this paper, accompanied by an elucidation upon how some of these paradoxical ideas contribute to a reinvestigation of romantic notions of the sublime. In *Summoning The Nereid Nerdz*, *Access Remote Fervour*, and *Dense Bodies and Unknown Systems*, the unseen and the unknown qualities of computation are represented as spectral figures clambering out of the multi-coloured, misty liquid, and reject ideas of computation as rational, egalitarian, technologically deterministic and emancipatory. The materials employed make reference to the industrial batteries, cooling tanks and rumbling servers that make up the contemporary offsite storage facility, and the apparitional images prompt the viewer to consider the formlessness of information and the unknown processes enabling our networked environment. As an artist and researcher, it is important to research, extrapolate and experiment with the aesthetics of lesser considered but necessary parts of networked computer systems and to seek past considerations from science and art.

The pursuit of aggregating all knowledge to create a utopian world of universal information access has a substantial legacy. There is an array of historical examples and of particular interest are the Library of Alexandria 300 BC to 150 AD [16] H.G Well's Information Society, articulated in 1904,[20] and Ferdinand Columbus' Universal Library of the sixteenth century.[28] It is only in very recent years, particularly after the great political shifts of 2016, that the techno-utopian belief of a peaceful, sustainable, self-regulating world will arrive with universal information access has been almost unanimously debunked.[4] Instead, the current dominant information tropes appear to be that of simplistic narratives, conspiracy theories, information silos, post-factual politics and environmentally catastrophic power draws are affecting global economic and political activities in real time. Sociologist Harry T. Dyer claims that we are seeing a *remystification* of the World Wide Web.[8] Whilst there is a seductive and compelling history of mystic properties being ascribed to new technologies, to re-mystify is to obscure and make opaque, a process of unknowing, unlearning and an unexpected departure from enlightenment principles.

Figure 2
Installation view, *Summoning the Nereid Nerdz* (2018)

The Cloud of Unknowing is an anonymous work of Christian mysticism written in the late half of the 14th century that has been revisited by twentieth century spiritualists such as Alan Watts and more recently by artist and researcher James Bridle.[4] Whilst the text speaks eloquently about love and humility, a driving impetus is to refute the ascertainment of knowledge:

And so I urge you, go after experience rather than knowledge.[2]

This mystic anonymous text has been revisited because it represents the unexpected side effect of having virtual access to supposedly all knowledge in this connected condition. Would Ferdinand Columbus or H.G Wells have predicted a wilful refute of information as a means to navigate this new networked terrain?

It is an interesting irony that the metaphor of the cloud for server farms that currently hosts a vast majority of the internet's information is also used as a metaphor for what is unknown. The association between clouds and the unknown has proved to be an enduring metaphorical connection, possibly because the human eye cannot see through clouds. Even in the era of enlightenment science, the theory of the Aether was developed as the speculative existence of a transmission medium that fills in space but cannot be seen. Isaac Newton speculated about invisible forces gaining density in his *Optiks* of 1718:

Doth not this aethereal medium in passing out of water, glass, crystal, and other compact and dense bodies in empty spaces, grow denser and denser by degrees, and by that means refract the rays of light.. And in passing from them to great distances, doth it not grow denser and denser perpetually, and thereby cause the gravity of those great bodies towards one another, and of their parts towards the bodies; every body endeavouring to go from the denser parts of the medium towards the rarer?[21]

The notions of the Aether and the "luminiferous aether" have continued to be terms of contemplation for physicists as a means of describing empty space as a form, discussed in Einstein's First Paper [21] in regards to relativity, by Nicola Tesla in theorising the empty space where electromagnetism by may exist and by Paul Dirac in the context of the speculative quantum vacuum. Both of which can be read about in Jagdish Mehra's *The Golden Age of Theoretical Physics*. [19] In both mystic and scientific traditions, the aether and cloudscapes existing just above us have stood in for what is unknown.

Cloud and remote server farms are now a dominant format for data storage and transmission but seldom cross into popular visibility or public discussion. Housed in offsite storage facilities managed by companies such as Google, Apple, Meta and Microsoft, the predicted estimated global data supply for 2025 is 180 zettabytes, or 1.8e+8 Terabytes. The power consumption of such facilities is large, with global usage for data storage estimated to be 30 billion watts annually, the equivalent total yearly output of 60 nuclear power stations. Whilst facilities with sustainable imperatives are being designed, heavily marketed and sporadically implemented, many of the largest data storage facilities or "carrier hotels" are retrofitted into the derelict

industrial spaces of the nineteenth and twentieth centuries. Here, former printing, manufacturing and automotive headquarters,[1] with strong floors, high ceilings and large elevator shafts, have allowed for the installation of industrial-sized server rows, backup generators and cooling systems. The large resource draw for such systems is only partially consumed by information processing and computation. The vast majority of water, fuel and power is dedicated to cooling systems and backup generators. As Douglas Alger notes in *The Art of the Data Centre*:

Data Centers have historically had a huge, negative impact upon their surrounding environment - consuming massive quantities of electric power and water, emitting pollutants through standby generator systems, and discarding materials detrimental to the environment in the form of UPS batteries and outdated computing hardware.[1]

The pollutants Alger refers to are the emissions of diesel backup engines that are kept running in standby mode, should there be an unexpected power failure. In Silicon Valley, many data centres feature on California's Toxic Contaminant Inventory.[3] Most data storage facilities run at full capacity, regardless of traffic or demand levels.[12] The water and power consumption of intensive hosting infrastructure could be compared with that of intensive farming practices and it is vital to include the aesthetics of these infrastructures when considering the landscape of the network. In addition to backup diesel engines, cooling tanks and high powered fans, industrial-sized lead-acid batteries, requiring regular replacement, provide a tertiary level of backup to avoid even a microsecond of loss in connectivity in the chance of both a power and diesel engine failure.

With escalating demand for bandwidth and growing person data consumption, it has been argued that the architectures of the digital age are being supported entirely by infrastructures of the industrial age, an arrangement that seems increasingly in opposition to sustained scalability.[11] It is this idea of industrial support systems for digital material that warrants particular aesthetic exploration. Such infrastructures and their processes remain largely invisible in popular conceptions of the network and warrant substantial aesthetic research. They remain systems and spaces with tangible inputs and outputs (data sent, data retrieved) but their processing and functionality remain largely unknown and invisible to all users of networked technology not directly employed in its facilitation and maintenance. They are effectively black boxes.

The term black box was adopted in the mid-twentieth century to explain a device, system or object that has quantifiable inputs and outputs, but where the process of computation or change is otherwise unknown. This is important in understanding the seen and unseen in network aesthetics, as it is a blanket metaphor applied to unknown transformations. In simple terms, the black box model can be applied to any process where there is an observable stimulus (input) and result (output) but the process through which this is achieved remains unknown.[17] It is defined by Norbert Wiener as 'an unknown system'.[27] In terms of logic systems, a black box could be akin to the x we understand in mathematics, although, whilst mathematics always endeavors to determine a value for x , the processes

and complexities of transformation within the black box can be deliberately and permanently marked as unknown or irrelevant. Mario Bunge and Martin Mahner explain in their essay *Function and Functionalism: A Synthetic Perspective* [17] that some black box processes are willfully overlooked (an example is an accountant only interested in the expenditure and income of a business, less the complexities of the cultural interactions that contribute to these figures), as well as processes currently obscured from human comprehensive analysis, such as algorithms engaging with big data sets, machine-learning and personalised information feeds.

The computational metaphor of the black box is of most importance in understanding the threshold within the network of the seen and the unseen, because it applies both to what is impossible to understand and what is wilfully ignored. Two of these I examine are 1) The unseen but nonetheless real spaces of remote data storage facilities, hidden and often less considered by the users of networked technology, and 2) the unknowable functionality of algorithms, machine-learning and their increased presence in the construction of the self. Wendy Hui Kyong Chun describes the black box as 'a powerful metaphor for everything we believe is invisible yet generates visible effects, from genetics to the invisible hand of the market, from ideology to culture'.[7] The black box metaphor is particularly important as it conflicts with a rationalist approach, whereby end objectives are to understand the workings of everything by way of observation and categorisation. The black box metaphor renders invisible sectors of computing as unknowable.

Chun's *Programmed Visions: Software and Memory* demonstrates with multiple examples how the unseen and unknown processing of software is likened to spectres, ghosts and apparitions in both developer communities and amongst users.[7] In her chapter "Daemonic Interfaces, Empowering Obfuscations", she reminds the reader that daemons (the name for algorithms that run background tasks on operating systems, such as a mailer daemon that makes repeated attempts to send mail but returns it to sender if the recipient address is unknown) are called such after daemons in Greek mythology. This term arose in 1963 at MIT's computer networking initiative Project MAC, which was the first iteration of MIT's AI. Lab.[6] As is the case with many programming metaphors, the term daemon started as a colloquial name to refer to background processing, but became its official term.[9]

A daemon in Plato's Symposium (c. 385-370 BC) is defined as 'a mean between fair and foul, good and evil... an intermediate power who conveys to the gods the prayers of men, and to men the commands of the gods' and has legacy in later classical literature (such as by Homer c.7 BC) as agents of hidden, benevolent work. Interesting to note in the classic definition is that a daemon is not necessarily malevolent, but autonomous in its actions and behaviour. One may speculate upon how these same character attributes came to be commonly ascribed to artificial intelligence. Brian Cantwell-Smith's interesting treatise on the social influences of computational innovation, *On the Origin of Objects*, [24] discusses the bi-directional processes between metaphor and innovation:

As so often happens, especially when a field is young, computer science employs terms and concepts borrowed from another place and time, using them initially in an essentially metaphorical way, but so as to gradually stretch their meaning until, as the community develops a surer sense of the layout and geography of the new terrain, they come to have literal, but computationally specific meanings. [24]

In so many senses, the lexicon of computation is a grand, metaphorical realm of evocative poetry. Seldom are new words invented to describe new technologies or systems, almost always words are taken from somewhere else. This is something that I indicate in my choice of materials in these works, especially when so many terms, such as clouds, fogs, mists and torrents, connect with the supernatural, the gothic and the romantic. Wendy Hui Kyong Chun reinforces this idea that supernatural metaphors and lenses are applied to the digital processing that occurs in the unseen or unknown spaces of computing:

Central processes for computation [are rendered] daemonic: orphaned yet 'supernatural' beings between gods and men, the undead, deified heroes. Indeed the interface is haunted by processes hidden by our seemingly transparent GUIs that make us even more vulnerable online, from malicious 'back doors' to mundane data gathering systems.[7]

Examining technology with a supernatural lens is a practice that predates historical record, particularly if we consider the shamanistic purposes of glyphs and creative mark-making as human-technology relations. This has been widely expanded upon by Jeffrey Sconce in *Haunted media* [22] and is evidenced below with Giovanni Fontana's drawing from circa 1420, of a figure with a lantern projecting a winged demon. In this drawing, the knowledge gap, or black box, of the apparitional demon is made explicit via the demonstration of the projector's functionality.

Fontana, in 1420, is enforcing that we project superstitious qualities upon new technologies. Sconce argues that the 1844 advent of the electromagnetic telegraph system and its code, developed by artist Samuel Morse, was the beginning of "disembodied communication" whereby, for the first time in human history, a human could send an immediate message without the delivery needing to be performed by a physical body.[22] The birth of the telegraph, radio and camera coincided with the emergence of the modern spiritualist movement and the advent of mesmerism, seances and performances by psychic mediums. As these technologies could channel the unseen and disembodied, such as receive telegrams from those in remote locations or reveal in photography that which is invisible to the human eye, there was a wave of pursuits and experiments to contact speculative entities also unseen, such as sprites, ghosts or the extra-terrestrial.[22]

Installation detail

This interplay between the seen and the unseen, between form and formlessness, between disembodiment and embodiment, between the digital and the industrial all contributed to *Summoning the Nereid Nerdz* (2018) that was researched, produced and first installed at Griffith University Art Museum in Brisbane. The video installation comprises a tank (240x92x20 cm) that is suspended from the museum ceiling so that it hangs 50 centimetres from the floor. In the tank are two 10 head ultrasonic misters, 250 litres of water and some sculpturally manipulated aluminium bonsai wire. When activated, the ultrasonic misters produce a thick cloud of vaporised water particles that spread across the surface of the water – a thick mist about 5 cm high nestles below the top lip of the tank. This misty surface becomes an undulating screen for the video projected from above. The video is a looped sequence depicting several different bodies emerging from beneath

the surface of a luridly coloured body of water. Their faces and bodies float to the surface, take a breath and clamber out, one after another. The colour of the surface of the water changes cyclically, moving from various hues of blue, purple, yellow, orange and green.

Figures appear in the mist in a non-fixed and transient way. Depending on the number of viewers in the museum space and whether there is any breeze from open doors or air conditioning systems, figures either billow up above the mist, taking on a life-sized, holographic, three-dimensional appearance, or sit flat and thickly on the still mist settled in the confines of the tank. The infrastructure of a heavy tank of water, a mess of cables and the sounds of the machines at work all reference the industrial architectures that house data. The mist itself marks the steam which powered the industrial revolution. The apparitional forms appearing in the mist can reference both the spritely interactions with other humans via the social network as well as the anthropomorphism for algorithms and unseen functionality. There is a common colloquialism for social media users, 'don't feed the trolls', and increasingly one would define a troll not as a fictional ogre from fairy tales but a disembodied malevolent destructive online force. The title, *Summoning the Nereid Nerdz*, provides references to classical mythology, with 19th century spiritualist techniques used to summon foreign entities via new communication technologies and the generative colloquialisms and interactions of online entities.

Figure 5
Illustration of hidden magic lantern projection on smoke
in Guyot's *Nouvelles récréations physiques et mathématiques* (1770)

Only after development and installation of the work, was it obvious that the apparitional quality of bodies appearing in atomised water particles references the pre-cinema magic lantern technology of the phantasmagoria popularised by Paul Philidor in 1792. Douglas Small writes about the advent of the phantasmagoria as a technology that was described as both transcendental yet materialistic. The earliest iterations were costly and occupied whole rooms of aristocratic mansions. As he noted in his thesis *Dementia's*

Jester: The Phantasmagoria in Metaphor and Aesthetics from 1700-1900:

The aesthetic which is derived from the phantasmagoria is... one which is deeply rooted in material culture. At the same time, it purports to depict something of the romantic, disordered quality of dreams. [13]

The phantasmagoria is interesting because it demonstrates enduring paradoxes in our attitudes towards technology. The artefact emblemises both innovation in scientific display technologies and a spectacular fetishisation of such a technology. As Small suggests, it embodies 'something deeply rooted in material culture', that is, the commercial storage and trade of objects, whilst simultaneously depicts 'something of the romantic disordered quality of dreams'. [24] This paradox between form and formlessness, between hidden server farms and ephemeral spectacle is an enduring characteristic of network aesthetics.

Figure 6. *Summoning the Nereid Nerdz* (2017)
Acrylic, water, looped video with sound, electronics
230 x 90 x 20 cm
Installation image

The use of water in this work contributes to traditions of other artists' use of it as a medium in video installation art, such as Bill Viola and Cecile B Evans. It is interesting to note the use of water metaphors to explore the otherwise invisible or difficult to comprehend passages of power and information. These include, but are not limited to, the currents of electricity, torrents of data, the streaming of

content, Twitter storms, channels of information, skimming articles with the eye as a pebble would skip across a pond, waves of media cycles, data fog, and those who surf the Internet as a means to explain the act of browsing. Sconce argues that water metaphors are most frequently employed because there is something unknowable about the changing currents, channels and behaviors of water in nature.[23]

To link that which is unknowable with occurrences in nature was a preoccupation of the nineteenth century romantic movement, aligned with Kant's notion of the sublime, which he defined as beauty that can be found in a formless object. This oxymoronic "formless object" is what is explored in *Summoning the Nereid Nerdz* (2017) via the use of heavy tanks and apparitional figures in mist, in the pursuit of what Lev Manovich posits might be 'the form of information'.[18] Chun furthers this by explaining how complex network architectures are increasingly aligned with the natural world, in that it comprises what is known and what is unknown; 'this paradoxical combination of visibility and invisibility, of rational causality and profound ignorance, grounds the computer as an attractive model for the natural world'.[18]

The sublime manifested in raging cataracts, perilous views from mountain tops, the forces of nature, expanses of uninhabitable landscape, the infinity of space and time, but also breath-taking artificial structures and powerful machinery. The concept of the romantic sublime provided a substitute for Christian cosmology displaced by the growth of science.[10]

And what is the sub-lime? It has something in common with the beautiful, but it is not order and harmony, and it does not necessarily give pleasure. Indeed, it can invoke the opposite sensation of being overwhelmed by the huge, the chaotic, and even the ugly, making one feel ecstatic to the point of pain, intensely alive and yet yearn for death.[25]

The huge, the chaotic and the ugly manifest in the aesthetics of offsite server farms and our inability to comprehend the macro-computations of big data algorithms. As Tuan suggests in *Romantic Geography*,[25] the sublime contains paradoxes of attraction and repulsion, of seen and unseen forces, of knowing and not knowing.

Figure 7.
Access Remote Fervour (2017-2020)
 Acrylic, water, looped video with sound, electronics

 Production and installation images

But everything, dear friend, nowadays, is ultra, everything is perpetually transcendent in thought as in action. No one knows himself any longer, no one understands the elements in which he moves and walks ... Young people are excited much too early and then carried away in the whirl of time. Wealth and vapidity are what the world admires and what everything strives to attain.
 Wolfgang von Goethe[15]

The romantic period is pertinent to this, although it may not initially seem so. Identified generally as an era spanning the late-18th to the mid-19th centuries, the reactionary romantic movement spanned literature, music, art, and craftsmanship, and occurred at the intersection of Europe's transition from an old world order to the new. In the 18th century, aristocracy still ruled the cultural imagination, but the romantic period captured the introduction of the new world orders of capitalism, industrialism, the advent of mass-printing and advances in science and telecommunication technologies. It is interesting to consider that romanticism has been cited as the first reactionary art movement.[5] Whether this was speculative horror at scientific advancements, as presented in Shelley's 1818 gothic novel *Frankenstein* [23] or the preference for introspective emotional truths over consumerist rationality, as explored by Goethe, criticality presented by romantic artists, to the times in which they lived, could be presented as a lens with which we can apply to the cultures of Silicon Valley innovation, machine-learning and agency in the politics of information ownership. The above excerpt, *Everything is Ultra*, written by Goethe to a friend, reads really no differently to how a contemporary writer may explain the connected condition.

We are swimming upstream against a great torrent of disorganisation, which tends to reduce everything to the heat death of equilibrium and sameness described in the second law of thermodynamics..... In this, our main obligation is to establish arbitrary enclaves of order and system. These enclaves will not remain there indefinitely by any momentum of their own after we have once established them. Like the Red Queen, we cannot stay where we are without running as fast as we can. We are not fighting for a definitive victory in the indefinite future. It is the greatest possible victory to be, to continue to be, and to have been. No defeat can deprive us of the success of having existed for some moment of time in a universe that seems indifferent to us.[26]

With the exception of a reference to thermo-dynamics, one could easily wrongfully guess this lengthy passage has been lifted from a passage by Romantic writers Goethe or Keats, yet is it actually an excerpt from cybernetician Norbert Wiener's *I am a Mathematician*. [26] One would not expect an excerpt from a post-war twentieth century mathematician to demonstrate so many characteristics of the romantic genre: noble, ill-fated struggle, the sublime chaos of matter, the pursuit of virtue in the face of certain failure, and melancholically euphoric existentialism. I make note of this for several reasons, one is to challenge once more reductionist assumptions for understanding and mapping information technology as belonging to purely abstracted

science, to reiterate that the mono-culture of forward-looking informaticists currently at the helm of innovation is decidedly new and to reinstate the language and attitudes of romanticism in current technological research. The excerpt again describes the aesthetics of networks as entropic, ephemeral, sublime and omnipotent. Ultimately, this excerpt attests that the very figure who argued that every behaviour in the universe could be mapped as an actant in a complex system, the father of cybernetics, is here writing that our fallible purpose is to carve out “arbitrary enclaves of order” and to swim “upstream against the torrents of disorganisation” to prevent “the heat death of equilibrium.” It can serve as evidence that the technological sublime is something on the minds of scientists as much as ultra-speeds of communication was on the minds of romantic writers.

Figure 10 *Dense Bodies and Unknown Systems* (2021)
Acrylic, water, looped video with sound, electronics
3 parts, each 240 x 90 x 20 cm

This format for installation has been iterated into both two channel and three channel works. *Access Remote Fervour* (2018) and most recently *Dense Bodies and Unknown Systems* in (2021) installed at the Art Gallery of South Australia. In *Summoning The Nereid Nerdz*, *Access Remote Fervour*, and *Dense Bodies and Unknown Systems*, the unseen and the unknown qualities of computation are represented in the spectral figures clambering out of the multi-coloured liquid, and function as media art metaphors that explicitly reject ideas of computation as rational, egalitarian, technologically deterministic and emancipatory. The materials employed make reference to the industrial batteries, cooling tanks and rumbling servers that make up the contemporary offsite storage facility, and the apparitional images prompt the viewer to consider the formlessness of information and the unknown processes enabling our networked environment. As an artist and researcher, it is important to explore, extrapolate and experiment with the aesthetics of lesser considered but necessary parts of networked computer systems and to seek past considerations from science and art.

Abstract

This paper presents a literature review rooted in Human-Computer Interaction research as the methodological basis for the proposal of a tangible interface called NUAGE. It is aimed at artists, performers and designers in the research field of Digital Live Audiovisual Arts.

Audiovisual performance combines musical and video arts together in a live artistic context. Tools to create such performances are often only software and do not provide the artists a wide range of interaction possibilities. A show where the performer's actions are hidden behind his/her computer screen can be visually less interesting. To provide guidance to designers and help them branch out from the traditional graphical user interfaces, we propose a different and structured design approach, Digital Live Audiovisual Arts, that builds upon Tangible Interaction concepts. We map Digital Live Audiovisual Arts by investigating its distinctive design intentions (expressiveness, performativity, participation, aesthetics and engagement) and proposing interface types taxonomy. To implement and validate this novel methodology, we developed NUAGE, an original performative interface. We thus bring together different perspectives on understanding Human-Computer Interaction and set a platform for future research on artistic tangible systems.

Tangible Interaction, Tangible User Interface, Digital Live Audiovisual Arts, Audience Experience, User Experience, Human-Computer Interaction

Introduction

Software-based music and video applications are widely used, easily accessible and have introduced new sounds and possibilities. However, a "Laptop Show", where the actions of the performer are hidden behind a screen, is definitively less interesting and comprehensive for an audience than seeing an artist perform with a complex instrument [25, 36]. As wittily highlighted by Klemmer et al., how can the audience know that "*the performer is not just checking his email?*" [23].

Aside from computers, new kinds of hardware tools have been developed to support and enhance audiovisual (AV) performers practice. Examples are the reacTable [21], the Live Cinema Instrument [25] and the uPoi [45]. Those interfaces

Figure 1: NUAGE interface prototype during audiovisual tests

seem to be a good alternative to laptops, providing more visibility and affordance to AV performances. However, hardware tools are not as easily accessible as software tools. Artists who make their own tools are often self-taught and may not have proper knowledge on how to build such interfaces. Moreover, there is a lack of scientific literature identifying the particular design requirements of AV instruments [30].

This paper addresses this problem by presenting a new promising approach, Digital Live Audiovisual Arts (DLAA). DLAA is a methodology that provides designers, artists and makers a structured understanding of the design needs of AV performative instruments. This, we hope, will foster research and design to branch out from the common computer interfaces and develop better suited and accessible interaction devices for both the user and the audience.

The following sections aim to map the novel DLAA approach. We start by defining its conceptual foundations to give the reader a better understanding of its main concepts. We then present the DLAA design approach by identifying

the distinctive intentions that can be achieved using tangible interfaces as performative AV instruments. Next, we introduce the DLAA taxonomy to identify the different design implementation types.

In the last section of this paper we put the DLAA methodology into action. We present NUAGE, an original AV interface developed using the DLAA approach. NUAGE is an interface made to control audio and video content in a live, real-time context. A picture of the interface can be seen in Figure 1. NUAGE is aimed to be used by an artist during a performance in front of an audience. The prototyping of the interface allowed us to test and validate the DLAA method.

Digital Live Audiovisual Arts

DLAA is a novel design approach that builds upon Tangible Interaction principles to guide the development of AV performative instruments.

Tangible Interaction takes its roots in Ishii and Ullmer own updated vision of Human-Computer Interaction (HCI) [18]. In 1997, they introduced the concept of Tangible User Interfaces (TUIs). Different from the traditional Graphical User Interfaces (GUIs), where “painted bits” on a screen are controlled by a mouse, a keyboard or a tactile interface, TUIs aimed for a more engaging and seamless relationship with the digital world. Ishii’s “tangible bits” concept focus on the physical representation of digital information, exploiting the richness of possible interfaces given by the “real” physical world [18].

Building upon those concepts, Hornecker and Buur Tangible Interaction framework focus less on the design of the visible interface but on the design of the interaction itself [11]. Apart from Ishii data-centered viewpoint on tangibles, their vision also includes action-centered viewpoints like movement, body and space centered interaction design. Tangible Interaction is an umbrella term describing an interdisciplinary research field encompassing HCI, Computer Science, Product and Industrial Design and Interactive Art studies, among others [12]. Hornecker and Buur described the characteristics of such systems and interfaces with four main design principles: tangibility and materiality, physical embodiment of data, bodily interaction and real space embeddedness [11]. The proposed model is thus based on these concepts.

The term “Digital Live Audiovisual Arts” is used in this paper in a nod to the term Digital Live Art (DLA) that was proposed in Sheridan et al. paper and described as “*the intersection of live art, computing and human-computer interaction*” [46]. By adding the “Audiovisual” term to DLA we bring together the notions of real-time AV performance, Tangible Interaction, Human-Computer Interaction, User Experience, computer-based art and artistic intent. DLAA has the particularity to combine different artistic design intentions such as expressiveness, performativity, participation, aesthetics and engagement under a single and common approach in cohesion with AV performances design requirements. Furthermore, it allows to study such intentions from the perspective of a direct user, the performer, and from the perspective of other people involved in the interaction, i.e. the audience.

Proposed Design Intentions Approach for Digital Live Audiovisual Arts

We present in this section our DLAA design approach structured by five main and distinctive design intentions: Expressiveness, Performativity, Participation, Aesthetics and Engagement. Those design intentions offer a wide perspective on the different goals a designer may want to achieve by developing AV performative instruments. While the design of Tangible Interaction systems has been studied before to pursue each of those intentions individually (examples are: [13, 21, 31, 37, 41, 45, 52]), DLAA has the particularity to bring all those key intentions together under a single and common approach that offers conceptual design guidance. Furthermore, it allows to study such intentions from a direct user’s perspective and from an observer’s perspective.

The five DLAA design intentions are defined in the following subsections. Examples and explanations on how they can be enhanced by Tangible Interaction guiding concepts are provided. Table 1 offers a summary on how those principles (physical embodiment of data, materiality, affordance, real-space embeddedness, bodily interaction) apply to the design intentions approach.

Expressiveness

Expressiveness can be described as the ability to transmit one’s emotions and intentions through his/her action. Expression is achieved in various ways with TUIs.

By analysing VJ practice, Hook et al. identified how TUIs help the artist express him/herself. They identified themes linked to affordance, physicality and the importance of liveness in the practice [10].

Ross and Keyson developed principles for designing expressive tangible interfaces[41]. The context and the nature of the interaction, as well as the different physical properties of the interface can enable creativity and expression in various ways. The authors give the example of a door, which can be hardly slammed or softly closed to express different emotions. They also highlighted how expressiveness is subjective and that it may be experienced differently by one another. Therefore, such individualism should be considered, allowed and maybe enhanced by the interface.

Correia and Tanaka interviews with AV performers highlighted the fact that artists want “*to be able to make visuals like a musician*” and *the desire to play an AV tool with the same expressivity and fluency as a traditional musical instrument.*” [6] The fact that the interface must be easy to use and flexible is also a way to make it expressive. On the other hand, complex interface can allow the user to become skilled and therefore explore and be creative [10].

Performativity

Performance is another key concept of DLAA. Hornecker and Buur stated that:

“Performativity implies that the detailed HOW of doing something is an integral part of the action’s communicative effect. [...] As an aside, performativity can be enhanced by tangible manipulation, as the material objects are visible as well and may require large movements” [11].

Table 1: Summary of the Digital Live Audiovisual Arts Design Intentions Approach

Design Intentions	Expressiveness	Performativity	Participation	Aesthetics	Engagement
Tangible Interaction principles	Affordance Physicality Liveness Individuality Complexity	Visibility Intuitiveness Unobtrusiveness Flexibility Intriguingness	Collaboration Modularity Controllability Understandability Multi-user	Attractiveness Enjoyment Resonance Coherence Appeal	Representativity Attention Involvement Usability Endurability

TUIs benefit to performance in various ways. Sheridan and Bryan-Kinns proposed guidelines on how to design interactive tangibles for performance [45]. Focusing on live and in-the-field performance, they iteratively design the uPoi and came up with six requirements. The design must be Intuitive (Responsive), Unobtrusive, Enticing (Visible and Attractive), Portable, Robust and Flexible (Controllable).

The studies of Correia and Tanaka showed that the majority of artists are concerned about whether or not the audience understands and feels the liveness of their practice [6]. The VJacket [53], was designed to enhance a VJ’s performance, making his/her movement connected with the video and therefore more visible to the audience.

Paradiso explains how tangible modular synthesizer attract the audience in shows [34]. The researcher stated that the sight of such an intriguing and complex instrument fascinates the public, which is indeed great for a performance. Jordà also stated that the visual feedback given by the reacTable brings “*the physical performance back to live computer music*”[22]. This helps the public understand the performance.

Participation

The participation DLAA design intention illustrates the relation between different artists that perform and create together. Participation also highlights the importance of the relation between the artist and the audience. The following examples demonstrate how some particularities of Tangible Interaction can contribute to this intention.

Collaboration between artists

Like highlighted by Jordà, few musical instruments are multi-user, still, music is well known to be a group (or band) [22]. The design of TUIs can address this issue. The reacTable [21], is an example of novel musical instrument explicitly made to promote collaboration. Its multi-user and shared-control tabletop interface enhance participation. Many researches state that tabletops are well suited for collaboration and a lot of collaborative tangible tools are based on that same principle [44, 48].

The Polymetros [4] is another example of musical instrument that promotes collaborative music-making. Developed for a wide and novice public, it consists of several illuminated buttons panels connected to a central hub. The physical presence of the individual alike panels as well as their disposition around the central hub invites to collaboration. The authors identified that the “sense of control” over their own contribution is very important for participants in a collaborative process. Each participant must be able to easily identify what they individually bring to the performance and what other participants individually add too. This can be achieved

with clear visual and audio feedbacks related with the participants actions.

Audience shift from spectator to performer

Tangibles can enhance audience participation in different ways. Discussed earlier, visual feedback can help the audience appreciate their experience. Another way to enhance their experience is by letting them be a part of the performance.

Sheridan et al. framework categorised the different stages of the audience involvement in a digital live art context [46]. They examined the transition between the audience’s behaviors of “spectating”, “participating” and “performing”. Spectating can be described as a passive awareness that a performance is going on. The audience does not interact with the performance, is simply watching and might not understand what is going on. Participating starts when the audience engage with the performance, interacts simply with it even though they do not fully understand its frame. The performing stage arises when the audience has gained skills and understand the meaning of its actions. This is when the audience can start to express itself and be creative.

To favorize the transition from spectating to performing, it is important that the audience understand how they can interact with the performance. While testing the uPoi, Sheridan and Bryan-Kinns tried to rise the audience attention by costuming herself, making her prototype visually interesting and having experts already performing with the object [45]. Taylor et al. reported that the intriguing nature of their tabletop video instrument attracted the audience to come try and play with it[49]. To encourage participation, a clear, direct, real-time correlation must be understandable between the real-life interactions and the digital outputs of the TUI. Affordance here is the key; some materials, sizes and shapes might suggest different interaction ways and outputs than others.

Aesthetics

Aesthetic is the affective appeal, perceived beauty, attractiveness and enjoyment we feel for certain characteristics of objects [8, 33, 37].

Shaer et al. survey on tangibles identified aesthetics as a promising field of research in TUIs [43]. Some researchers focused on the aesthetics of the physical elements of tangible objects, others on the aesthetics of interactions. The authors stated that “*arts-based research often aims for a poetic aesthetic that goes beyond form*”.

Hummels et al. research on aesthetic tangibles focused on their resonant aspects [13]. The appearance of an object must be coherent with its use, its purpose and its feedback. Petrelli et al. studied how the aesthetics of hybrid objects are

perceived by humans [37]. Objects mixing different sizes, shapes, materials and behaviours were evaluated to determine what impressions they gave to people. The researchers identified subjective attributes like “Interesting, Comfortable, Playful, Surprising, Pleasant, Special and Relaxing” to describe the objects. Their results show that certain aesthetics should be preferred to achieve certain impressions. Djajadiningrat et al. paper highlights that the visual appeal is not the only important aspect of aesthetics to consider when designing tangibles, the aesthetics of the interaction we have with the objects must also be considered [8].

Engagement

Engagement is the capacity of gaining one’s attention or devotion, maintaining it and doing it for a long period of time [27]. Different factors constituting engagement are defined in O’Brien and Toms paper: perceived usability, aesthetic appeal, novelty, felt involvement, focused attention, and endurance [32].

In DLAA, we are interested in the artist engagement towards his/her tools and methods, but we are also interested in the audience engagement toward a performance in which the artist is using tangible digital instruments.

User engagement

Csikszentmihalyi flow theory [7] propose that continued immersion and enjoyment comes from the balance between skills and challenges in one’s interaction. Building from this idea, the Wyeth framework [52] describes how the balance of TUI attributes, its representational and control qualities, leads to a more engaging use of tangible systems. As previously seen in the expressive design intention section, complexity and flexibility of interface controls are qualities desired by artists. Again, the role of a strong representation of the digital data, whether in a tangible or digital overlaying way allows for an affordable and intuitive understanding of the interface.

Audience engagement

Using appealing visible and comprehensible interfaces is also a good way to maintain the audience attention. In a laptop-based show, the audience may perceive the artist to lack of control over the occurring performance, due to his/her minimal or hidden actions. This can lead to a lost of interest and attention in the performance and therefore a lost of engagement [36]. Furthermore, encouraging the public to participate is way to make them feel involve in a performance. Those two ideas have been developed in the previous sections.

Digital Live Audiovisual Arts Interface Types

Building on previous categorisations of tangible systems[19, 24, 50, 51], the DLAA design approach proposes to structure the different tangible interface architectures possibilities in a way that applies more specifically to the peculiarities of AV performative systems. The following seven different interface types are proposed: Interactive surface, Constructive assembly, Token+constraint, Pressure-based interface, Wearable, Motion-based interface and Augmented common instruments. Figure 2 illustrates such concepts. We added the concepts of pressure-based, wearables and motion-based interfaces to the already existing notions of interactive surface,

Figure 2: Loose illustration of different types of interfaces: a) Interactive surface, b) Constructive assembly, c) Token+constraint, Inspired by [51], d) Pressure-based interface, e) Wearable, f) Motion-based interface, g) Augmented common instrument

constructive assembly and token+constraint systems. Our last category “augmented common instruments” is similar to the “augmented everyday objects” one presented by Ishii but is adapted to AV instruments [19]. It is important to note that AV tangibles interfaces are not necessarily confined into those categories and can combine two or more types of architectures into one.

One goal of this categorisation is to highlight the wide set of design tools available to designers while creating an interface. It provides practitioners with an overview of the design possibilities within DLAA. This section will also highlight how certain types of interface foster the design intentions mentioned in the previous section (see Table 2). Thus, this will help designers to better communicate, justify and evaluate their design choices.

Interactive Surfaces or Tabletops

Typical tabletop tangible systems contain physical objects whose presence and movements are tracked on top of a graphically augmented surface [19]. Those types of tangibles are frequent in digital live arts, perhaps the most known example is the reacTable [21]. Other examples are the mixiTUI [36], the Audiopad [35], the Media Crate [3] and the VPlay [49].

Constructive Assemblies

This second type of interface is based upon building blocks and LEGO™. This architecture implies the modular construction of a system created by the physical connection of objects or by the near placement of such objects [19]. The AudioCubes [42] are one example of nearby constructive assembly. Digital modular synthesizer can be classed as constructive assembly. They consist of several different modules who have compatible hardware connectors, that when patched together enable various sounds. By adding different patch connections, the artist creates unique music. Building on this concept, block assembly mimicking the behaviour of modular have emerged like Block Jam [31] and the Patchblocks [28].

Table 2: Implementation types and their associated design intentions

Design intentions / Implementation types	Expressiveness	Performativity	Participation	Aesthetics	Engagement
Interactive surface			X		X
Constructive assembly	X	X			X
Token+constraint	X				X
Pressure-based interface			X		X
Wearable	X	X		X	
Motion-based interface	X	X	X	X	
Augmented common instrument	X	X	X		

Token+Constraints

Ullmer et al. give a very exhaustive description of the token+constraint tangible interface type: “tokens are discrete, spatially reconfigurable physical objects that typically represent digital information. Constraints are confining regions within which tokens can be placed” [51]. In this architecture, the physical tokens can be manipulated and associated within the spatial or mechanical constraints of the system. The Log-Jam [5] system is an example of such architecture.

Pressure-Based Interfaces

Pressure-based interfaces are systems that responds to a physical force applied on them or on their components. Pressure-based interfaces can be mechanical switches, like the common and simple push-buttons. They can also be reactive to impact or sense the amount of pressure applied on them. Examples are MIDI piano-like keyboards, pads and haptic sensors surfaces [9, 26, 40]. The Polymetros [4] system is another example.

Wearables

Wearable systems are in continuous physical contact with the user’s body, unlike others forms of interfaces [38]. They can be used to track the user’s movement, like for example in the VJacket project [53], where sensors were integrated into clothing and the dancing movement of the user were used to interact with video projections. In the WaveForm system [2], the glasses and gloves worn by the user are used by the system to track the position and the movement of the user. The in-air gestures of the user are used to control video animations on a distant display.

Motion-Based Interfaces

Motion-based systems react to the physical displacement, acceleration or movement of the interface. For example, the maracas-like Rhythmism systems [20] need to be shaken or turned to modify the visual effects on a video. The uPoi [45] generates different visual and sounds according to the acceleration of the instrument when swung around the body of the performer. The Ashitaka [29] instrument reacts to its interface being stretched, twisted and moved around.

Augmented Common Instruments

This last type of interface is similar to Ishii description of “Augmented Everyday Objects” [19] but is adapted to the domain of Digital Live Arts. Augmented Common instruments take the shape and features of pre-existing artistic objects but

are digitally augmented. Examples are the MIDI keyboards and electronic wind instruments [1, 39, 47].

Interface types and DLAA design intentions

Table 2 highlights the prevalent implementation types usage for the realisation of the different DLAA design intentions. For example, the collaborative aspect of interactive surfaces has already been demonstrated several times [44, 48]. Also, wearable and motion-based interfaces may provide more visibility to the interaction and therefore enhance performativity. Interfaces requiring precises motions and constant attention such as constructive assembly and Token + constraints can allow for more engagement. Table 2 is to be used as a guide and taken with a pinch of salt since many different factor other than implementation types can contribute to the fulfillment of the design intentions. Other interface characteristics to consider, such as complexity and affordance, have been previously discussed in the design intentions section.

NUAGE Prototype

To put the DLAA methodology into action, we developed NUAGE, a tangible interface that controls audio and video content in a live, real-time and performative context.

Figure 3: Picture of the NUAGE interface prototype and it during audiovisual tests

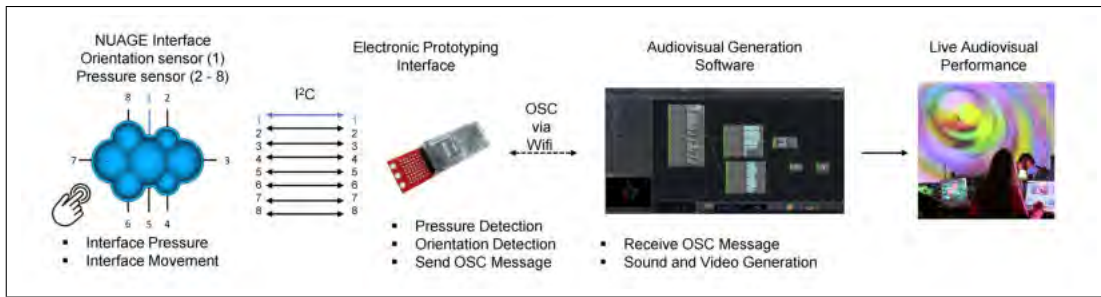

Figure 4: Functional diagram of NUAGE prototype interface

We aimed at developing an accessible interaction device for both audiovisual artists and their audience. The DLAA approach provided a structured understanding of the peculiar design requirements of such AV performative instruments.

DLAA's design intentions guided the NUAGE implementation choices of appearance and functionality.

The proposed prototype, pictured in Figure 3, is a mix of the pressure-base and motion-based type of interface described in the previous section of this paper. It takes the shape of a squeezable cloud that can be held in the hands of the user and freely moved around. Pressing on the different parts of the cloud and moving it around controls various audio and video effects.

The quirky and colourful appearance of the NUAGE makes it visually attractive and intriguing for both the audience and the user. This, as explained before, enhances performativity, engagement and meets the aesthetics design intention.

The intuitive usability of the interface leads to a greater engagement of the user. Indeed, pressing the interface is an intuitive action due to the softness of the material it is made of. The expressiveness and participation design intention are achieved due, among other things, to the possibility of moving the NUAGE around.

Therefore, the combination of the pressure and motion types of interfaces in addition to its visual and physical aspects allows NUAGE to meet all of the presented DLAA design intentions for audiovisual instruments.

System Architecture

NUAGE is a 3D silicone structure composed of seven adjacent hollow spheres or bubbles. Each of these independent hollow bubbles are equipped with a barometric air pressure sensor inside. An orientation sensor is also placed in the center of the interface. The sensors are connected to a micro-controller that sends the output values to a computer via WiFi and the Open Sound Control (OSC) communication protocol.

An external audiovisual content creation software, for example TouchDesigner or Max/MSP, can then receive the sensor values and generate different video and sound effects. This process is illustrated in figure 4.

Squeezing a bubble changes the air pressure inside of it. Therefore, this action could, for example, make the colour of an image change. Moving the interface and turning it around changes the output orientation values, this could perhaps change the rhythm of a music piece.

Creation of the prototype

In order to make the interface squeezable, the physical structure of the prototype is made out of silicone. To obtain the desired shape, a mold assembly in which the silicone was poured was developed.

The mold assembly is composed of two pieces, a base and a top cover. It is 3D printed. Pouring liquid silicone into the base, then closing the assembly with the top cover creates a half hollow section of the NUAGE. The NUAGE prototype is made of two sections of cast silicone. The sensors are inserted inside each bubble as shown in figure 5. The two sections are then glued together to create hollow bubbles.

The hardware implementation of the prototype was done with the I-CubeX line of products [17]. The electronic prototyping platform used is the WiDig [16]. It has 8 sensors inputs and it sends and receives OSC message via WiFi. The orientation sensor placed at the center of the interface is an Orient4D sensor [15]. It is connected to the first input of the WiDig. The air pressure sensors placed inside each of the seven bubbles are connected to the inputs two to eight of the WiDig. They are Air2D sensors [14].

NUAGE in action

The NUAGE prototype was used to create a live AV performance that will be presented at the Montreal Société des Arts Technologiques. The interface controls the audio synthetic generation and video projection on the immersive dome of 18-meter. The artist, at the center of the room, will only use the NUAGE, squeezing it and moving it around, to create a 360 immersive experience for the audience. Video capture of the event will be available here: <https://bit.ly/3jq5Eei>. This

Figure 5: Technical drawing of a perspective (a) and sectional (b) view of the interface and sensor assembly

performance will be a great moment for an in-the-field evaluation of the prototype.

Conclusion

This article presented DLAA, a novel approach to the design of performative AV instruments based on Tangible Interaction principles. We have seen how the key concepts of Tangible Interaction are applied in a distinctive way by DLAA. In order to map this approach, we detailed its peculiar design aspirations, characterised its interface types. We also presented the NUAGE prototype that implemented the DLAA methodology. This paper emphasized that the interaction with an interface should not only be studied from the point of view of the direct user but should also be studied more broadly if other people are involved in the interaction. Few researches consider the audience reaction to a performer using a tangible system, which takes a strong role in our DLAA approach. Future work should focus on investigating the audience understanding and perception of the performers' actions.

In conclusion, DLAA gives a better comprehension and perspective on how both the artists and the public interact and appreciate AV Tangible Interaction systems. It also structures, guides and systematizes the design process of such instruments. It provides designers with an alternative design approach that can be used in many different and artistic fields.

Possible City: colonial trauma and mediated space

Lawrence Bird

Space + Image, Sputnik Architecture
Winnipeg, Manitoba
lb@lawrencecywg.ca

Abstract

Electronic art occupies a transmedial space with other media including film, television, streaming video and, as this paper asserts, architecture. These forms of media are charged with the politics and cultural value of space, and these are often mediated through the image of the city: a media-space. This paper takes as its lens the mediated image of a mid-size, mid-western city: Winnipeg, Canada. It sets up a discussion of the image of this city by considering key examples of (industry-based) narrative media shot here, before moving on to works of independent film and media art. The paper makes the case that what visiting filmmakers are in fact “buying” is a heritage of historical pain: the legacy of colonialism embodied in urban space, indeed hidden there in plain sight. This legacy has only just begun to be visible to most Canadians, but it has been there for all to see as harvested by filmmakers and displayed on the screen, a sign or symptom of a deep malaise. A more complex relationship between city and image is revealed by what is done with the same urban spaces by independent film artists - and architects. Their crop exposes more completely the potential for new relationships between city and image, buyer and seller, authenticity and fiction, colonial legacy and possible city.

Keywords

Media, cinema, urban space, architecture, rural space, representation, independent film, Indigeneity, colonialism, transmediality.

Exchange (I)

Sean Penn’s *Flag Day* (2020) is named for June 14th, the anniversary of the adoption of the Stars and Stripes as the American flag. In this film Penn plays a counterfeiter, that is, a maker of signifiers – dollars – that represent the American state. A dollar needs to be real, authentic; it is on this that its value rests. Its authenticity assures the dollar’s other characteristic: its capacity to be exchanged for not just any other dollar, but any other thing. A flag is another signifier, and shares something with the dollar: it combines identity and interchangeability. If any of the flags arrayed here (Fig. 1), awaiting a parade, is replaced by a similarly designed flag, it will still mark the space in which it is raised – in this case, Minneapolis – as American.

Figure 1. A lonely Canadian maple leaf overlooks an array of star-spangled banners on the set of *Flag Day* (2020), in Winnipeg’s Exchange District. Image by the author.

In fact, though, the street where these flags are hung is itself counterfeit. This is not an American city, it is Winnipeg, a city that shares many qualities with the one it stands in for in this film: mid-western, riparian, the site of agriculture-based industry, a gritty city. This is the kind of environment that Winnipeg is frequently asked to play by a film industry drawn to it by cheap rates, solid media craftsmanship, and good tax breaks. The specificity of this place, a certain patina related to its social history, has been harvested by the film industry but also by a strong cohort of independent filmmakers and video artists. This paper will look first at the spaces the industry has harvested from Winnipeg’s urban spaces, identifying through them a social history and urban form characterized by trauma and brokenness. The same spaces are harvested by independent creators: indie filmmakers and media artists, yes, but also architects, whose discipline I will make the case should also be considered a form of media art. Each are working on their own craft, but they work in a shared space in more ways than one. They both contribute to the creation of what might best be described as a hybrid urban / media space, a manifestation of collective imagination that goes beyond the inheritance of pain and instead creates from that heritage a possible future.

Minneapolis is represented in this particular scene by Winnipeg's Exchange District, thirty blocks of former warehouses and financial service buildings dating from the end of the 19th Century. The area was named for the Grain Exchange, an institution which was once the centre of Canada's grain industry: the place where prairie crops were bought and sold. So it was from its early history about the exchange of money for goods, and back again. It may mean something then that theft, robbery – in a word, the heist – is a recurring subject in works of film and television shot in Winnipeg and Manitoba. These have included *Seven Times Lucky* (2004), *The Lookout* (2007), *High Life* (2009), *Foodland* (2010), *The Pinkertons* (2014-2015), and *The Parts You Lose* (2019). To these we might add this film on counterfeiting, *Flag Day*, and *J.T. Leroy* (2018), about a counterfeit person that briefly turned Winnipeg into Paris. We might ask ourselves: why are so many con and heist films shot here? What qualities of space do these harvest, and where do those qualities come from? To answer this question we'll turn to other genres of film, and space, associated with this city.

Figure 2. Still from *Horsemen* (2009).

Hollow

The Exchange is an imperfect representation of the 19th-century city. Its urban fabric is shot through with spaces decidedly lacking in urbanity: a sea of parking lots, and modern buildings, lapping up against the spaces of earlier times. These are the results of a phenomenon common in the post-war North American metropolis: the hollowing out of the inner city. The migration of the middle-class population to the expanding suburbs created voids in downtown documented in a number of industry productions. In a still from Jonas Åkerlund's *Horsemen* (2009) the cinematographer's eye identifies the urban desolation conveyed by generic modern buildings flanking a swath of parking lots adjacent to the Exchange District (Fig. 2). In this film these spaces are markers of an American city, one similarly hollowed out: Detroit. Around these hollows are clustered the remains of what was once a rich urban fabric, decayed now and gone to seed. It is from these seeds that the filmmakers harvest the setting for a story of the hunt for what at first appears to be just a serial killer.

Figure 3. Still from *Horsemen* (2009).

One of these spaces is the Bell Hotel at 662 Main Street (Fig.3). The Bell was built in 1906, when Winnipeg was at its apex, and considered a rival to Chicago largely because of its position at the centre of Canada's rail network. The city's decline in importance through the 20th Century hit institutions like the Bell hard, and by the 1980s it had become housing of last resort; a rooming house many of whose residents suffered from mental illness and addiction.

Desperation was part of the narrative of the area, and an aspect harvested by the makers of *Horsemen*, who set a ritualistic murder in one of the Bell's rooms. The dense and aged urban environment of the Exchange has a specific significance in Winnipeg's social history. Just north of the Bell, Main Street is crossed by a rail line that leads to a major rail yard. The east-west axis of the rail yard cuts the city in two, dividing it historically into a North End of poverty, where new immigrants made their home, and a south inhabited by a mostly anglophone elite. One of the homes in that southern part of the city is the site of a second, equally disturbing murder.

Figure 4. Still from *Horsemen* (2009).

Enclave

At the time the Bell Hotel was built and the Exchange was turning into a small Chicago, another part of the city was growing too. The city's wealthy were beginning to migrate to the early suburbs including Crescentwood and the tony

boulevard of Wellington Crescent. *Horsemen* harvests this neighborhood and a specific house as the site of another ritualistic murder, where the abuse of a child leads to the murder of a parent, and incidentally another child *in utero* (Fig. 4). *Horsemen* is a breeding ground for crimes in which children are implicated, but for which authority figures are ultimately held responsible. Crescentwood is still one of Winnipeg's wealthiest and most desirable neighborhoods.

Both the Bell Hotel and this house are the scenes of particularly grisly murders, but as the story unfolds they are discovered to be evidence of greater horror. The killer, or the leader of several killers as it turns out, has based the series of murders on excerpts from Revelations. The investigation uncovers that what has happened here is not about a mere murder, but the preparations for an apocalypse. This is another narrative trope for which films harvest Winnipeg's spaces; these have included, besides *Horsemen* and *I Still See You, How It Ends* (2018), *Category 7: The End of the World* (2005).

To elaborate on my earlier question: why might it be that in this media space narratives of con, heist, and murder bleed inexorably into narratives of apocalypse? Perhaps it is because the gritty and worn spaces these mediated stories tap into are in fact the products of a historical legacy of heist, murder, and apocalypse. To understand this, we'll turn next to another genre of film – horror – and another urban environment.

The suburb is that region which in the post-war era grew

Figure 5. Still from *Channel Zero: No End House* (2017).

fat as inner cities throughout North America grew thin. In Winnipeg the disjunctions created by the railway lines escalated as the city grew. As roads that had begun as cart-tracks were widened into highway-scaled boulevards, these thoroughfares – Portage Avenue, Main Street, Pembina Highway, and others – served the laying out of grid-iron post-war suburbs. Today curling roads carry a more current model of suburban development out into the prairie landscape. Such later models of land development create new enclaves cut off from the city proper. It is such a neighborhood which forms the setting of the television series *Chan-*

nel Zero: No End House (2017). Horror, and the monster film, has been a particularly fecund genre in Winnipeg; films shot here have included *Cult of Chucky* (2017), *Devil's Gate* (2017), *Grizzly Rage* (2007), *Maneater* (2007), *Hybrid* (2007), *Eye of the Beast* (2007), and *Midnight Man* (2017). *No End House*, and the neighbourhood around it, turns into a trap laid out in suburban geometry.

That trap has several manifestations, from the maze-like layout of the streets, to a cage around a residential traffic island in which a family is imprisoned (Fig. 5). This alternate neighborhood, accessed through a house which comes and goes, is populated by creatures who feed on the memories of those lured into the community. As in *Horsemen*, father figures are a threat to their children. Not incidentally, we learn through a reveal in the last episode of the series that the threatening father is an architect. The series is shot in Oakbank, a bedroom community outside Winnipeg. It presents the buildings there as simultaneously icons of homeliness yet eerily absent of any homelike qualities – places that align with what Freud termed the *unheimliche*.^[1] The condition of being without a home is manifested in several characters; a number of them are one form or other of *doppelgänger* – counterfeit people. The unfinished spaces that so often accompany newly-built developments – backs of closets, incomplete rec rooms – are discovered to function as both traps, and opportunities for escape. Another trap manifested in this space is a corn maze barring the way out of from the neighbourhood; hungry memories wander within it, and bodies well up from dark pools. An outlandishly tall water tower overlooks the community. Taken as a whole these spatial tropes depict a space part agricultural, part urban, but not satisfactorily either; a dream built on the idea of freedom from the city, that ends up becoming a prison. This is how suburbs are often interpreted: as places built to satisfy the desire for rural life that, in the end, destroy the farmland they are built over, erasing the memory of what came before.

Field

But in the case of western Canada, the farms themselves have been complicit in destruction. In the late 19th Century, in the period that led up to Winnipeg's rapid expansion that produced the Exchange District and Crescentwood, two major infrastructural projects transformed the face of the prairies. One of these was the railway, which as we have already seen splits Winnipeg in two. The network of rail lines and regional stations was part of an immense machine for distributing crops from sections of farmland: the Dominion Land Survey. Divided into mile-square sections, and subsections of these, a landscape formerly boundless and open became exchangeable, like currency. It was provided to new European immigrants in exchange for their transformation of the gifted land into wheat fields.

This gift had in fact been stolen. The early modern history of the area is a history of negotiation and conflict between First Nations, which in Manitoba include the Anishinaabeg, Cree, Oji-Cree, Dakota, and Dene peoples; newcomer populations centred on the forts of the Hudson's Bay Company, who governed Western Canada; mixed First Nation and European communities (mainly franco-phone fur-traders) who were to become the Métis nation; and the 1811 Selkirk Settlement, mainly of Scottish descent. Later in the 19th century these groups were to be increased by largely Eastern European populations, the farmers and urban working class brought to the prairies to fuel settlement. In Manitoba the First Nations were signatories of six treaties with the federal government, but they never received the amount of land which had been promised. Instead they were assigned unwanted squares in the grid, small reserves inadequate for survival. This story played out many times across Canada over the next century, including in areas where farmland was not at stake; some other resource, whether oil or hydroelectric power, always was. A legacy of displacement, disenfranchisement, and disempowerment has ensured that the effects of this early land grab have lasted to the present day.

The violence to the land was accompanied by violence to persons. The settlement of the prairies was accompanied by the transference of governance of western Canada from the Hudson's Bay Company to the federal government in Ottawa, as part of the incorporation of Canada in 1867. This grab of land and settlements they had inhabited for generations provoked the Métis people to form their own Provisional Government headed by Louis Riel, and to begin what came to be referred to as the Red River Rebellion. If the long-term intent of the railway was to carry crops east to Great Britain, its immediate role was to carry troops west to crush this assertion of Indigenous sovereignty. The rebellion was suppressed by the federal government in what was referred to at the time (by American observers) as a "military reign of terror," in which the Indigenous population was subject to assault, murder and rape. [2] This was the prelude to the founding of Winnipeg, and the boom which was to turn this wheat city into one of North America's key metropolises within a few decades.

Thus it is no exaggeration to suggest that the immense grid of farmland into which the prairie landscape had been transformed was an apocalyptic ground. The image of that

Figure 6. Still from *Capote* (2005).

agricultural landscape is today itself a crop, perennially exploited for its poignancy and a lingering sense of threat, as it is in *Capote* (2005), concerning the fallout following the brutal murder of a family (Fig. 6). In such stories Manitoba's landscape stands in for anywhere in the Midwest; throughout the region the land was coopted by similar regimes of colonization and control.

Figure 7. Concept art from *Things from the Flood* (2016). With *Tales from the Loop* (2015), this book was the basis for the television series *Tales from the Loop* (2019). Work of Simon Stålenhag; reproduced with permission.

Slough

As the grid of farmland was deployed across the prairies it collided with natural landforms and pre-existing patterns of land use. The result is a collage of grids that characterizes Winnipeg's urban fabric. Railways and roads shoot through this fabric, cutting it up while tying parts of it together. Winnipeg might be characterized by the rifts opened up between different parts of the city. As in many cities the gaps and tears in the urban fabric – between neighbourhoods, alongside and under major pieces of infrastructure, and along river banks – become no-one's lands occupied by the marginalized.

The history of colliding grids, rivers, roads and railways has produced a hybrid space that cannot be described as merely urban or rural, technological, agricultural, or wild. The gaps between its components have frequently become havens for the disenfranchised – as late as the 1960s, Métis shanty towns on the edge of the city or, today homeless encampments alongside the rivers, their inhabitants predominantly Indigenous. Aspen forest, copses and the remains of tall grass prairie are preserved here and there alongside pieces of hydroelectric or railway infrastructure. Always contaminated by their proximity to industrial infrastructure, these spaces lie fallow, though they are today under growing development pressure.

If we seek a figure in the landscape that could describe such a space, it might be the slough: a pond filled by seasonal flooding, often swamp-like. In its more general definition it can refer to a place of deep mud or mire; or a mass of dead tissue, shed or cast off from the body. These are the components of Winnipeg's fragmented urban form which is so productive for film-makers: the Frankenstein

space of media, which sews together different spaces, finds an analogue in a city of disjointed place.

If we can look at the prairie landscape as a space transformed by an immense infrastructural project meant to progress the world, a project with devastating effects impacting on the people who live in the gaps of that project, and producing a landscape from which unprecedented forms of life emerge, we might find interesting another recent piece of media shot in Winnipeg. This is the Amazon Studios series *Tales from the Loop*. Transmedially based on a series of paintings and episodic narratives by Swedish artist Simon Stålenhag, later to be elaborated in a role-playing game, the story is set in an alternate 1980s. It concerns a semi-rural community built atop a fictional piece of technology resembling a particle accelerator – The Loop. As the technology, and the state associated with it, ages and decays, it begins to malfunction. The landscape and people above it are effected. Buildings are overgrown with organicized cabling; carbon-based and steel bodies are transposed; time loops move people and creatures back and forth from the past; machinery leaks blood into environment (Fig. 7).

These stories are all set in spaces generated by the decay or derailment of industrial infrastructure, originally erected to coerce or control. While the tales from this Loop were originally set in Sweden, they have been relocated for the television series to an American mid-western state. And of course they are shot in Winnipeg. For like the spaces of the story, Winnipeg and the prairies are a rural-urban hybrid generated out of an immense technological and social project intended to transform the world, but which ultimately distorted everything that came before. This is a local story, but also a global one, as the easy transferability of Stålen-

Figure 8. Still, *Heater* (1999). Crossing Main Street with the heater. The Bell Hotel, pre-*Horsemen*, appears in the left background.

hag's tale from Sweden to Ohio to Manitoba – and back to the whole world – attests. These spaces articulate well the anxieties felt by other modern places, surviving as so many of them are amidst ruined projects of world-domination.

Exchange (II)

Winnipeg is, to use Owen Toews's term, a stolen city.[3] No matter how culturally significant is the Indigenous presence in this city today, the majority of Winnipeg's

population can be seen as pretenders: that is, those who set forth a false claim to ownership. As *Flag Day* suggests, perhaps this is inherently a counterfeit city. My thesis is that that is the subtext of all of the media narratives produced by industry here, the ones that buy up parts of the city – or their image – for international distribution. But the history that these spaces come out of is much more directly addressed, and with richer and more promising implications for the city, by the work of independent artists – in both narrative media and media art.

In Terrance Odette's *Heater* (1999), for example, two homeless men, one of them Indigenous, one white, navigate a labyrinth of roadways and parking lots between inner city and suburb in a quest to collect the refund on a stolen baseboard heater (Fig. 8). Noam Gonick's *Stryker* (2004) takes an Indigenous boy, recently arrived from the reservation, and sets him down in the middle of a gang war in the colourful yet dark streets of the North End. Mark F. Ennis's *Road of Iniquity* (2018) tells another story of a young Indigenous man caught between two poles of Indigenous gangsterdom. Rhayne Vermette's *Ste. Anne* (2020), named for a nearby Métis community, makes architecture and urban space a key dimension through which the filmmaker explores Indigenous experience (Fig. 10). Vermette's work is doubly interesting because in parallel with her film-making practice she has a practice in media art –

Figure 10. Production photograph, *Ste. Anne* (2021). Arlington Bridge over the railyard that splits Winnipeg into North and South.

including the production of numerous short films that intertwine analogue and digital media, and a number of video projection projects.

There are many other artists in Winnipeg operating across these boundaries. Local work shows a preoccupation with hybridity, both cultural and formal, that undermines straightforward classification. Vermette's filmmaking, for example speaks about the specificity of the Métis experience, which is profoundly local; yet she articulates it in the context of an international film culture. She constructs her experimental short film *les Châssis de Lourdes* (2021), for example, in part through direct quotations and recreations of scenes from the films *True Stories* and *Paris, Texas*, often translating them into French (Fig. 11). Her

work addresses tensions between belonging and alienation, often through the figure of technologized architecture.

Winnipeg was built on an Indigenous and Métis heritage, and technology has been complicit in the dismantling and dissimulation of that heritage. This is a local version of a global story. In the modern era the frameworks of technology, though they pretended to neutrality, were associated most often with European and Anglophone ambitions. The world became part of a machine run from a few locations in the world, and run not exclusively but predominantly in English. This produced a condition of weakness for anyone who did not share that place or that language, and found themselves on the receiving end of a culture which was increasingly homogeneous, and oriented toward capital and its dominant language. Strategies that can be used to oppose such power structures include carnival, polyphony, and polyglossia, as noted by Mikhail Bakhtin, who saw the role-playing in carnivals for example as a means by which the mighty can be criticized, and overthrown, by the weak. Hybridization of modes of discourse – one might say media – related to socioeconomic power can achieve a similar undermining.[4] Such strategies might offer a means of "weak overcoming" of the juggernaut which is the modern world.[5] They have the potential to undermine frameworks of power by existing between them – or by existing simultaneously inside and outside of them – occupying two separate worlds to deny either hegemony. These strategies are among those employed by Vermette in *Les Châssis*, as she takes words from one source, puts them in the mouth of others, to speak a truth that is specific to a family yet universal. But as I think can be gleaned from the picture I have painted of Winnipeg and its exploitation by mainstream narrative media, media-spaces harvested here by an industry come from away, representing a global market, are weighted with a similar poignancy. The whole process is engaged in a relationship of translation and transplantation very much inherent in this place.

That these preoccupations emerge, whether in the background or foregrounded, in commercial as well as independent local films, might suggest that the terms commercial and independent, global and local, are now unreliable descriptors. They undermine any straightforward notion of authenticity, and reinforce the idea that representation is always a lie: a lie which tells the truth. As a Métis artist, and an architect by training, Vermette and other young filmmakers are caught between several worlds: anglophone and francophone, Indigenous and European, architecture and media. Many others of her generation similarly manage life across borders, amidst the fallout of failed world-mastering projects. This condition has produced a shared capacity to be both anguished and canny, and an alacrity at negotiating boundaries. The work of these artists is transforming a culture once silenced by colonialism.

All this implies an openness to the non-binary; an embrace of hybridity; an acceptance of the incommensurate. We might speculate that in these conditions the border between real and counterfeit becomes complex and unclear

Figure 11. Still, *les Châssis de Lourdes* (2021).

and a new condition of Exchange is implied. If one thing cannot be opposed to another in any straightforward way, it cannot simply stand in for it; neither can it be traded for it. To represent, one thing must to some extent be translated into its Other. Old dichotomies between one and the other, between analogue and digital, between what is owned and what is shared, between art forms, and between high and low culture, do not serve us well today. The same can be said for the distinction between the city and its image, a relationship in which spaces and their representation become embedded in, bleed into, each other.

It should come as no surprise that the ground occupied by narrative media and media art, from which they harvest such spaces, is shared with the discipline which produces those spaces: architecture. These fields share much more than that. For one thing, if one definition of media art is art that foregrounds the technology from which it is composed – that is also a definition of modern architecture. Both media and architecture are entangled in the legacy of industrialization and commodification. They are both highly dependent on complex and global networks of capital, labour, and technology, networks that are successors to, and make use of the machinery that supported, earlier projects to master the world. The ruins of those modern projects are a preoccupation for both creators of space and creators of the moving image.

So the spaces that generate images and narratives, and the spaces on which and in which architects work, often coincide. The Bell Hotel harvested for *Horsemen* is a case in point. As will be recalled, this was the setting of a murder intended to pave the way for an apocalypse, and I have tied the site to a social history caught in a similar trajectory.

The filming of *Horsemen* took place after the 2007 acquisition of the hotel by Centre Venture, an arms-length municipal agency that has been charged with turning around the decline of Winnipeg's downtown. By 2011 – after *Horsemen*'s apocalypse – the building had been redeveloped into the Bell Hotel Supportive Housing Complex.[6] This included 42 units of permanent housing for individuals who have experienced homelessness, and shared facilities for cooking, dining, administration and cultural activities.[7] This is what ultimately became of the

Figure 12. Panorama view of Main Street, Winnipeg. To the left, the Bell Hotel Supportive Housing Complex. To the right, Thunderbird House and Pop-Up Winnipeg Toilet. Photograph by the author.

Bell's former role as boarding house, and it remains in this renewed and supportive role today. Across the street from the former hotel is Thunderbird House, designed by Indigenous architect Douglas Cardinal, which opened in 2000 as a centre dedicated to First Nations cultural support.[8,9] Adjacent to this could be found, in late 2019 (it's a nomadic project), the Pop-Up Winnipeg Public Toilet, a project by Bridgman Collaborative Architecture which provides heretofore neglected public facilities to the downtown.[10] These are only two of several significant institutions and social enterprises within a few blocks; they happen to both have noteworthy architecture.

None of these stories are straightforward. Centre Venture has been criticized for purchasing other affordable downtown hotels and, rather than finding new ways for them to serve their communities, shuttering them to facilitate other forms of development.[11] Thunderbird House is struggling to restore its financial footing, including the cost of maintaining its architecture in good repair.[12] But the area around the Bell embodies Winnipeg's struggle to negotiate the legacies of poverty and racial division that are writ in, and continue to play out in, the figure of this city – in media, as much as in the flesh.

Perhaps there is some redemption here, in the interplay between the city and its image: in the space between what it is, what it dissimulates, and what it represents. It is this cityscape which has been so productive of spaces that support the telling of mediated stories and the creation of media art which, somehow, smuggle across all boundaries their contraband of history and attendant trauma. Media and architecture are sewn together a little like the limbs of a monster, and work together on the transformation of the city in our imagination, and in the Real. They make of Exchange more than a simple purchase – perhaps something closer to a barter, or even a potlatch. In such a space, a divided city is never only that; the rifts that open up between us can prove to be a productive ground, fecund, a space for the Possible City.

In pursuit of the *Schizomachine*: for a(n) (*in*)possible listening

Maria Lucília Borges

Universidade Federal de Ouro Preto – UFOP

Campus Mariana, Brazil

maria.borges@ufop.edu.br / luciliaborges@gmail.com

Abstract

The *Schizomachine* is an ongoing work-research that consists in the development of a wearable neuro-biofeedback system for aesthetic-affective experiences. As all research is also a creative process, this work, thought to be introduced in an artistic context, crosses other fields beyond Art and Product Design, such as Computing, Biology and Engineering. In search of the realization of the ideas that emerged throughout the process, listening and sound (Schaeffer, 1966; Schafer, 1969; Cage, 1973; Pelling & Gimzewski, 2002) came out as important concepts, which have guided the research so far. This article addresses the intuitive path that has been traced from the very first idea to the very first prototype, with the aim of reaching other possible listenings.

Keywords

Listening; schizophrenia; sound object; sound body; affects; creative process; wearable interface; smart clothing; biofeedback; brain-computer interface.

Introduction

When Keith Richards wrote one of the Rolling Stones' greatest hits, he was asleep. He heard, in a dream, the framework of his famous three-note execution: the riff for (*I can't get no*) *Satisfaction* (1965). He woke up, recorded the riff on his little Philips cassette recorder, and went back to sleep. In interviews, Richards says that the next morning he noticed that he had put a new tape in the recorder, and when he re-wound it, he found 30 seconds of the riff and a murmur ("I can't get no satisfaction") of what would become one of the band's greatest hits (the remaining 40 minutes of the tape recorded the noises of his sleep).¹

In 2006, in the context of developing my doctoral research, I had a dream in which I heard two words: "schizophonic device". The dream had no context, no narrative or setting; it was just the sound of the words as if they were whispered, not to the ear but to (or through) the mind. Af-

ter hearing the words, the thought that I shouldn't forget them came to mind. I tried to get up and write them down, unsuccessfully. Between the weight of the body, which wouldn't react to the commands to write down what seemed to be an important idea for the thesis, and the mind, which doesn't stop working, even in sleep, I spent the rest of the night fighting deep sleep so as not to forget about the listening-dream. But I ended up forgetting. I woke up a few hours later with nothing to remember and no concrete clues like the one Richards found the morning after his dream. By mid-morning, however, I had a feeling that something had happened in my sleep. I vaguely remembered that I had had an important dream, and suddenly the word "schizophonic" sprang to consciousness. I then forced the memory of the other word that accompanied it, and the words that followed (system, device) may not be exactly the dream word, but they served as a starting point for my creation process to advance towards what would determine the directions of my research years later.

Solving problems or gaining insights during sleep is not uncommon, quite the opposite. Albert Einstein, Dmitri Mendeleev, Niels Bohr are examples of scientists who found answers to their concerns or research directions in their dreams. As every dream holds mysteries to be deciphered, between the dream and the reality of the research there was an unknown: what were the words heard in the dream about, after all? Composers Murray Schafer and Pierre Schaeffer seemed to hint at answers. The former, for his concept of *schizophonia*, and the latter, for the very nature of the dream: listening. Along with them, John Cage and his experience with silence: a(n) "*in*)possible" listening.

Between the dream and the completion of the thesis (2008) and beyond (2018), it took a while for the Schizophonic Device, now named *Schizomachine*, to begin to get a more tangible outline and a possible destination. Therefore, this article deals with the pathway of this research, between the idea and the concept, theory and practice, the dream and the possible.

<https://www.rollingstone.com/music/music-news/when-keith-richards-wrote-i-cant-get-no-satisfaction-in-his-sleep-236461/>

Between theory and practice: the idea and the concept

When Pierre Schaeffer proposed the term Concrete Music (1948), he considered as concrete only the sounds of the outside world (the noises) from which musical values could be extracted. Equally interested in the sounds around us that do not cease to affect us, it was John Cage who called attention to listening to internal sounds, the sounds of our bodies, while researching silence. In his experience in the anechoic chamber at Harvard University (1951), Cage described two sounds he had heard: a high-pitched one, from his functioning nervous system, and a low-pitched one, from circulating blood, as the engineer in charge explained to him. [1] The “silence” that Cage heard calls our attention to listening to the sonorous (and musical) potential of the body and to our inability to hear it.

In the field of science, researchers Andrew Pelling and James Gimzewski (2002) went beyond Cage’s experiment by demonstrating, through an Atomic Force Microscopy, that cells emit sounds that can be amplified to an audible range by the human ear. That resulted in a new area of Biology, which they called Sonocytology (the study of the sounds of cells). [2] This study shows that the listening cycle, as proposed by Schaeffer, acts in a constant movement of interaction and resonance between the body and the world, and it is up to us, listeners, to also listen to sounds from within as musical possibilities.

Listen!

In his long *Traité des objets musicaux* (1966), Pierre Schaeffer dedicates himself to the theme of listening, describing it as a circuit of sound communication, from “emission to reception (including its psychophysical and psychological characteristics)”, which would work in four steps. [3] He organized his method of listening (the “ordinary” listening) by following a schematic logic ranging from 1 to 4, read clockwise, beginning with *écouter* (listening):

In sector 1 - Listening, means listening to someone, to something; and through the intermediary of sound, aiming to identify the source, the event, the cause, it means treating the sound as a sign of this source, this event (Concrete/Objective).

In sector 2 - Perceiving, means perceiving by ear, being struck by sounds, the crudest, most elementary level of perception; so we “hear”, passively, lots of things which we are not trying to listen to or understand (Concrete/Subjective).

In sector 3 - Hearing, here, according to its etymology, means showing an intention to listen, choosing from what we perceive what particularly interests us, in order to make a “description” of it (Abstract/Subjective).

In sector 4 - Comprehending, means grasping a meaning, values, by treating the sound as a sign, referring to this meaning through a language, a code (semantic listening; Abstract/Objective). [4]

Although Schaeffer was inspired by Husserl’s phenomenology, a “resonance” (to use a musical term) is perceived between his modes of listening and Charles S. Peirce’s categories. The four modes of listening work in accordance with Peirce’s triadic logic (*firstness*, *secondness*, and *thirdness*), and even though one prevails over the others, we still go through the four-stage cycle.

From a semiotic perspective, if “hearing” (the French “ouïr”) is “perceiving through the ear”, and “listening corresponds to a more active attitude”, as suggested by Schaeffer (1966), would not *listening* be the second stage of our sound perception? If we start from this point of view, *Perceiving* (to perceive, “to hear” - *Ouïr*) would be the first in the process of listening (*firstness*); *Listening* (to listen - *Écouter*) would be the second one (*secondness*) along with *Hearing* (to understand, to get to know - *Entendre*), which also brings in French the meaning of listening, but listening with intention, like listening to electroacoustic music composers. *Comprehending* (to comprehend, to understand - *Comprendre*) would relate to *thirdness*, when the listening process is completed.

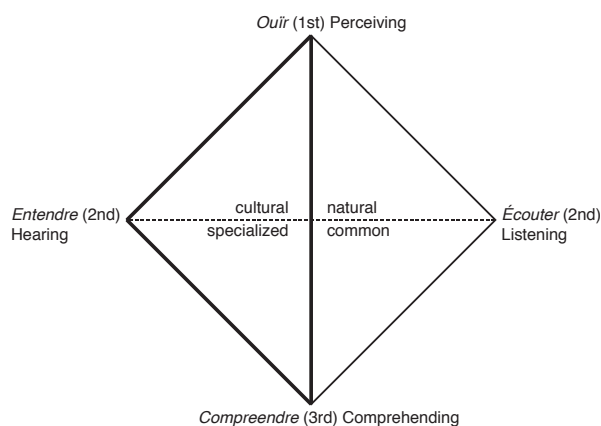

Figure 1. Proposal for a triadic listening cycle based on Pierre Schaeffer’s four listening modes. © 2021 by author.

This “listening triad”, beginning from *Perceiving* (1st) followed by *Listening / Hearing* (2nd) and *Comprehending* (3rd), is fulfilled whenever a sound affects us, and becomes more complex as our attention is drawn to certain equally complex sounds. The *entendre* (Hearing) calls us to listen more attentively than the *écouter* (Listening). Thus, it is highlighted in this study as a second stage (*secondness*) in both cultural listening and the specialist’s listening (musician, composer, sound technician), to distinguish it from our natural and common listening (*banale*)², when the *écouter*

² In addition to the classification of listening modes, Pierre Schaeffer analyzes auditory perception, organizing it into four groups:

(Listening) stands out.

Beyond ordinary listening, which takes place all the time even when we do not realize it, Schaeffer proposed *reduced listening*, through which the *sound object* would be reached: listening to concrete sounds (natural sounds from the outside world), from which musical values could be extracted.

Schaeffer uses the term *sound body* to designate the sound source where sounds derive from (an instrument, such as a piano, or any other object, such as a car). The *sound object*, a concept that guided all his research in *Traité des objets musicaux* (1966), is the sound itself, the “gross” sound (“raw sound object”), with its potential musical qualities. For the composer, it is necessary to “abstract” the origin (sound source) and the sense (values, “meaning-language”) of the sound in order to perceive the sound object (reaching the “qualified sound object”). [5]

As Pelling & Gimzewski have demonstrated through *Sonocytology* and the yeast cells, all sounds are potentially musical in an attentive listening, including the sounds of our bodies. As a *sound body*, the human body is a producer of sounds (voice, singing, “percussion-body”) just like any other musical instrument; as a *sound object*, it is a musical prospect, from which musical figures can be extracted

Schaeffer says that it is through consciousness that a “sound background acquires a reality”. [6] We could say that this “consciousness” lives not only in the mind, but also in the body, in each cell that reacts to sounds without our other “consciousness” noticing. When a sound reaches our ears, crosses or meets our body, it instinctively and indirectly becomes aware of its existence, as it keeps the memory of “ancestral sounds” on the skin, being even able to anticipate the next sound without its prior manifestation. There is a “sound wisdom” in our body.

On a micro level, even though certain sounds that pass through me do not immediately gain my full attention (from my awareness of “me listening/hearing”), my cells have already become aware of their presence, and will pay attention to them (by *listening*) soon then manifesting reactions that are often subtle (others not so much) in the form of hormonal discharges, for instance. The moment of the body’s reaction to the sounds that pass through us is a second stage (*secondness*), when the body “pays attention” to the sounds and reacts to them. All processing of those sound data and the conclusion about the type of sound, or what emotion was triggered by the sounds, or else any specific detail of those sounds corresponds to *thirdness* (in *comprehending*).

What we mean by this is that the external world is full of sounds that keep passing through us, and we do not realize that our inner world also produces sounds that resonate with the outer sounds. Schaeffer’s listening cycle, which we suggest here to function like the Peircean’s triadic logic, acts

natural, cultural, common (*banale*), and specialized or expert (*praticiente*). For the sake of practicality and the focus of the article, we will not go into detail about this classification

both from the outside in and inside out. On the one hand, we have the sound signs that cross our body, by which we are affected, and on the other, the sounds produced by the body itself: the body as a “receiver”, “sender”³ and “processor” of sounds, simultaneously. A *sound body*, a sign that performs sometimes as an object, sometimes as an interpreter of signs that are, in turn, sometimes sound bodies, sometimes sound objects.

The listening ear

In 1969, Murray Schafer coined the concept of *schizophonia* to describe the separation (*schizo*) between sound (*phono*) and its original source, as in the case of electroacoustic reproduction, when a voice or music is heard miles away from its issuing source. Before the emergence of radio and telephone, “(...) the instantaneous transmission of sound from one place to another was quite unknown. (...) Sounds were tied indissolubly to the mechanisms that produced them. In those days every sound was an original, repeated only in its immediate vicinity,” says Murray Schafer. [7] Technological advances and the possibilities of recording and transmitting sound by electronic means caused changes that Schafer saw as “dramatic”, hence the term *schizophonia* - “a nervous word”, inspired by the “drama” that the word schizophrenia evokes, according to the author. [8]

When he created this concept, Schafer did not consider other means of sound or musical production, in addition to electronic media and means such as the phonograph, the radio, the recorder, the loudspeaker and the telephone. Yet, he leaves the debate open when he mentions our ability “to feel into the depths of sounds with our muscles and nerves”. [9]

This extract suggests that we resonate with the sounds that surround us and incite our body movements from the mother’s womb, a memory that we bring to the world here and that the body recognizes to the sound of the most “ancestral” beats. If we take the human body as a potential musical instrument (a *sound body*, but also a *sound object*), we can suggest that *schizophonia* would be a condition of our existence even before the body becomes a body. Inside the uterus, the fetus listens to the sounds of the mother and recognizes them, and listens to sounds from the outside not knowing, at first, the source that produced them. The fetus not only hears the sounds but vibrates with them, it transforms itself into sound and thus goes on defining its sound, rhythmic identity (*becoming-sound*).

The fetus grows in the woman’s body and detaches itself from it at birth (*becoming-schizo*). One goes from becoming-woman to becoming-child. [10] It is *schizo* by nature: a *schizo-body*.

³ Herein we have adopted the terms according to Schaeffer in his Table of Listening Functions (“*emission* of the sound” / “*reception* of the sound”). [5]

Of the (in)possible ideas

In pursuit of the *Schizomachine*, the first idea that was designed brought the challenge of technique/technology and some issues that return to the point where it all started - the term paper project for my graduation in Graphic Design, *O Pulsar do Design* (1998).

Figure 2. *O Pulsar do Design* (The Pulse of Design), animated score created from the intersemiotic translation of Augusto de Campos's poem named *Pulsar*, with music by Caetano Veloso. © 1998 by author

From “how can sound be made visible?” - the question that guided this project - to “how can the inaudible of the body be made visible?”, I came to the proposal of a smart clothing with a sensor system that could capture and convert the “microsounds” of the human body into light. This idea was inspired by the findings of Pelling & Gimzewski's study (2002) on the sound of cells, and as one of the references, the *SKIN: Dresses* project (2006)⁴, developed within the *Design Probes* program, by Philips.

A body covering the body. A tight-fitting garment, like a second skin, with sensors distributed throughout its length, capable of capturing sounds (sound frequency) from all parts of the body and translating them into colors (light frequency). The body, covered by the device, would form a sort of map of different colors (a luminous body), whose sounds would not necessarily be heard (with the ears). All body sounds - the audible ones (through devices such as a stethoscope) and the inaudible ones (blood stream, heard in the anechoic chamber) - would be translated into color (light), creating a way to “listen to colors”: *a listening of the sight*. Those sounds could also be amplified to be heard no longer just as colors but as sounds.

⁴ <https://www.vhmdesignfutures.com/project/224/>

This first proposal by *Schizomachine* brought along the type of technology to be used as the main challenge. The visual concept of the interface suggested the need for bio-sensors, in which the textile itself was the sensor (wearable sensors).

Figure 3. First proposal of the *Schizomachine* interface. Second-skin clothing with biosensors located throughout its length. In transduction, the lights would turn on and change their hue according to the “inaudible sounds” of the body that were picked up by the biosensors. © 2008 by author (mannequin template: © 2014 by Prêt à Template)

The chosen technology should be effective for individuals from any culture, with distinct physical and physiological characteristics. It should also be non-invasive, discreet, and versatile enough to be used in any artistic context. For

Figure 4. An EEG *Schizocap*, a cap composed of thirteen dry electrodes coupled to a crochet structure and connected to six EEG sensors and six corresponding channels of the BITalino microcontroller board, which digitizes and transmits the signals, via *Bluetooth*, to a computer running the data processing software. Photos: Thiago Barcelos. © 2018 by author

this reason, *wearable sensors*, *smart textiles*, and *textile electrodes* would be the ideal device options for clothing design. However, as for the technical applicability, I have faced the challenge of finding available and affordable (low cost) devices in the market that met all these characteristics and that would work according to the needs of this proposal.

Besides that, a question both conceptual and technical about the very nature of sound arose in the process: between the physical signal and the perceived sound, between the sound that is heard and the signal that is measured, how can sound be defined? To step out of the world of ideas and advance into the field of possibilities, the limitations of this initial challenge showcased the need for adjustments to the proposal, which I will discuss below.

Between the dream and the possible

Between that dream in 2006 and the first prototype of a part of the *Schizomachine*, 10 years have passed, and some modifications were made to the initial proposal. From the concept, it was assumed that the human body is a *sound body*, whose vital signs (“vibrations”) change depending on the emotions produced in the relationships established in daily life and the sensations triggered in the encounter with Art (as is the case with blood pressure and heart rate, for example, which accelerate influenced by the intensity of the emotional discharge; and brain waves, which calm down when we are in a meditative state).

How would the body “sound” in its relationship with Art? Is it possible to capture the sensations (that which precedes

the emotions) produced in the encounter with Art? Such question remains open but has guided the research.

The *Schizomachine* presents itself today as a wearable system⁵ in progress, which aims to make some sensitive communication processes of the human body visible when in contact with Art, through methods of mapping and monitoring the spectator’s physiological parameters and converting those data into light during the aesthetic experience in a museum or art gallery. What is proposed is a *self-listening* experience, where the body is the object, the skin is the interface, and the sight is the listening: a *listening of the sight*. Yet, there is no intention of “sonifying” the data collected to be heard/listened to, as what is sought is an experience of visualizing the listening of the body sounds (vibrations), another possible listening.

The wearable system *Schizomachine* is initially composed of two microcontroller units connected to a central computer that will run a mapping software. The two units are called the *Schizocap* - an electroencephalogram (EEG) cap that generates the input data (the *input*), - and the *Schizobody*, functioning as a kind of wearable display where brainwave data (and later, pulse and heartbeat) will be visualized in the form of light (the *output*).

A first prototype of the EEG cap (*Schizocap*) was developed in 2018 (Fig. 4), when a pilot test with two EEG devices was carried out (DSI-24 Dry Electrode EEG headset,

⁵ Due to the complexity of the project, I have preferred to use the term “system” rather than “interface”, as the former more broadly encompasses all stages involved in the project, from the design of wearables to data capture from the devices, development of the mapping interfaces, as well as data analysis and transduction.

by Wearable Sensing⁶, and (r)evolution Plugged Kit BT, microcontroller board, biosensors, and dry electrodes from BITalino⁷). Regarding the design, at the current stage of the research it is necessary to test the *Schizocap* on different users in order to verify the feasibility and functionality of the technological devices adopted for the development of the cap (devices from the Portuguese company BITalino), as well as the material and technique used in the making the prototype (crochet and mercerized cotton threads). The tests, which would have been performed in 2020, after the project to be submitted to and approved by the Research Ethics Committee in Brazil, were suspended due to the coronavirus pandemic. As far as the system is concerned, there is a long path of research ahead to be covered, which involves collaboration with other areas of knowledge besides Design, such as Computing and Engineering.

The data recorded in the tests will be used in the development of the data mapping system (EEG) and the lights (LEDs). In addition to the electroencephalogram, it is also intended to test other biosensors such as electrocardiogram (ECG) and electromyogram (EMG) for further implementation in the system. The cap is part of an interactive artistic installation, where the full system (*Schizocap* + *Schizobody*) must also be tested in the final stage. The data from both tests will serve as a basis for adjustments to the system *design* (cap, clothing, and mapping) for subsequent exhibition of the work in a museum or art gallery.

Final considerations

Creativity is a complex process, of which inspiration is only a part. According to researcher Nancy C. Andreasen, “many forms of creativity, from writing to novel to discovering the structure of DNA” require a continuous and iterative process that includes multiple components such as “preparation, incubation, inspiration—a version of the eureka experience—and production”. [11] The dream described at the beginning of this article is just a flash of inspiration, part of a long and lonely research process, which now sets out in search of “allies” so as to effectively go beyond the world of ideas.

Several advancements have taken place in science and technology since that dream and the first *Schizocap* prototype. To expand the listening to body sounds beyond the anechoic chamber, to amplify the body’s inaudible sounds in another context outside a laboratory... it is all perhaps more possible today than it was ten years ago.

If cells vibrate and produce sounds, as demonstrated by Pelling & Gimzewski, (2002), if we are made up of cells, their frequencies also change depending on the affects that are awakened in our body, whether in our daily relationships

⁶ <https://wearablesensing.com/products/dsi-24/>

⁷ <https://bitalino.com>

or in the encounter with art, from which new questions arise: if we start from a semiotic viewpoint (Peirce) and take sensations as a first stage of the sensitive, followed by emotions and feelings (Damásio), would their signals manifest themselves first in the brain, before the body’s reaction (before what we call emotions)? What do brain waves tell us about emotions?

Dreams are about what is possible, as is Art, whose “function” is to “express possible worlds”. [12] All the questions that arose during the research, summarized here in this article, are, in fact, attempts to find a meaning for that listening-dream as part of a research method guided by intuition, and, as such, without linear logic or direction. Although the starting point is fruitful and the method coherent, the *Schizomachine* still remains in the field of possibilities, in search of a(n) (*in*)possible listening.

Acknowledgements

The author would like to thank Prof. Dr. Marcelo M. Wanderley, director of Input Devices and Music Interaction Laboratory – IDMIL, his PhD student Johnty Wang, and Francesco Tordini for the collaboration on the first steps of the development of this wearable system, as well as the Centre for Interdisciplinary Research in Media Music and Technology – CIRMMT / McGill University (Montreal, Canada) for welcoming and supporting this research in 2018 and in the beginning of 2019. The author also thanks the students of Journalism for the collaboration and the Universidade Federal de Ouro Preto (Brazil) for the support.

Author Biography

Maria Lucília Borges is Associate Professor at the Federal University of Ouro Preto – UFOP, Campus Mariana, Minas Gerais State, Brazil, PhD and Master in Communication and Semiotics by Pontifical Catholic University of São Paulo (PUC/SP) and Graduated in Graphic Design at State University of São Paulo (UNESP/Bauru). From her current position as permanent Professor at UFOP, since 2012, she has been teaching Aesthetics, Sound Art and Graphic Design to Journalism students, with whom she has been creating art installations, performances and exhibitions. Currently, her research is focused on Art (music and art installation), Affective Technologies (biosensors, neuro-biofeedback systems and smart textiles) and Sensitive Processes of Communication (silence, listening and human body’s affections).

Buildings as Audio Visual Synthesisers: Experiments Performing Live Music on Wirelessly Networked Multi-Speaker Media Architectures

Abstract

This paper presents an approach to expanding live music performance practices to encompass sonic media architectures. We demonstrate a method for creating a playable audio-visual synthesiser that incorporates the notion that the space itself is a medium for performance. We discuss the design concepts that inform this process, as well as detailing specific simulation tools and a creative workflow that facilitates development of performance experiments within architectural spaces.

Keywords

Media architecture, internet of sounds, spatial audio, live music technology.

Introduction

Live musical performance has traditionally been a significant driver of architectural design excellence, as well as media technology innovation. Opera houses and recital halls have been world-famous architectural sites throughout recent history, partially based on the social importance of live music for society, as well as the architectural excellence that may be shown in particular designs. Media technology development has also been propelled by musical performance contexts, and media architectures are a specific area of current research interest and technology innovation.

In this paper we seek to discuss an approach to combining these areas of interest, by augmenting music performance contexts with a media architecture that is controllable by typical musical DAW programs, and allows for creative experimentation with music, light, and space.

Background

Media architectures are physical augmentations of the built environment that bring audio, visual, tactile and sensing digital elements [6, 9]. Most work in media architecture focuses on visual elements – lighting and the design of non-standard screens that integrate with architectural forms [12, 11]. Researchers have also developed more complex systems that integrate interactive system design with media architectures [22, 13, 14] and have also investigated methods for incorporating kinetic and robotic capabilities into these systems [21, 16].

The incorporation of widely distributed speaker arrays into buildings is beginning to grow in prominence. Audio media

architecture is challenging for a number of reasons: introducing sound into the built environment has greater potential to be considered a nuisance (although light pollution is a recognised issue in media architecture [9]) and less well associated with providing added value to the built environment; and technically, massively multispeaker sound design is harder to achieve [8]. Nevertheless, a number of teams are developing media-architecture oriented sound design systems, including our own work developing frameworks for rapidly developing and deploying distributed sound installations.

In the area of live music performance, whilst the academic, experimental and art music worlds have long embraced more-than-stereo audio systems, the vast majority of music performance contexts remain largely bound to PA systems with stereo configuration. Factors at play include the fact that the stereo format is widely adopted by venues and is considered to be more manageable with a constant turnover of touring acts, and that there is also no strong incentive to go beyond stereo (indeed large venue PAs offer only a limited stereo experience). The technology to render sound using multi-speaker audio for these contexts has been readily available for some time [19], and indeed has long been standardised for cinema – another common public sound reproduction context. But the limited embrace of multi-speaker performance practices, as well as unclear experiential benefits for audiences, means it would still be considered novel today to see a local band performing on anything other than a standard stereo PA.

At the intersection of these two fields, live music performance can be performed *via* situated media architecture systems, inviting new conceptions of music performance and composition, and continuing a long-standing tradition of dialogue and interdisciplinary creativity between music and architecture [15].

Sonic Media Architectures Beyond the PA

Live music is strongly associated with the use of PA systems: a set of loud speakers into which various sound producing or processing equipment can be connected to render music in realtime. Sonic media architecture systems such as ours do not necessarily offer themselves as PA systems through which sound is played, but more as instruments that can be played. As we discuss below, in our case this is because with the wirelessly connected technology we use there is no way to stream multiple channels of audio to each speaker in a low-latency

Figure 1: Performing with the *Mind at Work* system using a laptop running Ableton Live, and a MIDI controller. © The authors.

way that is suited to realtime music making. Instead, the system better suits another paradigm, well known to musicians, of the MIDI (musical instrument digital interface) studio, where it is synthesiser control messages rather than audio that is sent to the rendering devices. In a MIDI studio, the audio output of the rendering devices (synthesisers, drum machines and samplers) are typically mixed back into a stereo mix for the studio loudspeakers of venue PA, whereas in our system, each device has its own speaker, distributed in space.

Historically, although the PA has been dominant for many years, a prominent alternative for musical rendering has been the world of mechanical musical instruments. Most commonly, mechanising musical instruments transforms them into acoustic rendering devices of digital content. Even after the appearance of radios and gramophones, mechanical instruments like player pianos remained popular, in part because the fidelity of recorded or broadcast media was so much more inferior than the sound of a genuine instrument in a space.

More recently the field of robotic music performance has extended how complex networks of acoustic rendering devices can be physically manifest and situated in space in interesting ways that relate questions of music performance and dramaturgy to questions of design. Taken to a theatrical extreme, the works of composer Heiner Goebbels, such as [1], situate mixed media including amplified and mechanical instruments into entirely mechanical theatre works. Robot artist Wade Marynowsky has similarly reconceptualised the operatic form as one that can be explored via interactive musical robots [18]. More generally, many music performers seek to engage with the built environment, to compose performances for specific spaces and to improvise with spaces. An elegantly simple example is the documented use of room acoustics by saxophonist Evan Parker, on records such as *Monoceros*, in which he constructs an improvised performance attuned to a specific, although relatively unremarkable, room [2]. This builds on experimental music's fascination with the creative contribution of space in musical processes of feedback most widely celebrated in Alvin Lucier's conceptual work *I am Sitting in a Room*. Back again in the digital world, the laptop

and mobile phone orchestra movement (e.g. [23, 24, 20]) has also embraced the acoustic potential of situating distributed speakers, typically co-locating each speaker with a live musician and their sound generating equipment (laptop or other portable computing device). As with our work, communication between devices here is largely focused on small control messages and the challenge of keeping time between different computer clocks and metronomes.

In this paper we present initial steps in a creative project situated at this intersection. We approach this work both as a creative practice-based research project to explore the aesthetic possibilities of live music performance with distributed sound-and-light sculptural designs, and as a design research project into the creation of a system that simplifies and reduces the effort in creating musical performances on distributed systems.

Design Concepts

In a number of previous studies [4] we have outlined our system design and software architecture in detail. Briefly, our system is built from a set of small raspberry pi computers outfitted with hardware that allows the connection of various display WS2812B Neopixel LED arrays, as well as audio amplifiers that allow the driving of small loudspeakers. Each of these computers has enough computational resources to synthesize audio signals and perform audio sample manipulation. These devices run runtime software that allows them to be connected to a WiFi network and managed from a central control interface, while retaining their autonomy, and we can use this central interface to deploy arbitrary software sketches to each of the devices without requiring re-initialisation of the devices [5]. We have used this system to iterate a number of design concepts [18, 3, 17] related to our central research question: how can we make it quick and easy to create rich distributed audio-visual content for site-specific media architectures. These design concepts are summarised in the following subsections.

Physical flexibility

In our system a creative team can design a physical sculptural arrangement of lights and speakers for a given location in any 3D environment of their choosing. They can then load it into a Unity environment which simulates our runtime system, allowing them to directly program light and sound behaviours in simulation. Work in progress includes simulating the first-person audio experience of walking through such a simulation. Once the real physical system has been built, the same computational model can be loaded onto the computing hardware and will work exactly as in simulation.

From a design research perspective, we have been very interested in the question of when specific design decisions get locked in. For example, a media architecture designer may come up with an initial sketch of a specific physical design of an array of lights and speakers (in the work in Figure 1, the bottom half of a sphere). They must then consider what kinds of media content might play out on that system, as well as how the system will be installed and what it will cost. These interplaying factors might lead to new iterations of the physical design.

In our design research we found that it was quite common for a design decision (such as the spatial design of lights and speakers) to be locked in, only to be revisited at a later date given new knowledge or thinking. We subsequently termed such decisions ‘fuzzy decisions’, and have attended to thinking about how we could support this iterative process of settling aspects of a design in light of how fuzzy decisions arise and are resolved: either by helping better anticipate factors that would influence a design, or simply enabling design factors to remain flexible for longer.

Technical constraints

Our approach is based on the idea of managing distributed sound by having multiple low-cost computers processing audio, and communicating with those computers over WiFi [7, 10]. This presents two key technical constraints: the processing power of the individual computers, and the network performance of the overall system (bandwidth, latency and stability). The network constraint means that our systems cannot behave like multi-channel audio systems, where you can stream sounds directly to speakers from a central computer.

In light of this, we have found it preferable to conceptualise the system as a “distributed synthesiser”, that receives global control data (notes and control parameters) from a central computer, and render sound over the array of speakers. Given this concept, we then treat the light components as just another output medium of the synthesiser. The latency of the network (around 100ms) is low enough to support basic realtime control from a central computer, but not as low as is typically desired in digital musical instruments.

The processor constraint limits the number of audio DSP processes that any one device can run. Thus within the conceptualisation of the system as a distributed synthesiser, each speaker is considered to be monophonic, and polyphony is achieved by distributing sounds across the array of speakers. For example, if you wish to play a chord on the system, a polyphony management process will distribute the notes in that chord across speakers.

Software flexibility

Our software approach is based on the idea of a runtime system that runs on each device, to which we can throw live-coded sketches in realtime over WiFi. In our latest version of the runtime, we have developed an approach of virtualising outputs (individual speakers or lights), so that we focus the programmer’s attention on writing code that describes how one individual output behaves. That behaviour can be easily deployed to the distributed array of computers, which automatically works out which device controls which output.

Much of our design work then focuses on how to conceptually separate out the added task of thinking spatially about the system as a whole: how sounds and lights move around and how audio and light parameters vary across space. Since the user has direct access to a programming API for programming the devices, they have the freedom to hack any part of this design. However, our design research has strongly pointed us to the need to impose some default framing concepts as a way of narrowing the space of possibilities whilst still allowing a vast array of creative options. Conceptually, we frame this in terms

Figure 2: (Top) A screen grab of the composition environment, comprising a virtual model in Unity, a coding interface in IntelliJ, and an Ableton Live project for live and timeline-based control of parameters. (Bottom) a more detailed view of a light configuration in simulation, with a light gradient mapped across the 2D surface. © The authors.

of the concept of ‘space enablers’: specific configurations of creative tools that place a rapidly accessible array of creative opportunities in front of a creative practitioner. Space enablers are designs that hit the sweet spot between the power of creation and the ease of creation. Our standardised architecture arises from integrating knowledge about the technical constraints of our system and the basic requirements of thinking spatially with a distributed computing system.

Figure 2 shows a workspace in which a physical arrangement is modelled in Unity, the code describing the distributed synthesiser behaviour is being programmed in IntelliJ, and controller data is being composed in Ableton. When deployed in the final system, the Ableton project stays open to control the system. The code is deployed to the runtime system running on multiple distributed Raspberry Pis. The spatial model is also loaded into the Raspberry Pis so that each device is aware of the physical positions of the lights and speakers it is controlling.

Jams in the Hueosphere

Jams in the Hueosphere is a series of live performance events held in Sydney, funded from a local government Covid relief fund to stimulate live music after the impacts of lockdown. The project was pitched to create a novel experience for audiences and also give a series of local artists the chance to experiment and develop their repertoire to new forms of digital media performance. Artists were invited to give live performances and to develop their own creative uses of the *Jams in the Hueosphere* technology. A challenge for the development of *Jams in the Hueosphere* was the limited time that would be available to work with the artists. Not only would the artists have limited time to experiment and develop their performances using the system hardware (due to other constraints such as access to the performance space), but given that this was a new software that was not fully user-tested, the

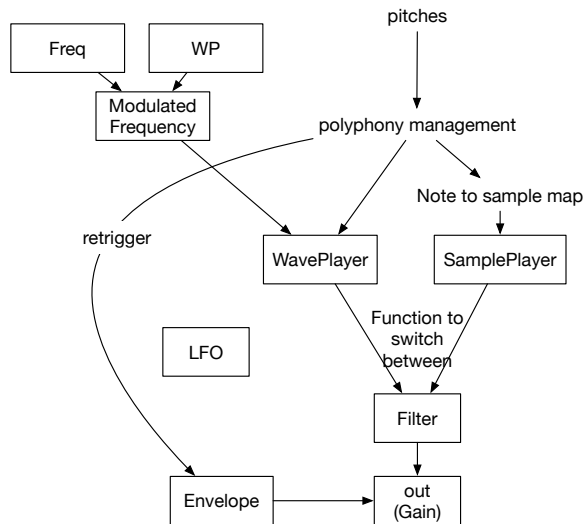

Figure 3: Our standard synthesiser architecture and Ableton Live controller device. © The authors.

potential to iterate the system in response to user feedback was limited. This is the context in which a general-purpose synthesiser architecture was developed.

System

Our development framework, *Happybrackets*, allows a program to be sent to a number of remote devices which then respond to incoming network messages from a controller computer. An audio API allows the creation of custom synthesiser signal chains, and equivalent processes for controlling lights. Typically we send the same synthesiser configuration to all devices and then work with global messages that control the devices *as one*. We then use the devices' physical positions as additional variables that can be used to map the global synthesiser parameters to create spatial effects. For example, we can easily create gradients of hue, frequency or filter strength, running across the space of the devices.

For the *Jams in the Hueosphere* project, we created a single synthesiser with a large number of variables and possible configurations (Figure 3). We then created a MIDI instrument device for Ableton Live which sends control messages to the network of devices. The result, from the musician's perspective, is something that looks and feels like a regular softsynth, except that instead of playing sound on the controller computer, sound and light is rendered on the system. Our Unity simulator can be used to view the design of the lights on the controller computer. The audio synthesiser includes functions for FM synthesis, sample playback, drum kits, wavetable synthesis, ADSR envelopes and LFO modulation: a standard suite of options for a synthesiser. The main difference with a real softsynth is how polyphony is managed: due to the computational limits of the Raspberry Pi, each speaker in the system is limited to monophonic playback. Polyphony is achieved by distributing the various notes in a chord across the system.

Figure 4: Spatial mapping strategies controlling colour hue. From left to right: variation radiating linearly from centre; variation mapped to angle around centre point; variation attached to discrete bands arranged linearly; specific zones of intensity. © The authors.

When a chord is played, each device chooses one note from the chord to play, according to a specified policy: either random, or based on the spatial position of the speakers (e.g., the lowest note in the chord would play at one end of the system, and the other notes would be located at different intervals along one dimension of the speaker array).

In addition, the user can select and modify a range of spatial strategies, including spatial envelopes, that dictates where on the system sounds and lights should be active, and spatial mappings, that dictate how some parameter varies across the space (e.g., hue or filter frequency). Spatial envelopes act like the envelopes used in sound synthesis, but are spatial rather than temporal. When the envelope is "fully open", all of the sounds and lights are active. The user can then choose to narrow the active zone, specifying a centre point and size parameters. In this way they can make sounds and lights move around the space. In reality, the sounds and lights are not moving, but simply being turned up and down depending on whether they are inside or outside of the active zone. A range of spatial mapping strategies are presented in Figure 4. Ongoing work includes refining this suite of functions to create an intuitive that can easily be manipulated to create spatial effects.

Creative Workflow

In our performance set up, a musical artist or band plays on stage with a standard PA system, but additionally, our system of lights and speakers is installed to flow up from the stage and over the heads of the audience. The musicians play as normal, using Ableton Live and any other instrumentation they like. Our synthesiser can be added into their existing Ableton Live rig so that as well as playing sounds out of the PA, they can control the distributed audio visual synthesiser. The parameters available in the interface of our Ableton Live device – including all of the synth settings, light mappings, the spatial control parameters and polyphony policy – work like any other Ableton Live parameters: the musician can pre-program control of these parameters into Ableton clips which can be triggered via the Ableton session interface, or they can connect any MIDI controller in and assign which dials and sliders will control which parameters (Figure 5 - See

Figure 5: Our system incorporates commercial and well-known DAW software and hardware interfaces with simulation techniques and custom software that links these existing music paradigms to media architectures. © The authors.

our videos for details^{1 2}).

As an example, if the musician wanted to have a synth pad emanate from the stage in waves, they could prepare a looping clip that updates the parameter that controls the position of the active zone to fly from one end of the space to another. They could then manually play chords on a MIDI keyboard. Running the clip would cause these chords to fly out from the stage. Alternatively, they could assign an XY joystick to control this position variable, and manually move the sounds around the space.

We have found this setup makes effective use of the rapid workflow available to musicians in Ableton. Rather than programming more functionality into our system, resulting in a more complex interface and codebase to manage, we leverage as best as possible the creative freedom that the Ableton interface allows. For example, it is easy in Ableton to map an LFO to any synth parameter, making it very easy to rapidly mix together different processes to create generative effects. Thus, for example, making moving waves of hue intersecting with moving waves of timbral variation becomes easy.

In addition, our code can easily be hacked, so that the synthesiser design can be updated and redeployed to the network of devices. For example, if the musician wanted the array of synths to have microtonal variation of their frequencies, this is not a feature available in our standard synth, but could easily be added by adding a random variable at the right point in the expression calculating the frequency.

Aesthetic Considerations: How do we play buildings as audio visual synthesisers?

Although we have designed the *Jams in the Hueosphere* system to be as seamlessly integrated as possible into a musician's workflow, sonically the system has very different properties to a regular PA, the speakers are small and have poor frequency response below 200Hz, and each one is powered by just a 3W amplifier. They are housed in custom 3D printed spherical enclosures that amplify well. This should also not be thought

¹<https://cloudstor.aarnet.edu.au/plus/s/ySXyK19veb1Nj2h>

²<https://cloudstor.aarnet.edu.au/plus/s/2sqoK689DpwL9Rx>

of as similar to existing wavefield synthesis systems as the audio signals to each of the speakers are not tightly synchronised to create specific audio effects. The sound field of the speaker array creates a special acoustic canopy that is distinct in the way that the distributed array creates multiple interfering sources. Rich pads, noisescapes and clusters of sound are rendered with a spatial richness that is distinct from a standard PA. Reverb and delay-type effects can be created through the movement and slight temporal delays of sounds. Careful sound design can create playful effects where the sound leaps from the stage. The experience can also be more interactive for audiences, who by moving around the space, can seek different 'stances' on the soundscape.

With the resistance of the stereo PA convention to disruption from new technological possibilities, we view this field of experimentation as an aesthetic niche first and foremost, rather than a contender to challenge how live music is rendered in the mainstream. However, this paper has shown how the technological affordances, and associated constraints, of rendering sound through massive networks of remote computational devices, both invite and demand new ways of thinking about digital music and its situatedness in space. Beyond our own experimentation, the system is awaiting its first deployment in a public space, having been deferred due to pandemic response restrictions in NSW, Australia. Our initial thoughts on the effectiveness of our designs and the creative possibilities that will be most effective, are being tested soon with a cohort of live musicians who have been commissioned to create new works with the system. Our philosophy of curating such performances is grounded in an ongoing examination of the relation between sound, space and musical aesthetic. We will explore how our system works with different sized PAs, musical minimalism, free improvisation, acoustic instrumentation and different configurations of our system throughout original spaces.

Conclusion

We have presented an approach to expanding live music performance to new forms of sonic media architectures. The technological solution space we have explored, driven by cost, flexibility and scalability, actually pushes us from thinking about such systems as distributed audio visual synthesises rather than PAs and displays. When embedded in spaces, these systems in turn evoke the idea that the space itself becomes a playable audio visual synthesiser.

Oliver Bown is an Associate Professor at the School of Art & Design, UNSW Sydney, and co-director of their Interactive Media Lab. He researches creative technology practice and is an electronic music maker. He is the author of “Beyond the Creative Species: Making machines that make art and music” (MIT Press, 2021).

Kurt Mikolajczyk is a musician, composer, and creative coder currently undertaking a Ph.D. in interaction design at the University of Technology Sydney. In 2019 he completed a Masters of Music at the Sydney Conservatorium of Music,

developing software tools for composing polytemporal music and a portfolio of works for jazz ensemble and laptop.

Sam Ferguson is a Senior Lecturer within the School of Computer Science and co-director of the Creativity and Cognition Studios at the University of Technology Sydney. He has a background in music performance, cognitive science, and psycho-acoustics and acoustics. He focuses on sound and music and their relationship with creativity and human experience, in contexts such as installation art, creative coding, and machine learning, as well as focusing on cognitive science. He has more than 80 publications in areas as diverse as spatial

hearing and loudness research, data sonification, emotion, and tabletop computing.

Benedict Carey's work branches aspects of computer science, musicology and cognitive science, focusing on analysis and creation of unique forms of music notation. Currently he teaches interactive media, rapid prototyping, music and sound production at the University of Technology Sydney and University of Sydney, is a research assistant in the Interactive Media Lab at the University of New South Wales, and is completing a doctorate in musicology at the University of Music and Drama Hamburg.

Possibilising Performance through Interactive Telematic Technology: Mental Dance

Carol Brown, Monica Lim

University of Melbourne
Melbourne, Australia

carol.brown@unimelb.edu.au, monicaml@student.unimelb.edu.au

Abstract

Mental Dance engages audiences in modes of performance that call attention to multiplicitous dimensions of the present. As an interactive improvised dance-sound-tech event, we invite perceiving attention to the mutable present as always already shaped by perception, prior experience, cognition and corporeal change. Neuroscientific research underscores our approach to a digital interface that proposes new relations between audience and performer as a result of repeated COVID-19 lockdowns. Using MediaPipe pose estimation technology to track dancers' movements from webcam feeds, we directed telematic rehearsals and performance of the work on Zoom where dancers in their home environments sculpt and respond to sound in real-time. Constraints such as forced isolation, lack of access to technology and space to move, were embraced to create a new type of collaborative performance where the screen becomes the stage and the interface between movement and sound. This workflow can be used to enable interactive telematic performance where collaborators are unable to be in the same physical space with no specialist hardware requirements.

Telematic performance, choreo-sonic, interactive dance, neuroscience, machine learning, embodied sound .

Introduction

Throughout 2020 and 2021, Melbourne, Australia was under strict lockdown for more than 245 days as a result of COVID-19. We could not leave our homes except for very specific reasons. All creative studios, performance spaces, universities and most workplaces were closed. At the time, we were developing an art-science collaboration where neuroscientific research into human cognition was used as conceptual reference for an interactive dance performance using wearable sensors. We were interested in the choreo-sonic and cognitive aspects of the relationship between movement and sound where the

movement creates and/or changes the sound, and how this resonated with neuroscientific concepts such as predictive coding and the Bayesian brain. [1]

Lockdowns meant that we could no longer collaborate in the same physical space, nor use wearable sensors such as accelerometers, gyroscopes, biophysical sensors or other devices such as infrared cameras, as the dancers did not have access to the required computer programmes or specialist hardware. To enable ongoing development, we had to harness ubiquitous technology that everyone could access. All collaborators were familiar with video conferencing apps such as Zoom, so using the video feed from Zoom for movement-tracking was identified as the easiest way to build the interactive system. The criterion was not accuracy, but accessibility and ease of use.

Thematic Concept

The project¹ begun in 2019 as an open-ended inquiry into how neuroscientific concepts can inform and be integrated into a creative process. The aim of the research was to delve into the possibilities of diverse combinatory elements – data, dance and sound – to create new forms of expression that generate unforeseen affects supporting and legitimising diverse experiences of mindbody relations. Through various interviews and visits to the neuropsychiatry lab, thematic threads were teased out for further creative exploration. These included current research into neurodiverse cognition for autism spectrum disorder and schizophrenia, and the research technologies used in the lab including EEG, MEG and fMRI. [2] Key phrases from the literature were extracted to inform choreographic scores such as ‘changing states’, ‘oddball’ and ‘past is present’.

In contrast to the diagnostic language surrounding neurodiversity, we looked at the human impact of living with mental illness, such as that experienced by dancers Vaslav Nijinsky and Lucia Joyce. [3] [4] Although we

¹ Recording of an online performance can be viewed at <https://vimeo.com/624934863>.

started in the lab, we wanted to end up *inside* the body with all its mechanosensory neurons and limbic emotions.

Collaboration

As inter-disciplinary artistic researchers, we were interested not only in the creative outcome, but the processes used for collaboration and development.

The collaborations were multi-layered, cross-feeding into each other in an iterative process over 18 months. Ideas formed in one session were taken up in other directions to create a matrix of material-data combinations. Figure 1 illustrates the collaborative links formed between all participants and their areas of mutual influence.

For example, references to Nijinsky’s iconic gestures in the choreography became an impetus to use Stravinsky’s *Rite of Spring* polychord as a sound sample. Neuroscientific concepts around human learning and predictive coding led to an exploration of unsupervised machine learning to categorise and map sound, resulting in a tandem performance by humans and machines simultaneously learning movement-sound relationships. [5]

Figure 1. Collaborative links formed between participants.

Performance instructions on breath and phrasing for the vocalist became part of the movement score. Interview transcripts with the neuroscientist became part of the vocal text. Bird sounds used in the EEG oddball auditory test became inspiration for sound samples and movement gestures. The responses of the dancers and the words used to describe their experiences were recycled and reframed into movement and sound ideas. This process of forming and becoming through cross-modal experiences led to an emergent outcome shaped by all participants.

Project Design

Telematic Technology

Rehearsals and performances were held over Zoom. Video feeds of the two dancers were screen-grabbed in TouchDesigner and rescaled to half their original resolution to improve performance.

TouchDesigner was then used to implement a Python script to run MediaPipe on each video feed. MediaPipe is an open-source framework by Google for building cross-platform machine-learning pipelines. [6]

In this case, we experimented with MediaPipe’s Face, Hands, Pose and Holistic (which combines Face, Hands and Pose) models. Holistic is the most comprehensive pipeline, enabling tracking of 543 landmarks on the body (33 pose landmarks, 468 face landmarks and 21 hand landmarks per hand). However, running two holistic pipelines in real-time was computationally expensive, leading to an unacceptably low framerate. Tracking fine detail of the face and hands was also less important for this project than overall body landmarks, so the decision was made to use the Pose model only (see Figure 2 and Figure 3).

Figure 2. Pose Landmark Model © 2020 Google LLC

Figure 3. MediaPipe Pose landmarks on Zoom video feed.

The Python script was adapted from code released by MediaPipe and the TouchDesigner implementation by Bryan Chung. [7] Selected landmark co-ordinates and joint angles were sent via OSC to MaxMSP for real-time sound processing. Audio output from MaxMSP was streamed to all collaborators and audiences on Zoom using the Loopback virtual audio device.

Choreography

Choreographically, the performance evolved through movement scores that became increasingly precise as the dancers and co-directors continued to develop and refine these during rehearsals. The dancers' sensorimotor skills and corporeal imaginations were continually being tested by the sound and the words being sung in the vocals. Their interactions with the sound relied on perceptual feedback and feedforward loops. Relations to pitch, timbre, voice, text, tempo and tone shaped and structured movement and action within a choreographic dramaturgy that was developed across four states or scenes: *Neural Networks*, *Noisy Voices*, *Lucia* and *In My Head*. Given the unfamiliarity of the dancers with the telematic environment they were working in, and the fact they could not see or sense each other (kinaesthetically, haptically or through breath exchanges), we relied upon coming to know the structure of the improvisation and referencing the gridded image of their partner through the screenic interface. This shaped a sense of parallel worlds that across multiple rehearsals grew to become intuitively relational. The multi-dimensional and multi-sensory habitus of the dancers performing in their home environments contrasted with the screenic interface with its two dimensional rectilinear framing. Choreographically, we played with proximity and distance, the tactile and the remote, opening vectors of relation across physical and virtual dimensions and pushing the apparatus to behave differently beyond the norms of the Zoom platform. Both dancers, in becoming habituated to each other's movements across rehearsals, developed a synergy which enabled them to shape the choreography from inside the system. We related this to the theme of neural networks as if the 'brain' of the dance was being lived in the sphere of these more than human relations.

Sound Design

The sound design had 4 priorities:

1. Using live vocals as a primary sound source.
2. Ability to convey conceptual links to the neuroscientific ideas.
3. Ability to respond to and express movement.
4. Capacity for dramaturgical development.

The emphasis on using live vocals arose from the impetus to research perceptual feedback loops between dancers and vocalist in addition to any digital feedback systems, allowing more layers of interaction and novelty to emerge. This interest in the *human* working in tandem

with the *machine* resonated with the conviction that advancing human betterment should be a central concern in all neuroscientific and technological advances, whether that be research into consciousness, neurodiversity, or Artificial Intelligence. The field of interactive sound-design is also dominated by digitally synthesised sound, and we wanted to expand the ways in which the classical and acoustic traditions could engage with new technologies. The use of Baroque countertenor technique in the vocal score (e.g. ornamentation) coalesced with granular synthesis controlled by movement, collapsing binary distinctions between human and non-human, old and new.

In developing text for the vocal score, phrases from Nijinsky's diaries were combined with scientific language from the literature and interview transcripts using a Markov chain generator. This produced unexpected combinations of technical and intimate language, a kind of technologically-mediated poetry. Selected text (e.g. 'deficit following brain', 'efficient white matter') was also used to improvise and develop movement.

However, the use of vocals as a primary sound source introduced constraints when designing the sound's interactive responsiveness to movement. These constraints include limited frequency range and timbre, as well as inconsistent gain and timing. Therefore, subtractive synthesis or spectral processing techniques were not effective. Instead, granular synthesis was used extensively for vocals, and this was combined with other digital processing techniques such as harmonisers and delay lines. Additional sound sources were added to create more layers of interaction with movement as well as to support dramaturgical development. These included sampled sounds manipulated through concatenative synthesis and filtered waveforms. Although the audio output was limited to stereo on Zoom, binaural sound spatialisation was implemented to accentuate movement.

Mapping

Mapping design has been extensively researched and shown to be vitally important to how an interactive system engages its participants, as well as the audience. [8] Whilst the focus of our sound design prioritised the integration of live sound and thematic concept, effective mapping was still required to give the dancers a sense of agency and control, and sufficient transparency for the audience to understand the movement-sound relationships.

Mapping movement using MediaPipe from a single webcam represented particular challenges. Critically, the depth (or z-axis) in the Pose model is an experimental value based on the depth of a particular landmark relative to the user's hips, rather than a true 3D value. [9] Therefore, it was difficult to compensate for the dancer's distance to the camera in analysing movement. The same movement or gestures produced wildly different results depending on the depth and orientation of the dancer to the camera.

A number of strategies were employed to mitigate this. Firstly, MediaPipe has the ability to output real world coordinates in metres with the origin as a point in between the hips, rather than relative to the screen as its default. Therefore, where the dancers' distance to the screen varied significantly, the world landmarks were used.

Mappings that produced specific effects were also limited to choreographic sections where the dancers' distance and orientation to the screen were consistent. For example, one section of the work allowed the dancers to adjust the gain depending on the distance between their wrists. Putting their hands together turned off the sound completely. This mapping relied on knowing that the dancers would sit down facing the screen for that entire section.

Using joint angles rather than absolute distances or rate of change measurements of coordinates (e.g. velocity, acceleration) also created more flexibility in dealing with differences in scale. However, the same pose with different orientation to the screen also resulted in very different joint angle data.

Therefore, where the dancers moved back and forth across the screen, a more general and forgiving mapping strategy had to be implemented where sound parameters would change with movement but did not rely on particular gestures or orientation. This included changes in filters, granulation parameters or pitch-shifting. This was particularly important where dancers would sometimes go off the screen completely or only had parts of their body onscreen with no facial information, as this would result in MediaPipe outputting no landmark information.

Using machine learning was also effective to create responsive and often unpredictable relationships between movement and sound, without requiring any explicit mapping of specific movement parameters to sound.

One advantage afforded by MediaPipe's Pose model is its ability to predict landmarks even where parts of the body are partially obscured or out of the screen, as long as there is sufficient information to recognise a pose region-of-interest (typically, a face). Therefore, provided the mapping design was flexible enough to utilise outlier values, the sound could still interact with movement where the dancers were only partially onscreen.

Conclusion

The research culminated in two public performances, one on Zoom and the other on Microsoft Teams. Through performance, the interdisciplinary layers of the work were manifest and made accessible to a globally distributed audience. The performers, though dancing at home, noted how performance nerves were present and how the experience of dancing telematically held a similar state of attention for them to traditional staging. We use the term 'empathy machine' to describe the sense of relatedness the tracking of attention through distributed cognition and corporeal activations demanded. The feedback loops and shifting improvised relations between dancers and data generated a constantly evolving expressive terrain that

audiences were invited to perceive and respond to. Audience feedback on the performances was overall positive, with most people reporting positive engagement despite the onscreen delivery. The use of domestic spaces received mixed feedback, with some in the audience enjoying the 'intimacy' and 'immediacy' of 'personal 3D spaces', whilst others found the 'home background distracting and diluting the emotional impact'. Many in the audience were intrigued by the technology and its potential for further exploration, both in performance and pedagogy. They were also interested in 'trying to figure out' the mapping design, and the impact on the sense of collaboration where movement by two different dancers in different spaces affected the same sound.

Although our shift to remote collaboration was forced by external circumstances, the exploration of a new mode of working resulted in us viewing the online rehearsals and performances as not just temporary, inferior replacements for the 'in-real-life' version, but interesting and worthwhile in themselves.

Future Development

The telematic workflow described in this paper can be used to create other forms of interaction. For example, audiences can participate to create sound, textual or visual interactions in a workshop, installation or performance context, unrestricted by geography and availability of specific hardware.

Multiple sound and visual controllers can also be networked, creating telematic ensembles. Whilst the movement data does not have the accuracy of mocap and is subject to latency, the system's ease of use and accessibility for anyone with a computer and internet connection make it a useful alternative for generating digitally-mediated human interaction.

Emergent

A post-pandemic living mobile gallery

Abstract

This project emerges from a series of reflections about the state and the potentials of the arts and their exhibition spaces in post-pandemic times. The pandemic of 2020-21 forced many galleries and museums to shut their doors for several months or forever. These closures have created a void in social gatherings and cultural events, urging artists and cultural workers to rethink ways of making, exhibiting and bringing their work to the general public. Now that the world slowly re-opens to social gatherings, we wonder whether we should re-invent the role of the gallery as an enclosed space altogether, by freeing it from the constraints posed by its traditional spatial and cultural configuration (real and virtual), and redesigning it as a multipurpose mobile object in dialogue with the city and its human and non-human dwellers. This choice is in part inspired by the first artworks and specimens this gallery will carry: a project at the intersection of art and science exploring “new life forms,” that is, living and imagined organisms emerging from digital, laboratory, and environmental contexts. The mobile gallery then acquires a new meaning: it is not just a new safe exhibition space, but also a space where emergent life is both debated and created, as well as an emergent “life” on its own.

Keywords

Emergent life, mobile gallery, postpandemic gallery, multispecies communication, relational aesthetics

Introduction

“Emergent” is a research creation project initiated in 2018, exploring ways in which we can better comprehend and, importantly, cope with, emerging life forms. Examples of these life forms can be found in the real world and in the digital world, resulting from digital world-making and artificial intelligence¹; from climate change-induced mutations and adaptations and from lab manipulation and fabrication of organisms². The project sought to foster dialogues between scientists and artists engaged with these subjects to various degrees and from different perspectives. This could be achieved through lab visits with the goal of sharing research and methods, as well as through public meetings and debates. Overall, Emergent asks the participants to take note of multiple stories built through layered and disparate practices of knowing [1] and invites them to “stay with the trouble” [2], that is, to purposely cross boundaries and collaborate outside their comfort zone and their preferred disciplinary realms. The project seeks to extend the dialogue to a larger public: in fact, its goal is to make space for reflections across different experiences and sites of divergence through and, importantly, with the arts – not with the arts as an addition or an afterthought – that would convey (not explain or illustrate) the dynamic forces converging into, and traversing, new, imagined, and difficult-to-study life forms. Thus, the project was expected to culminate in an interactive exhibition showcasing collaboration notes, objects and specimens, as well as artworks originated from, or illustrating the findings generated during the research phase. However, the

¹ For e.g. Artificial Natures, a series comprised of biologically-inspired complex systems to be experienced in immersive mixed reality and created by Graham Wakefield and Aru Ji (<https://artificialnature.net/>)

² For .g. organisms produced by synthetic biology, which prompted artist and designer Alexandra Daisy Ginsberg to propose that a new

kingdom, the Synthetica, be added to the three traditional kingdoms of life (bacteria, archaea, eukaryota); or genetically modified organisms such as GM mosquitoes, or the glowing rabbit Alba, conceptualized by transgenic art pioneer Eduardo Kac.

pandemic brought the initial plans to a halt as galleries suddenly had to shut their doors.

The sudden closure and the following online art race filling our home screens revealed that alternatives were urgently needed: new ways of doing art, reaching new audiences, and (re)inventing future spaces for the dissemination and enjoyment of the arts. These concerns became particularly relevant for the Emergent project, since its primary goal is to bring different voices together in a sustained dialogue. In fact, the unfolding of the pandemic highlighted the need to treat the gallery as an emergent space itself rather than just a venue.

The result was, for our team, a complete rethinking of what the gallery space means and represents: in a disrupted world where the need for safety limits the need for physical interaction, what would alternative formats, new forms of interactions, new safer and more inclusive spaces look like? Can we take the gallery to the streets and turn it into an emergent space? What possible experiences, what new dialogues can a redesign of the gallery as a living, breathing entity foster?

1 From the white cube ...

1.1 The city and the gallery

The notion of the white cube, a “sterile, windowless viewing room... a way to maintain neutrality while viewing artworks” [3] has been the assumed symbol of the traditional gallery and the main reference of the art world for many decades. However, the white cube was never the only place where art happened. Many artists have elected the streets, the city, their bedroom, the forest and the environment etc.. as their preferred stage.

Galleries and museums too have frequently exited their designated spaces and ventured outside, promoting public art, and commissioning large scale and site-specific installations. The Nuit Blanche franchise is one such event that brings a plethora of artists and cultural events to the masses, celebrating the city as an open, comprehensive gallery site. Public art has used the full range of media available, such as video projections, LED panels and responsive light fixtures, and variety of building materials such as wood, metal and plastic. Sometimes, these installations are simple performances with little, or no props, or technological support at all; sometimes, they experiment with new technologies or with repurposed materials fabricated in DIY fashion. Pioneering artists such as Barbara Kruger built large scale billboards, which covered the

facade of buildings with bold messages [3]; Krzysztof Wodiczko created spectacular and politically sensitive projections erected with the idea that “Monuments can be used for the living.” [4]; Rafael Lozano-Hemmer built interactive installations meant to engage the public and to evoke reflections on community engagement, politics, and technological impact [5]. By populating cityscapes, neighbourhoods and public buildings’ facades, these works have produced meaningful collective reactions, debates, and community engagements. LED screens and projection technologies have been gleefully adopted by many institutions and museums as a way to reach new and numerous audiences outside of their enclosed spaces. Some installed large screens on their facades; others populated cities’ billboards with colorful and joyous art, or with political and empowering messages [6].

1.2 Emergency plans under COVID19

Most of the above artworks were the result of well-planned commissions, and patient entrepreneurial efforts spanning years of programming and negotiations. But what happens when, all of a sudden, institutions have to close their doors mid-season?

The closure, it became clear, was not just temporary. In fact, after a short period of inactivity, many galleries and cultural organizations started to make emergency plans to continue a limited portion of their programming activity. Most galleries and cultural organizations moved online; the web was taken by a frenzy of events, mostly quickly-combed-together, often low budget, frequently performed on inadequate, yet readily available combinations of platforms such as Zoom, Skype, OBS, or Crowdcast. Sometimes pressured by funding agencies, many galleries engaged in a frantic race to reproduce their collections in a virtual format, offering virtual tours, online exhibitions and artist talks, or gamification of existing or already in-progress exhibitions.

A number of commentaries and articles observed how by preserving existing and pre-programmed work, rather than pressing pause to rethink their formats, institutions and galleries appeared to be understandably preoccupied with “keep[ing] things ticking” [7]. Clearly the products of unexpected circumstances, or the results of cultural and administrative pressures to fulfil their programming obligations to “keep going”, many of these events looked rushed. In general, they revealed little desire or little time to

open up discussions regarding a – realistic or imagined – post-pandemic scenario.

Several months into the pandemic, many galleries and art institutions appear to have decided to invest more in remote experience. In part, this comes out of fear for predictions regarding a possible decrease in the attendance of in-person events. An article in Financial Times asserts: “The most natural change in an era when human interaction is suspect is for galleries to bolster their digital presence” [8]. Apparently, change is already happening in major cities like London (UK), where “some galleries are changing their footprint, abandoning expensive street-level locations for an upper floor”. The Smithsonian Magazine suggests that in addition to building a more robust online presence, museums will have to think about new ways to reconfigure their architecture, in order to not run the risk of “becom[ing] cemeteries for objects that should actually be lived in the piece of architecture [9].”

1.3 A “licence to experiment”

One of the things that’s happening with the pandemic, the author suggests, is “the license to experiment”, which could lead to different exhibition formats, or a redesign of spaces inside museums and galleries. In fact, both the circumstances and the reaction that ensued called for a serious rethinking of what an exhibition space is and does.

Still, many decided to heavily invest in their online presence and to take advantage of new funding schemes encouraging to do so. For most museums and galleries, the solution appeared to always be inwards, that is, to remain within the institutional space (in the case of online exhibitions) or the space of the gallery or museum itself. This is also apparent in the way, upon slow reopening, many galleries have initiated new outdoor public commissions and site specific art interventions. These new initiatives take the gallery outside. However, they often remain part of an official and institutional programming meant to be visited and consumed by the very public that used to attend the gallery during pre-pandemic times.

In a post-pandemic world, as challenging as it sounds, a need for (re)socialization is crucial. In fact, never have human beings been craving each other’s physical presence like in this moment. Thus, some artists and independent art centers –usually smaller or with more fluid structure – decided to take a different direction. These artists found no use in reproducing collections and exhibitions online: their community-centered mandate suggested that simply

projecting themselves online could be potentially unproductive if not accompanied by a series of reflections on accessibility, community making and interaction [10]. Art can play an important role in creating new forms of safe resocialization by reaching out towards the public, rather than waiting for the public to come and get it. The solution, in this case, could be to transcend the gallery and allow the arts to spill into the city, thus helping reanimate and transform its urban space.

2 ...To the city square

2.1 The city as canvas

A few months into the pandemic, and with the reopening of galleries not in sight, there have been a number of original initiatives from independent organizations and individuals to physically bring back the arts to the city, rather than waiting for the city to allow the gallery to reopen. A variety of artworks, installations, videos, projections and performances made their appearance around neighbourhoods. These works initiated by art communities circulated around neighbourhoods and downtown core, claiming the city as their "canvas". Toronto hosted a series of art happenings under the name 'It's All Right Now' organized by The Bentway and curated by Black Speculative artist Quentin VerCetty [11]. The series consisted of commissioned texts describing the experiences of living under COVID19 in disadvantaged areas of the city: these texts populated billboards, were circulated on video trucks and appeared in posters around the city. In Mexico, Latin American art and activism collective Articulo protested national healthcare limitations in Mexico and Argentina with projections on buildings’ walls in various neighbourhoods [12]. In New Orleans, a performance truck titled Reality Breaker, brought colorful carnivalesque sceneries to different parts of the city by announcing and documenting its daily trips on Instagram [13]. In several cities, projections of Classic movie clips and video art animated the walls of apartment buildings during the days of strict lockdown. Pop-up performances across balconies, in parks, and in front of porches provided moral relief, tributes to the front line and essential workers, entertainment, and social and political commentaries. Across Europe, pop up mobile devices made their appearance around inner-city neighborhoods bringing art and performances, books and readings.

What characterized the experimental spirit of these initiatives was their mobile nature, spontaneity, and flexible structure. Most of these activities were seemingly attempting to bring the arts to the community, in part to provide comfort, in part to rekindle the relationships, the casual encounters and the sense of human connectedness and kinship that the pandemic had severed. Judging from the way these activities were welcomed, the neighbourhoods touched by them appreciated the gesture: even if for a moment, the deserted city came to life, and the gallery, this time on wheels, on temporary canvas, or on stilt would fill the streets, generating timid but enthusiastic crowds who politely and very carefully enjoyed the artworks while passing-by or observed them from the safety of their balconies and their doorsteps.

2.2 Re-building the gallery

Most of the above events were the products of extemporaneous ideas, that is, they were not generated from previously planned programming: they had an improvisational and fluid structure that allowed them to adapt to different spaces, to respond to specific and more urgent circumstances. But this fluidity is something that emerging and independent artists are very familiar with. While more established institutions and artist run centres preprogram their exhibitions a few years at a time, this is not the case for emerging artists. The absence of continuous funding makes it more difficult for them to make long-term plans and projects. Thus, their activity tends to have a more flexible nature. The lack of conventional exhibition space was partially solved by opting for venues such as abandoned and unused spaces, barns and cabinets. In turn, these venues often provided exclusive access to different audiences and more intense community engagement.

Because of the pandemic, galleries and museums found themselves temporarily evicted from their own home. Their reaction was not to think of alternative or to look for unexplored spaces, but to turn a place that already existed into something else. Re-building the gallery as a virtual place is not only encouraged by experts, donors, and funding agencies, but is also the first, and easiest way to revive the original physical space. In other words, their fate is unavoidably entangled with the space they were occupying before the pandemic.

2.3 Going mobile

For those of us whose work depends on, and benefits from, ongoing dialogues across disciplines, individuals, and communities, building a virtual presence is insufficient. This has become an important issue for the project Emergent. In fact, while enhancing existing traditional website-as-archive is important, it does not provide an important type of connection standing at its core.

Emergent encourages the fostering of “transdisciplinary hermeneutics’ whereby a symbiosis between different ways of knowing the world may be developed” [14]. Transdisciplinary hermeneutics could be articulated in different ways. First, as a project combining scientific specimens and research documents alongside artworks, it seeks to overcome what Kagan called cisdisciplinary knowing, that is “to mistake situated and partly valid knowledge and learning made possible by any given discipline, with a complete and self-sufficient access to knowledge of the world.” Second, ways of knowing are also situated. Therefore, Emergent also seeks to open dialogues originating from what de la Cadena calls “sites of divergence”, that is, those elements of disagreements pertaining to what constitutes knowledge that “could not be solved without undoing what each of the groups were in relation to their interest in common” [15].

Divergence, de la Cadena suggests, does not equal difference, but goes deeper. Sites of divergence imply that different parties have “interests in common”. However, the system of knowledge they belong to connects these interests in common to different practices and activities. The dialogues created by, and through, these sites of divergence are important because they become “an opportunity for the creation of concepts different from those [that] every participating knower brought to them.” In order to realize a multifaceted dialogue that not only overcomes disciplinary and education differences but also creates new discourses and understanding starting from sites of divergence, in-person confrontations, or close encounters discussions are very important. In fact, they can reach maximum power and intensity when they are conducted in person or are immersed in specific situation. As a matter of fact, they become even more necessary as long periods of physical distance and excessive screen time emphasizing the sense of sight have led to sensorial deprivation and intellectual isolation.

Inspired by earlier independent pandemic responses, which directly immersed themselves in and merged with the fabric of the city, we decided to take Emergent to the street.

The mobile gallery offers more than just an opportunity to initiate new, unexpected dialogues about emergent forms of

life. It might generate discussions about how we want to repopulate the city in a post-pandemic context and how it will look when habits and routines have been interrupted. This unique gallery concept may challenge how public art is consumed and may question the traditional configuration and the significance of the gallery as we know it. In other words, this mobile gallery might become emergent, just like the organisms it carries.

Figure 1 A view of the Mobile gallery from above

3 Post-pandemic anxieties

3.1 Unknown futures

Pei-Ying Lin is an interdisciplinary artist whose long term-project focuses on viruses and viral phenomena. Throughout a series of installations, she asks a recurring question: is it possible to domesticate a virus? and how? Can we become more resilient or more resistant to it [16]? One of her recent works consist in a performance during which dancer and choreographer Hsin Yu Chang gracefully dances through and avoids objects and appliances potentially infected. knowing the risks and using cautions is also a form of coexistence and cohabitation [17]. Lin's questions invite us to reflect on how we can cope with an immediate reality that may be virus free, but not anxiety free.

As lockdowns will be slowly lifted in a (hopefully) not-so-distant future, we might be left with anxieties about new social rules, and fear about new pandemics [18]. Months of physical distance have marked our bodies in significant

ways: we might burn of desires to socialize, touch and hug again as some epidemiologists have suggested, leading to a period of intense socialization similar to the “Roaring Twenties” [19]. However, the opposite might be true. Fear of contracting the virus might leave people with anxiety or what psychiatrists have defined as *Coronaphobia* [20]. This has been a major concern for the creative industries, leading them to major investments in virtual infrastructure. Regardless of which scenario will self-realize, we will probably have to deal with a period of transition during which our bodies will constantly make us self-aware of our distances and will make us feel vulnerable when we are in a public space. Challenging our discomfort by finding new, safer, way of socializing, of reclaiming public space, of making and celebrating art in the public might be the way we defeat the pandemic (and domesticate the virus). What risks are we taking when we try new ways to face our “new normal”?

3.2 The new gallery

During a performance/video titled “staying in touch: post-coronavirus art curating” the five artists converging in the virtual residency “Braiding Fiction” developed a speculative fiction in which art is the virus and art practitioners act as frontline workers. The result is a fictional interview with the curators offering a series of important reflections on the future of art, the gallery and human proximity. “I would rather die than live in a world where art spaces are closed.” Exclaims AN (Anise Neuchâtel) one of the curators of a fictional exhibition. Her expression contains a subtle criticism of the rush towards going exclusively virtual by most galleries and museums during the pandemic. “There is no old normal.” “... there is no normal.” While we must continue to exhibit art, attempting to return to a pre-pandemic order is unlikely, if not impossible. Therefore, it is important to continue to find new ways of collecting, curating, disseminating art. Another fictional curator, VL (Vess L) explains that the idea of art as an isolated object may be outdated in a post-pandemic era: “art not only becomes a part of the workplace, it becomes a part of the home, it becomes a part of the infrastructure of a city, it becomes part of the environment in an all-encompassing and really comprehensive way” [21].

With these ideas in mind, the traditional gallery with its four walls may one day become obsolete, its space become one with the city, merge with its streets, its buildings, the non-human habitants that have reclaimed back its spaces

during lockdown, and maybe even a new species of humans, radically transformed by the experience of isolation, at first fearful, then increasingly confident [22, 23].

As many galleries and museums invest online, change their indoor configuration to provide a safer exhibition

4 Mobile visions

4.1 Not a white box on wheels

Imagine a gallery in a not-too-distant post-pandemic future. Instead of collecting its artifacts into an enclosed space delimited by four solid walls, this gallery moves easily on wheels, adapting and interacting to its surroundings. The gallery take artworks around for a stroll, making appropriate stops to give the audience a chance to spend time with its content.

But this gallery is not just another white box on wheels. Instead of allowing the spectator only watch and observe, it encourages them to connect, interact, and play with its artworks, specimens, and documents; to engage in discussion with random passers-by; to act as connectors between the artworks, the mobile gallery, and the city. Conceived over several months and brainstorming phases, we designed *Emergent* as a living and breathing creature.

In fact, it could not be otherwise: its mobile/travelling nature requires its design not only to adapt to different

experience, or transfer some of their content to their courtyards, how can we make space for the arts in the city and use them to help re-build it and re-socialize it?

environments in different cities, but also to welcome a variety of artworks. For this reason, the gallery must contain modular parts that can be modified and moved to adapt to different circumstances. In addition, participants should be able to manipulate some of these parts so that they can reach and adjust them to their (physical and psychological) needs, allowing them to experience its content equally.

Because the gallery is meant to circulate in a public space, it should welcome different types of interactions. This is even more important in a post-pandemic situation, as participants may be experiencing anxiety to approach artifacts in an exhibition or become closer to other individuals. In the case of *Emergent*, the participant can stop briefly and simply admire the artworks, or can spend time to discuss their significance with other passers-by or with the artists. The mobile nature and modular design makes it possible for people to observe the artworks and the gallery from afar, or come closer.

The goal of *Emergent* is to establish multiple and different dialogues between audiences with different education and disciplinary interests, and audiences with common interest but different approaches to life and to the arts. To draw a variety of visitors and to better integrate the gallery with the urban texture of the city, the design is relatively simple and non-intrusive, yet enticing. The use of projections and user-friendly familiar technologies aims to better connect the gallery with the surrounding context and textures.

Figure 3. A preliminary model of the Periscope

The gallery contains a variety of artifacts and specimens, documents, material objects, and technologies that not only reflect and appeal to different disciplinary interests (natural science, different forms of art, academic documentation etc..) but also different activities and approaches to creative work (play, reflect, observe etc..). To this end, the gallery is organized in two main spaces: a more traditional space with a system of modular and movable boxes for exhibiting small and medium artifacts, and one devoted to exploration and experimentation. Inside the latter there will be light boxes with small artifacts and a periscope to allow viewers to explore the content of three petri dishes. This space is also equipped with mirrored projections which will be visible by looking through the peepholes strategically located at the front.

This structure is meant to be flexible. More specifically, it is designed to join in a dialogue with the artists and the artworks it carries, by adapting to their work, and by asking them in turn to adapt to its portable nature. Its appearance and structure may change too. In fact, Emergent was designed with modularity in mind: in this way, parts can be modified and adapted to accommodate different artworks.

Now in the prototype phase, Emergent was conceived with two main ideas in mind: sustainability and (human and multispecies) dialogue. During the brainstorming phase, we have become especially aware of the potential carbon footprint and the costs of transportation of this artifact, even despite its relatively small dimensions. This issue could be partially solved by creating a design that can be fabricated and assembled on site, rather than shipped. This solution would easily lead to using locally sourced material and to curatorial additions. A second solution would consist in creating a design that uses sustainable material and a compact package that can be easily flattened and reassembled. In both cases, the gallery becomes an artifact that local artists and curators must care for. In fact, every time the gallery travels to a new place, its content and fabrication would be entrusted to the care of different individuals who become accountable and responsible for its “well-being.”

Ultimately, Emergent is a socio/technical experiment devoted to act as a catalyst for heterogeneous and diverse dialogue, as well as renewed socialization. Will people stop by and admire the artworks it contains? Or will they be suspicious at the insufficient sanitation and physical distance it offers, fearing its exposure to numerous different environments? Will they take its passage and interactions as a way to rekindle human relationships with other strangers?

Aren't the casual encounters this gallery will facilitate similar to when we queue for an Americano or a sold out show, or when we sit on a bench reading a book and joyfully conversing with strangers? Could this artifact help us recover trust in each other and start repopulating the city differently, that is, in a more respectful, sustainable way?

4.2 Relational aesthetics

For Bourriaud, "producing a form is to invent possible encounters; receiving a form is to create the conditions for an exchange" [24]. Relational aesthetics sees art as a place of discourse where ideas are not only presented but also experienced. What we envision by creating this mobile gallery is a shared experience emerging between the audience and the artworks, between different members of the audience and between the mobile gallery itself and its surrounding environment.

According to Paiva and Cachinho, whether being located in a traditional gallery or roaming the streets, “artistic forms and practices always emerge in dialogue with their places” [25]. While the exhibition remains the same, we consider the mobile gallery a porous object, affecting or permeating the places it visits, changing the way they look and feel, setting dialogues with and among new audiences. In turn, the context and the space surrounding it will affect the gallery by investing it with new meaning.

We want the Mobile Gallery's structure to be both a dynamic vessel and an artwork. Displaying art can have a substantial influence on the spectator based on its delivery method. Thus, we aim to facilitate access to art through participatory engagement and interventions in urban spaces rather than through just looking from a distance. In the past, works like Pad Thai by artist Rikrit Tiravania [26] and Dongdaemun Rooftop Paradise led by Chan-Kook Park [27] engaged with the public as an intervention and created a shared experience spectacle. At the very core, space and intervention became the heart of the social, cultural, and artistic discourse. Such socially engaged art practices invite unexpected engagements and reactions from everybody involved. They consist "of collaboration and encounters in which the aesthetic perspective of art challenges conventional viewpoints and exposes different ways of being together" [28]. We see the mobile gallery fulfilling such a role as community-engaged art and social spectacle, by allowing dialogues between the public and art and the numerous and unique narratives that will unfold in-between. Furthermore, we have designed the gallery to

allow gallery-goers to construct their own space and arrange artworks: in fact, the gallery is no longer constrained by walls, but will spill into the surrounding space, into the square, it will use the buildings as screens, and the streets as its texture.

As mentioned before, art has occupied public spaces for a long time. In fact, it is no news that planners and urbanists have been very interested in using the arts to intervene in urban space, not only for its economic value, but for its social and atmospheric value. However, as Peters argues, there is "a qualitative difference ... between Flaneuring and inhabiting a system we normally do not know from the inside" [29]. In other words, it is only by experiencing, sensing and being able to explore with others that art can position itself in the realm of human interactions and social contexts. What we hope with this gallery is to stimulate and activate this process of experiential collaboration, by turning it into an artwork in and on itself. By offering this artifact as a safe and inviting space, we hope to initiate new forms of re-socializations.

5 Conclusions

According to de la Bellacasa "The question of how we learn to live with others, being in the world, is an opening to 'becoming with' - to be touched as much as to actively touch" [30]. A mobile gallery can sit there in the middle of the main city square or unobtrusively visit different neighbourhoods without doing much and not offering much incentives for interaction. However, when it is able to suggest stories, to attract people, to meaningfully interact with the space around them, it suddenly becomes alive. With this mobile project, we are imagining ways in which the gallery can thrive in a post-pandemic era, by becoming mobile and by turning itself into an artifact. In this way, the initial goal to create an interdisciplinary exhibition addressing sites of divergence regarding emerging life forms in art and science has evolved into a mission to turn the gallery itself into a new living and vibrant artifact.

While we design this artifact, we are blind. We don't know when the city will be ready to open up to social events. In the meantime, our still speculative project imagines a flexible and scalable artifact that can be easily build in different cities and vary and adapt every time, responding to the city environment, artistic and precautionary (technical) needs, and community access.

We foresee that with efficient social media presence, exciting artefacts and compelling programming, and liaising

with local art events, festivals and cultural venues, we will amass the interest and curiosity from the potential audiences. We want to create a culture of mobile art and be the pioneers who dare to challenge the sterile and stagnant art environment preconceptions. We want to make a platform that serves the community and is fascinating and straightforward. We welcome the public to be an essential ingredient within the mobile gallery concept and execution through reimagining and revitalising city's neighbourhoods.

ACKNOWLEDGMENTS

Emergent is a research creation [Insight Development](#) project funded by the [Canadian Social Science and Humanities Research Council \(SSHRC\)](#). The Mobile Gallery is being currently development thanks to the work and research of three talented Graduate Students and one undergraduate assistant from York University.

The Bartleby Machine

Bruno Caldas Vianna

Uniarts Helsinki

Finland

bruno.caldas@uniarts.fi

Abstract

The idea of disobedient machines is developed from the perspective of artificial intelligence, rather than fiction. Misbehavior in humans and machines is presented as a one of the skills which are indispensable for natural intelligence. Different approaches to AI are presented, from symbolism to emergism. The limits of computational formalism are presented, together with Hofstadter's theory of consciousness. It is argued that a machine cannot reach human intelligence unless it is also able to disobey. Hence, an exploration of algorithmic misbehavior is urgent for further development of AI for the arts and society in general.

Keywords

Artificial intelligence, art, symbolic AI, connectionism, convolutional neural networks, consciousness, Turing machine, volition, machine disobedience

Introduction

The story of science fiction is entangled from the beginning with tales of the misbehaving of entities invented by humans. Mary Shelley's *Frankenstein* (1818), considered by some as the cornerstone of the genre, depicts a creature that evades the control of the protagonist. Asimov's laws of robotics, which first appeared in a short story published in 1942, assume that a robot which follows such rules will never turn against humans. [3]

Yet, this is exactly what happens in *Blade Runner*, the screen adaptation of Philip K. Dick's *Do Androids Dream of Electric Sheep?* In the movie, replicants are androids which had gained consciousness and are fighting for survival while humans hunt them. In such a case, the emergence of a consciousness is a misbehavior in itself; a theme that appeared even in *Pinocchio*, where the wooden puppet gains a life of its own, only to start lying and mocking its creator, Gepetto.

We connect rebellion to self-awareness so much that even the refusal to do conscription service and other duties

is termed "conscientious objection". But how does science face the possibility of a man-made transgressive entity? The field of Cybernetics was created in the early years of computational theory with the goal of developing (in machines) and understanding (in animals) the mechanisms of control of automatic machines. Even if Norbert Wiener never mentions the term robot in the founding book of this science, his interest in feedback systems lays the grounds for development of robotics. The field of Systems Theory is a direct descendent of Cybernetics and, likewise, must face the issue of emergence of consciousness.

The most visible offspring of Cybernetics these days is Artificial Intelligence. Deep Learning techniques yielded impressive results in the last decade, with widespread adoption in commercial applications and sciences from biology to astronomy; it is also of particular interest for art practitioners and researchers.

Curiously, it is the tremendous success of AI that prompted some of its main researchers to notice how limited these results were in face of the main goal of the field, namely the creation of an *Artificial General Intelligence*, the singular event where a machine would have an intellect comparable to a human being.

In this article we will try to identify which role art plays in such tasks. Is it possible to imagine a machine as a creator, before they are even capable of analogies and metaphors? Will a program ever be able to refuse its own algorithm?

Symbolism and Subsymbolism

The different definitions of the capabilities of AI overlap each other and blend themselves with common strategies of the field. One of the most important distinctions is between the techniques that rely on logic and reasoning, and the ones based on massive data manipulation.

AI models based on rules are commonly named *symbolic*. "A symbolic AI program's knowledge consists of words or phrases (the "symbols"), typically

understandable to a human, along with rules by which the program can combine and process these symbols in order to perform its assigned task.”[33] Haugeland suggested the term GOFAI - Good Old-Fashioned Artificial Intelligence to describe the thesis that “the processes underlying intelligence (...) are symbolic”. [18] In the first years after the founding event of this science, a 1956 workshop at the Dartmouth college, that was the focus of the research: computers were learning the basic rules to play checkers, for instance. [5] At the time, researchers claimed that if a machine could learn to play chess, it would “penetrate the core of human intellectual endeavor”. [35]

One of the great challenges this approach faces is that the number of rules that would be needed to reach some equivalency to human intelligence would be astronomic. That didn’t stop the researcher Douglas Lenat to start collecting them: the project Cyc¹ is a massive database of codified “pieces of knowledge that compose human common sense”. [28] The last published version of the database has about 1.5 million general concepts (like eyes, sleep, night) and more than “25 million rules and assertions involving those concepts”.² After more than two decades, the project is controversial: scientist Pedro Domingos called it a “catastrophic failure”, citing the inability for it to evolve on its own. [11] Clearly, the effort to describe the world with formal rules is abysmal. When told a story about a person using an electric shaver in the morning, this system found an inconsistency, since it judged that a person could not have electrical parts.[15] While Cyc might not have brought mankind any closer to general intelligence, it is a successful commercial product with many applications.

But already back in the fifties, another approach was being developed in parallel, based on psychological research, and closer to human intuition and perception than rationalism. The method was initially known as subsymbolic. [24] The earliest example of a subsymbolic AI project is the Perceptron, a visual cognition device created by Frank Rosenblatt, based on the McCulloch-Pitts artificial model of the neuron.[31,39] Despite some early success, the model was very limited, as it could not benefit from the massive processing capabilities of today’s chips; in fact, the Perceptron ran on an analog contraption named “Mark 1”, where each neuron was individually wired to potentiometers. [19:1] More damaging to its reputation, though, was the book published in 1969 by Marvin Minsky and Seymour Papert named “Perceptrons”, where they criticized the limitations of the approach, in special the ability of a single-layer perceptron to implement the XOR function, a simple boolean logical operation that outputs true if the given arguments are different from each other. [32] This shortcoming would prove that perceptrons aren’t Turing complete machines, since the definition of such

machines is that they’re able to compute any logical function. Nevertheless, McCulloch and Pitts themselves had already proposed that stacked layers of perceptrons could be a Turing machine. [31] Also, it was later proved that with the appropriate activation function, even a single neuron can calculate the XOR function. [36] As we’ll see, the most successful applications of AI today use multi-layer perceptrons.

Probably the most convincing arguments raised by the Perceptrons book against this technique is that it would be too computation-intensive and that other strategies could deliver the same results. The first is still true to this day. Training a complex neural network model like GPT-3 consumed more than a thousand megawatts-hour. [37] In any case, funding for subsymbolic AI dried in the seventies, and symbolic AI came to dominate the field from that decade until the late 2000’s.. [2]

Connectionism and Deep Learning

The interest for neural architecture in AI slowly began to rise back in the eighties. The books on Parallel Distributed Processing by McClelland and Rumelhart - using basically an approach to artificial neural networks that later came to be known as Connectionism - sparked new ideas, once again. [42] Development was slow, still, due to computational power constraints. A notorious breakthrough happened with the adoption of multi-layered convolutional networks, which are particularly well-suited for processing images. The work of Yann LeCun, one of the main developers of *ConvNets*, did successful work in recognizing hand-written digits as early as 1989 [27]. His networks were based on Kunihiko Fukushima’s neocognitron design, first published in 1980. [13] Further refinements of the technique, including the application of gradient-based learning, contributed to its efficiency; by the early 2000’s, LeCun estimated that 10-20% of the checks in the United States were being processed by convolutional neural networks. [26,50]

On the symbolic side, impressive feats were also coming about. In 1997, IBM’s specially designed computer Deep Blue beat the world chess champion Garry Kasparov. It used brute computing power to analyze 200 million positions per second. [7] Even if it can be seen as the apex of GOFAI, it didn’t bring us any closer to the human intellect. Deep Blue couldn’t do anything other than play chess, and, as Melanie Mitchell quotes, “didn’t get any joy out of defeating Kasparov”. [33] Despite the boost in the stock value of IBM, the result was seen more as a proof of the limitations of computing in regards to general intelligence. [9] The frustration was echoed in Minsky’s own words a few years later, when he declared that the AI field “has been brain-dead since the 1970s”. [51]

Meanwhile, development on the connectionist side continued slowly. In 2009, the ImageNet database was

¹ <http://www.cyc.com/>

² <https://cyc.com/wp-content/uploads/2021/04/Cyc-Technology-Overview.pdf>

created, followed in the next year by a competition of the same name. Both were responsible for great leaps in computer vision. The database, inspired by the WordNet collection, contained millions of images classified into 5247 categories - dogs, cars, trees, etc. [10] It is worth mentioning that the database wouldn't be feasible if it weren't for the advent of Amazon's Mechanical Turk. This is a platform for distributed manual labor, whose workers did the heavy classification work. [52] This collection spawned the ImageNet Large Scale Visual Recognition Challenge (ILSVRC), with the first competition running in 2010. The goal was to use computer vision to correctly classify 200,000 photographs into 1000 object categories, with the most accurate algorithm taking the prize. [40] In the 2012 edition, the AlexNet deep convolutional neural net achieved an error rate of 16%, a breakthrough in image recognition. The network was based on Yann LeCun's work, and contained eight perceptron layers, instead of LeCun's original four. [25]

The results sparked great interest in CNNs, igniting a whole new cycle of research in AI. A quick search in Google Trends reveals that up until 2012, the terms connectionism and deep learning raised similar levels of interest. After this year, the interest in deep learning skyrockets, and the term is widely adopted. In 2014, generative adversarial networks (GANs) were invented, and with them the ability to replicate styles and features learnt from visual references. The last ImageNet challenge took place in 2017; by then CNNs had already surpassed human-levels of accuracy, with an error rate of less than 5%. [20]

More important than serving as standards for accuracy, the images from the set become the training data for the networks. Subsymbolic AI doesn't rely on rules for inference, but on massive amounts of data that "teaches" a network of artificial neurons through backpropagation, enabling it to perform certain tasks. This complex technique has proven itself to be incredibly successful, and it is widely applied by now. The translations made by Google, Tesla direction assistants, Apple's Siri, all of them use some form of deep learning.

Neural networks also left their imprint within the arts. The aforementioned GAN allowed artists to manipulate and generate images in new ways. [6] CNNs have created "new" Rembrandt paintings³ and Bach chorales⁴. But as it happened with the chess breakthrough in the nineteen-nineties, it is easy to realize that the new AI capabilities don't bring us much closer to human-like intelligence. Generative software needs to learn from hundreds of examples to be able to produce a convincing fake; it is not able to develop new styles or concepts. It needs a creative human behind it that can cobble together

such resources within an intriguing framework. Otherwise it becomes no more than a well trained forger.

Abstraction and Reasoning

The ability to make analogies by abstracting meanings and applying them onto different domains is essential to replicate human inventivity. As Umberto Eco notably stated, "No algorithm exists for the metaphor, nor can a metaphor be produced by means of a computer's precise instructions." [12]. This is still valid even with recent machine learning tools. Take, for instance, the title of this article. *Bartleby machine* is a metaphor for *disobedient machine*, built on previous knowledge of the character created by Herman Melville, a clerk that by his inaction stopped complying to orders.

I used a popular text-to-image tool named VCGAN-CLIP, developed in late 2021, to check what images a recent AI tool would generate from such prompts. The text "Bartleby Machine" produces a contraption similar to a typewriter outputting typed text, suggesting that the platform is aware of the literary origin of Bartleby. If I start with "disobedient machine", what seems to be a device holding protest signs is drawn, suggesting that it related the term disobedience with a demonstration (which per se is a disturbing evidence of bias). No such icons of rebelness appeared when I used the name of the character. Apparently the AI is not capable of seeing his subversive trace. This could be an effect of not having the context of this essay, which is a problem for machine learning since it can not be trained on unique data items. On the other hand, it could happen that the next generation will learn that Bartleby has a disobedience aspect and start drawing related images - which would also be limiting as the name might have been mentioned in a different context.

Analogies also happen to be really important in the learning process; they posit a path for general intelligence. Once I understand how to solve a problem in a given domain, I can apply this skill in a different context. But algorithms that obtained 95% performance in recognizing ImageNet objects can fail to recognize the same object if it comes from a photo that doesn't belong to the training set, or with imperfections such as soft focus or blurriness, which have little impact in human perception. [1,22]

This shortcoming was recognized, among others, by François Chollet, creator of the Keras, one of the most popular deep-learning programming libraries.⁵ Current machine learning techniques are doing impressive tasks, but they are *brittle*, a term used when a model won't perform well outside the domain in which it was developed. A really adaptive system would be able to make analogies and not need realms of data. Therefore, Chollet

³ <https://thenextrembrandt.com>

⁴ <http://www.flow-machines.com/history/projects/deepbach-polyphonic-music-generation-bach-chorales/>

⁵ <https://keras.io/>

proposed, in 2019, a new benchmark named Abstraction and Reasoning Corpus. [8]

Instead of using massive data to evaluate the skills of algorithms, this test offers three or four demonstration examples and one test example for each of a thousand tasks. The tasks are based on classic human IQ tests, but use a computer-readable graphical approach, detailing the “questions” on color pixel grids. A human can understand the challenge in each task and deduct the solution; current AI algorithms, however, have a difficult time. In a challenge hosted in 2020⁶, with hundreds of competing teams, the best performance was just above 20% of tasks solved. While it sounds disappointing, the outcome was celebrated by Chollet as a remarkable achievement. ⁷

But, is it creative?

Since abstraction is essential for creativity, and if Chollet’s approach is able to measure the potential of algorithms to make abstractions in order to solve problems, can we affirm that the ARC benchmark is also measuring creativity?

What is surprising, at least in my point of view, is that according to many classic definitions of creativity, it does, although the surprise comes from the definition rather than the measure. Science is so focused on solution-finding that even the earliest academic theories of inventiveness, like Wallas’ model, were built around the ability to solve problems. [45] More recent studies have criticized the limitations of measuring creativity only around skills of divergent thinking (a solution-seeking creative method) and achieving goals. [4]

Art practice is not necessarily related to goal seeking tasks. In fact, many powerful ideas emerge when the artist is not focused on any particular problem. And that is a crucial feature of the human mind. An artificial intelligence will not be comparable to humans if it won’t be able to aimlessly daydream.

This shortcoming didn’t go unnoticed in the AI community. Effort has been dedicated to the idea of objective-less computation. Joel Lehman and Kenneth Stanley have been working for a decade on the idea of novelty seeking without fixed goals. [53] An interesting experiment coming from this research was the PicBreeder, “collaborative art application based on an idea called

evolutionary art.” ⁸ Users of the website are able to explore a domain of images that can be “bred” by combining different pictures into a new one. This genetic approach allows one to begin with completely abstract forms and end up with images that resemble cars, animals, structures or are simply intriguing shapes. [41]

The PicBreeder itself begat breeds of its own, which remained closely connected to the development of machine learning art. In 2018, artist Joel Simon released the GanBreeder website⁹, which used a similar mechanism but was powered by BigGAN, a particular flavor of generative adversarial networks. It has now become a massive community and a powerful tool for AI artists, known by the name of ArtBreeder. It incorporated StyleGAN as part of its engine and it is used by commercial artists. In fact, it also became the pivot of a rights controversy. Artist Alexander Reben announced a project that sold versions of his GanBreeder works, hand-painted by Chinese artists. However another user of the site, Danielle Baskin, recognized Reben’s images as being originated from her creations. [49] The disagreement serves to expose that in all *breeder* tools, the creative source is not the machine, but the artist - or more, the community of artists and users. The weakness of the algorithm - namely, the incapacity to create aimless works - is fulfilled by humans. It does not intend to be a mechanic creator.

Lehman and Stanley also did experiments which were not human assisted: algorithms based on novelty search exhaust the possibilities within a domain of existing solutions in search of never seen answers. [43]. The examples are a labyrinth solving program, and another that helps a robot discover new ways of walking. Granted, these are very innovative methods to solve problems, but they take us again to the realm of achieving goals: leaving the labyrinth or inventing new gaits. In comparison, a child that is looking at clouds and has an idea for a story about a toothless shark wasn’t trying to solve a problem and might not have had the specific goal of producing a new tale.

Against the rules

We know that machines still lack many things that would make them think like humans. Many of these are related to the capabilities of creative people, like writers and inventors. But there is one talent which is particularly interesting from innovators and problematic for programmable machines: the joy of going against the rules. Traditional computers are limited by the fact that they must follow an algorithm which is set in the stone of a strict set of instructions.

⁹ <https://web.archive.org/web/20181130123706/https://ganbreeder.app/>

This argument was brought up by Arthur Samuel - who developed the checkers playing system in the nineteen-fifties - in his rebuttal of an article written by Norbert Wiener. [47,54] Wiener stated that machines “may develop unforeseen strategies” when playing games, but Samuel dismissed his concerns saying that no computer could create original work: “(...) the machine will not and cannot do any of these things until it has been instructed as to how to proceed”. Humans, on the other hand, have the choice of not following orders. But do we really?

Before facing the issues of computational formalism, we should at least acknowledge, if not open, one of the most challenging can of worms of thoughtful enquiry: the idea of free will. Can we choose our own destiny, or is it determined by forces external to our desire, like the environment, society and our own biological traits? The discussion started with philosophy itself, and the idea of determinism can be drawn within the greater picture of nature: are events pre-determined in an inevitable chain of consequences? In a deterministic universe, there seems to be less room for free will. Indeed, the discovery of laws of motion by Galileo, Kepler and Newton made the universe seem more like the work of a clocksmith. In 1814, French physician Laplace stated that all that was needed to compute the future is an intellect that knew the positions and forces acting on all bodies and were vast enough to analyze them.¹⁰ This all-knowing entity would come to be known as the Laplace demon. Newtonian determinism was put to test by many scientific discoveries after that, like the irreversibility of entropy dictated by the second law of thermodynamics and the indeterminism of quantum mechanics. But recent cognitive research pushed the scale towards determinism again. Studies of volition - the scientific field that investigates human will - shows that decisions are taken a few instants before we make them consciously; this would prove that they happen for neurobiological reasons, instead of a wilful whim. [16,17,29] In any case, proving or denying the existence of free will is not the aim of this article.

One of the most powerful arguments against the possibility of computers going against their rules is the definition of a Turing machine itself, which requires the existence of a set of behaviors to be executed according to the symbols laid down on a tape. [44] The only major difference between Turing’s proposal and today’s computer

¹⁰ “We may regard the present state of the universe as the effect of its past and the cause of its future. An intellect which at a certain moment would know all forces that set nature in motion, and all positions of all items of which nature is composed, if this intellect were also vast enough to submit these data to analysis, it would embrace in a single formula the movements of the greatest bodies of the universe and those of the tiniest atom; for such an intellect nothing would be uncertain and the future just like the past would be present before its eyes.”

is the use of random access erasable memory instead of a linear tape, an idea proposed by John von Neumann in 1945. [34] So if such a machine is defined by rules, it cannot go against them - it would stop working. We could consider a program that allows its code to be rewritten: that is the base of genetic programming, and also of games that let users change its rules like the hit *Baba is You*.¹¹ In fact, computer science never refers to rules being broken, but rather rewritten; like with any revolution or change of paradigm, the standards are not just gone, but replaced with new ones. But then it falls into a paradox: another set of rules is created around the possibility of setting rules. We’re just creating a higher set of laws that can not be transgressed, unless we create an even higher level of behaviors and so on.

This same paradox arose when Bertrand Russell and Alfred Whitehead published the *Principia Mathematica*, a major attempt at unifying and gathering proofs to the all existing mathematical corpus of knowledge so far. [46] A few years later mathematician David Hilbert formulated a program that questioned this effort in many ways. [48] One is of special interest to this paper: can all the methods organized in Russel and Whitehead’s compendium be proved by the rules provided in the *Principia Mathematica* itself? That is, is it self-proving, without the help of any external rule? “A formal system is *complete* if for every statement of the language of the system, either the statement or its negation can be derived (i.e., proved) in the system.” This possibility was aptly contradicted in 1931 by Gödel’s Incompleteness Theorems, which showed that a formal system cannot prove by itself that it is consistent. [38] Mathematics cannot pull itself by the bootstraps; programs won’t be able to change their own rules without a higher-level set of rules.

If we assume that humans have indeed the potential not to follow internally defined rules (like refusing to eat even if our body demands food), we can formulate the two following hypothesis: (1) the human mind is not a machine programmed by an external, higher mind, otherwise it would “stop working” and (2) artificial intelligence cannot be symbolically programmed and must emerge spontaneously, like natural intelligence did.

And in fact, one of the main strategies for the development of AI is the emergentist approach, which relies heavily on subsymbolic methods. Other strategies, as mentioned, blend together symbolic rules with neural network models. It must be mentioned that even these connectionist models are based on computers, and therefore are locked in to unescapable rules. Experimental work is being done with biological AI, but it is still in very early stages. [14]

Maybe there remains to be invented a brain-like machine that is not based on rules? Or maybe the aforementioned assumption is just wrong, since there is in fact a hardware-like set of rules to which brains are bound to.

¹¹ https://en.wikipedia.org/wiki/Baba_Is_You

Neurons do have a very simple mechanism, which has been deciphered by science decades ago. But how can these simple but unbreakable rules give rise to such rich and free behaviors? After all, if we use Gödel's proof on biological brains, the rules of neurons would be superseded by another higher set of rules and so forth, in an *infinite regress*; we would end up locked in some stone written code of different order, and yet we aren't.

A beautifully crafted theory to solve this contradiction was proposed by Douglas Hofstadter. [21] It is a shame to have to summarize it, but for that Hofstadter himself proposes the synthetic concept of strange loops. Strange loops, he says, appear in many places. A graphic example would be Escher's print depicting a pair of hands drawing each other. It also appears in paradoxical constructs such as "this statement is a lie", that contradicts itself permanently and can never be resolved. Such a paradox is connected to Hilbert's questioning of the rules that define themselves, but it was also formulated long ago by Epimenides, the Cretan philosopher who stated: "all Cretans are liars". Hofstadter also identifies strange loops in Bach compositions like the "Canon per Tonos", where the voices rise continuously, while the harmony modulates in a way that ends up back where it started.

These loops can be organized in more complex arrangements, where one hierarchy controls another, which controls another, which in turn dictates the rules of the first one. What his theory proposes is that our brains are a complex entanglement of such rules. We move from one hierarchy to another one that alters the rules of the first, then move back to it and update the regulations of a third, and on and on. "In our thoughts, symbols activate other symbols, and all interact heterarchically. Furthermore, the symbols may cause each other to change internally, in the fashion of programs acting on other programs. The illusion is created, because of the Tangled Hierarchy of symbols, that there is no inviolate level. one thinks there is no such level because that level is shielded from our view." The inviolate level of unchangeable rules here is the biological structure of our neurons. There would be no paradox in creating an insubordinate machine; we just haven't been able to build such a complex system yet.

One elegant consequence of this theory is that it removes the incompatibility between biological volition and indeterminism: our decisions might even be made on a chemical level, but they are impossible to predict and can always be influenced by other decisions of our own.

Building it

There is not a proof to Hofstadter's theory, and it is not clear if such a machine can be built. It is so hard to define consciousness that we are not even sure that we will recognize it when (if) an artificial one is created. It has been proposed, for instance, to use metaphor cognition

capabilities as a new Turing test to distinguish humans from machines. [30] The same can be crafted off disobedience: a program that refuses to follow its code or does it in a way that breaks its own rules would be displaying human, "conscientious" qualities.

The mere proposal of a disobedient machine makes room for a myriad of ethical problems. Beyond the warnings of science fiction - machines that decide to annihilate mankind and such - we don't even know if it would be correct to turn off a machine once it obtains some sort of consciousness: wouldn't this be the equivalent to killing a sentient being? We are already facing the issues of work replacement: what if people can be replaced in all tasks, including the creative ones? In many ways, we can be glad that insubordinate machines are not around the corner yet. But it seems like that for an artificial entity to become a complete artist, it will need the ability to bend and recreate its own norms of behavior. Some scholars, in fact, defend the idea that disobedience is the very path through which an AI can become a subject. [23]

More than a proposal, the disobedient machine shows that art must be in the path to be followed towards an artificial general intelligence. Artists can play with concepts of rebelness and abstraction with much more property than scientists; they can explore these ideas without the obligation of reaching goals.

If goals define the work of machines, a truly daydreaming state can only arise from an anti-work condition. The stance of Melville's character is a roadmap: his refusal to comply, his adherence to a state of pure contemplation during office hours, even facing the threats of unemployment and homelessness. A planned unfolding of this paper is the research on existing and developing systems of tangled hierarchies, overlapping and dominating each other in turns to create lazy, balky, contumacious, exquisite outcomes. A machine that would prefer not to.

Abstract

The colonial import of early media technologies, e.g. sound recording in Global South faced a stiff resistance from the local practitioners. In this paper, I am interested to investigate why leading South Asian musicians and sound practitioners were not enthusiastic about recording their voices on the shellac discs; and for a long time resisted recording their improvisational sounds as they were: offerings to nature and the situated environment. What were the reasons of their contention and resistance? I argue, the pre-colonial sound practitioners feared that recording technology would contaminate their performances by mutating the natural and embedded connections they uphold in their practice. By discussing this unknown history, the paper aims to shed light on the discourse on how do we inhabit and relate with nature, and transform our environments on the media.

Keywords

Sound recording, early media technologies, Global South, decoloniality, nature, indigenous knowledge, mediation, pre-modern sonic cultures, shellac, environmental sounds

Introduction

From the earliest days of sound recording, technology shared a fraught relationship with the pre-modern cultures in South Asia, including traditional music and sounds. Imperial companies and colonial ethnographers introduced the recording of sound in South Asia. Recording of musical performances, along with other forms of sounds, i.e. speeches, comedy shows, theatre and staged acts etc., within a studio setting and making them available publicly as objects for reproduction and as products for sale, had far-reaching social and sonic effects. Recording technology altered performance aesthetics for sound practices by limiting the duration, scope of improvisation, and by distrib-

uting vocal and instrumental music, and local sounds as fixed objects to a mass audience for the first time. Was it acceptable for local music and sound practitioners in South Asia, and in the Global South (e.g. South Asia, Africa, and Middle East sharing a fraught colonial history)? As I will show, there were resistances to recording the voices and sounds of the colonized subjects in South Asia. I am interested here to investigate why leading South Asian musicians and sound practitioners were not enthusiastic about recording their voices on the shellac discs; and for a long time resisted recording their improvisational sounds as they were: offerings to nature and the situated environment. What were the reasons of their contention and resistance?

The advent of sound recording in India was engineered by London's Gramophone and Typewriter Company in the early 1900s. The first recordings were made after 1902 by GTL's engineer Frederick William Gaisberg and the local agent George Dillnutt (Kinnear 1994). These early recordings were mostly made on shellac discs, as South Asia had an abundance of raw materials, e.g. resin, to produce shellacs. Therefore, the intention of the imperial company headed by colonial ethnographers like Gaisberg was to exploit the local resources for building a global business that would benefit the colonial powers. The early days of the Gramophone's recording industry in South Asia can be examined from various perspectives, including the obvious commercial, as well as historical, social, political, and technological. Through this critical engagement, it is revealed that the period in which these recording expeditions were made are the peak period of imperial expansion of the British colony in South Asia, and in many other regions of the Global South, through trade and manipulating new markets. These early recordings were marketed owing to colonial mapping of auditory cultures for exploitation and consumption to making profit. Likewise, musical forms

and intricate vocal renditions like Khayal¹ were adapted, rendered or compromised to suit the requirements of studio recording, marketing, and sales abroad; in the Global South, there was no such market before. As a result, many hybrid and mutated forms emerged, such as Thumri² and Dadra³, which were flexible, recording-friendly adapted version of Khayal sans the aural intricacy of a free and temperamental improvisation that tends to transcend the temporal and durational limitations. Practitioners of Dhrupad⁴, ancient-most surviving sonic form, fell way behind in this rat race for making quick money, as they were least interested to transmute their aesthetics of performing. Those who adapted to the business models of practice by a conformist approach to colonization of sound were most successful.

Among these recordings were the voice of Gauharjan, a so-called *tawaif* (or courtesan) from Calcutta and an exponent of light classical vocal music – popular and abridged song versions of a few ragas with a sensual, high-pitched and light-hearted rendition. The other early such songs for the recordings were performed by Miss. Soshi Mukhi, Miss. Fanni Bala, Miss. Sila Bai, Miss. Hari Dasi, and N.C. Chakraborty (Farrell 1993, Kinnear 1994), among others. As mentioned, missing in these recordings were many great voices of these times, Dhrupad and Khayal singers like Fayaz Khan, Alladiya Khan, et al, although they were regularly performing for hours on the stage at this time, as live performances were in abundance in South Asia.

¹ Khayal is a major form of Hindustani classical music associated with poetic lyrics and sung words based in a raga. In Khayal, ragas are extensively ornamented, and the style calls for more technical virtuosity than intellectual rigour.

² Thumri is another vocal form in Hindustani classical music that is based on the romantic literature. Thumri as a style is derived from Khayal in a shortened form.

³ Dadra is a shorter and light classical vocal form in Hindustani classical music based on certain simpler rhythm cycles or tala.

⁴ Dhrupad is one of the oldest forms of musical sound practice in India, and Alaap is its introduction, which is an elaborate and free-flowing introduction of the raga. While Dhrupad takes a few hours to present, Alaap takes more than an hour to establish the raga's mood through intricate building of sound without rhythm accompaniment.

One may ask why the serious Dhrupad musicians were unrecorded, but an amateur singer like Gauharjan was celebrated as the first historic voice recorded in South Asia even over few of the above-mentioned recorded local singers. The fact that the others were natives, and Gauharjan was not⁵, cannot be denied given the colonial-racial roots of early sound recording. Both her parents were Europeans, and British colonial officers could relate to her quite easily because of that racial lineage. She quickly figured out the economic potential of recorded sound as a commercial product for sales. Likewise, within a few years her income from sound sales picked up manifold. If the colonial and racial were the contexts for early sound recordings made in South Asia, the intentionality of doing exploitative business was at the center of it. But more importantly, Gauharjan rode to fame over others as she was more inclined to do business, and her colonial connection made her the prima donna of early sound recording in South Asia, while the Dhrupad and Khayal performers like Fayaz Khan, Alladiya Khan, were absent as they preferred to stick to the musical values, and were resistant to truncate their improvisation for the sake of adhering to recording technology, and advocated for live performance over recorded discs to communicate their art. This is the reason why the early sound recordings can be questioned of their historical importance, as they registered only a narrower section of sound practice.

It is needless to say that these early recordings were predominantly born out of colonial ethnographic expeditions for quantifying sound in the colony. They were made on 3-minute long shellacs discs as sounding objects or commodities for sale. They were meant for expanding European markets in South Asia using local material like resins, and

⁵ According to her biography, Gauharjan was born Angelina Yeoward in 1873 in Patna. Her father's name was William Robert Yeoward. Her mother was Victoria Hemming, who was born and brought up in India and knew Indian music and dance well. Angelina was their only child. She was baptized in the Methodist Church in Azamgarh near Allahabad. See: https://chandrantha.com/biodata/gauhar_jan.html

exploitative labor. They aimed for maximizing gains and minimizing costs (Parthasarathi 2009) in terms of using cheap local resources and making them available globally for sale through the colonial channels. There was little or no interest in the cultural practice and aesthetics of local music and sound as expressed in the officer's conduct. Moreover, Gramophone Company was quite disrespectful of the local musicians, whom it often termed as *damn natives* (Farrell 1993). There was little interest on the colonial officer's part to appreciate the sophistications that the traditional and pre-modern sound practices in South Asia possessed. The GTL's agent in Calcutta was John Watson Hawd. Hawd's interest in Indian music appeared to be squarely focused on business. In June 1902, his statement was, "The native music is to me worse than Turkish but as long as it suits them and sells well what do we care?" (Farrell 1993). Gaisberg, on the other hand, notes in his travelogue, "We entered a new world of musical and artistic values . . . The very foundations of my musical training were undermined" (Lubinski and Steen 2017). To the colonialist sonic ethnographers, it was largely a subservient continent to explore and plunder the resources. This plundering tendency reflects in the way local sounds were damaged in the early recordings and their aesthetics threatened. I have done research in one particular tradition or school of sound practice from Bishnupur, in Bengal (Chattopadhyay 2020, 2022). One recording from this elaborate style exists in a truncated and reduced form, hinting at what would be the quality in an original performance based on situated sonic improvisation, mostly inaccessible in a 3-minute recording on a 78 rpm shellac disc. There were also unsolicited interruptions made during the recording expeditions to serve the technological dispositive of sound recording. For example, at the end of her recording Gauharjaan used to say: "My name is Gauharjaan."⁶ The earliest recordings of South Asian musical performances are known by this high-pitched and flirtatious announcement, made towards the end of the recording to register the name of the performer.

⁶ One early recording can be found on the SoundCloud page of the project *Connecting Resonances*: <https://soundcloud.com/budhaditya-chattopadhyay/gauharjaan>

This declaration of the singer seemed to epitomize a proclamation with a European egoism that goes against the core essence of surrender to the nature in South Asian traditional sound practice such as Dhrupad. Within the edifice of the recording object on shellac discs, an advent of recorded alter ego would haunt its content, structure and style of presentation. It is then no surprise that many of the devoted local sound practitioners didn't want to record their practices in order to resist the mutating invasion of early recordings.

As I have briefly discussed in my essay "Unrecording Nature" (Chattopadhyay 2021), the *Alaap* section of a Dhrupad was based on a deep connection to the natural temporality and free movements between sounds, which would be curtailed in a recording, even though it would "capture" (Parthasarathi 2009) their voice for the market and for the posterity. Without a doubt, at the turn of the century South Asian sound practitioners found themselves at the cultural intersection of two worlds: the natural improvisational character of sound practices in South Asia, and the mutating modernist technological invasion by the imperial recording companies and their business-driven ethnographic expeditions as part of the colonial exploitation of local resources to profit from. Nevertheless, recorded discs opened up a portal for transcultural interactions even though heavily unbalanced in the power hierarchy at that time due to the predominant colonial structures of exploitation, undermining, and control. The early days of the Gramophone's sound recording industry in South Asia indeed marked a new phase in the interface between South Asian music and Europe. For the first time practitioners from the Global South entered the world of Western media in the form of shellac discs. But as shown above, this exposure was by and large a commercial initiative than a cultural *mélange* at that time. The main purpose of the recording industry was to put in place a crude capitalistic system within a community of practitioners who were devoted to their craft of embodied sound by true presence and subjective devotion to natural forces in their free improvisations.

Indeed, Ragas were reflections of natural temporalities, and each raga was dedicated to a time of the day. What recording industry incurred to this spatiotemporally free-flowing and natural practice of sound⁷ was to transform an emergent auditory situation into a cultural mode of transmission and Schizophonic consumption in the form of shellac discs. In this view, early sound recording was a deeply damaging intrusion. Broadly drawing on Walter Benjamin's notions of the loss of "aura" of art in its mechanical reproduction (1969), and more specifically referring to Theodor Adorno's thoughts on the gramophone (1990), one can develop a critical attitude towards recording technology, since the recorded sound objects "no longer possess their traditional reality" (Adorno 1990). Reviewing Adorno's position, Thomas Y. Levin comments, "Clearly the gramophone does alter the dimensions of the live musical event, transforming everything in a manner similar to radio into chamber music, i.e. music for domestic environment" (Levin 1990). Following this trajectory of the castrating of an alive sound into domestic object, one can contend that early sound recordings compromised the aura of sound in South Asia, reducing the elaborate, temporally open, and improvisational pre-modern sound practices into 3-minute recordings on a fixed media of shellac disc as deliverable sound objects. This is the reason why musicians, particularly more traditionally oriented Dhrupad musicians resisted recording, as they feared that the dedicated search for integrity and true voice would be contaminated. This disruption in South Asian sonic worlds was initiated by the colonizing forces. In many cases, this disruption was irreversible – as the mutating changes, e.g. from Khayal to Thumri, were later accepted as normative.

In view of this, many South Asian sound practitioners were reluctant to face the phonograph for a number of reasons, e.g. as shown, the spatiotemporal disembedding of sound practice from its value systems, that is, their embeddedness to natural phenomena and environmental spatio-

temporalities. There was also an apocryphal apprehension that the recording media would exorcise sounds of an artist's voice. Musicians' concrete concerns were centered on the sudden public availability of their art, and the limitations that recording imposed on performance time. Over the course of the last century, these concerns have shaped both the practice and the content of post-colonial sounds. However, after the independence, musicians have gradually innovated with recording, reclaiming the technology through long-form recording of their live performances as sonic traces, balancing adherence to customary structures with the compulsion to remain relevant. Currently, traditional sound practices like Dhrupad are surviving in a relatively appropriated form and format, through today's freer digital access and sharing, rather than being muffled by recording's dark beginning.

⁷ Music scholars such as Alain Daniélou have pointed out the natural spatiotemporality of the tunings and the sounds of Indian Ragas (1995).

Author's Biography

Budhaditya Chattopadhyay is an artist, media practitioner, researcher, and writer, and a professor at Critical Media Lab, Basel, Switzerland. Incorporating diverse media, creative technologies and research, Chattopadhyay produces works for large-scale installation and live performance addressing contemporary issues of environment and ecology, migration, race and decoloniality. Chattopadhyay has received numerous residencies, fellowships, and international awards. His works have been widely exhibited, performed or presented across the globe, and released by Gruenrekorder (DE) and Touch (UK). Chattopadhyay has an expansive body of scholarly publications in the areas of media art history, theory and aesthetics, cinema and sound studies in leading peer-reviewed journals. He is the author of three books, *The Nomadic Listener* (2020), *The Auditory Setting* (2021), and *Between the Headphones* (2021). Chattopadhyay holds a PhD in Artistic Research and Sound Studies from the Academy of Creative and Performing Arts, Leiden University, and an MA in New Media from the Faculty of Arts, Aarhus University.

Merging Art, Media, and Ecology: Diego Rivera and Ariel Guzik at the Cárcamo de Dolores

Claudia Costa Pederson

Wichita State University

Kansas, USA

ccp9@cornell.edu

Abstract

This paper examines two public art projects at Cárcamo de Dolores, in Chapultepec Park, Mexico City: Diego Rivera's *El Agua, Origen de la Vida en la Tierra* [Water, Origin of Life on Earth] (1951) and Ariel Guzik's *Cámara Lambdona* [Lambdona Chamber] (2010). Because these projects are new additions to existing literature on environmental themes in art history and media arts histories, the incipient focus is on addressing both their artistic and conceptual significance. Both conceived as creative engagements with water, Rivera's *El Agua, Origen de la Vida en la Tierra* is highlighted as the first underwater mural in modern art, with Guzik's *Cámara Lambdona* as a sonic installation created to restore the former's work. To additionally shed light on the artists' respective aims in merging ecology, art, science, and technology, this discussion then considers these projects' divergent articulations of human and nonhuman relations, and as well their kindred aspirations, to function as catalysts of a possible, more sustainable world. In including these projects, this examination shares current concerns with broadening the geographical scope of existing environmentally-themed art historical and media arts histories. Expanding upon this focus, this paper not only emphasizes the ecological arts in the Global South, but as well their interdisciplinary basis and media forms. Hence, it combines a global perspective with an interdisciplinary approach, which, echoing the projects considered, is moreover relevant for further developing the existing histories of the environmental arts.

Keywords

Human and non-human, Mexico, media arts, ecological arts, water, enchantment, modernism, post-modernism, muralism, sound.

Figure 1. Inside view of Cárcamo de Dolores with Diego Rivera's once submerged mural, *El Agua, Origen de la Vida en la Tierra* (1951) in the middle, and Ariel Guzik's sonic installation, *Cámara Lambdona* (2010) on the walls (left and right).

El Agua, Origen de la Vida en la Tierra

Located in the second section of the Chapultepec Park, and a central feature of the *Museo del Jardín del Agua* (Water Garden Museum), the *Cárcamo de Dolores* (the Dolores Chamber) (fig. 1) commemorates workers lost to the building of the Lerma System.¹ Built during the 1940s and subsequently expanded from the 1970s to the 1990s to become the Lerma-Cutzamala system, this vast hydraulic engineering project was then and is still today a vitally important infrastructure to Mexico City's population. (Presently, the Lerma-Cutzamala system supplies potable water to more than two million of the city's residents).[1] A feat of hydraulic engineering, the Lerma system was, at the time of completion in 1943, more significant as a symbol of Mexico's post-revolutionary modernization. One of many public infrastructure projects built under the leadership of then-President Miguel Alemán Valdés (1946-1952), it exemplified as such his administration's advocacy for state-led industrialization.² The *Cárcamo de Dolores*, along with Diego Rivera's mural *El Agua, Origen de la Vida en la Tierra* and its accompanying 100-foot-wide sculpture, the *Tlaloc Fountain*, was as such commissioned not only to indicate the location where the waters of the Lerma river enter the city, but also to cultivate popular support for the state's course of industrial development.

¹ The current Cutzamala-Lerma system was a later expansion of the Lerma system in 1976. One of the biggest water supply infrastructures in the world, it utilizes 7 reservoirs, a 127 km long aqueduct with 21 km of tunnels, 7.5 km koorindabell (what is this?) canal, and a water treatment plant. The water passes through the 127 km long tunnel under the western Sierra de las Cruces on its way to holding tanks near the Cárcamo de Dolores; then on to a second chlorinisation plant to remove toxins; and then aqueducts and pipes, with approximately 2,000km in the primary network of trunk pipes, and a further 12,000km of smaller pipes within each district.

² Representing the *Partido Revolucionario Institucional* (PRI (Institutional Revolutionary Party) which held uninterrupted power in

the nation for 71 years, from 1929 to 2000), *Alemán* was democratically elected as the first civilian president of Mexico serving from 1946 to 1952. His presidency became synonymous with the so-called Mexican Miracle, marking a period of rapid industrialization and economic growth fueled by newly discovered oil reserves in Mexico. While mired in political corruption and cronyism, Alemán's administration emphasized building and expanding the country's public infrastructure, including rail and road networks, vast damming and other hydrological projects (including the diversion of the Lerma river to supply water to Mexico City), a new campus for the National University (UNAM), and Mexico City International Airport.

Charged with this commission, the architect Ricardo Rivas (1913-1998) conceived of the project as a collaborative integration of engineering, architecture, and art; and, moreover, an exemplar of the 1910 revolution's promises of social justice and greater equality. In sum, the *Cárcamo de Dolores* evidences Rivas' belief that the integration of art and science, and social transformation are kindred projects, in this case, the more relevant as Mexico's postrevolutionary constitution enshrines the human right to water. Accordingly, Rivas designed the *Cárcamo de Dolores* as a small temple inspired on *mestizaje*, so fusing classical Mesoamerican and European architecture.³ The Mexican art historian Louise Noelle describes it as a small amphiprostyle temple (having columns at either end, but not along the sides), with a series of columns *in antis* in the front and back. [2] The building is in effect a resonance chamber built of cantera stone (a volcanic rock mined in Mexico and Central America) and with floor to ceiling glass entrance and exit doors and windows designed to allow light in. Inside, at the center, the water in the reservoir would catch the light entering and enliven the interior with reflections. The dome on top of the reservoir would moreover amplify the sound of running water. Subsequently, Rivas approached Rivera (1886-1957), who accepted the commission to paint the entire interior walls and copula. In the end, only the mural in the reservoir, *Agua, el Origen de la Vida*, and in front of the building, the *Tlaloc Fountain*, (Tlaloc being the Mexica god of rain and harvest) were realized.

Matching Rivas' interdisciplinary and political visions for the project, Rivera conceived his contributions similarly, as an opportunity to integrate art, science, and social change. Like Rivas, the artist proposed that water would both be a subject matter and a medium. The overarching idea, as he put it was "to create for the first time painting in movement".⁴ [3]

In practice, the mural, which covers the entirety of the reservoir's tunnel, floor, and walls, would edify viewers about a variety of narratives about water, spanning scientific, spiritual, social, and cultural meanings. Accordingly, Rivera structured this narrative loosely around contemporaneous evolutionary theories. So the painting was partially submerged (the water covered the floor and lower part of

The tank) to tell this story, which the artist began by way of depicting the primordial soup as theorized by the Russian biologist Aleksandr Oparin.⁵ [4] (In 1924, Oparin proposed that the development of life on earth resulted from basic biochemical exchanges between carbon-based molecules floating in the planet's primordial oceans, adding that the planet and life were intrinsically connected processes). In this wet part of the mural, Rivera accounted for the refractive properties of water and the visitor's elevated point-of-view by foreshortening and magnifying images of aquatic life (including microorganisms, plants and animals), which were based on contemporaneous scientific illustrations.

Progressing from aquatic to land-bound habitats, the dry part of the painting focuses on the significance of water for human evolution and for human life in the Valley of Mexico. Portrayed emerging from the primordial waters, two human figures representing the original couple loom large against the background of Mexico City's skyline. A reference to contemporaneous scientific theories of Africa and Asia as the cradles of human life, an African man (Fig. 2) on the north wall, and a pregnant Asian woman (Fig. 3) on the south wall, face each other. The panoramic background shows an arid and volcanic landscape punctuated with pre-Hispanic structures and modernist skyscrapers. In this urban scape, Rivera depicts modern urbanites of different ages and social classes enjoying the benefits of potable water, drinking, tending gardens, and swimming. (Notably, Rivera included a portrait of his daughter, Ruth Rivera Marín swimming, in a probable reference to her graduation in architectural engineering in 1950).⁶

Painted on the west wall, above the tunnel, which at the time carried the Lerma waters into the reservoir, two immense, cupped brown hands overflowing with water reference the spiritual symbolism of water in pre-Hispanic culture. Above the god's hands, one of the faces of Tlaloc peers in from the *Tlaloc Fountain* outside through the glass entrance doors (Fig. 4). On this and the opposite wall, to the east, Rivera prominently eulogizes the workers and engineers of the Lerma system. They are portrayed flanking the god's hands holding tools and bearing offerings of water to thirsty urbanites. Above the system of flow control gates directing running water into nearby tanks and the purification infrastructure, Rivera portrays Rivas and the head engineer

³ With roots in the word *mestizo* in colonial Mexico, and subsequently developed during the Independence era, the notion of *mestizaje* was reformulated in post-revolutionary Mexico as the state's ideology. In colonial Mexico, the word *mestizo* was loosely used as an ethnic/racial category of self-identification. During Independence, academics began using the noun *mestizaje* to denote the positive unity of race mixtures in modern Mexico. Post-revolution, this notion of *mestizaje* was mobilized and promoted by the state under the umbrella of *Indigenismo*, as a way of unifying Mexican identity. Among the most influential promoters of *Indigenismo* was the philosopher and statesman José Vasconcelos Calderón (1882-1959). Vasconcelos's notion of the Cosmic Race (1948) was both a rejection of Anglo culture and argument for the primary mission of an independent Latin America: to birth a new modern mestizo people destined to create a more just, equal world. Vasconcelos' position as the Secretary of Public Education (1921-1924) provided him with a powerful platform to implement his vision of the Cosmic Race. Among his beneficiaries are the Mexican muralists, including Rivera, whom was among the first visual artists commissioned to educate the illiterate masses about Mexico's *mestizo* identity through murals painted in Mexico's most important public buildings. Hugely influential for twentieth-century Latin American and Latin diasporic culture, this notion of *mestizaje* has been

challenged in the twenty-first century as a form of nationalism at the cost of cultural assimilation for all ethnic groups.

⁴ Rivera's interest in dynamizing muralism, and as well as in using industrial materials to develop new painting techniques, contrary to what he implies here, is not at all unique among Mexican muralists. In effect, Rivera's fellow muralist and nemesis, David Alfaro Siqueiros, is the most noted for his experimental approaches, which included techniques that had never been utilized before such as using industrial spray guns to paint a mural directly on cement and employing camera-projections to transfer sketches to the walls.

⁵ The artist met and sketched Oparin during one of his visits to Soviet Moscow.

⁶ Rivera Marín was the first woman to study architecture at College of Engineering and Physical-Mathematic Sciences at the National Polytechnic Institute of Mexico. Involved in designing both the Museum of Modern Art and the Museum of El Eco in Mexico City, Rivera Marín is most noted for the Anahuacalli Museum, which she designed jointly with the architect Juan O'Gorman to house 2,000 pieces from her father's collection of pre-Hispanic art. Built post Rivera's death in 1957, and opening to the public in 1964, the building was inspired on pre-Hispanic temples (teocalli). The word Anahuacalli means the house close to water in Nahuatl (Atl means "water" and nahuac "close to"), and like the fountain outside of Cárcamo de Dolores is dedicated to the Aztec rain god, Tlaloc.

Eduardo Molina surrounded by the team of engineers (Fig. 5). Underneath them, representations of chlorine and ammonia molecules illustrate the chemical composition of the disinfectant used to make potable water to viewers.

Altogether the mural is exceptional not only because of its illustration of water as an integral part of life's evolution, culminating according to Rivera's narrative in Mexico's modernization project, but also because of its unique integration of water to similarly dynamize its counterpart in art, Mexican modernism. Through this, it additionally assists Rivera's own quest for dynamic painting. To this end, the artist researched a variety of clear synthetic resins, eventually opting for a *polystyrene* solution (BKS-92 polystyrene) to protect the painting from the Lerma waters. [5]

Additionally, the mural's companion piece, the *Tlaloc Fountain* was similarly designed to be viewed from the dynamic point-of-view of air bound visitors. Located along the flying routes of planes servicing Mexico City International Airport, the giant mosaic-covered Tlaloc figure lying on his back half-submerged in water, was according to Rivera inspired on the "mounds" then being revealed through aerial photography (Fig. 6).⁷ [3] In modern art, the sculpture is as an early precedent to earth and land artist in North-America, such as Robert Rauschenberg's *Spiral Jetty* (1970) which similarly implied an aerial perspective. A nod to Rivera's patron, President Alemán, under whose administration the Mexico City International Airport was built, the *Tlaloc Fountain* was, in contrast to the remoteness of later earth and land art, conceived to be easily accessible because of its urban location.⁸ [3]

Figure 2. North wall, *El Agua, Origen de la Vida en la Tierra*.

Figure 3. South wall, *El Agua, Origen de la Vida en la Tierra*.

Figure 4. West wall, *El Agua, Origen de la Vida en la Tierra*.

Figure 5. East wall, *El Agua, Origen de la Vida en la Tierra*.

⁷ At the time, inbound and outbound planes flew this route at a lower altitude than is the case today.

⁸ Rivera describes the fountain as follows: "In this fountain I had the opportunity to realize the integration of painting and sculpture by submersion, which animates its forms. The sky is reflected in the watery mirror, which projects the spatiality of the sculpture unto itself. Maximum visibility is achieved from a heightened perspective. A stone body, polychrome, with its greens, reds, whites, yellows, created with marble, basalt, mayolica tile, stones of

various hues and tile fragments. Thus Tlaloc is visible from the sky and his movements are formally articulated to suggest mountain ranges. The modulations of the details of the vestments conjoin design with rhythmic movements and integrate into a uniform plasticity. Tlaloc provides liquid indispensable to human life and with his left hand plants four corn kernels, kernels which the poet Juan Rejano called "tenderly scented dentition".

Figure 6. Aerial photograph of Cárcamo de Dolores with Diego Rivera's *Tlaloc Fountain* (1951) in front. Museo Archivo de la Fotografía (MAF) de la Ciudad de México. Gobierno de CDMX.

Unfortunately, like much of the modern public infrastructure in Mexico, both the mural and the fountain fell into disrepair in the last decades of the twentieth century. As well, the polystyrene compound used by Rivera proved, early on within five years of completion, inadequate to protect the mural from the waters of the Lerma. Similarly, the *Tlaloc Fountain's* ease of accessibility and constant exposure to the elements resulted over time in extensive damage to the tiles and stones. To prevent irreparable damage, the Lerma waters were diverted from both the mural and the fountain during the first restoration, which began in 1990, and subsequently, in 2010, as part of the second restoration, Ariel Guzik (1960-) and his team were commissioned to ultimately reintroduce water again into the *Cárcamo de Dolores*.⁹

Cámara Lambda

Guzik and his team conceived *Cámara Lambda* as a permanent installation befitting of Riva's resonance chamber, and like Rivera, attentive to the dynamic nature of water. In this light, *Cámara Lambda* evokes a water organ as, like its ancient musical predecessors, hydraulically powered musical automata, its mechanism is activated by moving water.¹⁰ Guzik's water organ however is not a

reconstruction, but rather an adaptation and extension of such instruments.

So, the mechanism employs sensors to capture the flow and thermal noise of subterranean water near the building (the sensors are invisible to visitors). Mounted outside, on the building's back ledge, an antenna system collects additional data, including measurements of cloud movement, wind, rain, hail, sleet, solar light, and telluric currents (Fig. 7). The organ's *two* sets of copper pipes, which are arranged in bundles of three, with each set including sixteen bundles in total, are mounted on the North and South walls inside the chamber (Fig. 8).¹¹ As the installation's title indicates, the *Lambda* matrix, (a mathematical grid attributed to the Greek philosopher Pythagoras [fourth-century BC]) patterns the sounds and resonances of water, and atmospheric and telluric phenomena, combined. (Specifically, the data from the water sensors feeds into the harmonic scales, while the data from atmospheric and earth currents provide the compositions' subharmonic tessituras and nuances). Lastly, in the chamber, a lacquered wooden cabinet imbues a retro-futurist aesthetic and serves as an enclosure for the circuits and switchboards that make up the control mechanisms of the organ.

Cámara Lambda is but one example of Guzik's practice, which is based on his broad interests in art, technology, science, medicine, and ecology, and their intersections.

⁹ The *Museo del Jardín del Agua* (Water Garden Museum), which includes the Cárcamo de Dolores, is today part of the Museum of Natural History and Environmental Culture. Along with Guzik, the Mexican architect Alberto Kalach was commissioned to lead the restoration of the *Jardín del Agua*. Kalach is well known for his speculative project entitled *México Ciudad Futura* (Return to the city of Lakes), which foregrounds the restoration of the city's pre-Hispanic aquatic environment. Kalach's studio designed a pyramid-like structure on the West side of the Cárcamo de Dolores, to allow for a heightened viewing of the *Tlaloc Fountain* once again.

¹⁰ The tradition of automata spans artistic, entertainment, and scientific histories across the globe. As one of the earliest examples

of musical automata on record, the hydraulis, a water powered pipe organ is attributed to the mathematician and inventor Ctesibius (c. 285–222 BC) living in Alexandria, Ptolemaic Egypt. Hydraulic automata include not only musical instruments, however, but as well other mechanisms such as fountains and water clocks that shaped like humans and animals are designed according to predetermined instructions to appear self-directed.

¹¹ During my visits to the installation in 2018 and 2019, various guards noted that thunderstorms, windy days, and night time provide the best conditions for compelling melodies.

Working solo since the late 1970s, in 1990, Guzik founded the Laboratorio de Investigación y Expresión de la Naturaleza (LIREN, Laboratory for Research into Resonance and Expression of Nature) as an atelier dedicated to creating sonic installations that, in the artist's words, aim at cultivating enchantement.[6] *Cámara Lambda* exemplifies this notion insofar that, both in contrast to Rivera's celebration of dynamism in light of technological utopianism, and to the use of similar scientific and technological methods for extractive purposes (e.g., industrial prospecting), the aim here is instead to use science and technology to attune to the dynamic nature of matter and the material world.

Conceptually, Guzik's notion of enchantement resonates thus with the current fascination with matter and materiality as agentive and relational forces, referred to in the Humanities and Social Sciences as the Anthropocenic turn, nonhuman turn, and new materialism, to name a few terms. For instance, Guzik's evocation of enchantment echoes Jane Bennett's recent call for an "enchanted materialism". As she explains, conceived in contrast to modernist and postmodernist theories of disenchantment, enchanted materialism is critical theory as antidote to the alienation and detachment of our current epoch, the Anthropocene. In this light, the task of critical theory is then to cultivate a sense of wonder and captivation with matter so as to ultimately motivate greater attachment and care toward humans and nonhumans.¹² [7] For unlike disenchanting luddism, enchanted materialism takes relationships between humans and nonhumans (animals, technologies, environments) to be deeply intermingled and co-constitutive processes. Hence, Bennett prescribes encounters and "crossings" with heterogeneous species of life and matter as sources of "affective connection".[8] Guzik's practice aims at compelling such like encounters and crossings.

Yet, this is not to imply that Guzik's focus on enchantment is unique in art. In art history, the artist and art historian Suzi Gablik theorized reenchantment as already a concern integral to a strand of postmodernist art in the United States, notably by multimedia artists addressing environmental themes in relation to kindred interests in the connections between art, science, and spirituality. Expanding Gablik's geographical scope to the South, her definition of reenchantment likewise aptly sums up Guzik's orientation:

Reenchantment . . . means stepping beyond the modern traditions of mechanism, positivism, empiricism, rationalism, materialism, secularism and scientism—the whole objectifying consciousness of the Enlightenment. . . it also refers to that change in the general social mood toward a new pragmatic idealism and a more integrated value system that brings head and heart together in

an ethic of care, as part of the healing of the world.¹³ [9]

Similarly beyond Mexican modernity and modernism, Guzik orients art, science, and technology toward healing our fractured, alienated relationships with the environment and the more-than-human, and in so doing, with ourselves. It is not surprising then that this orientation brought prominence to Guzik's work in the context of post-modern Mexico, and specifically in connection with civic and governmental initiatives to 'green' Mexico City in the last decade, including ongoing projects aimed at renovating the city's public spaces and monuments, reducing air pollution, and educating the population about environmental issues.¹⁴ [10] Among these, the restoration of the Water Garden Museum (*Museo del Jardín del Agua*), where the Cárcamo de Delores is located, is the more significant in light of the failures of the modernist project, not least as mirrored by Mexico City's gravely deteriorated water supply system. As a case in point, the Lerma-Cutzamala system's hidden aging pipes and earthquake-damaged conduits throughout the city leak an estimated 40 percent of their precious medium. Peripheral neighborhoods have intermittent water service, if it reaches them at all. Almost all of the city's residents rely on bottled water. Thus far, the state's response emphasizes building ever larger hydraulic facilities in rural communities abutting the city and pushing for the privatization of water management as a solution to municipal budget problems and aging water systems. And yet, this course has also unwittingly invigorated environmental awareness and activism among civic society in Mexico. Spanning a diverse array of communities (including Indigenous spokespeople, environmental activists, academics, engineers, architects, and artists) they both oppose the state's neoliberalist course, as well as have proposed a variety of alternative models to water management. [10]

In echo of these communities, *Cámara Lambda* tunes into the need for developing ways of relating to *water* other than through unsustainable exploitation and control. It does this by literally encouraging playful, creative engagements with water that are also evocative of Bennett's foregrounding of sound as a source of enchantment. Expanding on Gilles Deleuze's and Félix Guattari's focus on the significance of resonances or "sonorities" for rehabilitating sensory access to the cosmos (their term for denoting "the energetic aspect of things, thoughts, matter" alive with movement and change), Bennett's notion of sound thus benefits human attunement to their proximity and co-constitution with nonhumans.[7] Similarly conceiving of enchantment as key to ours and our world's healing, Guzik's art, Gablik's art history, and Bennett's critical theory, are then kindred calls for cultivating creative practices and thought on behalf of "a more sympathetic and generous relationship with one's cohabitants".[8]

¹² Bennett traces theories of disenchantment to idealism (Kant), and neo-Marxist critical currents in Western philosophy (Max Weber and the Frankfurt School).

¹³ Gablik highlights in this context the work of the photographer Frank Gohlke, land artist Nancy Holt, installation and performance artist Dominique Mazeaud, installation and environmental artist James Turrell, and especially a host of eco-feminist artists, including Gilah Yelin Hirsch, Mierle Laderman Ukeles, Fern Shaffer, and Starhawk, among others.

¹⁴ In response to Mexico City's water crisis, two major state and local programs were devised. First, the National Water

Commission launched a massive US\$2.8 billion Water Sustainability Program in 2007 for bulk water supply, drainage and wastewater treatment for the period 2007-2012. In parallel, the government of the Federal District has launched a 15-year *Plan Verde* (Green Plan) that also includes extensive expansion of drainage and wastewater treatment facilities located outside of the city, in rural communities, as part of the plan's aim at sustainably developing the Valley of Mexico.

Merging Art, Science, and Technology

Anew enlivened with the resonances of water, in the last decade the Cárcamo de Dolores has attracted numerous locals and tourists alike, though, in contrast, less scholarly attention. So, while some scholars in Mexico wrote about the project since the restoration in 2010, Rivera's mural and Guzik's installation are still little discussed elsewhere.[2] [4]

This is the more surprising in the case of Rivera's *Agua, el Origen de la Vida*, not only given the importance of the work, which to my knowledge is the first submerged mural in modernist art, but also in view of the extensive art historical scholarship about the artist. The work is likewise relevant to the growing literature on the media arts in Latin America.[11] For example, in his pioneering study of the Mexican modernist avant-garde, Rubén Gallo profiles Rivera as a quintessential exponent of the technological utopianism typifying Mexico's post-revolutionary era in the 1920s and 1930s. [12] Rivera's projects at the Cárcamo de Dolores certainly fit Gallo's argument, given their subject matter, dynamism. Yet, the artist's use of a new industrial material to integrate subject matter and form (a submerged mural) also contradicts Gallo's contention that ultimately Rivera never reconciled his fascination with science and technology with his preferred technique, fresco painting.[13] Be that the artist's quest for dynamic muralism fell short, in retrospect, *Agua, el Origen de la Vida* is the even more poignant today for connecting art and science toward compelling creative connections with water.

Similarly, *Cámara Lambda* restores water to the Cárcamo de Dolores through sonic media. The installation is moreover exemplary of Guzik's overall focus on mobilizing art and technology for enchantment. Spanning a variety of environments and species, including plants, sea creatures, and urban and peripheral locations, this project aims at creating alternatives to our objectifying relationships with matter, the more-than-human, and thus also ourselves. Surely this is the more urgent a task in face of global climate change, and our denying, techno-utopian and luddite attitudes. It is thus as an environmental artist that Guzik began gaining international recognition. He represented Mexico at the Venice Biennial in 2013, and subsequently was nominated as one of "Visionary pioneers of media" at Prix Ars Electronica in 2015. Guzik has since exhibited widely in Mexico and Europe. In this contrast, scholarship about his work is still incipient in studies about the media arts in Latin America.[14] [15]

While reflecting the growing popularity of ecological art in global museums and other public exhibition venues, as a strand of ecological art in the Global South, Rivera's and Guzik's works at the Cárcamo de Dolores are also relevant for expanding on the interdisciplinary openness of global-oriented approaches in history of art and in media arts histories. Certainly, these works challenge accounts of contemporary global eco art framed in relation to the 1960s and 1970s earth and land art.[16] [17] Rivera's and Guzik's projects highlight in contrast simultaneous histories of ecological arts in which environmental themes intertwine with long-standing artistic engagement with science and technology in Latin American art. Hence poorly served by modernisms conceived exclusively in terms of spatial expansion, these works ask us rather to integrate histories of the environmental arts with histories of media arts in the Global South. From this perspective, Rivera's and Guzik's projects at the Cárcamo de Dolores broaden the transcultural scope of artistic trajectories concerned with the relationships between the human and the non-human, as well as altogether precede and parallel the "new" materialisms that have lately compelled scholars across disciplines in face of the Anthropocene.

Abstract

Throughout this text we will analyze some human concerns that are the subject of analysis in different fields of knowledge such as philosophy, art, science and technology. These concerns revolve around what is reality? what is fiction? what are the effects of hallucination? and what is virtuality? through different cultural products such as art, literature, cinema, psychoactive or entheogenic experiences, up to the most recent proposals of Virtual Reality and their forms of interaction. We will try to envision and propose new ways of perceiving reality, seeking a balance between the real and the virtual world. We will take a tour from the way we process reality and create fictions around it, to the illusionism that has constituted an important part of our search for consciousness, mediating between rationality and experimentation in the construction of new realities to finally make a proposal on Virtual Reality based on the therapeutic use of hallucinogens.

Keywords

Science Fiction, Virtual Reality, Psychoactive, Psychedelic, Hallucination, Entheogens, Psychotherapy, Art.

Introduction

The history of humanity, its evolution and development converge in the concern of asking ourselves who we are, where we come from and where we are going. These questions could be considered as the trigger for the construction of communities, societies, and entire nations. Ingenuity and human inventiveness continued to manifest from the stage of *homo habilis* to *homo sapiens*, from prehistoric times when stones were sharpened to perform various tasks, to our days of the use of Virtual Reality. Technology has played an important role in improving human tasks, so we have been able to adapt to different needs and different perspectives. Art, coupled with technology, has managed to exert paradigm shifts for societies. From optical toys and cameras to smart devices: all such things have not only modified our perception of the world but have also enriched our daily experience of the world. The transformative power of the modern image, wrought with amazing interventions of technology and computation, has destabilized the precept of reality in which

we live. Constant interaction with fiction, image, altered realities lead some philosophers, writers and artists to wonder if we are not living within a continuity of hallucination.

Over the years, people have woven an incredibly complex network of stories. Within this network, fictions such as Peugeot not only exist, but also accumulate immense power. The kinds of things that people create through this network of stories are known in academic circles as 'fictions', 'social constructs', or 'imagined realities'. An imagined reality is not a lie. [...]

Unlike lying, an imagined reality is something that everyone believes in, and as long as this communal belief persists, the imagined reality exerts force in the world.¹

We have developed a taste and growing faith for the imaginary construction of beliefs, myth and rites. We could say that we even find fiction more interesting than reality itself, since it is difficult to access a pure or complete reality. Only at the right moment of the present experience is reality manifested and exercised. Henceforth, memory, the anecdote and other different types of expressions and documentation represent attempts to outreach. And even breach, reality.

The paramount reality envelops them on all sides, as it were, and consciousness always returns to the paramount reality as from an excursion. This is evident from illustrations already given, as in the reality of dreams or that of theoretical thought. [...] The transition between realities is marked by the rising and falling curtain. As the curtain rises, the spectator is 'transported to another world.'²

Art has taken advantage of the unattainable reality through words, writing, song and music; through body in dance and theater; and through image in painting, photography or cinema; to name a few - magnifying reality, transporting the viewer to one of the many versions of reality that we have been able to produce throughout human existence art has led us to experience ecstasy through a form of fiction that belongs to the field of image. Illusion, according to Alfred Neumayer and quoted by Oliver Grau, is defined as follows:

*The illusion works on two levels: first, there is the classic function of illusion which is the playful and conscious submission to appearance that is the aesthetic enjoyment of illusion. Second, by intensifying the suggestive image effects and through appearance, this can temporarily overwhelm perception of the difference between image space and reality. This suggestive power may, for a certain time, suspend the relationship between subject and object, and the "as if" may have effects on awareness.*³

The production of illusions has found a fertile field in art as we consciously allow ourselves to marvel at what seems to differ from our own reality, and yet represents the reality experienced by the artist or the art producer, in our condition as individuals. The gaze of the other will never be the same as your own gaze; that is why the approach to experience of someone who is far from our inner world surprises us. In the same way in which our prehistoric ancestors discovered the world and its wonders for the first time, just as a child begins his experimentation with flavors, colors, or textures, marveling at them, the artist presents and represents thoughts. Being able to admire and experience the thinking of others with our senses is like entering an unknown dimension, like embarking on an expedition into a new territory.

Since the myth of Plato's cave where the bound prisoners looked only at the projection of light that represented reality, art spectators for a long time limited their interaction only to the gaze, the thought and the imagination that was motivated by that expression, according to Jean-Lois Baudry quoted by Lev Manovich.

*This immobility and confinement, according to Baudry, enables the prisoners/spectators to mistake representations for their perceptions thereby regressing to childhood when the two were indistinguishable. Rather than a historical accident, the immobility of the spectator, according to Baudry's psychoanalytic explanation, is the essential condition of cinematic pleasure [...] Alberti's window, Durer's perspectival machines, the camera obscura, photography, cinema—in all of these screen-based apparatuses, the subject has to remain immobile.*⁴

This immobility (as quoted in Neumayer), far from limiting the behavior of the viewer, considers a greater cognitive exercise that represents the assimilation of the visual proposal. Both Manovich and Grau begin their historical journey prior to new media and new technologies. Through their exposure it is possible to trace the contemplative tradition of spectators with respect to the arts and the infinite possibilities of art as a virtual projection of reality. This contemplation at a certain level could be understood or perceived as immersion, according to Grau:

Immersion can be an intellectually stimulating process; however, in the present as in the past, in most cases immersion is mentally absorbing and a process, a change, a passage from one mental state to another. It is characterized by diminishing

*critical distance to what is shown and increasing emotional involvement in what is happening [...] Immersion in the artificial paradises of narcotics, for example, as described by Charles Baudelaire, dream journeys or literary immersions past and present.*⁵

In modern times, both producers and observers seem to be waiting to participate in an alternate look, an altered vision, which in comparison with reality gives us a response to universal questions about our existence and origins. The tools used in some cases range from immersive spaces that have created murals with 360° landscapes to paintings - like windows that take us to other spaces, or novels that transport us to other worlds, melodies, songs, dances, or plays and theater that narrate our desire to access other worlds. Recently, cinema, television, the internet, smart devices, or Virtual Reality technologies have made the illusion of accessing other spaces virtually through telepresence. Brenda Laurel defines it as:

*a medium that allows you to take your body with you to other environments [...] you get to take a part of your senses with you to another environment, which can be created by computer, or come from a camera, or it can be a combination of the two.*⁶

However, experiencing the senses outside the body, so to speak, feeling that we are beyond possible physical distance, and are perceiving our immersion in other imaginary worlds through a contemplative gaze, repeating a practice and appreciating it with the surprise of a child who has just discovered the world, are all experiences that have also been possible through the stigmatized consumption of psychoactive substances, which have been documented in different ways, by different authors and through different means, some literally, and in others through metaphors. So, it is possible to intuit that they allude to ways in which it is possible to access other worlds, to alternate glances, to altered visions, perhaps in this research, and through all the efforts in which we have been participants, the intention hidden is to return to the origin that allowed the development of our consciousness, its expansion and the search for new knowledge.

Terence McKenna, in his book *"Food of the Gods: The Search for the Original Tree of Knowledge"*, was given the task of compiling historical facts that address the importance of entheogens or entheogenic technologies, as some psychoactive substances are also called, due to their ability to induce alterations in perception, mood, consciousness and cognition, with the purpose of generating spiritual development in sacred contexts. In this text, McKenna addresses that story from the book of Genesis, in which Eve

*eats and shares the fruits of the Tree of Life or the Tree of Knowledge, fruits that "please the eye and contemplation" [...] the fruit of the Tree of Knowledge gave them keen insights.*⁷

Although, this story is part of the myth of Christianity and the origin of humanity, the idea that a fruit provided ecstasy

in contemplation and a deep look inward, and acting as a shortcut in the search for knowledge has been established this early, it would seem. This narrative could represent one of the first antecedents of the possible consumption of psychoactive drugs. The same book of Genesis is an important part of literary productions, its veracity is in doubt, but it does not stop being a valuable example of human inventiveness and imagination revealing the search for experiences of an altered conscience.

In the book "Virtual Art, From Illusion to Immersion", Oliver Grau discusses the great frieze of the Villa of the Mysteries in Pompeii. Created around 60 BC. The frieze completely covers the walls of room number five, these 5 x 7 meter frescoes cover the entire gaze of everyone who enters the room, making them part of the scene where it is possible to observe Gods and humans living together in absolute ecstasy. This work represents the cult of Dionysus, God of the vine, the grape harvest, winemaking, wine, fertility, ritual madness, religious ecstasy and theater, so it doesn't seem fortuitous that Grau chose it as part of the works of art that have achieved the immersion of the viewer. He describes it as follows:

The picture is a gateway, which allows the gods to enter the space of the real, and, in the other direction, transports their mortal assistants into the picture. The glowing red color heightens the sensual and ecstatic atmosphere and its climax, the consummation of the sexual initiation rite, ultimately succeeds in involving the observer as well. With its suggestive exclusiveness and the resultant psychological effect, this pictorial form represents the maximum that the image medium of the fresco could achieve with the means available at the time.⁸

Following this divine line, during the XV and XVI centuries, we will bring to account one of the most popular examples of the Renaissance, the Sistine Chapel of Michelangelo, who had the ability to produce these images that seem to have the intention of taking us to that sublime world in heaven, in glory, in the company of angels and saints, a world unknown to worldly humanity and that resembles the hallucination of those who have had the grace to contact the depths of their spirituality, it would be precise to say that a good percentage of these venues in which a kind of divine adoration takes place have this mystical aura that motivates this introspection and connection with the spirit, be it its architecture, murals, paintings, sculptures that in addition adorn spaces, try to seduce us to the place that seeks our approach to the Gods in the kingdom of heaven, however it is possible that our desire to access this sublime experience, be a desire to return to the origin of those experiences of ecstasy, of encounter and immersion with our insides and our origins, as we have already mentioned before, not only art artificially allows us, deep meditation and the use of entheogens also makes it easier.

Some other literary works and artistic productions far from religiosity have led us to other worlds, making it clear that access to these other worlds was possible thanks to the consumption of substances of which we do not know for

sure their chemical constitution and which we have not issued a direct questioning, that is, we do not know exactly what was consumed by *Alice in Wonderland*, written by Lewis Carroll in 1865, although evidently a bottle with a liquid that says drink me and a cookie that says eat me is mentioned, they are not from the ordinary type, because these allowed her to grow large and then small to be able to access this exotic world full of hallucinations, in which characters of animal origin share their wisdom so that she can experience self-reflection and self-knowledge.

Later it is possible to point out that the rediscovery and playful use of psychoactive substances in the 60s coincides with the popularization of science fiction literature and cinema. Aldous Huxley, already enjoying popularity as a science fiction writer for his novel *Brave New World*, experienced the effects of psychoactive substances on his own, describing the effects in his essay entitled *The Doors of Perception*:

My body seemed to have almost completely dissociated from my mind –or, to be more exact, although my consciousness of the transfigured external world was no longer accompanied by an awareness of my physical organism– [...] –to feel that "I" was not the same as these arms and legs of "there outside".⁹

Again, referring to this sensory quality shared by art, psychoactive substances and more recently Virtual Reality. In 1971 Stanislaw Lem, a Polish science fiction writer, published a novel entitled *The Futurology Congress* in which he explored the idea of pscivilization where psychemistry encompasses all aspects of human life, from its diet to the search for knowledge, the humanity has been subjected to the use of pills that allow them to access knowledge:

Psychem, on our behalf, does what must be done to the old cerebralness—subdues it, soothes it, brings it round, working from within with the utmost thoroughness. Spontaneous feelings are not to be indulged [...] The fiendishness of it all is that part of this mass deception is open and voluntary, letting people think they can draw the line between fiction and fact. And since no one any longer responds to things spontaneously—you take drugs to study, drugs to love, drugs to rise up in revolt, drugs to forget—the distinction between manipulated and natural feelings has ceased to exist.¹⁰

It is possible to observe a more direct, but not literal, reference to the use of psychoactive substances related to a fictional environment and the popularized Virtual Reality.

In 2013, the filmmaker Ari Folman, takes up Stanislaw Lem's novel and carries out a free adaptation of the novel "The Futurology Congress", the film entitled "The Congress", like any adaptation, is far from the literary work, this could be divided into three key moments, which we will briefly describe below: the first is a present, temporarily very close to what we currently live in technological terms, here the digitization and subsequent virtualization of the physical image becomes evident, of the body and even of

the expression of human emotions, by means of an existing technology, such that it scans and transfers the data for its reproduction in video, cinema and television, to name a few audiovisual products; the second moment is the one that resembles the novel by Stanislaw Lem, with some distortions that allow us to approach and connect with the audience due to the proposal of a near future with an approach of truly probable possibilities, in this section of the film we see the protagonist immerses herself in Virtual Reality through a liquid substance that must be inhaled through her nose, in such a way that she can access an animated vision full of vibrant colors, situations and characters based on physical reality, but taken to a fictional plane; In the third and last moment of the film, as in the novel, the devastation of a world that has faced the excesses of the use of this new technology is appreciated, although society congregates in physical reality, each individual is isolated in his own thoughts and in his own fictions. The foregoing makes us question how close or far the fiction seems to reality. Considering these artistic, literary and cinematographic precedents in terms of experimentation with psychoactive substances, their effects and the emergence of new media that would take the form and power of a relatively palpable technology thanks to the development of engineers, designers and artists went to explore other forms of perception:

After leaving his job at the Atari company in the mid-1980s, Jaron Lanier, together with his partner T. Zimmerman, decided to commercially manufacture the famous "virtual reality" glasses, with which they opened an unprecedented dematerialized visual scenario of brain experiences that warned of the imminent technological avalanche, which today we maintain in vogue thanks to mobile devices that allow the construction of variable experiences in multi-support platforms and hypermedia scenarios. The commercial appearance of these glasses can be registered as the "material" birth of the daily experience of "the virtual".¹¹

From the point of view of Parra-Valencia, together with a series of events and proposals for future scenarios produced from science fiction, we reflect on what could be the future of Virtual Reality as a thriving technology that in recent years has become undeniable relevance, especially due to the diffusion carried out through the internet and an imminent access to the virtual universe, resulting in the spread of a digital virtual universe of infinite possibilities.

Mediation through Psychedelic Substance: Use and Creation of New Realities

As we were able to observe the aforementioned pieces of art and literary narratives taken to the big screen, they agree with the use of psychoactive substances, since both activities induce the visualization of images that could seem hallucinatory and that nevertheless are based or inspired by the experiences with physical reality to which we expose ourselves on a daily basis. It will then be possible to notice

the effects of Virtual Reality and how these are related to the effects produced by the use of psychoactive substances. In the case of psychoactive substances, we have been able to observe the stigmatization of their use and the scant research on some of them, even knowing that they have a history that corresponds to the construction of the cosmogony of civilizations that preceded us by thousands of years, in contrast to its prohibition less than a century ago. There is evidence that pre-Hispanic cultures have made ritual use of some psychoactive substances such as psilocybin from hallucinogenic mushrooms, mescaline from peyote, DMT extracted from plants such as *Mimosa tenuiflora* and THC from marijuana, all with the intention of achieving the expansion of consciousness and in the search for knowledge, however the rest of society has been limited by hegemonic entities that have established its use as illegal due to ignorance and perhaps also due to the threat posed by the questioning and destabilization of the institutions of power as McKenna points out in the following paragraph:

The costs of drug education and drug treatment are small relative to routine military expenditures and could be contained. What cannot be contained are the effects that psychedelics would have in shaping the cultural self-image if all drugs were legal and available. This is the hidden issue that makes governments unwilling to consider legalization: the unmanaged shift of consciousness that legal and available drugs, including plant psychedelics, would bring is extremely threatening to a dominator, ego-oriented culture.¹²

Although this text deals with the use of psychoactive substances historically, as a ritual way of entering altered states of consciousness, or a kind of shortcut to stimulate the expansion of consciousness, it should not be taken lightly, far from it, less as an invitation or suggestion, since the use of psychotropic substances is within a legal framework, which implies the full responsibility of the user.

The construction of new realities has started its journey for a long time, from technology, the concept of cyberspace appears for the first time in the novel *Neuromancer* by William Gibson published in 1984, it comes from the story of *Johnny Mnemonic* (1981), included in the volume *Burning Chrome* (1986), who describes it as follows:

Cyberspace. A consensual hallucination experienced daily by billions of legitimate operators, in every nation, by children being taught mathematical concepts... A graphic representation of data abstracted from the banks of every computer in the human system. Unthinkable complexity. Lines of light ranged in the nonspace of the mind, clusters and constellations of data. Like city lights, receding¹³

As we have been able to observe the illusion of Virtual Reality and the hallucination perceived in cyberspace do not precisely correspond to some external chemical stimulus, however, the individual experiences a sensation of reality. In this sense we can suggest some coincidences between the use of devices that refer us to Virtual Reality and

psychoactive substances, among these we can refer to the same mycelial network or mycelium, in which fungi reproduce, including hallucinogens, this network naturally emits information about the nutrients found on one side or the other of the forest, allowing the interrelation of plant species, Nic Fleming states:

*Hidden under your feet is an information superhighway that allows plants to communicate and help each other out. It's made of fungi. The fungal internet exemplifies one of the great lessons of ecology: seemingly separate organisms are often connected, and may depend on each other.*¹⁴

on which he agrees with the way the Internet connects people, transmitting information from one side of the world to another, favoring social relationships, not only for entertainment but also for knowledge.

Cyberspace represents an intangible area without fixed territory and where anyone can access with a computer from their home, their workplace or mobile devices. It is virtual, non-existent from the physical point of view and all those who explore this recently created space are called Netizens, individuals, subjects, public or private, who develop distance communications, expose their skills, generate interactivity for various purposes. For their part, those who have ventured into the exploration of the psyche through the use of psychoactive substances have been called Psychonauts, the term is attributed to Ernst Jünger, who used the word to describe Arthur Heffter in his 1970 essay on his own and extensive experiences with drugs *Annäherungen: Drogen und Rausch* (literally: "Approaches: Drugs and Ecstatic Intoxication"). Psychonauts carry out activities in which altered states of consciousness are induced for spiritual purposes or exploring the human condition, through shamanic rituals, archaic or modern drug users make use of entheogenic technologies. Both Virtual Reality and the consumption of psychoactive substances can cause a state of synesthesia, the alteration of the perception of time, the sense of identity and even empathy, among other effects.

It is important to mention that, just as psychoactive substances act differently, depending on the conditions in which they are consumed (both internal and external), Virtual Reality also produces different effects on subjects exposed to it. It will depend on the way in which Virtual Reality, like psychoactive substances, are used, the frequency, the purpose that is provided, can be as beneficial or as harmful as intended. Let us remember that its applications can range from medical uses that save lives to warlike uses of annihilation without excluding the new possibilities of playful experience.

Those professionally involved know that psychedelics are the most powerful instruments for the study of the mind that are possible to conceive. And yet these people often work in academia and must frantically try to ignore the fact that the answer has been placed in our hands. Our situation is not unlike

*that of the sixteenth century when the telescope was invented and shattered the established paradigm of the heavens.*¹⁵

The work is arduous, we cannot lose ourselves in the fascination of visions or hallucinations to which the consumption of psychotropics or Virtual Reality induces us. Let's take the experiences produced by these tools and do as a researcher does after observing kaleidoscopic images never seen before under the lens of his microscope, he takes notes, writes hypotheses and theories and acquires knowledge that will be shared with humanity, because after all, the serotonin that our brain produces is the most effective hallucinogen that we can find.

Virtual Reality Proposal

One of the most prominent experiences with psychoactive substances is visual alteration. This is achieved in such a way that audiovisual or cinematographic experiences could resemble or imitate kaleidoscopic vision or hallucinations that are often manifested during psychoactive experiences. These experiences may not be psychotherapeutic experience in themselves. Perhaps an adequate guide, like a psychotherapist who could act as a mediator is necessary so that the patient can find the origin of his discomfort and make the most pertinent changes to achieve stability, self-knowledge and self-awareness. Such curative acquisition helps integrate the body, mind and soul in a comprehensive healing.

Bringing Virtual Reality technologies to the field of Medical Sciences, particularly in matters related to psychology or psychiatry is not a novelty, research has been carried out, they stated in the following terms:

*VR offers a promising alternative to exposure in imagination. On the one hand, some patients have difficulty imagining, while others may resist or reject the memory of the traumatic event.*¹⁶

If throughout history we have been able to experience paradigm shifts of thought and social revolutions in which art and technology have played a leading role, it is possible to propose a hybridization that involves the benefits that have been attributed to psychoactive substances. Such acceptance allows its potentialization through immersion in Virtual Reality experiences in order to explore thought processes, and if possible in some way improve mental, physical and emotional health through entheogenic technologies and Virtual Reality art.

Artists from different times and different latitudes have seen fit to capture their visions. We will hardly be able to verify if these were obtained under the influence of psychoactive substances. Deep meditation or access to an altered state of consciousness reveals, however, the similarities between these artistic expressions are undeniable. In the art of mosques, or Huichol art of autochthonous people of Mexico or in the art of Australian aborigines, among many others, we can appreciate qualities such as repetition of geometric figures, the composition in golden proportion, vibrant colors and shapes that could have been interpreted and abstracted

only from nature itself, and the fractals that produce pleasure just from viewing of them.

Figure 3. Australian Aboriginal Art

These images coincide in being inserted in areas that involve meditative rituals or spiritual approach, where the body somehow calms down to focus its efforts on the contemplation of thought processes and the production of mental images. This experience could correspond to the intention to achieve a kind of enlightenment, to the search for knowledge or for mental or emotional peace. This type of images can easily be produced in Virtual Reality scenarios; however, it is possible to aspire to a chemical / biological and technological stimulation, which gives us a better understanding of the universe and our fellow human beings.

[...] in addition to the actual action facilitated through a telepresence interface (say, virtual surgery), there necessarily takes place, within the body of the participant, an embodied experience: a bodily processing of the action that has the effect of “making it real” for the participant. Indeed, it is precisely this “hallucinatory” dimension, applied to virtual reality more generally, that explains the capacity for the VR interface to couple our bodies with (almost) any arbitrary space, and not just spaces that are contiguous with the physical space we happen to occupy or even spaces that are like those we typically occupy”¹⁷

From these references, it is possible to account for the way in which science fiction, literature and art have given impetus and imaginative drive for realities that we have been able to build and experience together as a society. The new epistemology of hallucinogenic VR represents a means of carrying forward responsible applications of both entheogenic and Virtual Reality technologies, a use that allows us to explore human capacities in such a way where we can integrate mind, body, sensitivity, and correspondence with the universe and the realities that compose it. The realities that we create and develop, help us in better understanding and use of both natural and technological resources.

It is necessary to take our minds and research away from prejudices regarding psychoactive substances and their abuse. We cannot afford to turn our backs on what has shaped us humanly and culturally for millennia yet what unfortunately has only led us to a power struggle against their prohibition by controlling authorities. The denial of their existence leads to denial of windows of opportunity which may just be beginning to open and offer us a new future which would be more congruent with the nature that shapes us. This is especially needed when we could incorporate that experience on the path traveled through science, art and technology.

Author(s) Biography(ies)

Sandra CUEVAS, Master in Visual Studies and Bachelor in Graphic Design, both titles from UAEMéx. She has various diplomas in animation, screenwriting, art direction and computer and electronic programming. Professionally, she has collaborated in animation studios as Nickel Studios, Onirik Studio, Inzomnia Animación, Delotroladodelcero Films, working on projects that have been awarded the Ariel award by the Mexican Academy of Cinematographic Arts and Sciences and the Silver Goddess, among others. In teaching, she has been a professor in the degrees of Engineering in Technology and Digital Animation of the UVM, in Digital Art of the Faculty of Arts of the UAEMéx, in Design, Art and Interactive Technologies in the University Center of Art, Architecture and Design of the University of Guadalajara. She has been interested in issues related to imaginary production, creative processes, complex thinking, the use of new technologies, among other topics.

Reynaldo THOMPSON studied architecture at the University of Guanajuato and postgraduate studies at the Polytechnic University of Catalonia in Barcelona and the University of Texas at Dallas, the latter being where he obtained a doctorate in aesthetics studies focused on Contemporary Art.

He has participated in collective and solo exhibitions and curated shows in Mexico and abroad. He served as Head of the Department of Art and Business at the University of Guanajuato and is currently focused on research on art, science and technology in Latin America. His research results have been published in domestic and foreign journals.

He is a member of the National System of Researchers of the National Council for Science and Technology in Mexico and a member of the Ibero-American Observatory of Digital and Electronic Arts.

Tirtha MUKHOPADHYAY, PhD is Professor of Art and Aesthetics at Universidad de Guanajuato, Mexico. He is multi-disciplinary scholar who taught at Presidency University of India (1996-2000), University of Calcutta (2000 -2016) and at University of Texas at Dallas from 2002 to 2005, before migrating to Mexico. He was Fulbright-Nehru Senior Research Fellow at the University of California, Santa Cruz, USA from 2013-2014. His publications include books like 'Affective States in Art' (Proquest-UMI) 'Cezanne to Picasso' (Calcutta University Press, India) and more than 50 articles on creativity, cognition and aesthetics, digital art, visual anthropology and literature, that were published from reputed publishers like OUP, IOS Press, MIT and Atelier-Etno. Mukhopadhyay is also a poet in the Bengali language. He is the Chief Editor of an indexed interdisciplinary journal called 'Rupkatha' since 2009.

One + One = Three: The Added Value of Dual Degrees in Higher Education

Abstract

Can Arts & Science/Technology fruitfully co-exist in the minds and on institutional diplomas of contemporary scholarship? This paper considers how in the global terrain of higher education, the historic tradition of largely mono-disciplinary degrees is being challenged by programmatic complexities that co-join seemingly disparate realms of knowledge and investigation through the introduction of dual degrees. Aided by the benefits of expanding communications technologies, such degrees seek to bridge academic divisions while still contending with very separate intellectual cultures. The discussion takes both an historical and exploratory perspective; ranging from the examination of institutional formations to experiential examples provided by the authors, ultimately positing the central question of whether the expansion of dual degrees represents mere curricular innovation or some thing much more in line with a distinctly new approach to the structuring of intellectual foundation.

Keywords

Dual Degree, Higher Education, Educational Programming, Pedagogical Innovation, Interdisciplinarity, Cross-Discipline

Introduction

Amid a world-wide Covid-19 pandemic affecting many dimensions of education, the historical tradition of mono-disciplinary degrees is being challenged by programmatic complexities that co-join previously disparate realms of knowledge and investigation. The discussion that follows draws from two different profile-bearers. One works at the intersection of Art, Science and Technology and another mainly through Social Anthropology - in order to reflect on the value of university degree programs that allow for innovative learning and research paths.

Although approaches to new teaching and learning paradigms vary from place to place and are often shaped by a variety of local, regional and sometimes even national-level contexts (ranging from the nature of the educational organization to financial, socio-cultural and even political considerations), it is also clear that pedagogical changes may entail greater shifts as much as smaller changes. While perhaps not to the extent of a

paradigm shift in the vein of Thomas Kuhn (1), significant changes in academic division may herald new ways of thinking that mark significant leaps forward in human achievement. Whether this is indeed the case here remains to be seen, but it is nonetheless worthwhile to examine some of the differences in how higher education is being put into operation and thereby, being conceived.

The input for what follows comes on one hand from Nina Czegledy, whose international experience as artist, curator, and educator is strongly linked to interdisciplinary media art. Additionally, André Czegledy draws on expertise from Social Anthropology, integrating ethnographic interests in urban and business anthropology that often foreground institutional relations. Both authors have dealt with the challenges of educational programming within Higher Education organizations, and it is the aim of the current discussion to explore how a new approach to degree construction may lead to significant reassessment of the ways we understand the value of dual degrees. The discussion following begins with examining the Arts & Science/Technology divide in academia. Thereafter, we will examine the prospect of dual degrees, a form of academic programming that challenges traditional Faculty divisions and invites knowledge innovations through learning, research and applied productive collaboration.

Of Scientific Revolutions

In his often cited public lecture entitled “The Two Cultures and the Scientific Revolution ” (2) given at the [University of Cambridge](#), C.P. Snow lamented the intellectual divide between the natural sciences and the humanities. Although not emphasized by Snow himself, this is a divide that has its roots in the formalization of academic disciplines and the development of modern universities as higher education institutions in the 18th and 19th Centuries. Not least, it is related to the important lexical distinction with respect to the person of the ‘scientist’ (pace Lian Zhu & Yogesh Goyal 2019:1), (3) a professional but also cultural designation that has withstood – and engendered – status separation to this very day.

Snow argued that practitioners in both areas should build bridges to further the progress of human knowledge and benefit society. Such a perspective rejects the entrenched belief that cross-disciplinary communication is difficult and to be avoided. Furthermore, it recognizes that ostensibly separate domains of intellectual thought are far more arbitrary in and of themselves (in the sense of self-isolation) than needs be. Are we simply dealing with institutional inertia, or is there more to disciplinary separation than that? Over sixty years on, the established distance between the Arts and the Sciences still persists in most circles (and Society at large), despite significant theoretical and applied advances in knowledge through interdisciplinary fields.

In North America, foundation for plural academic training surfaced in the 1960s through the 1980s, largely by way of so-called 'double-major' degrees at the undergraduate level in Higher Education. Such degrees allowed students to focus on two disciplinary foci rather than one, albeit both of them within a single broader Faculty. They were developed in some parallel to nascent inter-disciplinary programs such as Development Studies, Global Studies, Gender Studies and Cultural Studies which all sought to address newer, topically-based concerns that possessed an contemporary currency but drew on older disciplines for theory and methodological grounding. Interestingly, neither double major programs (which were as much an administrative innovation as a curricular one), nor inter-disciplinary programs took particular inspiration from historic examples of plural academic training such as the precedent of Oxford University's *PPE* (Philosophy, Politics & Economics) program, a grouping that from the 1920s on acted as a 'modern' alternative to the traditional *Classics* degree that was criticised as backward-looking and ethnocentric.

In 2019, Sydney Welsh, an Environmental Studies scientist at the University of Victoria in British Columbia, Canada, was so frustrated with the situation that he wrote in the University's newspaper an open article inviting colleagues to push for interdisciplinary programs. He emphasized that:

„So, then, the solution to this divide is a third party. One that is educated in both art and science, one that can see how the two aren't so different after all.” (4)

For Welsh, the divide between the Arts and the Sciences remained acute enough to seek support on a cross-collegial basis for institutional change – and mobilize colleagues in a forum quite apart from the usual administrative meetings in which programmatic shifts are generally mooted. This is an example of the sort of grassroots and bottom-up

inspiration that we will later see as integral to the development of dual degree programs.

Even the casual observer of institutional change seems aware that there has been a general trend towards academic hybridization signalling an intense period of institutional transformation and revival of interest in interdisciplinarity. It has at least something to do with how in the 21st Century, the very character of learning has become different from what people were accustomed to. A good example of this shift of perspective and academic programming is governmental and institutional acceptance of academic conglomeration. More than a decade ago, educational representatives might have been heard speaking of STEM (Science, Technology, Engineering & Mathematics) as the basis for economic development, in particular. Indeed the STEM touchstone found particular potency within the political elites of the Developing World, so hungry for the sort of solutions approved by donor and multilateral aid organizations ranging from the smallest NGO to the World Bank. Yet relatively recently, this narrow panacea has been challenged by the emergence of a new grouping: STEAM (Science, Technology, Engineering, Arts, Mathematics).

What makes STEAM so interesting from the programmatic perspective is not the simple addition of yet another academic faculty stream, but the seeming creative dissonance accepted by the inclusion of the Arts into the preexisting bundle of so-called 'hard' programs. For example, when Wilfrid Laurier University in Ontario, Canada was considering the development of a new campus in the nearby town of Milton in order to strategically address demand to the immediate west of Toronto, early internal discussions in the 2010s raised the STEM grouping for subject focus, but by 2018 the STEAM variant became confirmed in official press releases - a shift encouraged by the recognition that Arts courses had an important role to play in creating a different sort of intellectual life and education on the new campus.

In addition to STEAM, it is increasingly evident that a wide range of interdisciplinary educational initiatives such as hybrid partnerships and trans-disciplinary collaborations are developing in such a mode that the very terrain of intellectual life is being re-wrought in substance as well as form. This is partly due to the emergence of new technologies as well as ongoing social change. Today's students have a preferred mode of activity and interaction that is frequently *not* in synchronization with traditional educational systems rooted in 19th century models of behavior and 20th century institutional structures. The parameters of formal education are shifting foremost in rich industrialized countries but also more ubiquitously on a global basis as new communications technologies

become widespread and, just as importantly, cheaper (for both institutions and individuals). The element of cost is most apparent in the proliferation of online courses as well as the contributions of 'external' classroom resources ranging from online films to Youtube videos, from off-site testing applications to remote guest speakers.

If anything, the current Covid-19 health pandemic has wildly accelerated the ways in which student feedback has given university students the chance to provide input, both within normal course structures and outside them. For example, when André Czegledy's courses were abruptly shifted to an online format in March of 2020 as Canadian universities responded to the Covid-19 pandemic, student-lecturer contact normally occurring before and after in-person classes needed to be substituted by remote means. At the same time, students began to increasingly organize themselves on an off-course basis in discussion groups that coalesced and dispersed from session to session, imitating informal internet fora. This signalled a departure from traditionally 'contained' class discussion, and is emblematic of wider trends in how students are engaging with their own organization of knowledge beyond the institution. A part of the evolving puzzle is how they are drawing on a wider range of information sources than ever before – sometimes despite the quality of such information.

Nevertheless, Peter C. Herman in his 2020 study of students' responses to online learning found that "for all their differences in age, gender, ethnicity, sexual orientation, citizenship and intellectual preparedness, they universally agreed on their evaluation of online learning: they hated it. There is no comparison, they said over and over again, between the two." (5) Although Herman could not fully anticipate the current health pandemic and its sudden effects on education (given his article was published in June) it is also clear that the addition of technology (on its own) is not enough. For this very reason, programmatic innovations do more than just change how teaching and learning is conducted, they verily test what we think about in our teaching and learning.

Cross Disciplines

While an increasing number of institutions have started to adopt – and even strategically feature – cross-disciplinary programs, even the best intentions cannot obscure serious challenges that spring from the very structure of academic division. This is to emphasize that educational strategies are deeply embedded in historic professional fields as well as contemporary culture. Consequently, professors as much as students continue to work from, as well as within disciplinary formations. Accordingly, interdisciplinary

pedagogy remains elusive precisely because its chief practitioners have rarely been exposed to learning (let alone teaching) in an inter-disciplinary environment from the outset. Their training as thinkers has invariably been of a siloed nature like the ICBMs of old which were sited within bunkers designed to operate independent of their neighbours. Similarly, academic disciplines have fostered their own lines of thought based on the internal development of ideas – as well as the construction of ontological cultures that deeply inform and influence even the ways in which academics communicate ideas to each other. For example, in his early training trajectory, André Czegledy witnessed how Business Studies as a discipline was extremely quick to accept Microsoft PowerPoint as a presentation tool well ahead of other faculties/programs – to the extent that the association between the two is now caricature as much as characteristic.

Macleod emphasizes that beyond the apparent institutional constraints for interdisciplinarity there lie cognitive obstacles as well. He notes specifically "the opacity of domain specific practices to outsiders, conflicting epistemic values, large conceptual and methodological divides and unstructured task environments" (6) To this day, education and training in any discipline within the Arts/Humanities/Social Sciences differs vastly from Engineering or Medicine, for example. Different ways of doing things, different scholarly emphasis, different referential terms, all lead to real complications for cross-disciplinary collaboration ranging from simple discussion to cross-faculty presentations to complex cross-institutional arrangements. Depending upon your disciplinary background: you substantially talk the same, look the same, think the same... or not.

To some extent, difference is understandable given the specific history, methodological specifics, ethical priorities and theoretical foundations that individual disciplines both possess and cherish. Such possession must be recognized by way of the longer history of broader social acceptance as well as institutional affirmation within the context of oftentimes limited collective resources. For this very reason, many academic sub-units representing specific programs have sought strategic advantage by separating themselves from others in order to establish distinction and reward in a zero-sum game of funding and administrative support. But does it need to be a zero sum game? For concurrently, this ongoing situation of independent orientation gives one pause to wonder whether more cooperative strategies of teaching, learning and research might bear equal fruit, if given the chance.

Dual Degrees

If the divide between Arts and Sciences/Technology persists, then how to address it in a creative, programmatic manner? As the aforementioned Sidney Welsh posited:

”Is it too much to consider that exposure to cross disciplinary training leading to dual graduate degrees might resolve this situation? ..The solution to this divide is a third party. One that is educated in both art and science, one that can see how the two aren’t so different after all... (ibid)

What is a dual degree and how might it bring new and different benefits to intellectual pursuit? Dual degrees fundamentally involve a course of studies leading to two separate degrees/diplomas from separate departments and often independent, broader faculties. They may come under other terms such as combined degree, conjoint degree, joint degree or the designation of double graduation program –but the commonality of parallel achievement nonetheless persists. This is qualitatively different from the ubiquitous double major degrees at the undergraduate level, or the multi-disciplinary programs leading to a single diploma distinction. The parallel nature of dual degrees not only invites dual registration in separate academic programs and separate faculties – but also the possibility of two degrees emanating from more than one university. The latter prospect is a significant departure from the simple inclusion of training and/or experience across or between institutions (like so-called Third Year Abroad programs wherein students spend an academic term at a foreign institution to broaden their intellectual and cultural horizons). It also presupposes the ability of universities enfolded in different countries to work together. This is not just administratively challenging (on top of academic programming); it also needs to encompass the reality of two completely independent legal systems that govern the issuance of academic degrees in respective countries. Understandably here, there is an institutional inertia involved in the creation of dual degrees. Simplified, the administrative workload is significantly magnified, and throughput is endangered because of the high demands on the time and effort necessary for completion. Nonetheless, the perseverance of select universities in developing dual degree programs also raises the prospect of important learning innovations along with the ability to feature such cooperation as a mark of competitive curricular provision.

An important point to make in favour of dual degrees is their frequent use of digital connections in order to integrate ongoing studies between programs, between faculties, between universities and between

countries/continents. Simply said, they are technology-demanding and technology-intensive. In other words, the premise of dual programs as a meeting place of intellectual thought highlights broader communications as a basis of curricular support. This means that the application of communication technologies to take students beyond a single classroom becomes increasingly normative. In much the same way, during the current Covid-19 health pandemic, the shift to online instruction has entailed a reassignment of the overall status of technology. As Mishra, Gupta & Shree point out in their early analysis of the impact of the coronavirus on Higher Education:

”Previously, e-learning, distance education and correspondence courses were popularly considered as the part of non-formal education, but as of now, it seems that it would gradually replace the formal education system if the circumstances enduringly persist over the time.” (8)

A wide range of dual degree programs exist in Canada as of 2021 (9). The largest segment is co-anchored in either MBA or Law degrees, a presence that betrays wider social bias regarding professional career applications later in life. Not surprisingly, dual degrees in Canada and elsewhere are seldom available in Arts & Science/Technology, marking the difficulty institutions as much as individuals have in administratively as well as cognitively resolving the perceived divide between them. Of course, there are exceptions. Nina R, Erika O. and Sarah M of Wonder put together a list of (USA) Arts Universities that collaborate with technology-focused Universities to offer some joint degree. Noteworthy examples include Stanford University which has a graduate design program jointly with its School of Engineering. The Rhode Island School of Design and Brown University Dual Degree Program provides a Bachelor of Art or Bachelor of Science (Wonder). Stanford University also offers a graduate art & design program that is a joint program through the School of Engineering. (10) Such programs represent but a referential selection of a growing number of dual degree opportunities. Yet their very existence, it must be recognized, goes against many of the existing prejudices within both Education and Society. In such regard, dual degree programs often have their origins in grass-roots (that is, student and teaching faculty) inspirations as much as top-down initiatives. This dynamic cuts against the grain of standard curricular development trajectories. and aligns with broader societal trends in advocacy emblematic of democratizing technological phenomena like Social Media.

Nina Czegledy’s visits to academic institutions with dual

degrees has reinforced her conviction of their value. In terms of personal experience, this is part and parcel of a longer history. Some fifteen years ago, she visited the Digital Arts Department at the University of the Witwatersrand in Johannesburg. It had pioneered an Art & Engineering program/degree which remains active today and has been advertised as follows:

“Digital Arts as an Engineer focusing on Game Design, you’ll be afforded the chance of combining more traditional aspects of Electrical and Information Engineering with the creative and functional aspects of games... The BEngSc (Digital Arts) is intended to produce graduates that can become specialist practitioners in the technological arena of software development within a game context. You will attend half of your courses in the School of Electrical and Information Engineering. Here you will do Physics, Maths, Electric Circuits, Software Development, and Electromagnetic Systems with Game Design as the core subject.” (11)

Another example for us is Aalto University of Technology in Helsinki, Finland. It offers several dual degrees, including Communications Engineering & Machine Learning, and Data Science & Artificial Intelligence. For illustration, when Nina Czegledy visited its New Media Department, she saw a presentation by a student from the Music Faculty researching collaborative project possibilities *with* Media Art students. Moreover, students completing their first year in some double degree Aalto programs can move institutions to EURECOM for their second year – ultimately receiving two Master’s degrees, one from each university. This sort of cooperation within the mechanism of dual degrees gives us a good example of how such programs can set precedents for curricular opportunity to create a broader terrain of education – and maximize wider institutional resources in the process. (12)

Bridging the Gap/Closing the Divide

In 2017, Nina Czegledy visited the Nano Lab of the Visual Communication Design Department at the Federal University of Rio de Janeiro (UFRJ); The Nano Lab is a highly unusual place, a cross-disciplinary venue exploring artistic interfaces with natural organic elements in telematics environments. IBM Research advertises the Nano Lab as the first Nanotechnology Lab in the Brazilian IT industry and part of a \$4 million investment. Its work

seeks to bridge the gap between Arts and Science//Technology by providing a dedicated space to move beyond disciplinary boundaries. During Nina Czegledy’s visit, Gabriel Bastus, a student from the Electronic Engineering program presented his research implementing Artificial Intelligence features into art projects. (13). He emphasized how exposure to an Arts environment gave him the chance to consider inserting technology in new domains of operation.

There seems to be a keen interest in the Nano Science and Media Art connection. Thinking ahead by generation, the UCLA School of Arts in Los Angeles hosts the Sci|Art NanoLab Summer Institute for high school students to introduce the possibilities of Art|Science collaboration. This engagement is part and parcel to pursuing and promoting an evolving “Third Culture” of knowledge generation..(14)

Today, a gap still remains between theory and real cross-disciplinary practice, between formal educational scenarios and rapidly developing making activities. Yet during the COVID-19 pandemic, basic features of teaching and learning have become particularly fragile and susceptible to change, unintentionally lending strength to the same communication technologies that underpin dual degrees and evolving cross-disciplinary programs and activities bridging the World. Children are taught basic electronics in on-line museum workshops. Adults take courses to brush up on their digital/communication skills. So-called ‘hackatons’ are popular and social media effectively permeates our lives. The lecturers, instructional leaders, as well as the students, frequently work in mixed teams, connecting from remote locations to collaborate in hybrid environments. This creative explosion has not been pre-planned. It has at least something to do with a generational emphasis on novelty that has become such a dominant theme in global culture supported by internet browsing, ‘instant’ information and digital communications. In other words, one of the engines of curricular development may have less to do with institutions, and more to do with the broader general environment that they operate in. This increasing seamlessness of interior to exterior is (not coincidentally) mirrored in the personal lives of a new generation of students as used to communicating their identities online as anywhere else.

While immense progress has been achieved in curricular development with regards to the first steps of establishing dual programs as a viable educational option, critical issues remain to be unraveled. As recognized by Culver, Puri, Spinelli *et al* (15), dual degree programs seem to have unexpected outcomes that include personal rather than professional gains in the evaluation of their graduates. This

is compounded by a lack of understanding regarding the nature of such programs by employers, as well as the their perception that graduates are not necessarily more valuable. The last point is densely revealing. Firstly, because the doubling of received accreditation is commonly not recognized. Secondly, because the expansive and intensive nature of double degree programs is also often overlooked. Inasmuch as such concerns undercut the motivation for dual degrees, it is important to add nuance to the picture. Reference to Fleming, Mahalinga, Shortiss *et al* (16) is valuable here, The authors note how initially, employers do not value dual degrees on an intrinsic level, preferring instead to lay stress on technical skills and numerical/academic results (in a study conducted with Engineering students). However, the caveat is that in the later stages of an employee's career, it is the broader expertise of the dual degree which give one greater chances of promotion and is more appreciated.

This reality brings us to an important question, even if only to act as point of reference going forward beyond the current discussion: How do cultural differences play a part in the dual degree context? The question raises the issue of how dual degree programs must pay special attention to addressing cultural dynamics as a matter of inception as well as operation. Beyond the organizational dimension, such attention needs be both pedagogical and content-driven, for as Loreto R. Pietro recently notes in "Concerns about teaching culturally diverse students in a cross-disciplinary sample of higher education faculty":

"A greater acceptance of culturally diverse students was also associated with a faculty assigning greater importance to incorporating content regarding cultural diversity into their courses, and spending more time discussing diversity issues in class." (17)

Such questioning underlines the significant hurdles still to come. To some extent, such international cooperation may not be fully solvable because of the social, economic, political, constitutional/legal and cultural differences at play between institutions. At the same time, there is positive cause to reflect on the significance of what is happening.

Of Shift and Significance for the Next Generation

Despite numerous conferences and publications on the subject, the central question of whether traditional educational paradigms will change fast enough for the demands of an emerging generation remains substantially unanswered as always. Institutions of higher education are notoriously conservative, however innovative in

knowledge creation they may be, and however influential their campuses are in fostering cooperation. This is not entirely surprising, as they are entrusted with the weight of both inspiring the development of minds at the highest level of intellectual achievement, and with protecting young adults still transitioning from being receptive learners to active leaders within communities. For many learners, it is in higher education that the parameters of thought become finely tuned, irrespective of divisions established as early as elementary school. For this reason, the development of dual degrees actively revises ontological paths to accept the juxtaposition of knowledge and its development, with creativity unshackled from disciplinary boundaries.

David Bohm, the visionary quantum theorist, was an early proponent of a creative impulse in and between the Arts and the Sciences. He maintained that creativity is fundamental to human experience and predicted that someday, Science and Art will merge. (18) He later declared: "Creativity is, in my view, impossible to define in words. The scientist emphasizes the aspect of *discovering oneness* and totality in nature. For this reason, the fact that his work can also be creative is often overlooked. But in order to discover oneness and totality, the scientist has to create the new overall structures of ideas, which are needed to express the harmony and beauty that can be found in nature" (19) Will this merger finally take place in the persons of dual degree students to form a new balance, maybe develop a new educational ecology embraced by their degrees?

Our discussion has sought to relate some of the hazy background of dual degrees, as well as emphasize the challenges their establishment places upon institutions and participants alike. While it would be claiming too much to assert that dual degrees will change the landscape of higher education by and of themselves, there is little doubt that such programming will continue to sharpen discontinuities with traditional forms of reference. This is no mean feat given the structural rigidity of institutionalised education. As a consequence, the real question for stakeholders in dual degree programs is to what extent will the tension between administrative needs on the one hand, and educational innovation on the other, be serviced by heterogeneity rejecting coalescence. If only the former, then the existing division between the Arts and Sciences/Technology will continue unabated, largely because of a marginal incentive to change entrenched institutional positions/practices. The latter, however, could unlock new avenues of knowledge application as well as creation. This could mean that no longer would it be necessary to call in an artist *or* designer in order to aesthetically/ergonomically (re)work a material product – as the range required could be found in

a single creator. Any previous creator or inventor, etc. might have once been schooled in a single discipline, but now they could be sensitive to a broader and holistic set of dimensions in addressing complexities of overall development. So while - once upon a time - it was in the best interests of academic disciplines to establish and protect the boundaries of their field - so as to exert self-designated control over the knowledge domain of their claim - the creative prospects inherent in dual degree programs may yet challenge the old guard and its limitations.

Author Biographies

André P. Czeglédy is Associate Professor of Anthropology at Wilfrid Laurier University and former Head of its Department of Anthropology. He has lectured variously at the University of Cambridge, the Budapest University of Economics, the University of the Witwatersrand and now Wilfrid Laurier University. His chief research interests lie in Business Anthropology, Urban Anthropology and more recently Museum Studies. Such research has involved ethnographic fieldwork in both post-socialist Hungary and post-apartheid South Africa, chiefly looking at the dynamics of rapid change societies. His long-standing writing partnership with Nina Czeglédy focuses on

the intersection of Science/Technology, Art & the Body, paying special attention to dynamics of visualization and power.

Nina Czegledy is an independent curator, media artist, researcher, an educator based in Toronto, Canada. She collaborates internationally on Art & Science/Technology projects. Upcoming: 2022: *A Light Footprint in the Cosmos*, Substantial Motion Research Network, Vancouver, *Sensoria, the art and science of our senses* Laznia, Contemporary Art Centre, Gdansk, Dobbie Debate on-line game, Balance Unbalance, New Zealand (co-curator). Abstract

The paper presents the context and inspirations for the *Flower Antenna*, a large-scale, hovering, sculptural sound installation that combines sound and transmission art, computational textiles, and architectural design. Computational textiles include microcontrollers and other electronic components as well as use the natural property of the fabric to communicate information to people. The *Flower Antenna* was exhibited at the Museum of Modern Art's (MOMA) *Reconstructions: Architecture and Blackness in America* during the spring of 2021. The authors discuss the use of electromagnetic waves via an electronically active textile construction as a form of non-visual media used to represent the paradox of Blackness and the presence of Black people in architecture in the wake of the history of slavery in the United States. Electromagnetic waves are neither seen

nor recognized by most people, yet they shape the spaces people inhabit and support almost every part of society today with the use of invisible networks cast by the internet and its structures. This artistic project contributes to a discussion and reconstructing an understanding of Black culture in transmission arts, textile design, and in architecture.

Keywords

Electromagnetic waves, architecture, sound installation, media art, computational textiles, textile design, antenna, Blackness, race, America.

Introduction

This paper presents the inspirations and context for the *Flower Antenna*, a large-scale, hovering, sculptural sound installation that combines sound and media art, computational textile design, and architectural design. The *Flower Antenna* was exhibited at the Museum of Modern Art's (MOMA) *Reconstructions: Architecture and Blackness in America* in New York City during the spring of 2021. The authors discuss the use of electromagnetic waves via an electromagnetic textile construction as a form of non-visual media to represent the paradox of Blackness and the presence of Black people in architecture in the wake of the history of slavery in the United States.

The *Flower Antenna* is an elliptical-shaped flower, 21 feet (6.4m) long by 15 feet (4.5m) wide. The sculpture operates as a large receiving antenna picks up the frequencies of electromagnetic waves passing through the gallery space, and through a logarithmic amplifier circuit, converts the received frequencies to sound waves to be heard in the installation space. 34 knitted textile cones are suspended around a lightweight elliptical ring that is attached to the gallery ceiling. The cones are hung closer to the ring at one end of the long axis and drop down to the floor at the other end creating a rising section underneath the piece (Figure 1). The project has a pink underbelly made of conductive copper and cotton yarn used to create the conical forms that is electronic and is used to sense electromagnetic waves which is then translated as sound in the gallery space.

Background

There are two principal metaphors that operate in the *Flower Antenna*, and that have inspired the use of electromagnetic waves as the media to carry the work and connect it to the Black diaspora: the wake, and invisibility.

The Wake

The first metaphor derives from author Christina Sharpe's concept about 'the wake' as the disturbance that is created behind a ship moving through water. In her book, *In the Wake: On Blackness and Being*, Sharpe discusses a wake created by slavery that remain as ships crossed the Atlantic Ocean with human property. [1] The wakes she describes are the after-effects of slavery on aspects of Black life in the United States and globally by the slave trade. She asks scholars, artists, and other cultural producers to "stay in the wake", which is to work in a way that does not

"seek to explain or resolve the question of this [Black] exclusion in terms of assimilation, inclusion or civil rights, but rather depict aesthetically the impossibility of such resolutions by representing the paradoxes of

blackness within and after the legacies of slavery's denial of Black humanity." (14)

Sharpe names this paradox of the wake and uses it to understand "how slavery's violences emerge within the contemporary conditions of spatial, legal psychic, material and other dimensions of Black non/being as well as in Black modes of resistance" (4) [2] Further, in a descriptive passage, (Anon Author) writes that the *Flower Antenna*

"links to an invisible urbanism floating above and through the city on electromagnetic waves. These waves are a new global ocean and traversing it in our everyday practices is as perilous as the Atlantic of the Middle Passage. Will all bodies be slaves in these global waters? Who will be seen and who will not? What new but invisible boundaries are being constructed in this electromagnetic city? All bodies lie in its wake. So, there is wake work to be done on this new ocean that is fast shaping our lives." (55) [3]

The *Flower Antenna*'s use of electromagnetic waves as a media is meant to call visitors' attention to this invisible electromagnetic system that connects all of us through the internet, the radio, and other devices that rely upon electromagnetic waves to function. In fact, these waves produce a new electromagnetic ocean that also has been used by dominant culture to *reproduce, again*, systems of service and profit extraction, exclusion and oppression of Black people. This electromagnetic ocean is an invisible wake that we all live in. The *Flower Antenna* calls attention through its explosive form to this wake.

Invisibility

The second metaphor used in the work regards the invisibility of Black people as an aftereffect of slavery. This paradox of Blackness is described in Ralph Ellison's *Invisible Man*:

I am an invisible man. No, I am not a spook like those who haunted Edgar Allan Poe; nor am I one of your Hollywood-movie ectoplasms. I am a man of substance, of flesh and bone, fiber and liquids - and I might even be said to possess a mind. I am invisible, understand, simply because people refuse to see me. Like the bodiless heads you see sometimes in circus sideshows, it is as though I have been surrounded by mirrors of hard, distorting glass. When they approach me they see only my surroundings, themselves, or figments of their imagination - indeed, everything and anything except me.

Nor is my invisibility exactly a matter of a biochemical accident to my epidermis. That invisibility to which I refer occurs because of a peculiar disposition of the eyes of those with whom I come in contact. A matter of the

construction of their inner eyes, those eyes with which they look through their physical eyes upon reality. I am not complaining, nor am I protesting either. It is sometimes advantageous to be unseen... (3) [4]

Contemporarily and historically, Black people in the United States have been made invisible through systematic oppression and discrimination. Ellison points out to us the possibility of using this unseen place in a broken system for artistic expression. In describing Louis Armstrong's music, Ellison notes that Armstrong is not aware he is invisible; he is someplace else "[that] he's made poetry out of being invisible". Ellison hears the breaks in time in Armstrong's music and "you can slip into the breaks and look around" [5]

The invisibility and yet presence of Black people and Black culture is much like electromagnetic waves, where Black culture has always been present, yet not fully acknowledged. The insistence on being present by persons who are invisible causes a rupturing and ripping of the fabric of life in the United States and in other nations globally where human and civil rights are not deployed in equitable ways. The rise of the Black Lives Matter protests, and historical protests over the killing of George Floyd are social ruptures caused by the invisibility of Floyd and Black people.

Electromagnetic waves are always here, and have always been here. "We are bathed in these waves, TV, broadcasts, probably telepathic messages, from other minds deep in thought." [6] Or, as Richard Feynman writes about the inconceivable nature of the number and types of electromagnetic waves that we are intersected by and live in but do not realize. "IT IS ALL REALLY THERE," [7] It remains to us to craft devices to tune in, in the poetic break of time, if we hope to survive together. The artist Kerry James Marshall uses rich and multilayered colors of black to great effect to elicit this feeling of absent presence he understood after reading Ellison's book [8] (Figure 2).

Electromagnetic Arts in Black Culture

There are artists working in fields such as interactive and electronic art, sound art and music, furthering the black diasporic mission, or as Sharpe says, looking for the aesthetics of this condition. Among Black, African American, and the African diaspora, there are artists and activists who have taken to working in electromagnetic art (as a type of electronic art), primarily in the form of transmission art and radio for creative and critical purposes and expressions. For example, Mbanna Kantako (also known as Dewayne Readus) pioneered the artistic and political practice of microradio while living in a public housing project in Springfield, Illinois. As a Black activist, he began the station WTRA for political organizing in 1987 among the residents of his housing project. Today

WTRA is known as the Human Rights Radio, and is now an international organization. [9]

Figure 2 Kerry James Marshall, A Portrait of the Artist as a Shadow of his Former Self, 1980 ©LACMA

The Prometheus Radio Project of West Philadelphia broadcasts from a secret location as WPPR, or West Philadelphia Pirate Radio. In an act of defiance against the FCC (Federal Communications Commission based in the United States), they broadcast without license, noting that at the time almost all radio stations in the United States with FCC licenses are owned by only a few corporations. The information distributed through commercial and corporate owned radio has traditionally not benefited Black communities, thus motivating WPPR. WPPR was reborn in 1998 from the take down of Radio Mutiny that served an African American community of West Philadelphia. [10] Most of the sonic works by the artists Mendi and Keith Obadike of Black Sound Art reference the Black experience. This duo have created many sound installations that also cross into live performance that includes original music and dance. Their project *Four Electric Ghosts* (2009) made in Toni Morrison's workshop tells the story of the afterlives of 4 ghosts. [11] The Obadike's also have sound installations in galleries that focus specifically on more abstracted sound including a piece titled *Ring Shout for Octavia Butler* that uses recordings of the Earth's electromagnetic waves and is "underscored by circularly panning audio recordings of the Earth's electromagnetic atmosphere". A third piece, *Blues Speaker for James Baldwin* uses the glass facade of a building as a method to deliver the sound, thus turning the building into a speaker.

[12] The examples of radio and Black diasporic sound archiving, remixing and projecting are crucial to understand the context of this project. The critical concern of the *Flower Antenna* is to sense invisible electromagnetic fields as raw media. This media is a metaphor to carry ideas about the invisibility and presence of the Black diaspora.

Electromagnetic Fields as Artistic Material

Electromagnetic fields are composed of electric and magnetic fields that oscillate in perpendicular planes, that are interdependent and locked in co-existence. These fields draw analogies to “ether” and “atmosphere” as an omnipresent force or an “abstract everywhere” [13] that form the environment in which we exist. Electromagnetic fields are “invisible, intangible, and inaudible” [14] passing through the objects and spaces that make up our built environment. Most electromagnetic fields are artificially produced by telecommunications that compose the modern world, while the Earth itself produces its own electromagnetic field that resonates at a very low frequency (3 – 30kHz). [15] Through demodulation and amplification, these fields can be detected and translated into sound.

Artists have been working with electromagnetic fields as a form of artistic material over the past century, for example John Cage [16], Alvin Lucier [17], Takis [18], Robert Barry [19], Christina Kubisch [20], Joyce Hinterding [21], Scanner [22], Akin O. Fernandez [23], Pe Lang [24], to name a few. Artists’ engagement with EMF suggests that they present as malleable, formable material that can be used for artistic purposes.

Sonic Aesthetics of Electromagnetic Fields

The indeterminate and irregular sonic expressions of EMF picked up by the *Flower Antenna* present at times as “noises, bleeps, blips, and pulses” [25], as well as static and screeching sounds. These sounds have no beginning and no end; they are persistent layers of multiple transmissions that intermingle with one another as they pass from background to foreground in our sonic awareness. Sound artist Valerie Dubois has described specific signals found within the high frequency spectrum. To Dubois, Bluetooth signals present as high, steady-pitched sounds that, when mixing with other signals, start to create a sonic texture where “medium to fine grain particles intertwine in the foreground, while a more fat and gross granular texture lies in the background”. [26] She describes WLAN as expressing a dry, persistent ‘pa.pa.pa.pa.pa’ sound, and the sound of GSM as a “morse code that displays an aggressive character” and that does not evolve over time [27, *ibid.*] These sounds are site-specific, yet they transcend the architecture of the gallery

space, and draw our attention to the immediate invisible through an act of affective listening.

Fibre Arts and Black Feminist Cultures and Networks

Within the United States, Sharbreon Plummer writes in *Haptic Memory: Resituating Black Women’s Lived Experiences in Fiber Art*

“The erasure of Black women’s presence and voices has been a significant problem throughout the course of history—including artistic discourse. Although progress has been made in terms of visibility, there is still an enormous amount of work required to rectify the effects of white supremacist hegemony on Black women’s artistic progress” [30]

[Plummer] argues that not only do Black women artists exist in a space of double-subjugation due to the intersections of race and gender; those who choose to work in the medium of fiber are also faced with the historical baggage and discrimination that accompanies craft-based mediums) [31]

Furthermore, [Plummer argues] that

“Traditional Eurocentric methods of interpreting fiber-based work are limited in their ability to effectively account for the specialized relationship that Black women have to materiality. While literature surrounding women’s work may account for the gendered history of fiber and textile-based practices, Black women’s contributions and distinct relationships to labor and creativity are in need of continued exploration. Plummer proposes looking at the intersectionality of Black women’s experience” to account for Black women’s lived experiences and creative outputs.” (13) [32]

The intersectionality Plummer refers to is Kimberly Crenshaw’s concept of intersectionality that looks at gender, race, class as interconnected systems, that exist in an environment structured by supremacist hegemony. [33, *ibid.*] For Plummer Black Feminist Thought, work done by Black women working on the margins of an emergent larger women’s movement, and theorized by the sociologist Patricia Hill Collins provide methods to understand and resist dominant values placed onto Black women. [34, *ibid.*] In addition the writings of Collins and others provide critique against a dominant system.

Rose Sinclair, a British based textile designer and professor writes speaks about the notion of Caribbean all-women textile networks in the UK in the ‘50s and ‘60s that generated social and economic change. These clubs used “life and oral stories to tell the untold”, while the women’s textiles “embody both material culture and diasporic tales”.

These clubs and the women in them have provided new ways to think about textile networks and their impact in textile design. [35] As a designer she discusses the invisibility of the Black woman in the crafting space, not appearing in mainstream magazines and literature. These are places that provide a maker a liminal space that “allows for the reader a construction of creative methods through which they understand portrayal of self and by extension representation.” (112) [36] Without self-representation, the envisioning of a (possible) future or its creation can be limited.

Women Working with Large Textile Structures

According to Oghazian and Vazquez, there are at least three scales of consideration working with textiles for large architectural structures. First, there is a micro or stitch scale that demands close attention to stitches and the structure of the textile emerging. Second, there is a mesoscale that the structure of the emergent fabric. Finally, there is a macro scale that demands consideration of textile behaviour for making large parts of the structure that shelters people. A designer working with textiles for architecture must move between multiple scales between small micro-scale and the macro scale of a shelter. [37] The *Flower Antenna* is a large-scale installation work that uses the textile as architecture: that is, it takes up and produces space. There are a few artists whose work takes up space working in bespoke knitting or textiles that use interlooping (I.e., knitted or knotted textiles) and that produce space as architecture. Janet Echelman is an artist who works with netted structures that attach between buildings over large plazas or in large indoor spaces. An example of Echelman’s work may be seen in her piece *Earthtime I.78* in Vienna, installed in 2021.

[38] Echelman’s vibrant coloured structures are suspended in the air, seemingly floating freely above viewers’ heads. Another artist using knotting to make works that produce spaces for children to play such as *Woods of Net* in Japan is Toshiko Horiuchi MacAdam. Her work *Fiber Columns/Romanesque Church* reconstructs a church arched passage. [39] *Soft Civic* built in Columbus Ohio in 2019 by architect Bryony Roberts, is a knotted play space for children. [40] The work of Mette Ramsgard Tompson at the Center for Information Technology and Architecture at the Royal Danish Academy uses industrial knitting for architectural-scale structures such as the *Hybrid Structure* in the central square of Guimaraes, Portugal: Largo do Toural constructed in 2016 or *Isoropia* built for the Danish pavilion at the 16th Venice Biennale. [41, 42] Other designers that work with knitting for large structures are Jenny Sabin a designer in New York in the project *Lumen*, a structure that changes colors based on the amount of light was installed in the courtyard of the Museum of Modern Art’s PS1 in 2017. [43] Heat responsiveness is used in the

works of knitted tension structures *Patterning by Heat* by Felecia Davis and Delia Dumitrescu. [44] The work of Jane Scott with MUDD Architects, in the *Bioknit Pavilion* in Cubbitt Park, Kings Cross, London in 2019 uses inflatable technology combined with 3D knitting. [45] While there are men working with knitted textiles in large-scale architectures, for example, Sean Alquist and his *Social Equilibria – Orchids Playscape* [46], this area of large-scale architectural knitting currently seems to be populated mostly by women.

Electromagnetic and Transmission Arts in Textile Art and Design

Textile antennas are generally designed for applications such as receiving and transmitting from wearable electronic systems. [47] However, alongside their functional properties textile antennas can also be carriers of metaphor and meaning, and therefore present in various forms across art and design. In Ebru Kurbak and Irene Posch’s work *Drapery FM* [48], a large, knitted textile is suspended from the ceiling in a gallery setting. Knitted copper rows and wales of the textile are separated by dielectric wool yarn stitches to form textile-based resistors and capacitors that make up the tuning circuit. The signal antenna is knitted within the same textile structure as the soft tuning components, resulting in a fully soft FM transmitter. Nearby radios in the gallery space are tuned to the FM frequency of the textile and can listen to an audio recording of the hand-knitting machine working as the textile antenna was knitted. The work presents as soft electronic art, merging textile materials and techniques with the intangible and invisible medium of radio waves.

In *Listening Space* [49], Afroditi Psarra uses software-defined radio (SDR) to record satellite passes in proximity to her listening station. These transmissions are translated to audio waveforms that are assigned as yarn and colour changes on a hand-knitting machine to produce pattern changes. The pulses that make up the transmission signals are represented with black and white yarns, as signals and void. Psarra’s use of knitted textile on which to transpose the satellite transmissions was for the purpose of archiving the transmission that would otherwise be lost to the ether due to their temporal nature.

Erin Lewis’ *Ambient Energy Harvesters* [50] is a series of textile antennas that use various yarns and textile structures to yield different frequency ranges. These large, reconfigurable textile antenna structures are suspended from trees in the dense Swedish forest where they pick up electromagnetic waves from free space and, through a half-wave rectifying circuit, convert the waves to a usable power source. The power can be used for practical and artistic applications, and functions in remote places. Lewis

states that “positioning them in the forest reveals a contrast between expectation and reality -- where EMF surrounds us not only in urban environments, but in nature environments as well.” (142) [51]

Description of the work

The *Flower Antenna* is a 21' (6.4 m) by 15' (4.5m) knitted textile receiving antenna sculpture. The sculpture is suspended from the ceiling from a light 20lb (9kg) fiberglass ring that holds 34 parametrically sized cones that hang from this ring. The cones are attached to the fiberglass ring by rope. The knitted cones are made of industrially knitted cotton and copper and cotton yarns, tensioned with aluminum hoops at each end. Fine fiberglass rods provide intermediate ring support and straight fiberglass members the weight of the entire work is 200lbs (90kg).

The cones for the Flower Antenna were knitted on a Shima Seiki Whole Garment knitting machine that permitted seamless tubes as well as integrated pockets that held the compression system of lightweight fiberglass rods (Figure 4). The project was installed at the Museum of Modern Art in New York, as part of the *Reconstruction: Architecture and Blackness* exhibition in America the spring of 2021. Authors David and Lewis worked to develop a functioning receiving antenna (Figure 3). The project uses invisible electromagnetic waves to build upon the metaphorical relationship of invisibility of Black culture and as an artistic expression in textiles using a medium that is invisible.

The project translated invisible electromagnetic waves in the gallery to sound through its industrially knitted material. During the exhibition at MoMA during Covid-19 restrictions there was not an opportunity to record and understand how people interact with this antenna. There was no opportunity to tune or play with the potentials of the materials or aesthetics of the sound. This work is planned for a future installation of the project.

EMF-Sensing Electronics

The *Flower Antenna* uses a logarithmic amplifier circuit (Figure 5) that detects high frequencies in the range of 2.4GHz and 5GHz, which spans Bluetooth, WiFi, GSM, and GPS, and other intermittent spectrum noise. The circuit has been adapted from the open-source design of Howse and Mizayaki's *Detektors* circuit used for sonically expressing EMF [52] [53], though has been modified to allow for the knitted petals of the *Flower Antenna* to affect the frequency of the signal based on the textile antenna properties. The circuit interprets the radiant qualities of the textile material over an area, and the scale of the radiant surface to set the gain of the signal. Further, the position and scale of the *Flower Antenna* in the gallery space is directionally

sensitive to the reception of electromagnetic waves within the frequency range. The final presentation carries a quality of indeterminacy due to the auxetic qualities of knit materials when stretched in a frame, in addition to the qualities of the MOMA gallery which includes interference and reflection from building components and the dense electromagnetic environment in which the MOMA gallery is situated.

Exhibition

The *Flower Antenna* was displayed for three months in the MOMA Gallery. A speaker was set up at the entry into the part of the gallery that the antenna sat in, separated from the knitted piece by a threshold (Figure 6). When visitors walked into the space, they heard the high-pitched squeal of the antenna. Some participants reading the gallery description of where the sound was coming from sent a partner or friend over to the antenna to see if they could change the sound of the piece by going very close to the piece but were stopped by gallery minders as well as a tape guard marking the ground. People were not able to get close enough in this gallery. A second installation of the piece is

planned so that the authors can play with the antenna and hear how it changes as bodies get very close to it.

Contributions and Future Work

This work makes a contribution to artistic practice related to Black culture, in particular in the United States. Contributions include the design of a large scale, space producing or architectural structure made of textile that has the added functionality of performing as a wide band antenna. The authors have used this networked textile as a way to tune into the disruptions and turmoil that roiled the United States initiated by the murder of George Floyd. This event resonated globally and is a historic and transformative moment. By tuning in to this broken system, as artists, cultural producers, designers, we can, in that paradoxical system, remake another vision for a world [54] In spite of the persistence of a historic system that pushes out and de-values Blackness, we can invent a place of creativity, freedom and life affirming values.

The Medium is the Environment: Digital Materialism, Digital Art, and the Climate Crisis

Kevin T. Day

School of Information, University of British Columbia
Vancouver, Canada
kevinday@mail.ubc.ca

Abstract

Contrary to the notion of immateriality and commonplace imageries such as the cloud, information and communication technologies (ICT), from individual devices to the general infrastructure, are grounded in the natural world, ranging from the materials needed for production to the e-waste that is produced through planned obsolescence and aggressive consumerism. Despite such entanglement with the material substrate, the environmental implications of ICT usage is overlooked by the ICT industry, as it continues to exploit natural resources and cultivate a culture of consumption. Such socio-political landscape warrants an exploration of potential counter tactics in the field of digital art. This paper examines the environmental implications of ubiquitous ICT manufacturing, deployment, and usage, using the theories of new materialism and digital materialism. Following these theoretical lenses, the paper proposes that a focus on the material is necessary in digital art, which functions as an antithesis to the abstracting act of information/data and its purported immateriality.

Keywords

Environment, climate crisis, digital art, interactive art, digital materialism, new materialism, ICT

Introduction

As the information consultant Gerry McGovern cautions, “Digital trains us to treat energy as a limitless, free resource ... In tech industry, the more energy we consume the more money they make. The tech business model involves the maximum exploitation of cheap energy. These cheap and “free” models feed the fires of the climate emergency.” [1]

Contrary to the notion of immateriality and commonplace imageries such as the cloud, information and communication technologies (ICT), from individual devices to the general infrastructure, are grounded in the natural world, ranging from the materials needed for production to the e-waste that is produced through planned obsolescence and aggressive consumerism. Despite such entanglement with the material substrate, the environmental implications of ICT usage is overlooked by the ICT industry, as it continues to exploit natural resources and cultivate a culture of consumption.

Such socio-political landscape warrants an exploration of potential counter tactics in the field of digital art.

This paper examines the environmental implications of ubiquitous ICT manufacturing, deployment, and usage, using the theories of new materialism and digital materialism. Following these theoretical lenses, the paper proposes that a focus on the material is necessary, which functions as an antithesis to the abstracting act of information/data and its purported immateriality. To explore this possibility, the paper will outline the author’s most recent interactive video installation, which consists of a series of smoke machines that will emit smoke based on the gallery’s data usage, combined with an animation that foregrounds the natural environment and its entanglement with the digital.

The Digital and the Environment

McGovern’s main argument is that the digital is not green. Every digital transaction has a very tangible environmental cost, but because of this social narrative and delusion we have about the immaterial industry and the cloud, where the cost of every online is trivial, we tend to overlook this fact. For McGovern, this has created an online culture of speed, volume, and waste, everything from our insatiable desire and expectation for more storage and faster loading times, to all those unused apps we download, to the excessive data mining and advertising, to the fact that search engines provide thousands of search results that one wouldn’t consult, to planned obsolescence and insufficient recycling of e-waste, to clunky websites with unnecessary code which require more energy than necessary to operate, to all of us simply expecting to be online all the time. All of these activities, ranging from the creation and dissemination to the storage and operation of data, consume energy.

In other words, digital culture is harmful for the environment both in the material energy used by the industry, and the culture that the industry has created. It is, for McGovern, an accelerator of consumption. Diving deeper into specific areas within digital culture, such as Internet usage, streaming media, and blockchain, this concern is echoed by several researchers. In December 2020, Obringer et al. reported that home Internet usage after the onset of the pandemic has increased 15-40%. The team speculated that the “global carbon footprint could grow by as high as 34.3 million t of

CO₂e if remote work continues until the end of 2021. This increase in carbon emissions would require a forest twice the size of Portugal to fully sequester all the emitted CO₂e.” [2] The team repeats some of McGovern’s recommendations, such as deleting unused content from cloud storage, turning off video during virtual meetings, and refraining from streaming videos at HD.

Recently, Marks et al. released a report that demonstrates that streaming videos online is responsible for over 1% of the world’s carbon emissions, which is rising. The report supports a previous study done by the Shift Project, and also echoes the recommendation from Obringer et al. to decrease streaming media by relying on local access and to avoid the compulsion to watch HD videos. In particular, Marks et al. noted the presence of the Jevons paradox, where increased energy efficiency actually leads to more energy consumption, supporting McGovern’s argument that ICT cultivates consumption with a rhetoric of speed, convenience, and supposedly cheap resources. As they write, “the availability of online video has created new consumption patterns, driven by addictive design, which cancel out any energy savings. Streaming video exists within a market-driven feedback loop of infrastructural expansion and consumer demand.” [3]

Marks et al. pointed out while the environmental cost of streaming video is concerning, the carbon footprint for AI, Internet of Things, and blockchain is even more significant. According to the *New York Times*, as of September 2021, the mining of Bitcoin alone consumes more energy annually than energy consumption in Finland. As the writers succinctly pointed out, in gaining security (and wealth) through electricity, “the system wastes energy by design,” contributing to both carbon emission and e-waste. [4] “It is connected to the physical world of fossil fuels, power grids and emissions, and to the climate crisis we’re in today.” [5]

The Digital and the Metaphysical

Having highlighted some of the environmental implications of ICT operations, the paper will now pinpoint a link between computation and metaphysics, and propose digital materialism as a suitable counter to information/data, against both its binary logic and erasure of the material. As Kate Crawford writes, instead of “the ideology of Cartesian dualism in artificial intelligence: where AI is narrowly understood as disembodied intelligence, removed from any relation to the material world,” there is an urgent need to recognize that “artificial intelligence is both embodied and material.” [6]

A variety of scholars have pointed out the alignment between the metaphysical assumption of the knowing subject being separate from and therefore superior to the world of static and knowable objects, and the binary logic of information. As Stephen Wilson writes, “by its very nature, digital representation requires the breaking apart of phenomena

and their representation by symbolic bits.” [7] Under the epistemic model of the digital/informational, such representations create the conditions for knowing, where a subject comes to know the world through data-based representations that consist of bits. And this onto-epistemology, which assumes worldly phenomena can be represented as information for the rational and detached knowing subject to consume, is an information-based way of knowing.

For the philosopher Hubert Dreyfus, whose work is critical of AI’s representational claims, such information-based way of knowing, or an information-processing model of the mind, is a legacy of the Cartesian way of knowing that privileges the rational mind and its quest to abstract the world into facts and principles. Instead, Dreyfus insists that the representational claims of AI cannot account for the everyday phenomena and embedded contexts of the world. Drawing from Heidegger’s concept of understanding-of-being, Dreyfus questions “that the shared world ... could be represented as an explicit and formalized set of facts,” negating the conceptualization where the subject is a floating mind, detached from the world while keen on making sense of it. [8] Against the notion that everything can be encoded, David Golumbia similarly writes that “we are material beings embedded in the physical and historical contexts of our experiences ... ‘thought’ and ‘language’ and ‘self’ emerge from those physical materialities.” [9]

Digital Materialism

Through the model of ‘agential realism,’ the new materialism philosopher Karen Barad proposes “a new understanding of how discursive practices are related to the material world.” [10] Her model confounds the distinction between culture and nature, human and nonhuman, negating the Cartesian representational model where methods of representation are assumed to represent the objects of the world faithfully and neutrally. Ambitiously, her critique aims at everything from language’s claim to represent objects, to political parties’ claims to represent people, to scholarly theories’ claims to represent the world. I would make the argument that ICT’s claim to represent the world through data can be filed under this category as well.

Barad proposes instead a ‘performative’ model of looking at how fluid ‘agents’ are always entangled and interact (or intra-act, to use her preferred terminology) with one another, both human and nonhuman. She argues that “knowing does not come from standing at a distance and representing but rather from a direct material engagement with the world.” [11] In fact, even “theorizing must be understood as an embodied practice.” [12] In doing so, Barad also eschews the distinction between theory and practice, words and things, discourse and materials, subject and object. Thoughts, concepts, and knowledge also consist of physical materials.

Taking the discussion into the digital landscape, Baruch Gottlieb’s theorization of digital materialism is instructive

here, for it aptly combines the polemic of AI and its decontextualization outlined by Dreyfus with the new materialist teachings of Barad. As Gottlieb writes, “data is not immaterial ... there is no cloud, only someone else’s computer.” [13] Against the myth of the cloud, which contributes to an emancipatory and utopian rhetoric of digital media, he insists that “digital media technologies require enormous material resources to function,” material in the sense of the literal matter needed for the process of fabrication and operation, and the often-overlooked human resources needed to sustain the industry. [14]

Computational devices are material all the way through, from the raw metal and the chemical processes of the chips to the polymer of the pixels and the electric processes that activate the various parts of the CPU. In addition, we need to consider the underwater Internet cables that are affecting marine life, the effect of the mining industry that is necessary to produce the parts of computer chips, the energy cost of data farms, the e-waste that is created by the rapid obsolescence and consumerism promoted by the digital industry, among others, but also the materiality of unpaid and exploited labourers, in addition to these environmental consequences. These material layers stand in distinction to the myth that information is immaterial, therefore the cost of doing business is next to none, which positions digital media to be inherently predisposed to a more egalitarian and democratic state.

The concept of digital materialism emphasizes the political relationship between the sovereignty of informatics and the subjugated materiality that the world is embedded in. To explore digital materialism in digital art necessitates not just the acknowledgement that code and information are also materials embedded in the world, interacting with all other materials, but also the need to examine the material conditions that give rise to and sustain digital media assemblages and the binary logic that undergird all computation – which subordinates the material and elevates the abstractions. If the digital is linked with metaphysical abstraction that unethically separates mind and body, discourse and matter, humans and nonhumans (such as the environment), then a focus on the overlooked materiality of the world, especially within ICT assemblages and networks, offers a potent counter.

The Medium is the Environment

With the intention of foregrounding the overlooked materiality of ICT assemblages, the final section of this paper will look at a data-driven video installation that the author is currently working on.

Examining the intersection of ICT assemblages, the human body, and the natural environment, the project *The Medium is the Environment (Mica Dam / Zoom / Hsinchu / Vancouver / Site C Dam)* (Figure 1) asks the following question: How does the digital environment subjugate both the human

environment and the natural environment? The project asserts that ICT assemblages accomplish this through 1) its omnipresence, evident in its global scope, from being manufactured in Taiwan (where the author was born), all the way to its deployment in Canada (where the author currently resides), and 2) its instrumental exploitation of the material world as resources for the ever-expanding information and computation industry.

The project is an interactive video installation that consists of two parts: 1) a downward video projection of an animation that depicts the entanglement between the human body, land, and digital media, and 2) a series of smoke machines programmed to release a certain amount of smoke depending on the data-usage of the exhibition/gallery space.

The animation will depict the blending together of screens (in common configurations such as Zoom), bodily forms and functions (such as breathing and heartbeats), and various human and natural environments (such as energy production facilities embedded within the natural landscape in Canada and microchip manufacturing plants in Taiwan). It insists that there is a close and fraught relationship between digital media, the human body, and the natural environment. Underpinned by these three aspects, and situated within the pandemic, the piece analyzes the ubiquity of the interface such as Zoom, ICT’s encoding of the world, the global lifecycle of ICT assemblages, and the environmental impact of the significant increase in the usage of ICT.

The animation, which resembles a mock data visualization and sci-fi interface, contains several scenes, such as the scanning and measuring of land, floating screens becoming ‘environmental,’ breathing interfaces, ‘clouds’ emerging from found footage of the Taiwan Semiconductor Manufacturing Company (TSMC) factory and its manufacturing process, and the merging of the digital, human, and environmental/material. In doing so, the animation foregrounds ICT assemblages’ global footprint, and tackles their continued exploitation and subjugation of the material (land, environment, nature).

In addition, two to four interactive smoke machines will be placed around the projection, intermittently releasing smoke, depending on the data-usage of the space. The project is designed such that the more data is used, the less clearly one can see the projected animation. Implicating both the gallery space and the viewers within this system, the project focuses on the amount of environmental impact our digitized lives are having on the planet, focusing on the materiality of something supposedly immaterial. The installation frustrates the viewers’ desire to consume content, while rendering visible and tangible the amount of data the gallery space is using, and highlighting the entanglement of the viewers’ attention and bodies within the industry of ICT.

The two components of the project (animation and smoke machines) are designed to inextricably link our digital lives, promoted by the encoding practices of the ICT industry,

Figure 1. *The Medium is the Environment (Mica Dam / Zoom / Hsinchu / Vancouver / Site C Dam)*, 2021, 3D model. © Kevin Day.

with the very palpable and material presence of smoke, and by extension, with the materiality of our bodies and the world. Both of the latter are the intentionally and unintentionally marginalized stakeholders within the infrastructure and industry of ICT, in the form of exploited natural resources (in the manufacturing, operations, and usage of digital media) and human resources (workers and users).

As Crawford writes, the operations of AI and the computation industry in general exert their forces through abstraction and extraction: “abstracting away the material conditions of their making while extracting more information and resources from those least able to resist.” [14] Materiality is simultaneously that which is erased and that which is exploited. Especially in light of our current situation with COVID-19 and the exacerbation of such digital condition, emphasizing the material impact of the digital industry is imperative.

Conclusion

This paper has outlined the current and urgent issues of the environmental footprint of a variety of components within the ICT industry, including the impact of Internet usage, streaming media, and blockchain technology, under an overall rhetoric promoted by the ICT industry that cultivates speed, volume, and waste – an insatiable encoding apparatus that leverages the myths of immateriality and being ‘green.’

With the intention of creating socially-engaged digital art practices, the paper argues that there is a need for digital art to tackle the issue of ICT assemblages and their contribution to the climate crisis. To that end, the paper has proposed to consult the scholarship of digital materialism as a response to the environmental issues above, but also to the theoretical link between the digital and the ontological model of the metaphysical subject vs. worldly objects.

Digital materialism is a very fitting theoretical lens to use in this context, as not only does it 1) highlight the importance of focusing on the matter of the material world, which is appropriate for the current context of the climate crisis, but it also 2) offers a cogent counter argument against the sovereignty of information and data, which is based on the presumed metaphysical hierarchy of the rational subject dominating the worldly objects. As such, digital materialism offers not only a fitting and forceful critique to the digital (both to its environmental footprint but also its metaphysical legacy and dominance), it also suggests a focus on the world, environment, and materiality as an appropriate and urgently-needed counter.

The project noted above is only a first attempt at realizing such a counter, through both its content (entanglement of digital media, body, and environment) and form (an installation that releases smoke as more data is used), but I would suggest that digital materialism offers a productive theoretical lens and counter tactic for digital art to tackle the climate crisis.

Author Biography

Kevin T. Day is a Taiwanese-Canadian media artist, art educator, and media theorist. His practice and research, encompassing sound, video, graph, web, and interactive installations, examine contemporary art's critical capacity in response to the current socio-political issues of digital culture. Day received his PhD with a focus on media art and art education from the University of British Columbia. He has presented at numerous conferences such as SIGGRAPH and ISEA, and has published in the top international journals for art and technology such as *PACMCGIT* and *Leonardo*. His work had been generously funded by the Canada Council for the Arts and SSHRC. Currently, he teaches digital art in the UBC Bachelor of Media Studies program and the politics of media and information at the UBC School of Information.

Star-Stuff: A Shared Immersive Experience in Space

John Desnoyers-Stewart

School of Interactive Art and Technology
Simon Fraser University
Vancouver, Canada
desnoyer@sfu.ca

Abstract

Inspired by Carl Sagan and emerging from the ashes of a rejected design, *Star-Stuff: a way for the universe to know itself* is a unique immersive experience that transforms immersants into galaxies and constellations. The two-player hybrid experience can be used telepresently or in a physical installation, connecting anonymous strangers through abstract virtual bodies. In this paper, I describe my inspiration and the open, intuitive process by which *Star-Stuff* was developed. I outline design decisions made along the way and present observations made during the artwork's first public exhibition.

Keywords

Immersive Installation, Telepresence, Virtual Reality, Abstract Embodiment, Social Connection, Space Art

Introduction

“We’re made of star-stuff. We are a way for the cosmos to know itself.”

Carl Sagan [21]

As a child watching *Cosmos*, Carl Sagan’s words resonated with me in a way that continues to drive my curiosity to this day. Watching that already well-worn VHS while sheltering from a cold winter’s day on the Canadian Prairie undoubtedly changed my life. It led me on a path of endless inquiry as I sought to better understand the infinite world that surrounds us. That inquiry has led me down a meandering path of self-discovery that recently crossed a serendipitous opportunity to pay tribute to Sagan’s as yet unmatched voice of inspiration.

As many children do, I grew up dreaming of being an astronaut. I stared at posters of space shuttles and a ceiling covered with glow-in-the-dark stars as I drifted off to sleep. Eyes-closed, I dreamed of visiting Jupiter, Saturn, of seeing the inside of a black hole, and imagined what the ‘edge of the universe’ might look like. I yearned to go to space and see the Earth, planets, stars, and universe from a new perspective.

I continue to marvel at the wondrous achievements that companies like Space-X manage to achieve. Yet I can’t help but feel like we’ve lost our way. Through the steady privatization of space travel, capitalism has extended its hegemony toward the final frontier. While NASA struggles to get us back to the Moon, billionaires posture and flex their dominance over the Earth by their capacity to leave it behind. Certainly, the Space Race was fueled by a similar posturing with nationalist ambitions, and it was tainted by its underlying mission to deliver nuclear warheads more efficiently. But somehow it felt more inspired, more poetic as the technologies that assured our mutual destruction simultaneously propelled our species further outwards into the Cosmos.

The nations whose rivalry drove the development of this technology finally came together with the construction of the International Space Station. This historic endeavour has delivered decades of groundbreaking scientific research in the interest of all humankind. It was *our* collective pursuit. One that brought humanity together in the pursuit of knowledge.

Today, we are sold the commercialization of space as ‘democratization.’ Corporate interests will purportedly make the stars accessible to the masses in ways that a bureaucratic institution never could. Certainly, I may be able to travel to the edge of space within my lifetime, despite not becoming an astronaut. However, this commodification of childhood dreams changes our relation to space.

As with many promises of democratization, it becomes a machine for furthering the gap between those with and without. Our skies become polluted with swarms of profit-producing satellites and our ambition for returning to the Moon shifts from the human drive to see how far we can go, to mining its vast resources. Space becomes yet another resource to be exploited, suffering for it as so much of our own planet already has. Commodification strips space of its poetic quality, its mystery which arouses our curiosity so greatly—its capacity to elicit poesis, to inspire us to make something new.

We need a renewed perspective on the Universe. One which is not clouded by the ego of out-of-touch CEOs but is fueled by childhood dreams of what lay beyond our skies. Carl Sagan saw the universe as something which can help us to understand ourselves. In *Cosmos*, he continuously reminds the viewer of how looking outward enables us to see deeper inwards. [21] Even external observations are often motivated by intrinsic questions of self-reflection. For example, the persistent existential question of ‘our place in the universe.’ We seek to belong [3], not only as individuals, but as a species. We yearn to find our place in society and in the Cosmos.

The social Virtual Reality (VR) experience, *Star-Stuff: a way for the universe to know itself*, began as a ‘happy accident.’ One born from listening to that childhood voice of intuition when a particular aesthetic emerged through open experimentation. Here, I will describe how playful experimentation, listening to intuition, and inspiration from scientific knowledge led to the creation of a simple yet profound moment for ‘the universe to know itself’ from a new perspective.

Inspiration & Guiding Principles

In creating *Star-Stuff* I was inspired by several beautiful and awe-inspiring VR experiences beyond *Cosmos*. In particular, I was inspired by the perpetually relevant work of Char Davies which identified and challenged the same problematic assumptions about VR that we face today. VR is an embodied experience [13] and as Davies did with *OSMOSE*, I seek to incorporate the body within the experience rather than leave it behind. [8] I aim to go beyond simulating everyday experiences, instead re-framing the immersant’s perceptions to offer an expanded view of reality.

I am also inspired by *Spheres*, a VR journey through space and time. [18] Instead of struggling to evoke the scale of the planets and universe as many space-oriented VR experiences do, *Spheres* gives us a god’s-eye perspective where the planets become instruments. Immersants play with the Solar System and fall into the depths of a black hole before traversing the history of the universe back to Earth. In the same vein *Star-Stuff* seeks to allow immersants to playfully dance with the stars.

Star-Stuff also builds upon my previous immersive artworks, *Body RemiXer* [9] and *Transcending Perception*. My VR experiences are what Bourriaud refers to as relational artworks. They aim to create “free areas, and time spans whose rhythm contrasts with those structuring everyday life...” [7, p.16] I use VR to re-frame participants’ perceptions so that they might see a stranger in the same light as they see a friend or even themselves. I seek to create social affordances which encourage self-expression and inter-human connection. By altering social norms and temporarily hiding superficial appearances I hope to make immersants feel more connected, not only to those who they interact with but humanity at large. To achieve this, I give participants room for interpretation and appropriation [14] so that they might make the experience their own.

These experiences are not about some external narrative or the content of the experience itself so much as they are about re-framing immersants’ view of themselves and those who they meet. As such, in developing these experiences I endeavour to consider the many trajectories which may unfold [4], supporting entry into the experience through progressive engagement [11] and giving space for connection, discussion, and reflection when possible. Importantly, I consider where the experience might lead immersants long after their experience—how might it reshape their perspective on themselves, humanity, and the universe? Even if only in a small way.

Design Process & Decisions

Star-Stuff began as an artistic experiment. A VR sketch of sorts wherein I was exploring different aesthetics of abstract bodies that could fit the aims of a VR performance I was working on. Exploring various possibilities in Unity’s VFX Graph, I created several such sketches. While I found what I was looking for, along the way I created many rejected sketches. Yet, while they didn’t fit that project, each seemed to offer up its own potentiality for future projects. One in particular, that traced triangles from random vertices on the surface of a mesh, reminded me of the appearance of constellations. Rather than leave it abandoned as a failure, I investigated where such an ‘accident’ might lead.

Constellation Body Aesthetics

I began by making the visual effect more constellation-like, adding flickering stars to the vertices and varying the brightness and size of the traces and stars. While in the original sketch I had sought to erase connections that did not conform to the body, now those long connections between ordinarily disparate limbs were desirable and fitting (see Figure 2).

Asymmetric body representation. From the beginning, *Star-Stuff* was conceived as a two-player telepresent experience that would enable immersants to interact and play with each other in a unique way. As such, the design of the virtual body was critical in how immersants would experience themselves and others in the experience. Typically I would emphasize the use of a synchronized first-person full body representation and a virtual mirror [9, 10] as these can facilitate embodiment. [23, 12] However, in this case the traces

Figure 2: The constellation body. Immersants see others represented in this way. Photo by the author CC BY-SA 4.0.

of the constellation body interfered with the view of the rest of the experience. In light of this I showed only the hands (see Figure 3). My aim was to direct immersants to their capacity to interact using their hands while guiding their attention towards the other immersant's body rather than their own. Given that a mirror would not make sense in the context of this experience, I relied instead on immersants' interpretation of other avatars as a mirror of their own appearance.

Altering perception of self and other. The hands were tracked using the Oculus Quest 2 allowing for a very high-fidelity representation. While there is considerable flexibility in how VR representation can be extended to bodies considerably different from our own, [25] a need for precisely responsive hands was identified in my experience developing earlier VR experiences including *Body RemiXer* [9]. The hands used in *Star-Stuff* are very visually abstract; however, agency over that abstract appearance is supported by precise movement and scaling of the hands and fingers.

Embodying an avatar can reduce our implicit biases towards others through increased association. [17] In this way, the common appearance of the hands and bodies is designed to evoke a sense of oneness by allowing immersants to see their fundamental sameness as "being made of star-stuff." The experience temporarily suspends superficial appearances and allows immersants to see one another from another perspective.

Moreover, altering the responsiveness of one's virtual representation can affect the perception of the physical body, making it feel heavier or lighter. [16] In *Star-Stuff* the constellations do not directly and immediately follow the body

Figure 3: Constellation hands are all the immersant sees of their own body. Photo by the author CC BY-SA 4.0.

and hand position, but are instead attached through a virtual spring and damper. This was used to make immersants feel larger-than-life while also encouraging slower, meditative movements.

The hands were represented using 19 joints each while the entire body of the other immersant is represented using only 22 joints. However, social presence can be elicited by a simplistic array of as few as 13 dots so long as those dots are dynamic and moving. [5] The Quest 2 is limited to tracking head and hand positions so *Star-Stuff* uses Root Motion's VRIK inverse kinematics plugin¹ to estimate the position of the body from those 3 basic points. This can result in an awkward misaligned representation as the system is under-constrained. The movement is simultaneously familiar yet uncanny, resulting in a desirable humanoid yet alien appearance.

Intimate stellar heartbeats. Going beyond the more direct constellation representation I created a virtual galaxy which was emitted from and orbited around immersants' bodies. I decided to generate the stars from the immersants' heart to try to evoke a sense of intimacy. As heartbeat has been shown to evoke intimacy in VR, [15] the stars are emitted in a heartbeat pattern, pulsating at 60 beats per minute. The stars' birthrate, initial velocity, colour, and brightness all vary with this simulated heartbeat. As can be seen in figures 1, 2, and 4, new stars are redder and that redness pulsates, slowly dissipating as the stars go off to live out their own independent lives. While the current version is solely visual and artificial, future versions will incorporate heart rate tracking and audio feedback to further reinforce this effect.

Simulating Galaxies with Particle Systems

The constellation bodies and stars which comprise the galaxies are simulated using Unity's VFX Graph particle system.² I wanted the experience to be aesthetically enjoyable while allowing immersants to implicitly learn about the Universe. As such, the design was a compromise between a realistic portrayal and an aesthetic which fits the artwork.

¹<http://www.root-motion.com/finalikdox/html/page16.html>

²<https://unity.com/visual-effect-graph>

Realistic stellar evolution. The stars follow a life-cycle inspired by actual stellar evolution. [19] Each star is generated with a random mass which determines how it will evolve. The smallest stars are dim white and red dwarfs that have the longest lifespans. These stars stay relatively static over their life, quietly fading away as they reach maturity.

In the middle of the range are the ‘main-sequence’ stars like our sun which vary in colour from orange to bright yellow. These stars have considerably shorter lifespans and transform into red giants as they reach maturity and run out of fuel, simulating the life-cycle of our own sun.

The most massive stars in the simulation are blue giants. These are the brightest and shortest lived stars, lasting only a few seconds before they implode. These massive stars have a chance of producing a supernova proportional to their mass. The immersant can watch as these huge stars grow and then collapse before bursting into a brief bright flash of light.

The life-cycle of the stars varies between 5–100 seconds, creating considerable variation in the stars’ appearance while allowing their life-cycles to be witnessed. The pacing was arrived at through repeatedly testing the experience to find a rate at which the general mass of stars seem to linger forever while focusing on a singular star reveals its dynamic and evolving nature.

Emergent patterns from two-body gravity. The movement of the stars is simulated using a modified gravity simulation. Simulating the actual gravitational relationship between tens of thousands of stars would be far more than the Quest 2 could handle. Instead, a two-body gravity simulation is used. Every star is attracted towards a center of mass at the approximated hip location of each immersant. To encourage the emergence of a galaxy-like aesthetic, the stars are accelerated tangentially around the hips’ vertical axis and stars that stray too far from this disc are drawn back in. Scrolling Perlin noise is used to randomize the forces acting upon the stars.

This layered simulation produces results that are simultaneously emergent yet consistently fall into a predictable overall aesthetic that evokes the appearance of a spiral galaxy. I wanted control over the stars to remain somewhat elusive to evoke their mass and power. Basing the gravity simulation around the hips gives participants limited control over the stars’ behaviours. The stars tend towards staying lower on the body, keeping the immersants’ view of each-other clear. Immersants can drastically alter the orbits of the stars by crouching or leaning over as the stars will begin to orbit more vertically. Moving between crouching and standing can lead to a resonant oscillation of the stars that begins to look like waves, evoking the sensation of standing in a cosmic ocean. By moving closer together or further apart, immersants can greatly vary the paths that the stars take by shifting the centers of mass.

Preventing simulator sickness. Standing in space amidst stars that continuously rotate around you has the potential to cause motion sickness. As such, I carefully considered and tested the disorientation and discomfort caused by the experience. The pacing at which the stars orbit the immersant are a carefully tuned balance between facilitating interaction and optimizing comfort. Stars that move quickly respond to

interaction more readily, but can lead to disorientation. I arrived at an optimized pacing through repeatedly testing different speeds until I found something that was fast enough to respond but slow enough as to cause no discomfort. I then tested the experience with friends and family with varying prior VR experience. The resulting pacing fit well with the meditative nature of the experience.

Originally, I had assumed that a ground plane would reduce disorientation and motion sickness; however, in this case it had the opposite effect. When it was combined with the orbiting stars it seemed to provide an overly strong frame of reference which led to rapid disorientation even at low star velocities. In the end, simply providing a static star background provided the best outcome.

Fluid Interactions

I also wanted to give the immersants a direct and playful way to interact with the stars while remaining calm and meditative. To accomplish this, I incorporated a simple fluid simulation which treats the hand as a point in the stellar ether. Stars closer to the hand are quickly accelerated up to the velocity of the hand while those farther away are effected less up to a 0.5 meter radius. This evokes a sensation similar to splashing in water.

Figure 4: One immersant splashes stars into a huge column. Photo by the author CC BY-SA 4.0.

I wanted to avoid more rigid interactions typical in VR experiences as the stars would then lack any weight or inertia. Instead, the stars respond in a way that evokes a subtle sensation of resistance. This kind of response can evoke tactile sensations known as pseudo-haptics [20] which have been reported with similar small virtual objects such as butterflies.

[6] Slow, careful movements barely disturb the stars while fast sweeping ones can launch the stars into huge columns as seen in Figure 4. To encourage further opportunities for meditative interaction, I also allowed immersants to catch stars if they were gentle enough. By holding a hand out in the path of a star they could catch it; however, moving too quickly would cause the star to evade them.

This design allows for an experience that is equally playful and meditative and open to a broad range of interactions allowing immersants to appropriate it for their own use. *Star-Stuff* is equally engaging whether standing still mesmerized by the stars' evolution and movement, carefully catching stars and reaching out to the other immersant, or making bold expressive movements that form ethereal sculptures in space.

Sound Design

The sound design for *Star-Stuff* took a relatively basic approach as I wanted to focus immersants' attention on the visual experience. Thus, the sound design focused on encouraging immersion. Immersants hear a spatialized rumble from their own bodies as well as their partners', evoking a subtle but important sense of auditory presence. The choice of music for this experience was essential to immersion and was an intuitive and serendipitous choice. I had been listening to Dale Nichols' music³ as he is creating the soundtrack for the main project which *Star-Stuff* spun off from. I kept coming back to the same two intimate and entrancing piano pieces throughout development, and as such asked to incorporate these fitting pieces into the finished artwork. The result is a soundtrack and visual experience that are enmeshed with each other, rounding out the experience into a finished product.

Simple Telepresence

Star-Stuff was designed to provide telepresent experience in the simplest way possible. It uses Photon PUN 2⁴ to synchronize immersants' bodies across multiple headsets using only the position and rotation of the head and wrists. This allows immersants in the same room or on opposite sides of the world to connect with relatively minimal lag and bandwidth. The telepresent version randomly connects a pair of immersants while the co-present installation always connects the headsets in the same room. Randomly connecting immersants is intended to evoke curiosity through anonymity. Immersants might plan to meet each other in *Star-Stuff* at a particular time, yet they cannot be sure that the other body they see is the friend with whom they had arranged a meeting.

The rest of the body is extrapolated using VRIK inverse kinematics. This allows for a full-body representation while minimizing the bandwidth required for synchronization. The simulation is run independently on each headset. While this results in some subtle asymmetry in the experiences, it is sufficiently deterministic to reliably transmit immersants' gestures and interactions.

³Dale Nichols' music can be found on Spotify and Apple Music.

⁴<https://www.photonengine.com/en-US/PUN>

The experience is limited to two immersants to encourage an intimate experience. The ethereal bodies are designed to acknowledge their lack of physical presence while still evoking a sense of social presence. While touching the other's body is not likely to evoke any tactile sensations it is designed to encourage a sense of 'visual touch' akin to that described in PluginHUMAN's [*i miss your touch*] [22] where immersants interact with and touch each other's bodies as if they were physically present.

Becoming a Galaxy

These design decisions come together to produce a conceptually simple experience that leads to relatively complex emergent and dynamic interaction. It allows for a peaceful moment to contemplate our place in the universe or a vast playground to meet and experiment with friends and strangers.⁵

The experience is designed to slowly and steadily immerse the user in the experience. It begins with the same quote that this paper opened with, drawing immersants' attention to their poetic relationship with the universe as "a way for the universe to know itself." [21] In this initial phase they can only see their hands and no stars are generated, giving them some time to become acquainted with this new view of themselves. Once the quote ends the system connects to the server and tries to connect to another immersant. Once connected, the galaxy stars begin to be generated. The galaxy shape slowly emerges over the first minute or two. When the system successfully connects with a second immersant their body slowly fades into view and begins generating stars. Immersants start 3 meters away from each other giving them room to interact independently or choose to come together.

Through this networked social experience *Star-Stuff* aims to utilize proven strategies for connection including play, reflection on unity, and a shared transcendent experience to evoke a sense of connection to humanity and the universe [24].

Exhibition

Star-Stuff was exhibited at the hybrid VR festival, *V-Unframed* at Vancouver's Centre for Digital Media in October, 2021. Over 500 people attended the COVID-19 safe event over the course of 3 days.

Physical Installation

Despite being conceived for telepresent use, *Star-Stuff* was easily adapted to a co-present physical installation. Two Oculus Quest 2s were used with parallel virtual spaces to facilitate social distancing as shown in Figure 5.

While I would ordinarily calibrate virtual spaces so that the physical and virtual overlap, here making them parallel allowed immersants to experience *Star-Stuff* in a way similar to how they would have connecting remotely from home. The offset simultaneously provided a COVID-safe interaction between strangers and afforded interactions uniquely possible without a physically synchronized other. Immersants could hug, dance, play, fight, and even walk through each other without fear of losing tracking or running into anyone.

⁵A video of *Star-Stuff*: <https://youtu.be/eRukMyGcVcI>.

Figure 5: Layout of Star-Stuff at V-Unframed.

A large projection reflected the virtual space like a mirror to evoke curiosity and give onlookers a glimpse into the experience. A second projection was directed at the floor for subtle ambiance. The stars' orbits were faintly visible and occasionally splashed onto the immersants' physical bodies, further reinforcing the connection between their bodies and the visuals.

Fairy lights were used as a pragmatic compliment to the installation's aesthetic. The Quest 2 tracking performed poorly with the matte black curtains on one side of the installation. The fairy lights provided a fitting point of reference which significantly improved tracking performance as seen in Figure 6.

Figure 6: The physical arrangement of *Star-Stuff* at *V-Unframed*. The immersants are right next to each other in the virtual experience despite being physically separated. Photo Julia Read, 2021 CC BY-SA 4.0.

Observations

From opening to closing the experience was continually in use. There were only a few brief moments where the installation was stopped to replace a headset that had run out of battery or encountered technical difficulties. As a result, it fully occupied myself and one volunteer in initiating immersants into the experience and managing the lineup. Due to its popularity I was unable to conduct interviews as initially planned; however, here I present my observations which were captured in photographs and field notes.

A simple yet engaging immersive experience. Participants consistently lingered much longer than expected. From the outside it sometimes looked like they were not engaged but they seemed to get lost in the experience and would easily spend 8 minutes with the installation whether engaging actively or standing still. This timing aligns with the duration of the two songs used for the soundtrack so it's possible that immersants assumed the experience was over when the music stopped. At first, we left immersants to play freely, but it quickly became clear that we needed to limit interaction to 4 minutes to keep the line manageable. Fewer than 10 immersants removed the headset in less than this 4-minute limit, suggesting most were quite deeply immersed and engaged with the experience. Many commented as they left about the fitting choice of the music and how it 'made the experience.'

Slow immersion into another reality. The slow introduction of various elements seemed to work well. Despite having seen the projections immersants were still surprised to see their hands and another body appear in the experience. Each new element was frequently accompanied by an audible gasp as immersants recognized their virtual hands and this strange other being standing across from them.

Intuitive and open to exploration and appropriation. While a few immersants were unsure of 'what to do' or 'what the experience was about' most engaged with the experience freely with minimal prompting. Facilitators only had to guide immersants to look at their hands, the other body, and to try 'playing with the stars as if they were water' to encourage exploration. Most immersants recognized their constellation hands as their own when asked 'can you see your hands?' However, on some rare occasions they had to be guided a bit before making the connection.

I observed a wide variety of engagement from standing completely still to dancing or sometimes moving very erratically about the space. The slow orbit seemed to provide more timid participants with a dynamic painting to watch as it changed shape on its own. Meanwhile, the splashing interaction provided a natural way to engage more actively and invited playful exploration. Regardless of how they engaged, immersants regularly seemed to have enjoyed the experience suggesting that they may have been able to appropriate it to suit their personality, interests, and level of comfort.

Real social behaviours in virtual space. I observed many repeated social behaviours ranging from aversion to dancing and hugging. Many immersants would share their stars with

their partner by splashing them in their direction, like splashing someone while playing in a pool. I saw several pairs touching their hands together as shown in Figure 7 in what seemed to be the most common form of visual touch afforded by the experience. Despite not physically touching, immersants could be seen behaving *as if* they were touching, keeping their hands in close contact without passing through the virtual body, moving them together side-to-side.

Figure 7: Two immersants touch each other’s virtual hands. Photo Julia Read, 2021 CC BY-SA 4.0.

The interaction seemed to vary considerably depending on immersants’ existing relationship. While some strangers would interact playfully with each other, often the pairing was uneven, with one extroverted immersant directing their attention towards the other, while the other immersant seemed to just want to do their own thing. Some could even be seen avoiding the other immersant and one person specifically complained that the other virtual body kept invading their space despite physically being at least 2 meters apart at all times. This suggests that the abstract constellation body evoked a sufficiently strong sense of social presence to elicit a proxemic response. [2] This evasive strategy also aligns with the equilibrium theory of intimacy [1] and suggests that perhaps more could be done to encourage a shared level of intimacy in the experience. It is possible that the experience would be less invasive in a purely telepresent setting and that this aversion may have been the result of the stranger’s physical presence.

On the other hand, families and friends were observed exhibiting very close and intimate behaviour. Children played and ran around each other, sometimes subverting the system by overlapping their bodies or peaking out from under the headset. Several people were seen hugging virtually. While they were not physically aligned, they embraced each other’s avatar as if they were (see Figure 8). Some immersants also danced together in a variety of styles including ballroom dancing with one hand on the shoulder and the other holding hands.

Figure 8: Left: immersants hug virtually. Right: their offset physical hug. Photos Julia Read, 2021 CC BY-SA 4.0.

All in all the installation was very well received and was a favorite among those interviewed by the event coordinators. Despite the long line and short timeframe to visit other installations, several immersants returned for repeat playthroughs. Sometimes they just wanted to go back in and explore, while other times they brought a friend or family-member to share in the experience. One person in particular returned at least 4 times over a two-hour period. As the exhibition was drawing to a close I let them play freely with their sibling for over twenty minutes.

While the parallel experiences worked well overall it did evoke some confusion about the identity of the other. In some cases this was interesting as immersants commented on the other body being a reflection of themselves or some other remote body, not connected to the person they had entered with. However, for the most part immersants seemed to make the connection and were simply confused by the discrepancy between the visuals and sound. In the future I would likely have the immersants either completely co-located so that they can physically touch, or would have the immersants offset but facing each other rather than being completely parallel.

Conclusion

By following an intuitive design approach inspired by an originally ‘failed’ design I created one of my most successful immersive experiences. *Star-Stuff* was not conceived from a precise or specific plan but emerged through an iterative, intuitive process that was free to meander and develop as needed. The result was a meditative yet playful experience which fits Carl Sagan’s vision of renewing our perspectives of ourselves by looking out to the Cosmos. Immersants could connect with each other in a new way while simultaneously learning about the evolution of stars. Observing interaction at *V-Unframed* allowed me to see the joy and curiosity it evoked in immersants while better understanding the interactions it affords and improvements that might take it further. *Star-Stuff* demonstrates that abstract immersive social experiences can bring humans closer together, inspire a new generation, and provide a new “way for the universe to know itself.”

Acknowledgments

Star-Stuff was made possible through funding from the Canada Council for the Arts. Thank you to Dale Nichols for providing fitting music. Thanks to the organizers, Alliance Française, Kreis Immersive, and volunteers. Thank you to testing and setup support from Ekaterina R. Stepanova, Stephen Crocker, Stephanie Desnoyers, and Katie Campbell.

Abstract

This article is the culmination of an intervention designed to improve active engagement with emerging technologies at a public mixed reality event. An opportunity arose to experiment with the design of interactive audience experiences at the *The Fun Palace: Carnival of Mixed Realities*—an event that took place in 2019 and featured 10 installations with close to 400 attendees. A number of strategies emerged to increase attendee engagement that may be useful for xR developers, museum curators, and event producers that present interactive technologies and installations publicly.

Keywords

Mixed reality events, installation, virtual reality, engagement

Introduction

The first section of this article asks the reader to reimagine two mutually influential concepts common to hardware and software development that inform how human experiences are designed at public events. One, is the term mixed reality (MR) that has evolved over time to describe human interactions within specific technological constraints and affordances. The other term is *users*, often describing people who interact with any technology. In the second section of this chapter, we will detail a specific investigative case, *The Fun Palace: Carnival of Mixed Realities* where strategies were implemented to increase engagement.

I: Rethinking Human Interactions at Public Mixed Reality Events

Oscillating Between Physical and Virtual Realities

The design of events in public spaces involving multiple types of interactive technologies is in growing demand. Assumptions are often made of the type of human interactions that will occur. *The Fun Palace: Carnival of Mixed Realities*

aimed to identify those interactions and consider them in the design of the event. While some installations were curated with familiar interactions in mind, others were designed to experiment with contrasting interactions that traversed the continuum of physical and virtual realities. The experimental nature of co-constructing the event informed how we would come to define it as mixed reality: dependent on the shared experiences each person would have oscillating between the physical and virtual realities of the space. Where virtual realities can be isolating, we sought to make them social through this oscillation, driving human-human interactions mediated by human-system interfaces.

We draw from Milgram and Kishino's (1994) definition of mixed reality as a malleable continuum between virtual and physical realities that connects the virtual experience to its physical surroundings. [1] Milgram and Kishino's "virtuality continuum" predates associations with specific hardware devices, such as Microsoft's HoloLens 2 and Magic Leap One, allowing us to design experiences that re-orient our focus away from specific technological affordances, and towards a variety of different human-human and human-system interactions in public spaces. This experience-oriented framework informed the following prompts: What are the needs of mixed reality event (MRE) attendees and how do we design experiences that captivate those curious but not yet engaged?

From User Experience to Human Experience

People who come to MREs may do so to experience the latest interactive and immersive technologies that go beyond the everyday, hoping to try out something they might not normally have access to. The event is a social one for many, where they go to share in those experiences with their friends. The term *user* is commonly applied to describe event-goers as the *users* of the technology. This term carries with it a hierarchical assumption, that the system is meant for the *user* to control rather than to experience, and extending from that, an obsession with *usability*. As suggested by Dervin and Reinhard, this leads to "user-oriented terms [that] privilege systems over people by rhetorically making

systems and use of them the center of attention.” [2] However, this does not accurately represent the complexity of human-human and human-system interactions that take place during public MREs.

When the center of attention shifts to the human experience, then our *user’s* entire experiential journey needs to be considered, as well as how we refer to them. The complexity of the actions they perform are not limited to *using* but encompass a wide breadth of social interaction. They may walk around aimlessly, or search for specific types of experiences. They may enjoy watching others experience something, and might take everything in first, understanding the installation at a distance before trying it for themselves. Avoiding the term *user* acknowledges this complexity and avoids privileging the designed experience over those unexpected and peripheral ones that might be just as important to the social encounters such a public event seeks to facilitate.

Our so-called *users* have also been defined as *audiences* given that their journey may include passively or actively watching others. These are what Dervin and Reinhard call, “amorphous groups of individuals that communication, media and information systems attract or entice with arrays of offerings of particular genres, programme types, or content.” [3] Semantically, this term is not accurate since many audiences tend to watch something intentionally performed, and refrain from interacting with a performance to avoid impinging upon its predefined intentions. Even interactive performances that have challenged the performer/audience divide still refer to the role of an audience. During MREs the audience-performer boundary is fluid, as the interaction in this social space is performed and observed by an audience. Some people interact with different types of installations and technologies and others watch them. In fact, the same individual can be both the observer and the observed. In this way, we quickly come to the realization that if we are to design for events that offer numerous types of interactions, it may be better to abandon the terms *users* and *audiences* altogether.

As Dervin and Reinhard remark, “[human beings have increased] control over their access and use of all manner of information and entertainment systems”. They claim that we may benefit from no longer seeing MRE attendees as “users or as audiences but rather as persons with agency.” [4] The agency that people have when they journey through an MRE and choose what they wish to experience and what they do not, may help us define different levels of engagement within that continuum between physical and virtual reality. While we have identified that the people attending such an event should not be classified as users or audience members, we leave the development of an alternate term for future discussion. The varied levels of engagement any one person may have at any one time during an MRE makes it difficult for us to neatly categorize them as either user, audience, observer, participant, immersant, etc. For simplicity we will refer to them as attendees of our event as this term implies nothing more than their presence.

II: Designing for Engagement on a Continuum Between Physical and Virtual Realities

The Fun Palace: Carnival of Mixed Realities was an MRE prototype intended to investigate human responses to a variety of interactive experiences (shown in Figure 1) across a range of the virtual/physical and passive/active spectra that might increase their engagement.

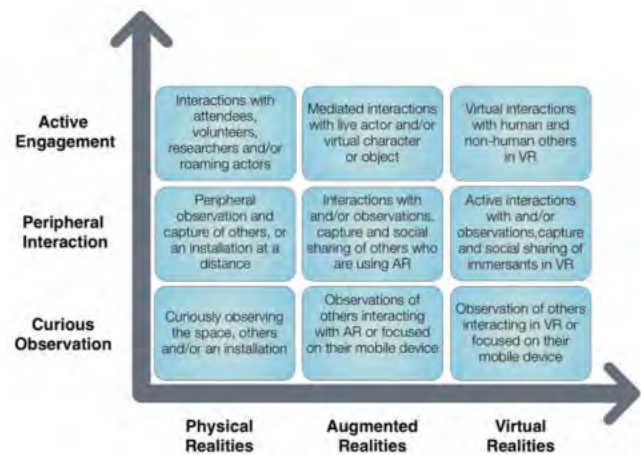

Figure 2. Public Mixed Reality Event Engagement Grid CC BY-NC-ND 4.0.

Our approach to designing for engagement drew from theatrical staging and user experience design traditions. Conceptual frameworks exist for designing engagement with technology such as that proposed by O’Brien and Toms [5], yet none are specific to MREs. Combining these traditions with Milgram and Kishino’s MR Continuum, we mapped different types of anticipated engagement (curious observation, peripheral interaction, and active engagement) within and between physical and virtual realities that we anticipated and designed for (Figure 2). *Curious Observation* included observation that usually led to further engagement. As attendees engaged, they demonstrated *Peripheral Interaction* with others from afar with the intent to learn and try, captured others in AR or VR, and shared their experience across social channels. Those *Actively Engaged* socialized

with other attendees, volunteers and actors, became participants in a study, experienced different levels of interactivity using AR, or immersed in VR.

Engaging Installation Designs Mapped to the Engagement Grid

Each installation for *The Fun Palace* was submitted to a call for proposals and considered for how it might contribute to engaging a diverse audience in a multitude of ways. The *Small Stage* installation offered a site for more traditional audience-dancer engagement allowing audience members to choose different combinations of visuals and music that would inform the choreographed work. *Body RemiXer* proposed several forms of engagement, from curious observation of impromptu physical performances to active interaction with others mediated through a VR headset and body tracking. *JeL* was an immersive experience which sought to connect people through breathing. This experience actively engaged participants in a mostly virtual reality where their breath controlled the movement of a jellyfish and growth of a coral.

The Piano Bar tasked people to play the “correct” notes on an 88-key piano that corresponded to specific synaesthetic colour values, engaging them in a virtual puzzle that others could observe or help with. *Boids* allowed attendees to control a flock of birds projected on a screen through different body movements. *Colossus* actively engaged participants through a Muse 2 headband that triggered an ambient soundscape and visuals corresponding to their brainwaves in a virtual reality presented through a VR headset. Actors roamed *The Fun Palace* ushering attendees who appeared less engaged into a secretive *Curiosity Booth* to interact with actors in the roles of modern curiosities, through an iPad, drawn from the underbelly of social networks.

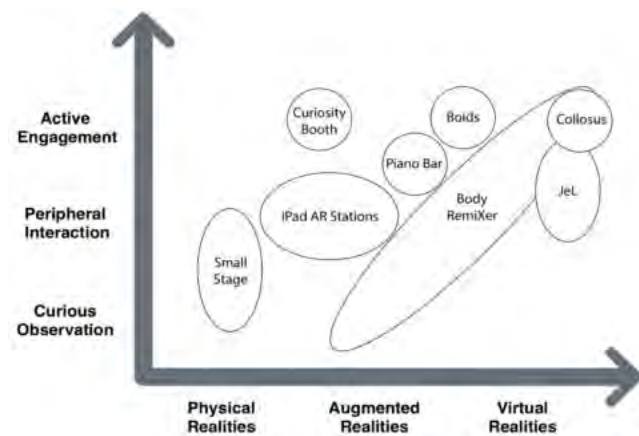

Figure 3. Installations plotted on the Engagement Grid CC BY-NC-ND 4.0.

To reduce the potential for disengagement and increase opportunities for active engagement we designed for multiple interaction points and implemented the strategies that follow.

Plotting Engagement Before, In-Between and After Experiences

Following O’Brien and Toms’ framework, several features of *The Fun Palace* catalyzed different human responses before, in-between, and after their experiences, creating many “points of engagement” to keep attendees engaged and re-engage them as needed. These included roaming actors identifying those waiting and/or those who appeared bored to provoke interaction, guide them to a shorter line-up, or to enter the *Curiosity Booth* (Figure 4).

Figure 4. Posters hiding the entrance to the *Curiosity Booth* by Photo © Andreas Psaltis, 2019.

iPad stations (Figure 5) were available to attendees anytime in several locations and large markers on a centrally positioned scaffolding structure triggered augmented reality animations providing opportunities for engagement between installations.

Figure 5. iPad Station with AR brain describing installations. Photo © Andreas Psaltis, 2019.

Timed group activities occurred every hour and a live master of ceremonies drew everyone’s attention to twelve to fifteen volunteers holding their mobile devices in the air showing an animatic of a whale viewed through an AR application. The activity culminated in a conga line (Figure 6) that allowed us to rotate our growing list of attendees and provide them with a sense of closure.

Figure 6. Attendees in a conga line. Photo © Andreas Psaltis, 2019.

Post-experience activities included different research teams intent on capturing attendee experiences of specific installations and of the overall Fun Palace experience encouraging attendees to engage in a reflection of their experience. Some experiences, such as *Body RemiXer* were designed for open engagement, allowing attendees to directly approach the installation without waiting in line. Instead, they could interact through projections while they waited to put on the VR headset following a model of progressive engagement that allowed for interaction up to their level of interest and comfort. [6]

Increasing opportunities for social exchange through multi-person experiences

During the curation process we intentionally planned to include experiences that would simultaneously engage multiple people, increasing throughput and opportunities for social exchanges. The *Small Stage* seated audience experience allowed for 17 people every 15 minutes. *Body RemiXer* afforded up to 6 people to engage simultaneously for up to 10 minutes, allowing all 400 people to engage freely over the 4-hour event. *Boids* allowed 2-3 people every 2 minutes while *The Piano Bar* challenged 45 attendees per hour. All the installations provided opportunities for simultaneous participation, offering many opportunities for interpersonal engagement during and in-between each experience.

Figure 7. Peripheral and Active Engagement with *Body RemiXer* by Desnoyers-Stewart et al. Photo © Melissa Dex Guzman, 2019.

Disrupting Expected Boundaries

The physical and virtual boundaries that constitute a play area, especially in VR installations is usually well defined. In the case of *Body RemiXer*, the boundary between viewer and participant was made intentionally unclear to pull attendees into the experience. The result was a fluid liminal space in which curious voyeur could suddenly become part of the interactive work. In many ways this fluid boundary was exploited by several of the installations as they could be observed from afar through large projections, drawing curious observers until they fully engaged with the piece.

Stage the entire physical space with lighting, set and sound

Lighting was designed to set the ambience of the space along with a more pragmatic function of lighting specific AR markers required by four installations. Eight projected screens were used to afford multiple viewing angles and drew curious observers into being more actively engaged. These projections allowed attendees to witness others in VR, interact with some installations, and observe AR experiences enlarged from smaller devices.

A rich ecosystem of sound drew attendees to certain areas while headphone experiences could give them reprise from the audio carnival. Sound played through over 17 different speakers and 10 different sound systems on both headphone-based and amplified systems. The sonic ecosystem provided attendees with multiple instances of sound realities that were each related to the individual experiences around them, yet existing within the same space where attention was distributed and in constant negotiation.

Relating to the Engagement Grid as we Emerge from Covid-19

While our engagement grid was developed within a pre-pandemic social experience, our recent involvement in a post-pandemic event revealed that the grid is still applicable. The V-Unframed 2021 exhibition consisted of multiple mixed reality installations in the same physical hangar as *The Fun Palace*.

We observed similar human behaviours when it came to engaging with each installation despite mask wearing and social distancing regulations. The event required all attendees to show proof of vaccination against COVID-19 prior to entry, and a limited number of attendees were permitted in the hangar at any given time. Attendees roamed freely throughout the hangar, interacted with one another between time spent at each installation and VR headsets were worn along with masks in most instances.

Upon encountering the *Star-Stuff* installation at V-Unframed, some individuals engaged in curious observation perhaps waiting for another attendee to try the installation first. Some curious observers transformed into actively engaged participants in VR regardless of the constraints of mask wearing and social distancing.

Figure 8. Children playing in Active Engagement with each other via the Virtual Reality of *Star-Stuff* at a post-pandemic exhibition by John Desnoyers-Stewart. Photo Julia Read, 2021 CC BY-SA 4.0.

Even in a post-pandemic world where attendees' social norms have been significantly altered by nearly two years of social distancing and limited time in shared public spaces the Public Mixed Reality Event Engagement Grid continues to be a useful tool. By providing opportunities for engagement spanning this grid, V-Unframed 2021 was able to encourage a renewed sense of community and encourage the formation and strengthening of social bonds amongst those who attended.

Conclusions

Our MRE prototype offers an opportunity to implement strategies that transform curious observers to more actively engaged attendees. To succeed in that transformation, we believe there is a need to design beyond the on-screen experiences that dominate the attention of installation creators and event producers. An environment which facilitates various types of engagement through different means is essential to an engaging MRE. As we emerge from the Covid-19 pandemic the importance of intentionally designing human interactions in public spaces is even more important.

Author(s) Biography(ies)

Dr. Patrick Parra Pennefather is an award-winning composer, designer of asynchronous, synchronous, blended and hybrid instruction, teacher, researcher and disruptor. He has mentored multi-disciplinary teams co-constructing scalable digital prototypes with over 50 companies and organizations in games, mobile dev, Mixed Reality, VR, AR, education and the arts. Patrick has facilitated human-centred workshops in-person and as a virtual cat for EA, Riot, Microsoft Games, and many others in the xR space. He's published multisyllabic words in the fields of 3D, Sound Design, xR, VR, MR, Bio-Medical Visualization and Agile application development. He's an Assistant Prof at UBC Theatre and Film, and a founding member of the Master of Digital Media (MDM) Program.

John Desnoyers-Stewart is an interdisciplinary artist-researcher who creates immersive installations and performances to encourage new perspectives on immersive technology and to better understand its true potential. Through his artwork and research, he hopes to encourage social connection and collaborative creativity, exploring positive social applications of abstract embodiment in virtual reality.

Abstract

Based on the notion of the Datacene, understood as the time when data directly affects the social, cultural, economic, political, and even affective structures of the present. In this article we propose how Big Data and Artificial Intelligence give rise to the Internet of Behavior; a new technological paradigm that has incredible potential to induce human behavior. Since ancient times, human beings have always wanted to predict and alter the future, but in the last ten years, this wish is beginning to become a reality thanks to great recent advances in the field of social engineering, raising serious doubts about social control and the loss of freedom. In this context of analysis, we present two projects developed within the framework of ACTS. Data Biography shows the enormous amount of digital traces that we generate daily and composes, from them, the biography of a person. On the other hand, Machine Biography investigates how current artificial intelligence techniques can predict and induce future human behavior. Both projects invite us to consider from a critical perspective the present and future of the social transformations produced by Big Data and AI.

Keywords

Prediction, Artificial Intelligence, New Media Art, ACTS, Internet of Behavior, Datacene, Big Data.

Introduction

Predicting has always been one of the main objectives of the human species. Having the ability to anticipate becoming was a key factor for human survival in primitive times. The constant observation of atmospheric conditions, with the intention of finding certain behaviors that could serve as a guide to know at what time of the year to sow, was one of the great advances in knowledge of the time that allowed the development of agriculture in the Neolithic, about 10,000 years ago. At that time, the prediction was probably based on analytical methods and some specialists in the arts of divination would soon begin to develop the ability to modify future behavior, such as to affect the weather and thereby benefit the crops of the epoch. Some of these so-called magicians, the most intelligent and sane, knew their limitations but took advantage of deception to obtain important social privileges. [1]

This operating structure has been adapted throughout history to different civilizations. In all of them we find different divinatory arts: geomancy, palmistry, Tarot, scrying, divination with corn kernels, etc., until we reach such highly developed social systems such as the Oracle of Delphi.

A particularly interesting case is the evolution in the prediction of atmospheric phenomena; where we can see a progressive improvement in the understanding of the phenomena of nature and consequently in its prognosis. This process begins in the year 340 a. C. when Aristotle defines the term meteorology in his Meteorological book [2] where for the first time observations and speculations about the origin of atmospheric and celestial phenomena are described. But it is especially from the 16th century on, with the inventions of the anemoscope by Leonardo Da Vinci and Galileo's thermometer, when the science of meteorology begins to develop progressively up to the present day. The progressive increase in data collection on the behavior of nature, due to the invention of certain scientific data collection technologies (thermometer, barometer, anemometer, etc.), made it possible to improve the prediction of atmospheric conditions using probabilistic methods. Throughout this process, we can see how the ancient divinatory methods have evolved to the science of current prediction with a good level of precision, currently it is considered that atmospheric predictions are quite reliable up to three days in advance.

In the last ten years, the social sciences, like meteorology, are developing an incredible evolution of their predictive method. Probabilistic analysis of human behavior is becoming more accurate thanks to the increasing amount of digital traces provided by Big Data. In addition, for some years we have been observing in amazement how Big Data together with computer psychology have been able to affect some key decisions of our recent history such as the 2016 United States elections, which resulted in the presidency of Donald Trump, or the “Yes” in the Brexit referendum held that same year. In both cases, Cambridge Analytics [3] used a powerful, never-before-seen social engineering system that had the ability to modify human behavior. From this moment on we ask ourselves: can we consider that those magicians who since the Neolithic aspired to control the future of our civilization have finally found a system with which they can really achieve their aspirations?

Scientific predictions

The scientific predictive method tells us that if A is true then B will also be true as long as this rational structure is formed by a logical system based on the truth test, thanks to which any experiment has to be reproducible to ensure its veracity. Obviously, all experiments must limit the field of study since it is impossible to carry out an analysis that encompasses all of nature as a whole. This partial sense of reality works with bounded models and hidden variables

with the intention of simplifying reality and being able to carry out multiple partial tests of it. We are, from a philosophical point of view, before a model that aims to establish knowledge by making reality the real. Understanding the real as that to be studied and that therefore is not yet experimentally proven, such as, for example, some concrete phenomenon of nature, which as we analyze it, we can contrast, thanks to the empirical procedure, some of its elements and / or dynamics turning them into reality.

If we look at atmospheric predictions, the models are always an idealization, a simplification given the impossibility of covering all the variables in the environment. But as we have already commented, these predictions are correct in a close period of time, currently up to three days, because, as Edward Lorenz [4] showed, a minimal change in the adjustment of the initial variables of a system makes the result of the same according to advance in time is totally different.

The social sciences, on the other hand, is an area of study where scientists have traditionally had more difficulties in predicting human behavior because even in the case of being able to get to know all the variables of the system, traditionally it cannot be determined with accuracy of the relationship between them since they are very complex dynamics and are also composed of systems with high dependence on the initial variables, as in the aforementioned case of meteorological prediction.

But these limitations are changing in recent years with the emergence of the Internet of Behavior (IoB) [5] understood as the extension of the Internet of Things (IoT) that reveals and processes significant information about our behavior. Using emerging technological innovations and developments in machine learning algorithms, this new technology is both descriptive and proactive, which means that it helps to analyze, but also to detect which variables to influence to achieve a certain result in the end user.

Datacene

Datacene emerges as a period that is assuming a true knowledge revolution, by challenging established epistemologies in the sciences, social sciences and humanities, and generating paradigm shifts in multiple disciplines. The true protagonist of this hybrid space that makes up the Datacene is the massively tirelessly generated data that fuels Big Data. Hand in hand with Big Data are emerging new forms of empiricism that declare "the end of theory", the creation of science based on data instead of knowledge, and the development of digital humanities and computational social sciences that propose radically different forms of make sense of culture, history, economy and society. [6]

In this context of massive data generation, we can understand the Datacene as a metaphor for the society mediated by data, in which an immensity of heterogeneous data is recorded, stored and analyzed. These data, together with the incredible potential of new artificial intelligence techniques that use Big Data as training for the operation of predictive algorithms, are significantly transforming our society. As [7] points out, the use of algorithm-based decisions in the public and political sphere can be problematic, because current machine learning algorithms

do not respond to a sequenced and predictable structure of orders, but rather their internal functioning is opaque and autonomous, acting as a black box of which we do not know its true inner workings. These algorithms need large data sets or datasets to train their operation and if these data have a certain bias it is known that the AI model generated from them will also reproduce the same bias. Therefore, the value of these algorithms falls largely on the datasets used for their training, since they are responsible for their proper functioning.

Data Biography: writing the biography in the Datacene

At the time of the Datacene, we could affirm a priori that we are at the perfect time to develop the realistic biographical model, due to the immense personal information accumulated in Big Data. This apparent objectivity, where the information in principle is shown to us as an optimal resource to trace the biographical account of a person, from which we can later, using predictive algorithms, artificial intelligence and semantic analysis (among other computational methods), extract and generate results relating to psychological profiles, desires, behavior, etc., in addition to having precise information on the location and places that the biographer has visited.

But this vision is at least simplistic, since the quantitative record of our actions can be biased, partial and induce erroneous interpretations about the life of the subject to be biographed [8]. In the same way that the criticized slogan "know your numbers to know yourself" of the Quantified Self [9], promises us an improvement in personal health and well-being through intensive monitoring of our biometric data, data biographies they can show us a reductionist and biased interpretation of the biographed subject.

Figure 1. Data Biography, Clara Boj & Diego Díaz, 2017

Data Biography [10] tries to compose a global physical biography with 365 books printed in a single edition (one per day), which compiles the trace of the digital data generated by Clara Boj and Diego Díaz throughout the year 2017 in which we hacked our mobile phones with a spyware and, thanks to this, we capture all our digital traces to generate the Data Biography work. This biography is made up of 365 printed books (one per day with a total of more than 40 thousand pages) and a 24-hour film narrative (showing the 8760 hours that make up the entire year).

If a biography is the life of a person narrated by another and consigns those aspects of his life most relevant and everything that, in the eyes of the rapporteur, may be of interest to it, this research tries to make a speculative design

proposal on how the biography located at the current moment could be traced, from the data captured from our digital trail in social networks, WhatsApp, emails, visited websites, google searches, images, gps location, etc.

Figure 2. Data Biography, detailed view, Clara Boj & Diego Díaz, 2017

Each of the 365 books is numbered correlatively with a total about to forty thousand pages and this immense volume of books shows the enormous amount of data that we generate and donate to Big Data daily. Located on a shelf where the title of the work can be read, each column collects a month, each book a day and each line collect an action carried out, where the temporary record and the different data of this are shown: the type of action (GPS location, email, WhatsApp, Facebook, Skype, etc.) and its content. The videos and photographs are shown in image format, which generates a list of information that allows the visitor to read all the actions carried out by us during the year 2017.

Scientific predictions and determinism in the Datacene epoch

With the emergence of the Datacene some scientific theories have gained popularity as Laplace's demon. Published in 1814 it was the first articulation of causal or scientific determinism. According to Laplace if someone (the devil) knew the precise location and moment of each atom in the universe, the past and future values of it for any given time would be deductible from those data; could be calculated from the laws of classical mechanics [11]. The followers of Big Data have recognized the figure of Laplace and raised this deterministic possibility from the data, where we have a noisy vision of the reality provided by the immense amount of data generated and stored in the Big Data.

From a deterministic point of view, a good part of this data is noise, which prevents us from accessing the signal, so the job consists of cleaning this data to be able to access the information it contains, the patterns hidden in it. The limitation of this theory resides in that in practice mathematics falls short in the analysis of society, from propositional logic it is impossible to demonstrate certain statements since there are more propositions than demonstration, so not everything can be demonstrated, although the initial hypothesis may be reasonable, but the problem is undecidable and it cannot be validated due to the impossibility of proving or refuting a certain predicate based on others. An example of this is the Super Bowl impossibility theorem [12], by which it is stated that the real effects of advertising on the sale of products advertised

during this famous event cannot be accurately measured. The effect of advertising is subject to a lot of noise so it is impossible to deduce its direct consequence, the effect of this action cannot be affirmed or denied since in real life the parameters that can affect it are so many that it is impossible to create a mathematical model that can consider them all.

Although, although it is true, the models are increasingly broad and powerful, with a greater number of parameters and input variables. A great benefit of Artificial Intelligence algorithms is machine learning that has been a true revolution, since they learn from the analysis of massive data from the real world, such as recurrent neural networks that are an excellent system to find the signal hidden in the data as they are great at finding patterns of behavior. But its internal functioning, in the case of deep neural networks, is opaque and no one can be a true connoisseur of it, behaving like a black box that can lead to unforeseen results. In this sense, some data scientists believe that we are entering an age where alchemy has relegated science to second place. In the words of Ali Rahimi (AI expert): "We are building systems that govern healthcare, mediate our civic dialogue and influence elections. I would like to live in a society whose systems are built on verifiable, rigorous and exhaustive knowledge, and not on alchemy" [13]

As our computational tools have become more advanced, they have become opaquer. For Elon Musk, controversial CEO of Tesla, the biggest concern has to do with the AI that lives in the network and that could autonomously harm humans. "[AI] could start a war by making fake news and falsifying email accounts and fake press releases, and simply manipulating the information" [14], this sci-fi scenario in a way has already happened, although it has not transcended of the digital world, when in November 2017 the artificial intelligence of the video game EVE Online got out of control and unleashed a battle between three cosmic flotillas without any human participation [15].

Machine Biography: predicting the future with deep neural networks

In this project we have made a predictive biography for the year 2050 of Clara Boj and Diego Díaz using Artificial Intelligence techniques based on Deep Neural Networks which have been trained with all our digital activity (GPS locations, digital conversations, photographs, videos, etc.) collected during 2017.

Figure 3. Machine Biography, Clara Boj & Diego Díaz, 2020

In recent years we are witnessing a true revolution in the field of Artificial Intelligence thanks to advances in Machine Learning, where the new algorithms of Deep Neural Networks (DNN) have given rise to the so-called Deep Learning (DeepLearning). The rapid evolution of

these algorithms, their versatility and incredible potential, are affecting our society in many different areas; from helping to preserve endangered species to sophisticated face recognition techniques for surveillance and social control. But one of the most controversial fields is its ability to generate predictions and also create false information (deepFake), entering a new era where the veracity of the information is apparently impossible to contrast.

Figure 4. Books detailed view. Clara Boj & Diego Díaz, 2020

In Machine Biography we use the data captured during the year 2017 for the previously presented Data Biography project. With all this information we have trained different deep neural networks to generate our foreseeable digital activity in the year 2050 and we have reprinted the resulting data to create another 365 books that will form the work Machine Biography; a predictive biography created by artificial intelligence where the limits of what is true and what is false are blurred and the very veracity of the information is questioned at the same time that it is proposed to analyze the creative capacity of artificial intelligence.

Figure 5. Machine Biography, detailed view. Clara Boj & Diego Díaz, 2020

Conclusions

In this publication we have presented recent research projects that invite us to question ourselves from different points of view about the social transformations exercised by the Internet of Behavior at the time of the Datacene. In the case of Data Biography, the work challenges us: if we had to write a biography of a person today, what would be the most appropriate means of gathering information about him? And more specifically, what form could this biography take? Based on this question, we structured the entire research methodology that gave rise, after the study of Big Data, to the compilation of our digital traces and the formal concretion of the resulting artistic work: a Data Biography, composed of the record of all our digital activity during 2017.

This same structure of thought was used in 2019 for the Machine Biography research, in this case the fictitious starting hypothesis was: can machines predict our future? From this perspective we build the final work composed of a predictive biography of our activity for the year 2050, the technology used for the construction of this biography were different predictive models of Deep Learning trained with our digital traces collected during the year 2017.

The general objective of our research is to carry out a critical reflection on the paradigm shift brought about by recent improvements in the predictive capacity of human behavior in social engineering. This new and powerful weapon of social control is still in a primitive phase of development, but its enormous potential makes it necessary to study and discuss its possible transformative actions.

Abstract

In 2019 a team of multi-disciplinary researchers undertook a research project entitled *Identifying Successful STARTS Methodologies* (ISSM) (2019-2021)¹ in order to analyze the innovative and collaborative strategies utilized by the global Science, Technology and Arts (=STARTS) Prize Winners and nominees. The aim was to identify and articulate successful STARTS Methodologies through a series of interviews and in-depth case studies of the recognized projects. The project culminated in a series of case studies and an exhibition at the *Made in Wolves Gallery* at the University of Wolverhampton, UK, and further presented at UK Garden of Earthly Delights at Ars Electronica in 2020. The project identified three emerging themes: the significance of building a new language of art and science through a third space, the process of anti-disciplinarity as an emergent form of practice, and the importance of different ways of knowing through art and science. A number of the case studies and themes are presented here alongside images from the exhibition.

Keywords

Art-Science, STARTS Prize, ISSM, *treelab*, *This is Grown*, *Library of Ourselves*, *The Murder of Pavlos Fyssas*, *Future Flora*, *Virophilia*

Introduction

It is now over fifty years since the ground breaking 1968 exhibition *Cybernetic Serendipity: The Computer and the Arts* at the ICA in London and this was a critical point in time that saw artists, scientists, and engineers explore the use of new technology for ‘creativity and inventiveness’[1]. Since then there have been intermittent developments in art and science collaborations with the 21st century seeing a significant increase in interest in interdisciplinary practices. There have been some attempts to articulate a more comprehensive set of methodologies for collaborative science, art, and technology research processes although exemplars of cross-disciplinary collaboration have

emerged ‘as a discrete paradigm in need of its own definitions, rules and recognition’ [2] [3] [4]. In 2019 a team of multi-disciplinary researchers undertook a research project entitled *Identifying Successful STARTS Methodologies* (2019-2021) in order to analyze the innovative and collaborative strategies utilized by the global Science, Technology and Arts (=STARTS) Prize Winners and nominees. The aim was to identify and articulate successful STARTS Methodologies through a series of interviews and in-depth case studies of the recognized projects.

The STARTS initiative is led by the European Commission and incorporates a number of related projects funded projects in Horizon 2020 including the STARTS Prize. The focus of the STARTS Prize is on high-end innovative collaborations between artists engaged with science and technology, and technology and science research laboratories open to bring artists into the laboratory environment. The STARTS Prize has ran for five years (2016-2020)², each year two prizes are awarded, one for Artistic Exploration, the other for Innovative Collaboration. In addition ten projects are given an Honorary Mention each year. A focus of the STARTS Prize is on showcasing achievements, encouraging further collaborations and honoring the inspiring individuals and teams involved.

Case studies of the STARTS Projects

Four case studies were presented at the project exhibition in the *Made in Wolves Gallery*, University of Wolverhampton, UK in 2020 each having received Honorary Mentions from the STARTS Prize: *Library of Ourselves* by the art collective BeAnotherLab (Honorary Mention 2017), *Treelab* by sound artist, Marcus Maeder and tree physiologist, Roman Zweifel (Honorary Mention 2017), *The Murder of Pavlos Fyssas* by London based interdisciplinary research agency Forensic Architecture (Honorary Mention 2019), and *This is Grown* by designer Jen Keane (Honorary Mention 2019).

¹ The project was funded through the competitive IRIS initiative at the University of Wolverhampton, UK.

² The STARTS Prize will run for another term of 4 years from 2021 until 2024.

The Murder of Pavlos Fyssas

'We think that artists also have a claim to truth. We understand that evidence doesn't speak for itself, we understand that we need to have interpretation, we understand that we need to represent. We need to make visible and explicit.' [8]

Project Description

Shortly after midnight on 18 September 2013, Pavlos Fyssas, a young Greek anti-fascist rapper, was murdered in his home neighbourhood of Keratsini, Athens. Forensic Architecture were commissioned by the Fyssas family and their legal representatives to reconstruct the events of the night from audio and video material made available to the courts: the resulting investigation and report establishes a timeline and reconstruction of events that led to the murder, demonstrating the complicity of police – who were present at the scene before, during, and after the murder, but failed to intervene [9].

Jury Statement

By revealing state complicity with Golden Dawn in the murder of Pavlos Fyssas, this project continually and meaningfully encourages an increase in public dialogue on nationalism, immigration, and politics. The jury found that although the questions raised by the project were yet unresolved, they may be more relevant than ever the current global-political moment [10].

Case Study

Forensic Architecture³ is an interdisciplinary research agency, based at Goldsmiths, University of London, who use architectural techniques to investigate human rights violations and cases of state violence. Incorporating artists, photographers, videographers, sound engineers, and weapons experts, Jacob Badcock visited their studio in New Cross, South East London, to interview assistant director, Cristina Varvia, in January 2020. Taking their STARTS Prize nominated *The Murder of Pavlos Fyssas* as a point of departure, our case study focuses on Forensic Architecture's 'archaeological' approach to media artefacts and the built environment, emphasising their ability to make otherwise imperceptible acts of violence perceptible - to reveal that which is hidden through the close analysis of materials. Following their own self-reflexive analysis, we understand Forensic Architecture's practice as an 'investigative aesthetics' which brings art to bear on the production of legal-judicial truths. Going further, we identify how Forensic Architecture collapse binary art-historical distinctions between the aesthetic and the epistemological: - for Forensic Architecture, the artist, as much as the scientist, the mathematician, or the anthropologist, has a claim to truth.

³ Forensic Architecture received the Ars Electronica Golden Nica award in 2021 for their project *Cloud Studies*.

Library of Ourselves

'How bizarre it would be to conceive of an I without an us' [5]

Project Description

Library of Ourselves is an interdisciplinary project used to create transformative encounters between communities in conflict. It was built using *The Machine To Be Another* – a highly adaptable Creative Commons system that bridges cognitive science and virtual reality techniques to create empathic-driven experiences [6].

2017 Jury Statement

The jury felt that the BeAnotherLab team was highly successful in utilising VR technologies as a true empathy machine – allowing the user to be placed into another person's body, and to experience the world through their eyes [7].

BeAnotherLab are an interdisciplinary art collective whose main base is in Barcelona, Spain although the group are distributed worldwide (Amsterdam, Paris, Zurich, Sao Paulo, and New York). The nine members of the collective are from wide ranging backgrounds including Anthropology, Computer Science, Digital Arts, Cognitive Science and Conflict Resolution. Dr Denise Doyle visited the *BeAnotherLab* collective at their Hangar studio in October 2019, where she interviewed five of the nine members, and participated in a debriefing from two members of the Collective from their recent trip to Jordan where they were filming the stories of Syrian and Iraqi women refugees for a project based at the University of Birmingham, UK. The resultant immersive narratives will be added to the ongoing *Library of Ourselves* archive. Dr Doyle went on to interview the remaining members of the Collective during the COVID-19 lockdown. Through the many interviews conducted, it became apparent that the most significant aspect of the approach of the group is their commitment to understanding embodied experience through the many fields that they inhabit. (Some have undertaken PhD level research in neuroscience to 'validate' their findings). Our case study further emphasises their shared belief in the ability to engender empathic response in others through immersive virtual reality technologies.

This is Grown

'I think it's imperative to have both a design perspective and a scientific one. One, to just validate the work, but also, I think, it becomes richer in the final outcome' [11]

Project Description

This Is Grown was motivated by a frustration with plastics and a visible disparity between scientific research and design manifestations around natural materials. Taking an organism-driven approach to material design, the project began under the premise that a greater understanding of

nature could help us not just replace the petrochemical based materials of today with more sustainable ones, but perhaps allow us to devise entirely new systems of making and categories of materials previously unimagined [12].

Jury Statement

This is grown. is a project by Jen Keane that proposes a ground-breaking solution to our troubled relationship with nature. Working at the intersection of design and research, Keane has transformed her frustration with plastic pollution into an actionable idea for reducing the amount of plastic waste [13].

Figure 1. *This is Grown Shoe* (2018) designed by Jen Keane. Photo Credit: Adam Toth. Courtesy of the designer

Fig. 1 is a photo of one of the shoes designed and ‘grown’ by Keane as part of her project. Taking an organism-driven approach to material design, the project began under the premise that a greater understanding of nature could help us not just replace the petrochemical based materials of today with more sustainable ones, but perhaps allow us to devise entirely new systems of making and categories of materials previously unimagined.

Case Study

Our case study investigates the nature of the interdisciplinary working and collaborations between artists and scientists in this project, focused on biological alternatives to synthetic materials. Several interviews were carried out to create dialogue for later qualitative analysis; these conversations included reflections on the very nature of and relationships within the collaborative context and cognitive space formed that facilitated creation. For ease of interpretation and to gain a deep perception of the views of participants that reflect the nature of relationships in art/science collaborations a simple thematic analysis approach was chosen to interpret the data and begin to answer the research questions set by the project and develop a conceptual framework to better understand and represent the data. Coding allowed the development of three themes under which perceptions from interviewees could be grouped that reflected the nature of collaborative activity between artists

and scientists. The three themes identified were; Emotions, Technology, and Knowledge. These reinforce each other and converge to create the transformative intersection where art and science meets and the collaboration occurs. This relationship is not simple and involves a quasi-state or epistemic super positionality that requires further investigation.

TreeLab

‘I want to create an experience of the abstract term ‘climate change’. An experience that is shareable. Once you’ve made this experience of a suffering tree, you may be able to discuss that with others who experience the same art installation’ [14]

Project Description

Treelab’s project *Rendering Ecophysiological Processes Audible* sought to connect sounds that occur in trees with ecophysiological processes and thus investigate render perceptible experiences of plants that are not noticeable to humans [15].

Jury Statement:

The jury was impressed with the unusual pairing of a plant physiologist and a researcher in computer music and sound technology in their work to bring the unheard sounds of trees to the surface; their collaboration resulted in a joint research project on complex environmental data collection and sonification [16].

Figure 2. Spatial audio version of trees: *Pinus Sylvestris*. Courtesy of Marcus Maeder and Roman Zweifel.

Case Study

In September 2019, Richard Glover flew to Zurich to interview TreeLab, made up of tree physiologist Roman Zweifel, and sound engineer Marcus Maeder. As *TreeLab* developed, the researchers realised that if they could make these stress-induced plant signals perceivable to humans, an abstract concept like climate change can be made tangible through an installation environment. Through qualitative analysis from interviews, this case study explores the different roles played by the collaborators, and the conse-

quences for their own distinct academic fields. Maeder's approach is underlined by his philosophy that artists and scientists meet on a 'different plane' to one inhabited by either party; this different plane best facilitates cooperation by both researchers. The task for artists is to develop a common language with scientists through an engaged study of their discipline, which can take considerable time – two to three years in the case of *TreeLab*. Zweifel acknowledged the deep interaction that arose from Maeder's desire to understand the meaning behind the scientific data, rather than simply translating it as material to be employed in artistic work. Equally, Zweifel acknowledges the artistic realisation as a much more effective mode to facilitate heightened public understanding and impact of the urgent environmental data, in comparison to standardised journal publication routes. Maeder similarly recognises the importance of shareability of the installation experience, to prompt further discussion and exploration. The case study emphasises the shared understanding by both researchers, from very different fields, that for public presentation to bring about societal change, a transition to the *emotional* is necessary

Emerging Themes

The project identified that through this process of interdisciplinary collaborations three themes emerged:

(1) Building a Language between Art and Science

A number of the artists and scientists who work together over the long-term describe how they have to build a 'third space' or have to meet on 'another plane' in order for them to communicate and find a common language. The artist needs to understand the language of the scientist, and the scientist needs to understand the language of the artist – but this can happen best in a newly created space. Any long-term collaboration as an artist engaged in science means developing a real knowledge of the science.

(2) Anti-disciplinarity as a form of Emergent Practice

Through the case studies undertaken there is evidence that there is an emergence of anti-disciplinary practices that do not fit within existing academic disciplines. These practices develop by necessity – with manifold methodological and theoretical approaches required to address complex problems (i.e., climate change). Some projects are anti-disciplinary by design, emphasising the significance of aesthetic practice for knowledge production. Also noted is that new technologies can create inherently anti-disciplinary spaces (i.e., virtual reality) where artists live and thrive.

(3) Different Ways of Knowing

As the recent COVID-19 pandemic has highlighted we are dealing with a time of great complexity and uncertainty and there is a need to work in new ways to solve global and societal issues. It is critical for the arts and humanities – in conjunction with the sciences – to embrace different ways of knowing, enabling greater insights for meeting the challenges of the contemporary world. The

methodologies and collaborations in art, science, and technology that support the work presented in this exhibition further attest to this.

The ISSM Exhibition

The threats of the COVID crisis have also brought about new opportunities such as participating in a distributed Ars Electronica Festival in 2020 and this actually prompted us to host our project exhibition early in order to showcase the work of the project alongside some of the winners and honorary mentions of the Prize. The exhibition was originally intended to showcase the interim results of the project at the project conference in early July 2020. Due to the COVID-19 pandemic the conference had to be cancelled. However, an opportunity to be part of the Ars Electronica Festival 2020 in Linz, Austria virtually through the UK Garden of Earthly Delights presented itself and the exhibition was installed in the University's *Made in Wolves Gallery* at the main campus in July 2020 until June 2021 [17].

Figure 3. The ISSM Exhibition featuring Virophilia installation. Photo Credit: Denise Doyle

From the STARTS Prize 2020 we were keen to host the work of Taiwanese artist Pei-Ying Lin, given the immense global impact that COVID-19 was having. Her project *Vi-*

rophilia investigates the possibilities of human-virus encounters and one part of the installation is a 7 metre high scroll that lists all known viruses in the world, with space for more to be added [18].

Another part of the *Virophilia* project installed in the exhibition was a cookbook written for the 22nd century where humans have learnt to live with and accept viruses as part of a greater ecosystem. Of note is the *Influenza Egg on Rice*, but equally there are many strange combinations in the cookbook itself (see Fig. 4).

Figure 4. The Influenza Egg on Rice recipe in the *Virophilia* Cookbook. Pei-Ying Lin. Courtesy of the Artist.

Also included in the exhibition was an installation of the *Future Flora* project by Giulia Tomasello and a shoe and some material examples from the *This is Grown* project by Jen Keane, presented above. Fig. 5 features the installation of *Future Flora* containing the harvesting kit Tomasello designed for women to treat and prevent vaginal infections [19]. *Future Flora* aims to encourage the symbiotic relationship that raises the beneficial presence of microbes and bacteria in the human body, suggesting an alternative: to wear probiotics and keep our body healthy. It is aimed at women who wish to take control of their own bodies as a precious and intimate practice of self-care.

Conclusion

The IRIS initiative was developed in order to encourage cross-faculty interdisciplinary research within the University of Wolverhampton, UK and to create strong international partnerships that could withstand the challenging years of research funding ahead outside of the EU. The Director of European Collaboration at Ars Electronica, Veronika Liebl, noted that the project promised 'to bring valuable insights and knowledge of the versatility of these STARTS collaborative practices, consequently helping STARTS to improve future measures in encouraging processes between artists, scientists and technologists.' [20]. Future research aims to test these emerging themes and outcomes in a series of artist-scientist residencies in order to further support this interdisciplinary work in arts, technology and science that can make a real societal impact in the world.

Acknowledgements

Thank you to the University of Wolverhampton, UK for the financial support through its International Research and Innovation Scheme (IRIS) in order for this research to be undertaken, and for the support to travel to Spain, Switzerland, and Holland in order to undertake some interviews face-to-face.

Click::REVU: an optophonic sound installation

Paul Dunham, Mo H. Zareei, Dugal McKinnon, Dale Carnegie

Victoria University of Wellington

Wellington, New Zealand

paul@dunham.co.nz, mo.zareei@vuw.ac.nz, dugal.mckinnon@vuw.ac.nz, dale.carnegie@vuw.ac.nz

Abstract

If traces of past media remain in contemporary forms of media, how can these traces be appropriated and applied in the creation of a sound-based installation? This paper presents *Click::REVU* a sound installation developed by the first author. The work blends physical characteristics of an early sonification device, the Optophone – a device that translated optical data to sound - to create an illusory presence through a scanner mechanism from a multifunction printer. The work’s compositional structure reduces the scanner’s image capture ability to an indexical relationship that is expressed as a minimal soundscape of drones and clicks. As a media archaeological sound-based artwork, the ideation of *Click::REVU* has depicted a form of optophonics through the interpretation of early 20th century Optophones. These forms, as archival sources of knowledge for reinterpretation, have informed the development and realization of this work, one that is expressed through a genealogically related contemporary form of media, the contact image sensor scanner.

Keywords

Sound art, media archaeology, optophonics, Optophone, obsolescence

Introduction

If Benjamin said that history had hitherto been written from the standpoint of the victor, and needed to be written from that of the vanquished, we might add that knowledge must indeed present the fatally rectilinear succession of victory and defeat, but should also address itself to those things which were not embraced by this dynamic, which fell by the wayside - what might be called the waste products and blind spots that have escaped the dialectic. [1]

Request, Theodore Adorno

Theodore Adorno’s observations of Benjamin are made within a critique of the modern subject’s dread of backwardness. However, they equally provide an examination of the possibilities of this backwardness as a refuge from modernity where the past can live on in the present. Joel Burges posits that such refuges can harbor historical possibilities which can be excavated “for

alternative itineraries to a present in which capitalism has co-opted modernity.” [2] Thus, by engaging in counter historical thinking, the “presence of the past can disrupt this temporal form of linear progress by constellating those temporal elements.” [2]

One perspective as a critique of new media is media archaeology. While some see that the “methodological repertoire of media archaeology has been geared to discourse analysis”, media archaeology allows for the exploration of the material possibilities of obsolete media through an engagement with the physical artefact. [3] Calls for such an engagement with media are not new and have arguably been ever-present in the creation of media archaeological art.

This paper presents *Click::REVU*, a media archaeological sound-based installation developed by the first author. The work utilizes elements of the *Optophone*, a device designed to “substitute the ear for the eye” by making optical signals audible, in its ideation and realization. [4] As media archaeological experimentation, the work is informed by a relationship between contact image sensor (CIS) technology prevalent in low-cost multifunction printers and the Optophone via the light sensing technologies developed through the 20th century. As such, the Optophone shares a media genealogy with optical devices developed in the early 20th century as precursors to later developments that include the automated conversion of images into machine-readable text (optical character recognition), image sensors embedded in digital cameras and scanning technologies and the compact disc. This relationship between past and present forms of optical media informs a conceptual and aesthetic approach for the appropriation of one such form of media, the CIS mechanism (Figure 1), in the creation of *Click::REVU*.

The next section provides a brief introduction to media archaeology as creative practice and a survey of related works. Following this, the paper presents a brief introduction to the Optophone and its development. Next, *Click::REVU* is presented where a system overview and aesthetic and compositional strategies are described.

Figure 1. CIS mechanism

Media Archaeology as Artistic Practice

A plea for new directions in media archaeological research issued by Andreas Fickers and Annie van den Oever in 2013 specifically called for an experimental approach to media archaeology over discursive enterprises through the historical re-enactment of past media technologies. [3] *New Media Archaeologies* (2019) extends Fickers and van den Oever's entreaty through a series of essays by highlighting the contribution that experimentation can make to understanding media archaeology. Again, they argue such an approach can "stimulate our imagination of the past" through the "sensual and experiential potential of technical objects, which ... has hardly been broached hitherto in technology or media historiography beyond a purely aesthetic consideration." [5]

Noting that media archaeology is being executed in artistic ways, Jussi Parikka attempts to articulate a creative methodology for practicing media archaeology that contextualizes artworks as such. He suggests several themes for resurrecting old media in contemporary contexts. Therefore, media archaeological artworks "that visually engage with historical themes" can invoke "alternative histories that offer critical insights into the assumed-natural state of digitality" using obsolete artefacts. [6] These works may "engage with emerging media cultures" by drawing on concrete archives as a means of "working like an historian" to an artistic end. [6] A sensual engagement with the artefact, whether a past or present form of media, is a way of opening technologies to expose the "buried conditions of our media culture." [6]

Related Works

A diverse range of artists and many works have been discussed through a media archaeological lens. Such works include those by Paul DeMarinis, Bernie Lubell, Lynn Hershmann and Michael Naimark amongst others that incorporate explicit references to past analogue and mechanical machines in their work. [7] Inspired by Etienne

Jules Marey, Lubell's *Etiology of Innocence* (1999) contains a hand pumped mechanism based on the heart that powers various "bouncing, breathing, beating" mechanisms. [8] DeMarinis' installations emphasize the "material or mediating experience of specially designed artifacts" by creating *counterfactual artefacts* that "occupy a creative space at the boundary between actual and possible worlds." [9] Examples within this context include *The Messenger*, a work that presences early telegraph experiments alongside Internet communications. Another are those included in *The Edison Effect* (1989-1996), a series of sound sculptures that play a range of obsolete recorded media using laser beams including wax cylinders, 78 rpm records and a clay cylinder (Figure 2).

Figure 2. *Fragments of Jericho*, from *The Edison Effect* series

Described as a mediation between music, memory, and time, these works defamiliarize the familiar by "distorting, de-arranging and de-composing the musical material" by merging the raw noise of the medium with the inscribed sounds to create a "havoc of misinterpreted intentions and benign accidents." [10]

Contemporary examples of sound-based works engaging with media archaeology can be found in works by Morten Riis and Stephen Cornford. Riis situates his *Steam Machine Music* (2010) (Figure 3) as post-digital glitch giving the machine's material physicality a pivotal role in its performance via an aesthetic of failure.

Figure 3. *Steam Machine Music Instrument*

He writes “the malfunction of machines is a constantly continuing factor for the use and existence of technology”, as evidenced by the “inevitable errors of the machine through the pre-electronic case of mechanical music.” [11] Examples of Cornford’s work include *Binatone Galaxy* (2011), *Migrations* (2014) and *Constant Linear Velocity* (2016). These works consider obsolescence not as an end but an opportunity to reconsider the functional potential of abandoned devices and their movement from production to pollution.

It is not the intent of this paper to cover the range of possibilities for media archaeological sound art. This review has presented several examples of works that exist in a media archaeological context. Even whilst focusing on activities of tactile engagement with media artefacts as an approach to the creation of sound art, the field is increasingly diverse and, at times, difficult to distinguish between what is explicitly intended as media archaeology and those works that exhibit characteristics of such approaches. However, it is within this diversity of possibilities that *Click::REVU* is situated, not only as a sound installation foregrounding the materiality of the physical object, but one explicitly informed by a media archaeological approach to historical media representations. Developed as a part of the first author’s doctorate research, this work has emerged out of an inquiry into unlikely relationships between obsolete and contemporary media and an aesthetic reimagining as a sound-based installation. The work is the last in the portfolio of artworks developed to realize the research’s theoretical framework.

The Optophone

One result of the First World War was the need to physiologically reconstruct human bodies. This need produced an increased demand for prosthetic technologies. [12][13] One area of sensory loss was sight. Whilst braille had been available as a tactile substitute for sight since the early 19th century, technological innovation surrounding the war years provided an opportunity for other forms of sensory prosthetic devices to “relieve the disabilities of the

blind.” [14] One such device was a little-known invention called the Optophone. As a sonification device, the Optophone translated optical data to sound. Fascinated with the relationship between electricity and light and the conductive properties of selenium, Edmund Edward Fournier d’Albe’s early experiments and research led him to develop a means of providing a “complete electrical substitute for the eye.” [14]

Background

First demonstrated in 1912, the exploring Optophone (Figure 4) was a device to aid visually impaired people with orientation in their environment. [15] Fournier d’Albe stated that the blind could navigate around obstacles by listening through an adapted telephone receiver to hear a series of clicks or rasping generated by differences in light intensity. However, the instrument was not without criticism. One critique was of need. “The blind problem is not to find lights and windows but how to earn your living.” [14] With this in mind, Fournier d’Albe presented a redeveloped Optophone in 1914.

The reading Optophone was “designed with the object of enabling blind persons to ‘read’ ordinary letter press by means of the ear.” [4] With this development, d’Albe added a musicality to the tones used to represent text as sound. Using a numbered ratio from the musical scale, the reading Optophone produced a series of eight notes; G, C, D, E, G, B, C, E, from which “both concords and discords could be obtained according to the letters exposed.” [4]

Figure 4. The Exploring Optophone

In what was termed a “white-sounding” Optophone, the black letters were read by omitting notes from the scale rather than by what notes were sounded. As a form of subtractive synthesis, white space was heard as a discordant “chaos of notes” with a letter characterized by the absence of a note or notes as it was read by the Optophone. [16]

In 1920, Fournier d'Albe, along with optical engineers Archibald Barr and William Stroud, were issued a patent for “new and useful improvements in Optophones.” [17] Improvements included a reversal of the action for reading text and a change in the tonal range. The revised device was termed the “black-sounding” Optophone (Figure 5) because, as a form of additive synthesis, it was the letters themselves that produced sound, thus producing no sound in the intervening “white” space. With this, the tonal range was reduced to G, C, D, E, G. [18][19] Arguably, with these harmonized changes, it was easier to hear and learn the different chord variations in relation to the characters. [20]

Figure 5. The Type-reading Optophone

Related Developments

Whilst the development of prosthetic sight-to-sound technologies waned with the emergence of optical character recognition (OCR) technologies and speech synthesis, some research and development after Fournier d'Albes original Optophone are worth highlighting. Some notable devices include the *Battelle Optophone* (1960s), Charles Carle's *Lexiphone* (1963) and Mauch Laboratories *Visotoner* (mid-1960s), a self-contained battery operated Optophone and the *Cognodictor* (mid-1970s), a recognition reading machine consisting of an optical scanner and a speech synthesis engine. [21] Similarly, various research has been undertaken to develop devices that interpret three dimensional, or distance-to-object information, something increasingly commonplace with advances in image capture and analysis technologies. [22][23]

As a media archaeological exercise, Tiffany Chan et al.'s contemporary rendering of the Optophone is described as a practice-based method of understanding media history

¹ *Click::REVU* is currently near its final completion. Full video documentation and further images will be available when a camera-ready version of the paper is required.

through a tactile engagement with the “material particulars of historical mechanisms.” [24] Such an approach provides an understanding of the presence of past media embedded in contemporary culture and technology through a series of overlapping temporal layers. Chan et al.'s remake of the Optophone does not seek to reconstruct an equivalent device nor to replicate previous experiences of the device. Rather it seeks to highlight “what we cannot retrieve, repeat, or translate in the present” to foreground differences and absences as a refrain from “flattening the many versions of optophones into the optophone.” [25][26] Such flattening of perspectives, as noted by Chan, has contributed to an oversimplification and imprecision concerning certain narrative histories of media. As Druckery argues, history is “not merely the accumulation of fact, but an active revisioning, a necessary corrective discourse, and fundamentally an act of interrogation—not just of the facts, but of the displaced, the forgotten, the disregarded.” [27] It is this ‘flattening’ of historical narratives and connecting seemingly unrelated forms of media that has contributed to the ideation and realization of *Click::REVU*.

Click::REVU

Click::REVU (Figure 6) is an sound-based installation that repurposes and foregrounds the CIS mechanism as the primary visual element for the work¹. In its intended use, the CIS mechanism is generally concealed within a larger structure, analogous to an organ within a body.

Figure 6. *Click::REVU*

Removed from the shroud of darkness of its natural habitat and its support structures (e.g., interfaces to image formation, formatting, and engine control) the CIS itself has become visually impaired as it struggles to see in its new environment. The mechanism's movement is reduced to a series of horizontal gestures, symbolic of its utilitarian and repetitious function. Creatively appropriating and

Figure 10. Exposed CIS mechanism

Compounding this difference, the construction and assembly of the structural elements of the work produces subtle nuances in the rhythm of the mechanism. The glass platen which the CIS originally sat upon, as a window for it to see through, is reversed to face the audience. This aligns the work nearer to the purpose of the Optophone as a visual aid for the sight impaired. To this, the illusory body of the Optophone emerges through the CIS as it enables the vocalization of variations of light and dark.

Click::REVU interweaves elements of the Optophone by adopting Fournier d'Albe's concept of interpreting type based on bands of light, each keyed to a different frequency. Fournier d'Albe's incorporation of musical elements for the Optophone can be considered an aesthetic attempt to make the auditory output more attractive to listen to after the roaring noise and buzzing tones of the earlier exploring Optophone. This aestheticization of sound is represented in *Click::REVU* through the use of modulated sine tones using frequencies in relation to musical scales.

Compositional Strategy

Click::REVU's sonic presence combines the 'musicality' of Fournier d'Albe's reading Optophone with the electroacoustic materiality produced by the movement of the CIS mechanism described in the previous section. The scanner mechanism's repetitive gestures and the fixed frequencies of the sine tones appear homogenous. However, each movement exhibits moments of difference in its return and repetition.

Click::REVU uses the notes G, C, D, E, G, B, C, E associated with the white-sounding Optophone. The representation of Fournier d'Albe's early reading Optophone, as the composition *White*, reads a data value from within the programmed strata range and applies it to affect a specific tone function. This begins with a wavering drone comprising a chaos of notes. As the data values are read, tones change at different intervals. Interfering with the drone's rhythmic texture by the imposition of small movements in the individual frequencies is a way of

introducing rhythmic difference. By disrupting the continuous, or linear, repetition of each sine tone, the drone's rhythm becomes cyclic, as return and difference, through the variations introduced in the process of return and renewal.

The simultaneity and diversity of sine tones create moments of harmony and discord, as diverse rhythms interact to maintain a metastable equilibrium between them. An arrhythmic presence exists as a dysfunctional interrelation of rhythms experienced by introducing discontinuity to the sine tones through the irregular presence and absence of sound. At a macro level, the work's rhythms are modulated by the mechanism's electromechanical and programmatic movement. This relationship, modulated by slow changes in environment light, does not interrupt the rhythms but modifies them through the light's diurnal cycles. This interaction between the mechanical and organic elements, experienced by the creation and discovery of new rhythms through repetition and difference, presents a novel interpretation of an optophonic work in *Click::REVU*.

These variations, translated into a presence and absence of sound, interferes with the discordant drone by imposing discontinuous moments within the individual sine tone frequencies. In addition, a by-product of this discontinuity is embraced as a part of the resulting sound. Heard as clicks, these are an artifact of the disruption to the sine tone as it is turned off and on at varying points in each waveform's amplitude. This granulation of an already fragmented ability to see adds a further textural layer to the soundscape.

A Media Archaeological REVU

Utilizing an experimental form of media archaeology as a speculative approach to explore the artistic potential of media can be one way of creating intriguing parallels and connections between past and present media. Such connections have been used to inform the ideation and realization of an idiosyncratic optophonic creation. Such non-discursive insights into the past can also stimulate our imagination, allowing one to "reflect critically on the hidden or non-verbalized, sensorial, corporal, and tacit knowledge" through an engagement with these artefacts. [5] [28]

Click::REVU has focused on the material elements of the Optophone to create a presence of the artefact through the body of a contemporary mediatic form. The work does not reveal the working of the Optophone through itself. Instead, it was interested in the temporality ascribed to such devices as sensorial traces of past articulations, their intriguing noises, functionality, and physical construction.

The work constructs a form of expression based on the practical realization of Fournier d'Albe's prosthesis by utilizing elements of his Optophone. These elements are reimagined through a form of contemporary media, not as a device tightly coupled to sight and sound but as an interpretive sound-based installation. Utilizing a form of contemporary media technology to interpret past media

creates an awareness of characteristics of them as traces of the past in the present.

Conclusion

This paper has presented *Click::REVU*, a sound-based installation. As media archaeological research, *Click::REVU* is a part of a portfolio of works that have, by employing different media archaeological approaches, have reinterpreted obsolete and contemporary media as sound-based installations. The previous works, *Click::TWEET* and *Click::RAND* have been presented respectively at ISEA2020 and NIME2021. [29][30] Media archaeology, as an approach to inquiry, can be a way of seeing the possibilities of alternative historical narratives between the past and present through the convergence of obsolete and contemporary media technologies. Making such connections and representing familiar things in unfamiliar ways through artistic methods may impart a sensation of things as they are perceived and not as they are known. Approaching the conceptualization and realization of the work through media archaeology, *Click::REVU* imagines an optophonic form that is an interpretation of Fournier d'Albe's early 20th century research and development. Blending physical characteristics of the reading Optophone's sound, the work's composition reduces the sense of light and dark to an indexical structure that is expressed as a minimal soundscape of drones and clicks. The combination of rhythms produces continual moments of arrhythmic disruption. As such, this reinterpretation of archival knowledge informs the creation of *Click::REVU*, expressed through a distantly related but contemporary form of media, the contact image sensor scanner. Reimagining the past through the present, the work reconfigures the existence of the Optophone within a broader history of optical technology and sensory prosthetics. Just as the Optophone was developed as a visual aid for the sight impaired, media archaeology as a form of creative practice, can provide alternative perspectives in which to see the world.

Abstract

How might we come to *know* the particular qualities and affordances – as well as the constraints and biases – of the medium of Virtual Reality (VR)? Responding to this situation from the perspective of *Educations and Societies*, we submit that more nuanced understandings of the qualities (aesthetic, narrative, experiential) and affordances (conceptual as much as technical) of the medium can be gained if VR is approached as a form of cultural *and* research practice. In this paper we will present a curated selection of innovative creative research projects developed at SensiLab, a trans-disciplinary research centre based at Monash University in Melbourne, Australia; and do so in the interest of exposing some of the investigative ways that practitioner-researchers (media artists, creative technologists, content producers) are extending understandings of both studio practice and the medium itself by engaging deeply, experimentally and reflexively with immersive imaging technologies. Illustratively, these dynamic, discovery-led *PhD* projects – undertaken by Sojung Bahng (visual artist and filmmaker), Oscar Raby (VR director) and Lucija Ivšić (performing artist) – reveal how we might come to *know* the medium *through* practice in an iterative way by investing in creating, making and exhibiting throughout the research process.

Keywords

Extended Reality (XR), Virtual Reality (VR), Cultural Practice, Practice-Based Research

Introduction

Extended Reality technologies, such as Virtual Reality (VR), appeal to creative practitioners (filmmakers, visual and performing artists alike) who are drawn by the promise of augmented and virtual reality technologies for producing ever-more immersive, compelling and affective experiences. This paper asks: How might we come to *know* the particular qualities and affordances – as well as the constraints – of the medium of Virtual Reality? We submit that by approaching VR as a form of cultural *and* research practice, more nuanced understandings of the aesthetic, narrative, experiential qualities of the medium and its affordances (conceptual as much as technical) can be gained. Featuring a cross-section of representative projects developed at SensiLab¹, we will ask questions, offer explanations and share reflective insights gained through practice-based research investigations that thoroughly embrace a culture of experimentation.

Through curating a series of project “snapshots” that highlight the innovative creative research being undertaken within SensiLab, our exposition will showcase some of the investigative ways that practitioner-researchers (media artists, creative technologists, content producers) are extending understandings of both studio practice and the medium itself by engaging deeply and reflexively with immersive imaging technologies. Selected projects by Sojung Bahng (visual artist and filmmaker), Oscar Raby (VR director) and Lucija Ivšić (performing artist) embrace some of the broader challenges of XR by seeking to define the language of new media forms and exploring process and procedures (technical,

¹ SensiLab is a trans-disciplinary research initiative hosted at Monash University in Melbourne Australia. Conceived as a creative space where new connections can be made between Art, Design, Computer Science and Technology, our ethos acknowledges that new thinking emerges from diversity, genuine collaboration, and an openness to the unexpected. Comprised of story tellers, artists, makers, hackers, designers, developers, musicians, coders, scientists, theorists, luthiers and builders, our collective research explores the innovative creative applications and undiscovered opportunities of technology. Research undertaken by members of

SensiLab is typically interdisciplinary, linking IT and creative technologies with fields such as health, urban planning, design, media arts, as well as cultural heritage. Working across disciplines, methods and materials, we approach each inquiry with curiosity and rigour in order to learn through creating. We acknowledge process as well as outcome, and value the experiential and the sensory as modes of knowledge. VR as Cultural Practice is one of the lab’s designated research themes along with AI as Cultural Practice, Speculative Design and the Multisensory Museum.

creative and critical) that stretch the narrative and experiential parameters of their respective practices. Bahng, Raby and Ivšić will share grounded insights into selective aspects of their creative research and how their studio investigations are testing the boundaries of the VR medium itself, in relation to spatial imaging, storytelling and exhibition-making. Illustratively, these dynamic and discovery-led *PhD* research projects will reveal how new discoveries are made iteratively through making, building and creating throughout the research process, not only at the culmination of their inquiry. Together, these inspiring case studies challenge preconceptions about VR specifically, and where the medium fits into the repertoire of expressive, investigative and experiential options available to visual artists, designers and researchers alike.

Frames of Reference: VR as a form of cultural and research practice

Defining VR as cultural practice

The potential of immersive digital technology to tell stories in powerful, new and affective ways has been embraced by contemporary filmmakers and visual artists. At the risk of over-simplifying the range of motivations that drive creative practitioners, it is not an especially remarkable observation to say that ‘as with the application of all new technologies, artists are driven to probe, experiment with and sometimes break the machine, challenging the possibilities of the medium’ [1]. Even while the promise of Virtual Reality (VR) has been around since Jaron Lanier’s pioneering efforts in the 1980s, cultural producers from across the contemporary visual and performing arts spectrum, ranging from Ólafur Eliasson to Tsai Ming-liang and Björk, continue to be drawn to the much-heralded ground-breaking potentialities that exist between immersive storytelling, filmmaking and Visual FX cinematography for VR as an art form. For instance, Marina Abramović’s *Rising* (2018), produced in collaboration with Acute Art and realised using the HTC Vive platform, exaggerates the heightened sense of self-consciousness that the medium can precipitate; while *Clouds over Sidra* (2017) – produced in collaboration with Samsung and the United Nations by Gabo Arora with filmmaker Chris Milk’s VR-dedicated production studio Vrse – provides a compelling

example for how a strong empathetic connection between the viewer and subject can be achieved with VR cinema.

However, developing other ways of “seeing” that extend beyond the depiction of virtual forms demands an appreciation of the actual nature of the immersive experience of Virtual Reality. As in the case of Alejandro Iñárritu’s celebrated *Carne y Arena* (2017), the visual and narrative potential of Virtual Reality is taken beyond the pre-defined boundaries of the moving image by extending the application of digital technologies associated with computer-generated imaging from the virtual screen into the real space of gallery installation. In order to connect the subjective act of viewing with the social – and, by extension, political – space it’s located within, we would do well to consider how we might come to know VR as a properly experiential medium, rather than an exclusively visual one [2].

Defining research practice

As a creative technologies laboratory spanning the faculties of Information Technology and Art Design and Architecture, each with their own established disciplinary foundations, SensiLab finds itself in a unique position to demonstrate, as well as critically reflect upon the nature of research and its contribution towards realising what our *data future*² might look like. At its core, SensiLab is driven by the creative engagement of people with technology. Despite the diversity of research areas and applications that SensiLab embraces – from virtual heritage reconstructions using VR technologies to specialist medical wearable devices, new performative musical instruments and creative artificial intelligence systems, all projects have their foundation in practice-based research.

Practice-based research (or Research-creation³ as it can also be known) is a mode of enquiry that seeks to generate new knowledge through practice. Often, this mode draws upon investigative processes that involve gaining knowledge through physical exploration and direct action; or achieving *know-how* by engaging creatively in making, doing, building, experimenting and experiencing. It has been argued that ‘the innovative and critical potential of practice-based research lies in its capacity to generate personally situated knowledge and new ways of modelling and externalising such knowledge while at the same time, revealing philosophical, social and cultural contexts for the critical intervention and application of knowledge outcomes’ [3]. While practice-based and practice-led research⁴

² The Monash Data Futures Institute (MDFI) was established in 2019 as a university-wide initiative bringing together leading cross-disciplinary expertise to address future transformations driven by Artificial Intelligence (AI) and other forms of digitalization in relation to questions of human empowerment, sustainable development and positive change.

³ According to the Social Sciences and Humanities Research Council of Canada (SSHRC), Research-creation can be defined as an approach to research that combines creative and academic research practices, and supports the development of knowledge and innovation through artistic expression, scholarly investigation,

and experimentation; where the creative process is situated within the research activity and produces critically informed work in a variety of media (art forms) whose contribution to knowledge cannot be reduced to its interpretation or analysis.

⁴ Linda Candy distinguishes between the different types of contribution that practice-based and practice-led research make. In the case of practice-based research, the contribution to knowledge recognizes the artefacts themselves as creative outcomes, manifestations or embodiments of the research; whereas, in practice-led research, the contributions concern new knowledge about practice itself and its implications to the cultural field. See: Linda

have existed for many years in the creative arts – in areas such as design, fine art, architecture, music and performance – the research cultivated in SensiLab aims to expand the domain and enlarge the scope of how research through practice might be applied in the creative technology field.

Broadly speaking, knowledge can be classified into forms of propositional knowledge (facts), procedural knowledge (skills), and acquaintance knowledge (objects). Tacit knowledge, on the other hand, is, by definition, an implicit form of knowing that cannot readily be communicated linguistically, where learning how to do something can only be gained through the act of doing it. In effect, “knowing-how” as opposed to “knowing-that”. This kind of knowledge is dynamic, embodied and inseparable from the experience of doing; it recognises that all knowledge is situated in activity, as ‘practices of knowing in being’ that are integrally bound up with their social, cultural and material contexts [4].

For the most part, what practitioner-researchers do involves building physical or virtual artefacts and prototypes that in some way embody the ideas they are thinking about through making, or that test the physical, functional or material aspects of the subject of their research inquiry. Even in the age of digital tools and methods of fabrication, situated cognition, performativity and materiality play important roles in this investigative process, something that is often underestimated in technology-driven research. These processes draw on the individual nuances and subjective nature of experience, often multi-sensory, including kinaesthetics, proprioception, touch, sound, light, even smell and taste [5]. Ultimately, it is the connection between human experience and artefacts – including artworks and design prototypes – that embodies critical knowledge.

Because of the difficulty that codifying such knowledge implies, it is important to acknowledge the challenges that tacitly acquired understanding presents for articulating and sharing this “know-how” beyond the researcher themselves. The work of Donald A. Schön has been highly influential in developing just how vital the act of reflection is to creative forms of knowledge [6]. Applicable to design problem-solving as much as knowledge production, Schön identified reflective practice as a continuum that operates across three levels: ‘knowing in action’ (which is driven implicitly by the expertise of the practitioner); ‘reflection in action’ (which involves conscious acts of improvisational problem-solving that occur during the process of production); and ‘reflection on action’, whereby the practitioner considers their actions in an effort to articulate their decision-making process and form understanding of their practice. It follows, that it is incumbent upon the practitioner-researcher to recognize the relationship between materiality and discourse involved in their creative research – or what might be described as a ‘material-discursive practice’, whether through reflective

analysis or as a means of maintaining a reflexive engagement with the very basis of practice itself. [7] While apparently at odds with the more objective and rationalistic emphasis associated with scientific research, research through practice is not in conflict with this, but rather gives due voice to subjective experience and demonstrates the (critically) important values that experience – in all of its specificity (of culture, gender, positionality, affect and so on) – brings to an enhanced (and increasingly nuanced) understanding of the world.

Three Practice-Based Investigations

The curated exposition that follows will reveal some ways that we might come to *know* the medium *through* practice (in both formative and summative terms). We hope that by demonstrating how a spirit of adventurous inquiry infuses a practice-based research methodology that emphasises the values of cultural and knowledge production in equal measure, these short, focused accounts by Sojung Bahng, Oscar Raby and Lucija Ivšič will illustrate some guiding concepts applicable to creating affective artworks and mediated experiences that will both inform and inspire others to embrace the challenges of VR in critically reflexive ways.

Sojung Bahng

Sojung Bahng’s PhD research (*Cinematic VR as a reflexive tool beyond empathy*) investigated VR as a cinematic and rhetorical device to elicit self-reflection and awareness in sociocultural contexts. Seeking to go beyond the notion of an *empathy machine*⁵, a concept that is too-readily used as a means of understanding of quality of viewing experience associated with the medium itself, Bahng’s investigations focused on ways that presence and embodiment can elicit a sense of identification and critical reflection in the viewer. The set of VR projects produced as part of her practice-based research – *Floating Walk – Gangnam Kangaroo* (2017), *Anonymous* (2019) and *Sleeping Eyes* (2020) – emphasised the limitations of immersive engagement. Instead, she designed storytelling methods aimed at promoting a sense of physical estrangement and cognitive disorientation. Through introducing more reflexive elements into the cinematic narrative of these works, Bahng provided the viewer with scenarios to explore unfamiliar sensory experiences that encourage them to reflect on their own sensations rather than simply immersing themselves in the virtual environment.

For Bahng, VR was approached as the main artistic medium for her research practice. Her studio-based investigations exploited three constraints associated with VR media, namely 360-degree video, mobile interactive VR and

Candy, *Practice based research: A guide* (Sydney: Creativity & Cognition Studios, University of Technology, Sydney, 2006).

⁵ The term *empathy machine* was first used by Chris Milk at the TED conference in 2015 to describe the propensity for VR to democratise human experience and strengthen the empathetic

connection between the viewer and subject(s) represented in the media. See: Chris Milk, “How virtual reality can create the ultimate empathy machine”, Ted website, accessed October 22, 2019, https://www.ted.com/talks/chris_milk_how_virtual_reality_can_create_the_ultimate_empathy_machine?

navigable interactive VR. Her creative research was influenced conceptually by the *estrangement effect*⁶. Inspired by German playwright Bertolt Brecht's use of various staging and acting techniques to break simple immersion and prevent audience members from identifying with the characters and situations in his stories, she translated this approach (which is also referred to as the alienation- or distancing-effect) to cinematic VR storytelling in order to promote embodied reflexivity in more phenomenological and ontological ways. Distinctively, Bahng also drew upon Buddhist philosophy, particularly in relation to *meta-awareness*⁷, which is a mode of self-reflexive awareness that lets people observe their multiple sensory experiences while experiencing them. Across the studio processes involved in conceiving, designing, prototyping and producing these creative works, Bahng was able to identify and test the function of reflexive elements based on certain technical constraints associated with various forms of spatial interaction, and through embracing experimentation, managed to introduce new storytelling and aesthetic methods into her work.

Bahng's creative processes meshed productively with the theoretical and methodological questions guiding her research. She asked: What are methods and techniques related to Cinematic VR that enable the medium to be approached as a reflexive tool that exceeds certain idealised framings of empathy? How can reflexive VR storytelling effectively elicit self-reflection in response to sociocultural situations and contexts? And ultimately, how might Cinematic VR artworks provide viewing experiences that encourage the viewer to critically reflect on issues of alienation, disconnection and isolation? These lines of enquiry enabled her to examine how the technical infrastructure and material properties of VR shape the viewing experiences associated with each of her artworks. For example, *Floating Walk – Gangnam Kangaroo* harnesses the potential of a 360-degree video as a means of autobiographical self-expression and an autoethnographic tool that promotes the reflexive thoughts about migrant identity. *Anonymous* contributes design factors and technical implementations for using VR to elicit self-reflection on loneliness and death. While *Sleeping Eyes* demonstrates how phenomenological and participatory engagement in VR storytelling can elicit critical awareness of

narcolepsy and counter social ignorance. (Figure 1) Collectively, this body of creative research provides in-depth knowledge about reflexive modes of immersive storytelling while considering the various technical, design and narrative elements available to Cinematic VR in a creative-critical way.

Oscar Raby

Oscar Raby is an accomplished VR director and documentary producer working in the field of real-time narrative VR. Through his production studio, VRTOV⁸, he has developed corresponding creative workflows and technical pipelines tailored to VR media production. Inspired by Dziga Vertov, the Russian filmmaker who explored the potentialities of new moving-image technology at the beginning of the 20th Century, Raby's critical approach towards understanding VR through knowing its *technê*⁹ exemplifies that of a 'reflective practitioner'. This stance recognises that the type of innovative applications that Vertov and his collaborators derived from the movie camera were not centred on the way they embraced this industrialised piece of technology, but rather in how they embodied its unique language, as expressed in its famous dictum: 'I am a mechanical eye. I, a machine, show you the world as only I can see it. (...) I decipher in a new way a world unknown to you'. [8]

⁶ The *estrangement-effect* was Brecht's principal means of overturning a sense of unwitting complacency in the viewer (and by extension society at large). As an aesthetic technique, Brecht would 'stage theatre in such a way that the viewer is denied the habitual comfort of forgetting that they are watching a play and becoming (what psychoanalytic film critics call) sutured into the events on stage. Thus, he would discourage actors from "becoming" their characters and using that to elicit the empathy of the audience, preferring that they create a sense of "distance" between themselves and their character that would put the audience in two minds about what they were watching' (Buchanan 2018).

Ian Buchanan, *A Dictionary of Critical Theory* (2nd edition) (Oxford: Oxford University Press, 2018). Also, see: Bertolt Brecht, *Brecht on Theatre* (New York: Hill and Wang, 1964).

⁷ Meta-awareness involves the ability to take explicit note of the current contents of consciousness. See: Bhikkhu Bodhi, "What does mindfulness really mean? A canonical perspective", *Contemporary Buddhism* 12(1), (2011):19–39.

⁸ <http://www.vrtov.com/>

⁹ The term comes from the ancient Greek τέχνη (meaning art or craft) and used in general reference to a technique, principle, or method by which something is achieved or created. The Stanford Encyclopaedia of Philosophy makes note, however, that '*Epistēmê* is the Greek word most often translated as knowledge, while *technê* is translated as either craft or art. These translations, however, may inappropriately harbor some of our contemporary assumptions about the relation between theory (the domain of "knowledge") and practice (the concern of "craft" or "art")'. (See: <https://plato.stanford.edu/entries/episteme-technē/>)

In his case, Raby's current PhD research provides him with a platform to revise the assumptions that the medium carries along with it, on its technology layer (hardware, software) as well as the language embedded into it. His practice-led critique takes aim at the identifiable features that are already present (or *preset*) in the software environments used to create VR works, such as Unity's *Timeline* or Unreal's *Actors*, with the ambitious goal of defining a materiality that is not the simulation of something else, but the *actual* material of Virtual Reality.

For Raby, Virtual Reality has been instrumental in the observation of the thought processes involved in thinking about narrative circumstances, character motivations, and stories that ultimately become the experienced work. The self-referential nature of VR, namely, in that it presents a situation to be *acted upon*, is a place in which the moment of engagement with the spectator/user can facilitate the witnessing of their own thought process as they find themselves navigating the situation. This particular feature of the medium has two crucial aspects to it. Firstly, singular interpretation is actively resisted since real-time narrative is naturally expansive in the creation of meaning because this process is performed by a necessarily active *reader*. Secondly, the thought process exercised and witnessed *within* the artwork can be exercised again *outside* the artwork. It is in this realm that the work is capable of activating a powerful, political reverberance.

Figure 2. Oscar Raby, *Assent* (2013). Production screen capturing Skanect software showing a 3D scan of Raby as a character in *Assent*. © The Artist.

The current wave of VR has been regarded largely as a medium of isolation and individualism. Somewhat paradoxically, these same features place it in counterpoint to the barrage of social media engagement and connectivity that has prevailed in the same era. Discounting that the convergence of these two positions has already been well and truly initiated (one only has to note the prominence of Facebook in the technical and commercial drive of the technology), Raby's research inquiry presents an opportunistic and timely response that both takes stock of how the medium of VR has evolved under these cultural conditions and captures

the epochal tension between the individual and the collective with a tool and language that stems directly from it.

At the current juncture of his research, Raby is progressively working towards codifying a practical method of development that prioritises the narrative construction of time over the prevalent metaphor of spatial simulation. As a way of bridging the concerns that have sustained his creative practice, Raby is revisiting the first work he produced in VR, *Assent* (2013), as the basis of self-reflective critique. (Figure 2) By deconstructing the technical and conceptual settings involved in its original production, Raby is seeking to expose how the experience of time is created in the medium. While the actual form that the thesis will assume remains open-ended, this inquiry-driven project illustrates how theory and practice might correspond with each other *productively* across inter-related processes of analysis, critique, prototyping and creative production; ultimately, giving rise to new knowledge about the time-based nature and programmed methodologies of VR.

Lucija Ivšić

Even though VR technology is not her main form of creative practice, it has nonetheless found itself playing an influential role in Lucija Ivšić's initial studio investigations as part of her recently commenced PhD studies. At this formative juncture, VR has served primarily as a didactic tool that has enabled her to create surreal environments to inspire further exploration. By purposing VR in this way, and through immersing herself in this investigative process, valuable insights into the kinds of relationships we establish with physical spaces have been gained. Ivšić's research inquiry draws upon a posthumanist approach to identity. [4] The self is exposed, in all of its multiplicity and performative aspects, as a certain identity, character or role we play in accordance with the specific social context in which we perform. This act of identity formation might also be studied as an assemblage that does not begin or end with the individual but rather extends to surrounding places and objects. In this respect, the places we dwell in, like our home or workplace, simultaneously form and reshape our identity as well as their own behaviour through the relationship we maintain with them. This relationship is reciprocal and can generate unique behaviour patterns that shift or alter our perspective of how we experience and see places. That being said, throughout the preliminary experimental phase of her practice-based *PhD*, VR technology has enabled Ivšić to transform intangible and otherwise transitory qualities of spatialised data, acquired from 3D scanning and processing of point clouds, into a comprehensible whole. The dichotomy inherent to the VR medium, that being the blending of both cinematic (real) and artificial (game) spaces, is exactly what has allowed Ivšić to audio-visually (re)construct virtual environments that contain commonly imperceptible and ephemeral constituents that make up our real-worlds.

Figure 3. Lucija Ivšić, *What homes are made of: The Architecture of Displacement* (2021). Production still. © The Artist.

In *What homes are made of: The Architecture of Displacement* (2021), Ivšić has embarked on an artistic exploration of the intangible components that every place consists of. (Figure 3) By underscoring memory through visualising elements such as the fall of light on surfaces and the sound of materials, she is questioning the relationship we enact with the spaces we have known and come to know. Her work asks how this knowledge affects our identity versus the identity of the place itself; and questions the role that memory plays in our perception of these places. What sensory components of daily situations are stored forever, constructing the notion of *home* in our memory, and how does that translate to space itself, enacting and adding up to an existing identity of ourselves and of others. By deliberately recording binaural sounds present on an ordinary Sunday afternoon in the apartment she grew up in in Vinkovci, Croatia, and strategically placing them within her current apartment in Melbourne, Australia, Ivšić materializes the importance of *time* (Sundays) and *place* (home) in the process of memory stimulation. The visual model of her Melbourne apartment was generated from point clouds generated with LIDAR. Through this technology and its immediately recognizable aesthetics, a VR scene is constructed from meticulously measured spatial points, varying in density, simultaneously creating exact, almost photographic resemblance of reality, yet adding an obvious dreamlike ambience. This work was designed to take advantage of VR specifically by seamlessly blending two realities that exist simultaneously on opposite hemispheres (Europe/Australia; then/now; real/virtual) to create a window into the first-hand experience of displacement. While the viewer is granted access and invited to inhabit this otherwise mundane yet personal place, one is immediately unsettled by the true origin of the sounds they hear, and how they synthesise with the visuals they are able to surreptitiously inspect. Inspired by the expressive spatial poetics of Gaston Bachelard – who wrote that ‘Memories are motionless, and the more securely they are fixed in space, the sounder they are’, Ivšić has called upon VR to give expression to this sense of displacement by registering our feelings to the spaces we live in as a way to “see” how memories are etched and intertwined so deeply in our everyday lives. [9]

Upon Reflection

In this paper, we have considered practice-based research as a mode of enquiry that generates new knowledge through practice, i.e. by actively making, doing, building and experimenting. Creative practitioners intuitively understand that the generation of new knowledge is embodied in their practice and emerges in the studio as part of a material-discursive practice; often involving the use of knowing-how types of knowledge, gained through physical exploration, direct action, performance and experience. Here practice is concerned not only with achieving resolution, in the form of definitive creative outcomes, but with gaining greater understanding of the reflexive processes by which the practitioner-researcher achieved them.

The three cases represented here highlight some of the unique qualities of knowledge production that research through practice enables: by placing an emphasis on making and learning through experimentation, instilling a spirit of inquiry that values process as much as outcome and embracing implicit forms of knowing. As these examples attest, research through practice can benefit how we might come to *know* new technologies – i.e. the communicable and expressive qualities of the artform and its aesthetic language (as in the resolved or speculatively developmental work of Sojung Bahng or Lucija Ivšić, respectively), or as a means of challenging the predispositions and idiomatic structures that (quite literally) underwrite the basis of the medium itself (in the form of software processes and code; as per Oscar Raby’s critique). Equally committed to the values of creativity and research, these dynamic, discovery-led *PhD* projects make important contributions towards building the know-how of communities of practice in emergent fields of cultural and knowledge production.

Sojung Bahng is an artist and filmmaker working as a postdoctoral researcher and instructor at Carleton University (Ottawa, Canada). She completed her *PhD* thesis (*Cinematic VR as a reflexive tool beyond empathy*) with SensiLab at Monash University (Melbourne, Australia) in 2020 and is presently a Postdoctoral Research Fellow in the School of Journalism and Communication at Carleton University (Ottawa, Canada). Sojung's VR works have been exhibited or screened at many international festivals and symposiums, including FIVARS (Canada), SIMA (USA), BIAF (South Korea), TSFM (Italy), TIAF (Georgia), TEI (Australia) and ISEA (UAE).

Vince Dziekan is a Senior Academic and Practitioner-Researcher at Monash Art Design & Architecture (MADA), Monash University, Australia. Vince's work engages with the transformation of contemporary curatorial practices at the intersection of emerging design practices, creative technology and museum culture. The scope of this interdisciplinary investigation has been outlined previously in his book, *Virtuality and the Art of Exhibition: Curatorial Design for the Multimedial Museum* (Intellect/University of Chicago Press, 2012), and more recently *The Routledge Handbook of Museums, Media and Communication* (co-edited with Kirsten Drotner, Ross Parry and Kim Schroder, Routledge, 2018). He has published widely in traditional, scholarly as well as non-traditional modes through his independent curatorial practice. He is associate editor of *Curator: The Museum Journal* (Wiley), general editor of *The Encyclopaedia of New Media Art* (Bloomsbury), founding curator of *MWX*, the exhibition initiative of the Museums and the Web conference (Museweb), and Series Co-Editor of a newly launched book series, *Critical Perspectives on Museums and Digital Technology* (Routledge).

Lucija Ivšić is a Croatian-born emerging new media artist, composer and experienced performer, currently residing in Melbourne, Australia. At just 14 years old, Lucija formed Punčke, one of the first all-girl bands in Croatia. Over the course of a decade, Punčke releasing five critically acclaimed albums, being nominated for an MTV EMA Award in 2014, and playing over 400 shows worldwide. Relocating to Melbourne in 2019, Ivšić commenced her practice-based *PhD* research at SensiLab, Monash University. Resonating posthuman visions, Ivšić's work explores identity formation and the relationships we establish with physical spaces through VR and mixed-media installations. Lucija holds a Master's Degree in Geodesy and Geoinformatics from the University of Zagreb, where she specialized in remote sensing technology (laser scanning).

Jon McCormack is a research Professor in the Faculty of Information Technology, an Australian Research Council Future Fellow and director of SensiLab, a bespoke, trans-disciplinary research

centre, based at Monash University in Melbourne, Australia. A practicing artist, he is the recipient of more than 19 awards for both artistic creativity and technical research, including the Eureka Prize for Innovation in Computer Science, the Lumen Prize for Digital Art (still images). In 2016 he established the practice-based *PhD* within the Faculty of Information Technology. A first for *IT* doctoral research in Australia, this innovative form of *PhD* encourages creative and dynamic projects that make discoveries through making, building and creating.

Oscar Raby is a visual artist and creative director at VRTOV, a Melbourne-based Virtual Reality studio behind the projects *The Turning Forest* and *Easter Rising: Voice of a Rebel*. His autobiographical Virtual Reality documentary *Assent*, has been part of Sundance New Frontier, IDFA DocLab and Sheffield Doc/Fest (where it received the Audience Award for Cross-platform) as well as festivals in Australia, Canada, USA, Mexico, the Netherlands and the UK. Oscar completed his *Masters in Animation and Interactive Media* at RMIT (Melbourne, Australia) in 2013 and commenced his *PhD* research with SensiLab in 2010 focusing on the software metaphors underpinning the development of narrative XR work.

Qatipana: Towards the possibility of Cosmotronics and Technodiversity

Abstract

This essay revolves around the concepts and processes of Becoming and Individuation where a functional model based on the articulation of an information processing system based on the approaches of the philosopher Gilbert Simondon is evidenced; This research aims to observe a sensorimotor cycle performed by the cognitive system of an Artificial Intelligence agent. To establish this model of biological inspiration, we used the concepts of information and modulation in Gilbert Simondon and information in cybernetics of Norbert Wiener and Stafford Beer. These resources force us to ask ourselves the following question: How does mono-technology and computerization of cultural techniques influence the nature of knowing the affection of being with others (people, things, animals)? To answer this question, an interdisciplinary study (arts, sciences, information technologies) is offered on the effect of this symbiosis and how it can be seen in the full use of knowledge about the fundamentals of living and non-living matter. The architecture is called Qatipana (a Quechua word that denotes the flow of information processing systems), although it cannot be considered as a systems theory, it has the utility of being able to explain some empirical observations that are presented here. In conclusion, the implications and limitations of this model and the research that is being carried out to present its utility and probability as a technodiversified model of the algorithmic cognitive system are part of the issues of communication and affect in the decisions that this cybernetic system provides.

Keywords

Decolonizing, individuation, art, cosmotronics, ecosystem.

Introduction

The objective of this artistic research is to develop a hybrid architecture that we have called Qatipana (a Quechua word that denotes flow of information processing systems), although it cannot be considered as a systems theory, it has the utility of being able to explain some empirical observations that here I present. The implications and limitations of this model and the research that is being carried out to present its utility and probability as a model of an algorithmic cognitive system are part of the questions of communication and affect in the decisions provided by this cybernetic system.

To achieve this objective, the research revolves around the concepts and processes of becoming and individuation where it shows a functional model based on the articulation of an information processing system based on the approaches of the philosopher Gilbert Simondon (*L'individuation à la lumière des notions de forme et d'information*, 1958); This process aims to model the sensorimotor cycle performed by a cognitive system of an Artificial Intelligence (AI) agent. To establish this model of biological inspiration, we use the concepts of information in cybernetics by Norbert Wiener (1948), information and

modulation in Gilbert Simondon, and the approaches on cosmotronics and technology diversity of the Chinese philosopher Yuk Hui.

In the hypothesis of this research we affirm that to the extent that we provide a focus and view on the technologization of the world as a process of individuation, taking Simondon's concept in this becoming; We foresee that an artificial agent and its environment can be out of phase to resolve their tensions and give rise to physical or living individuals that constitute a system and go through a series of metastable equilibria, from this approach it is possible to demonstrate their capacity for invention as a clear example of a way of transindividual individuation (referring to the human being), which thanks to the information that the artificial agent acquires and recovers through this "subjectivation", which integrates perception and affectivity; allows the creation of new norms or artifacts settling in their evolution, as is its use in the case of bioeconomy and cognitive capitalism (Fumagalli, 2010), thus suggesting the hypothesis that AI could also be an extraterrestrial intelligence (Parisi, 2019) and not just an application of a vertical power. As described here, this process is highly visible in tracing the history and operability of the ecosystem concept: from theory of mind to resilience politics. By locating the ecosystem discourse within longer philosophical conversations surrounding the relationship between organic unity and algorithmic normative potentiality, it allows building an ecosystem proximity to algorithmic organicism theories, better understood by its full political implications: "the perception of the whole earth as an ecosystem (as in the Gaia hypothesis)" (Pasquinelli 2017, 320). Like the "recursive irony" that defines the technological hybridization of the ecosystem, to use the phrase of Pasquinelli (2017), these operations reveal the critique of political economy, which is more than a coincidence of the result of the industrial division of energy and information as an abstraction of work; driven by fast-paced capitalism, as global warming is made visible by the same epistemological tools that drive the problem. Such is the recursive trap of planetary computing.

The provocation poured into this research regarding large-scale forms of environmental governance is important and, as highlighted above, in line with a longer set of historical transactions that can be traced back to questions that place the organic individual in relation to the all social and technological. Indeed, as the history of the ecosystem shows, this form of governance is already identified in policies as resilience.

On the other hand, this project addresses ways of constructing epistemologies generated from the field of new media art. On the one hand, we observe an increasingly intense interdisciplinary collaboration with

science and technology, on the other hand, art, design and technology are converging under the force of the cultural industry. In science, simulation has overturned established epistemology, as scientific experiments, the fundamental research method proposed by mid-20th century science, now require collaboration with computer simulations. In 2013, the Nobel Prize in Chemistry went to Martin Karplus, Michael Levitt and Arieh Warshel, who since the 1970s have been developing simulations of molecular dynamics. From the field of the humanities, we have observed the emergence of a new heavily funded discipline, the digital humanities, which coincides, after the concept of the inhuman proposed by Lyotard in 1986, with discourses on posthuman philosophy, cyborgs, object-oriented ontology, etc. In light of the transformation brought about by telecommunications technologies, we can revisit Lyotard's hypothesis on the destabilization of the concept of the modern. Where is this concept of the human going after the post, or beyond? Should we not demand a new form of orientation after the dominance and disorientation of the notion of humanity as a cultural construct, perhaps an orientation that does not impose even the will to dominate the policies that are constituted outside of the human?.

Qatipana as a proposal to Technodiversity

In a relatively short period of time, there has been an explosion of new technologies that have infiltrated all areas of life and irrevocably altered our ways of living. The consequences of this technological permeation are ontological and epistemological, and they do it without problems, since we see that our world changes everyday.

We could argue that digital practices, such as experimental works of art and representations, serve as criticism's mechanisms and have an indirect effect on the social and political. Although a redefinition of this term is certainly needed, since they question the very nature of our accepted ideas and belief systems regarding new technologies. In this sense, digital does what all avant-garde art does; it is an experimental extension of the socio-political and cultural aspects of an era. In this way, technology would then imply a reconfiguration of our embodied experience. When the mind and body cannot reach the meaning it addresses, it builds its own instruments and projects a mediated world around it. Rather, being separated from the body, technology becomes part of that body and alters and recreates our experience in the world.

Faced with such phenomena, the concern is being born to develop a research project that focuses on observing, analyzing and collecting information on the learning and individuation processes (Simondon, 2009) of the algorithms for organizing new modes of subjectivation in human and non-human nature. This type of observation presents new directions for research in the relational-transactional intersection of contrasting disciplines of the arts, humanities, science and technology, and in doing so, presents philosophical questions for future research on human connectivity in our digital age. This main questions are now focus nowadays in media studies:

How does the computerization of cultural techniques produce new forms of subjectivation? How does the concept of mono-techniques already imply the notion of "chains of operations" and, therefore, a permanent (retro) coupling between living and non-living agencies?. The last question is also closely related to the

society and working life.

On the other hand, the possibility of approaching to reflect on what has been raised so far arises from the concern to work from "the epistemes of the becoming". For this, I am dedicated to the development of a work called Qatipana and is posed as follows: A machine that can observe and learn from a natural system and uses the data that arise from its behavioral patterns as a source of "transduction" for the agency of a material and immaterial ecology. From this observation, the project focuses on the use of artificial intelligence that has the ability to identify repeated coordinated actions within a natural system. Artificial Intelligence (AI) stores and transforms these actions into events to which it assigns different behavior gestures to the living organism and to itself, creating an autogenerative habitat according to the logic of decision-making that it produces through weather. To achieve this, an analog signal collector and a transmission device, capable of performing its own biological maintenance and an audiovisual platform that allows the amplification of these biological signals, will be developed. The resulting process will be transmitted live through a server channel, where the coevolution process can be monitored in real time, revealing that AI are capable of taking various forms depending on the situation. Under this logic and thinking from non-human intelligences, it can be argued that generative art is inheritor to the field of research, that in 1968 Jack Burnham called "Systems Aesthetics"; he said: "We are now in transition from an object - oriented to a systems-oriented culture. Here change emanates, not from things, but from the way things are done " (Burnham, 1968: 2).

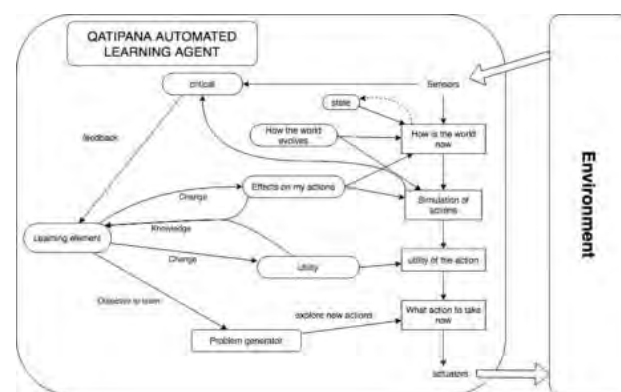

Figure 1. Example of architecture (information flow) in Qatipana, 2019 @Renzo Filinich.

In conclusion, the implications and limitations of said model and the research that is being carried out to present its utility and probability as a model of an algorithmic cognitive system are part of the communication and affect issues in the decisions provided by this automatic system. Cosmology is not pure theoretical knowledge; in fact, ancient cosmologies are necessarily Cosmotekhnical. Taking the notion of Hui (2017) we can give a preliminary definition of Cosmotekhnics here: it means the unification of the cosmic order and the moral order through technical activities. Modern technology has broken the traditional relationship between cosmos and technique; it becomes a gigantic force, which transforms every being into a mere "permanent reserve" or "reserve" (Bestand), as Martin Heidegger observes in his famous 1949 lecture "The Question for Technique" (Heidegger 2016). In this way, they somehow adopt a series of behaviors that allow them to act like other entities, without necessarily

replacing what they imitate. From an analytical and epistemological result, the work process acquires an interdisciplinary approach, proposing a strong cross between applied sciences and the humanities, thus generating a research space for communication and non-anthropocentric concern based on an autogenerative system of non-human intelligence.

Finally, it is emphasized how the relationship between art-machine-natural systems coupled with the concept of Cosmotronics by Yuk Hui¹ provides us with an excellent theoretical device to investigate the role of technology in relation to improve our understanding of a pluralistic techno-diversity under a Latin American cosmopolitics.

Discussion or results

Uexküll proposes “a walk through unknown worlds” (Uexküll 2016), worlds strange to us but known to other creatures, “as diverse as the animals themselves” (Uexküll 2016). To do this, he suggests, we must create an imaginary soap bubble around each creature. Each of these bubbles contains only the perceptions that the creature has access to and then forms its own true world. Each of these bubbles represents the world as it appears to the organisms themselves. As each organism perceives differently, there are as many of these worlds as there are organisms in nature. Uexküll does not consider organisms as mere objects but as subjects whose essential activity consists of perceiving and acting. Everything that an organism perceives is part of its perceptual world [Merkwelt], while everything that an organism does is part of its operating world [Wirkwelt]. The perceptual and operational world together form a closed unit called Umwelt (Uexküll 2016). In this way, even if the same objects are present in a certain environment, they will not be perceived in the same way by different organisms and will not have the same meaning for them.

The second important Uexküll concept to consider in this context, that is, when it comes to the relationship between an organism and its environment, is that of conformity with a regularity [Planmäßigkeit]. Uexküll calls conformity to a plan the force of nature “that combines multiple details into a whole by means of rules. The higher rules, which unite things separated even by time, are generally called plans” (Uexküll 1926). Elsewhere, Uexküll defines conformity to a plan as “a rule that extends through time and space”, “a rule in living nature, which is revealed even in the mechanical processes of the organism” (Uexküll 1926), and as a super mechanical law ”(Uexküll 1926). Conformity with a regularity is responsible for the creation of all organisms and their Umwelten, it is like the score that presents the “melody”, that accounts for all nature. Ultimately, conformity with a regularity ensures perfect complementarity between the different organisms and their Umwelten.

Through this notion, Uexküll expresses himself against the concept of adaptation. From the point of view of adaptation theory, in fact, “each organism is the product of influences to which it has been exposed for thousands of years” (Uexküll 2010). Through countless cycles of trial and error, organisms reach their proper form, a final product adapted

and congruent to the conditions of the environment in which they are found. Through this look by von Uexküll, multiple possible crossings between the technical medium and those organic materialities that dispense with technological supports are possible to find in a particular geography. If the first moderns provide us with a mechanistic vision of the world through geometrization (Kepler, Galileo, Newton, Descartes among others) and experimental science (Bacon and Boyles), now with cybernetics as the realization and concretization of organicist thought that began to culminate in the late eighteenth century, can we finally end modernity with cybernetics? Do we not already find in cybernetics, and its planetary version, the theory of Gaia, a generic logic that rests on the recognition of the relationship between the living being and its environment?. In this way, in Qatipana these questions are transposed within the Latin American context, raising questions such as: What is the decolonial turn within digital platforms in their algorithmic causal assemblage?, taking into account that the social assemblages that they articulate are, in first, assemblages of the sensible. Taking the notions of Uexküll, we recognize the need to rearticulate the notion of modernity, that is, “the exterior created from the interior” (W. Mignolo 2006), border thinking is an epistemological position that emerges from the colonial difference. Not as the result of rejecting modernity, but of clinging to a thought and feeling rooted in a body situated in the exteriority of modernity (W. Mignolo 2000), Mignolo calls this an “epistemic disobedience”.

Understood as an alternative to this ontogenic explanation, the concept of symbiotic body in Qatipana, in this way can be seen as the transduction of the organism and the machinic environment, this symbiosis, provides a better original (technical) complementary model for the precise reason of which invests in the creativity of the incarnation. Therefore, instead of assuming that technical and living evolution face each other extrinsically, Qatipana bets everything on the intrinsic correlation of the two: machinic environments can become triggers for creative evolution precisely because they are at stake in embodied life., and embodied life can induce modifications of the hybrid environment precisely as a means to intensify itself, to exert its margin of immortality. In fact, if the body and the environment are transductive correlates, they cannot be considered separate from each other, which means that the Qatipana concept of the symbiotic body, taken as a model for the epiphylogenesis of the human being, outlines a return to the original condition. of human technogenesis: the recursion that joins the crust and the Flint. And, based on this original condition, this research proposes to reconstruct a different culture, one that, unlike Stiegler's proposals for technically supported (tertiary) memory, never cuts its links with incarnation as the hinge that connects the body. and the environment, the zoo and the technical. No matter how complex the culture becomes, it will always harbor, at its very core, the symbiotic transduction of life before any further division. That is why an artistic revolution and its relationship with technological media is necessary.

According to Canguilhem, Uexküll reverses the problem of the organism-environment relationship, since he affirms that the characteristic of the living is to create a medium for itself while the study of a living being under experimental conditions is to impose a medium. In short, to ensure harmony and the perfect fit between organisms and their environments, Uexküll advocates the existence of a predetermined world, a world in which the tunnels of life

¹ According to Hui's technodiversity (2020), science and technology should be understood as means to return to life, thinking about the local in terms of knowledge systems, as paths towards true pluralism or “multiple cosmotronics”, to use the Hui's key concept in this context.

are fixed and predestined: "Starting from these immutable factors that determine all life in the world, we come to see that life itself is based on fixed laws, which conform to a plan" (Uexküll 1926).

The Qatipana project advocates a shift from thinking about "new media" as a set of discrete objects to understanding media, old and new, in terms of the interconnected and dynamic processes of mediation. It also describes what is at stake in this change of thinking about the media only as elements within our reach to recognize our entanglement with the media on both a sociocultural and biological level. This argument will lead us to pose the following question: if the media cannot be completely outsourced from the subjects or "users", then how could "we" engage with "them" differently? We must also consider the political and ethical implications of such commitments.

One way to outline these key debates about new media in media, communications, and cultural studies is to draw on the work of philosophers such as Martin Heidegger and Bernard Stiegler to explore the relationship between "media" and "technology" and to advance in a proposition that mediation is an intrinsic condition of being in, and becoming, with, the technological world. From this point of view, a possible hypothesis arises that reveals mediation as the underlying problem and sensibility production agency that operates through bioinformatization, through algorithmic-digital calculations, that is, a machinic individuation process. As the role of this essay is, first and foremost, to provide a theoretical framework (a toolbox with the concepts we work with throughout this essay), it also seeks to distinguish between the question of mediation and the question of media (information). This distinction is primarily heuristic, that is, tentative and pragmatic, and the purpose of separating mediation from the media will be to clarify the relationship between them. Henri Bergson's (*élan vital*) philosophical method of division and reintegration, re-appropriated by Simondon (transduction), is particularly useful for this analysis. This "method" proposes three things: (1) that we distinguish between "true" and "false" problems, (2) that we distinguish between differences in degree and differences in kind, and (3) that we consider the object of our inquiry insofar as to its temporality. This last law, or rule, is the most important to Bergson, and it will be the main means by which we seek to distinguish between means and mediation.

In this section, I would like to qualify, if not effectively correct, that statement by placing its ecological - or, as I would prefer to say, transductive - conception of the "technological body" in the context of recent theoretical debates² on life and its correlation with the concept of human. Doing so will demonstrate that the Qatipana understanding of the incarnation of "the living" is more sophisticated than we previously realized and, consequently, that it is deeply rooted in a comprehensive theory of life.

In his theoretical articulations and practical projects, which remain equally concrete, Simondon foregrounds the original coupling of embodied human life with what the

Macy scientists called the "informational environment."³ As an original supplement, in the transductive correlate of the human body, the information constitutes the basis of any activity that would inform the "epiphylogenetic" evolution of the human being (evolution by means other than life, following the concept of the philosopher Bernard Stiegler). Here I try to analyze the consequences of this radical gesture for our understanding of life, the human and the state of the techniques in / how the union between them. Because if technology, considered as a primary dimension of the living, constitutes the basis of the very existence of the human, we can see the human as a means of "perceptual faculty", under the dual aspect of a generic form and operative ontology (Koch 2019); then it can be expected that the inversion of technology as a means for the intensification of life will have important evolutionary consequences. As has been observed, the purpose of the provocative program in Qatipana will be the constitution of an architecture of "reversible destiny" and its most recent formulation of a "crisis ethic."

Under this purpose, we can take Simondon's thought, and this is his revolutionary contribution to philosophy, one should think of individuation not from the perspective of the individual, but from the perspective of the process that originated it. In other words, individuation must be thought of in terms of a process that not only takes the individual for granted, but is its result.

In Simondon's words:

If one supposes that individuation does not only produce the individual, one would not attempt to pass rapidly through the stage of individuation to arrive at the final reality that is the individual, one would try to understand ontogenesis in all the progression of its reality, and knowing the individual through individuation, rather than individuation through the individual (2009, 5)

Thus, the epistemological problem lies not with how technology leaves the domain of the human in the course of becoming technologies, but with how these processes of 'externalization' (Stiegler 2002) change the very concepts of, for example, number, image, comparison, space, time, or city. However, the anthropological category of "exteriorization" does not fully do justice to these processes, as they operate retroactively and recursively on the original techniques. Along with the concept of the text and the book, the practice of reading has also changed in the course of digitization and the algorithmization of knowledge processing; Along with the concept of comparison, the practice of comparison has changed since it is (for example of images) it has become an operation that is based on data extraction and machine learning. On the other hand, conversely, we must also consider, in an archaeological and mediatic way, the technological state of life as a starting point from which to ask what cultural techniques were used in the first place.

That said, what we can then observe is a completely integral conception of embodied life: one in which life is, from the beginning, a bios, that is, a life endowed with a supplementary dimension, as in supplements. reason or politics that have co-determined the western philosophical conception of the human being. However, the supplement

² For example, we have the Critical Zones sample. The Sciences and Politics of landing on earth at the Zentrum für Kunst und Medien (ZKM), curated in 2020 by Bruno Latour and Peter Weibel, where they discuss a new turn of the "human" in their habitation of the earth and its ecological politics. <https://zkm.de/en/exhibition/2020/05/critical-zones>.

³ Some of these scientists who participated in the Macy meetings (1946-1953), and addressed this topic were Arturo Rosenbluth, Margaret Mead, Gregory Bateson, Heinz von Foerster.

in question in the Qatipana “ecosystem”, in its architecture as such, is not that of reason or its politics, but the supplement of its architecture itself: the original relationship of the “individual” properly speaking with something exterior, with the environment (Umwelt), the transduction of the architectural body itself. If this original relationship forms the basis for subsequent transductive materializations of the body in / and the biosphere, up to the point of knowledge proper (the ontogenetic relationship envisioned at the beginning of this section), its bodily origins indicate an affiliation with that other Greek term. for life, zoe, the root of the same term (zoology) that is considered complemented in the epiphylogenetic evolution of humans and other species.

Conclusions

Recent developments in high-tech fields, such as robotics, nanotechnology, computer science, and the entire spectrum of genetics, bio, and neuroengineering, suggest that contemporary culture is not only on the brink of a new scientific revolution and technology, but is already entering a qualitatively different period in its historical evolution. A distinctive feature of this period is the ultimate exploration of the foundations of living and non-living matter, and the application of discoveries in this field to the physical nature of the human being. This is a radical departure from the past, when the application of technologies was directed primarily to the outside world, not to humanity itself. It seems that never before has the price of such scientific development been so high: humanity is beginning to reform itself according to its own conceptions of its biological structure and evolution.

This research aims to be deliberately global in scope, deals with examples from a variety of systemic, ecological, planetary scenarios and explores the resonances between them to constantly work between theoretical and empirical perspectives in a Latin American context. Although the analysis surrounds our own experiences of the work during the investigation, we do not imagine Qatipana as a report on these commitments. Therefore, it is not surprising that these investigations between art-science-technology, mark new precedents, fascinating and at the same time terrifying, and are considered by experts in the arts and humanities as a subject that requires deep contemplation and analysis. To what extent are particular experiments in this field ethical? What are the prospects for the widespread application of new technologies? What kinds of worlds will they create? These are just a few of the questions that are subject to lively debate in these disciplines.

In the same way, Latin American artists have not been kept out of the public discussion about what is being developed, interpreting in their works both the formal and conceptual characteristics of the new technologies.

One of the best known references in this field is the Chilean Juan Downey, for him, the use of new technologies was as relevant as the questions about the context in which the question about art was posed. On the one hand, Downey is usually mentioned among the pioneers of video art, at the same time as Nam June Paik, but we also see his approach in Chile in 1973, with his work *Anaconda*, when he wants to place a large snake of this type on a map. of the country, representing how the great North American mining company did not accept to lose extractive control. On the other hand, his experience with the Yanomami

people in the Brazilian jungle, living with them to assimilate their ways of representing space, as opposed to the use of the video camera or the western conception of architecture.

In a line that could be defined as close, there are also the explorations of the Argentine artist Luis Bénédict, who since the end of the sixties began a path of exploration between science and art focused on the recreation of the variables of the construction of a habitat as “materials , new techniques, new expressions ”, and “ Microzoo ”. Likewise, at the 1970 Venice Biennale, he presented his work "Biotron", made with the scientists Antonio Batro and José Núñez. Both artists have been implicitly or explicitly associated with cybernetics, representing a time when technique had to take on interdisciplinary challenges, but also strengthen the balance between natural, social and technological aspects.

We believe that digital practices, such as experimental works of art and representations, serve as criticism and have an indirect effect on the social and political, although a redefinition of this term is certainly needed, since they question the very nature of our accepted ideas and belief systems regarding new technologies. In this sense, digital does what all avant-garde art does; it is an experimental extension of the socio-political and cultural aspects of an era. As such, technology would then involve a reconfiguration of our embodied experience. When the body cannot reach its intended meaning, it builds its own instruments and projects a mediated world around it. From this point of view, it would be plausible to compare the techno-socio-epistemic historical processes that Latin America went through since the conquest, the Andean peoples have known how to Andean a large number of techniques originating in Europe, to integrate them into their system, without undermining their identity, while keeping unity systemic and its logical cohesion. However, this “enriched” Andean technology is no longer handled purely or exclusively, but partially, and together with a growing number of technical elements originating from modern Western technology. In fact, now "modernization" often means des-andinization and Westernization of technology. Halogen technical elements are penetrating more and more rapidly and in numbers in the Andean countryside. This process is so violent and accelerated that the selective adoption, its andeanization and the integration of these elements in the Andean system, become impossible. The peasant handles them as a risky and strange alternative to the system.

By way of conclusion, we can elucidate that human evolution is inseparable from the evolution of *téchne*, the evolution of technology. One cannot simply think of the human being as a natural animal, isolated from the external material world. What he becomes, and what he is, he is essentially tied to techniques from the beginning. Leroi-Gourhan, tells us about it in his text "The Gesture and the Word": "The appearance of tools as a species [...] characteristic that marks the border between animals and humans" (1971 p. 90). It is in this context precisely where we can give life to the Qatipana symbiosis, an ontological cross between the artificial and the natural, from the particular to the universal, whose communication extends to the informational and energetic plane (Filinich and Chibey 2020). And he opens us to the question, where do we have to recognize Latin American diversity; so that later we can develop it further?.

Forging Emotions: A Deep Learning Experiment on Emotions and Art

Amalia Foka

School of Fine Arts, University of Ioannina
PO Box 1186, Ioannina, 45110, Greece
afoka@uoi.gr

Abstract

Affective computing is an interdisciplinary field that studies computational methods that relate to or influence emotion. These methods have been applied to interactive media artworks, but they have been focused on affect detection rather than affect generation. For affect generation, computationally creative methods need to be explored that lately have been driven with the use of Generative Adversarial Networks (GANs), a deep learning method. The experiment presented in this paper, *Forging Emotions*, explores the use of visual emotion datasets and the working processes of GANs for visual affect generation, i.e., to generate images that can convey or trigger specified emotions. This experiment concludes that the methodology used so far by computer science researchers to build image datasets for describing high-level concepts such as emotions is insufficient and proposes utilizing emotional networks of associations according to psychology research. *Forging Emotions* also concludes that to generate affect visually, merely corresponding to basic psychology findings, e.g., bright or dark colors, does not seem adequate. Therefore, research efforts should be targeted towards understanding the structure of trained GANs and compositional GANs in order to produce genuinely novel compositions that can convey or trigger emotions through the subject matter of generated images.

Keywords

Deep Learning, Affective Computing, Visual Emotion Datasets, Generative Adversarial Network (GAN).

Introduction

The notion of emotion, as we understand it today, was established through scientific research in various disciplines. Emotions have been studied from the perspective of various disciplines, including psychology, neuroscience, sociology, medicine, history as well as computer science. As a result, the question "*What is an emotion?*" will rarely generate the same answer from different scientists or individuals [1]. This is primarily due to the different basis of the emotional phenomena or theoretical issues studied from every discipline. The main questions asked for emotions are: where they originate, what physiological, behavioral, and cognitive changes they produce, what are the different expressions (e.g., facial) they induce, and what are the subjectively experienced feelings.

Emotions also have a long-standing relationship with art. Baroque art intended to appeal to the senses and emotions. Romanticism rejected the formality of Neoclassicism and, instead, embraced emotion. In Expressionism, artists depicted the world with distorted images to express their own feelings. Many theories of the expression and experience of emotion in art exist [2].

Katja Kwastek [3] has studied the aesthetic experience of the recipient in the case of interactive media artworks, which too often includes the arousal of emotions. In non-interactive works, the recipient's emotional experience is staged in the past tense; either an artist represents the emo-

tions he/she has experienced or plans the desired emotional experience for the recipient, albeit it is mostly subjective. In contrast, interactive media artworks are located in the present tense. However, as Kwastek notes, even if the interaction process leaves scope for the unexpected, the orchestration of emotional experiences is designed in an even more explicit manner since feedback processes have to be programmed into the technical system implementing the artwork.

Consequently, affecting computing methods become extremely pertinent for orchestrating emotional experiences in interactive media artworks. However, affective computing research is, to a large extent, concentrated on detecting rather than on generating or triggering emotions. Accordingly, interactive media artworks that consider affective computing methods also mainly utilize them for affect detection.

If the problem of affect generation is considered, then computational creativity methods need to be explored, which most commonly involve Generative Adversarial Networks (GANs), a deep learning method. When considering the generative process of GANs, and more importantly, when they are intended to generate affect, the utilized training image datasets are of crucial importance.

The experiment presented in this paper, *Forging Emotions*, explores the use of visual emotion datasets and the working processes of GANs for visual affect generation, i.e., to generate images that can convey or trigger specified emotions. It appears that researchers attempting to build visual emotion datasets have almost reached a consensus on the most appropriate methodology for that purpose. Their methodology consists of querying social media for tags with words for emotions (e.g., anger, disgust, fear, sadness) to collect images. A validation procedure is then performed where quite a large number of people confirm if the emotion tags are correct. *Forging Emotions* aims to confront the idea that querying social media with a single word can result in a set of images that truly visualize what an emotion is. Moreover, it aims to question the validation procedure utilized to account for the subjectivity of emotions. Finally, it aims to explore the working processes of GANs for visual affect generation and which visual aspects of the generated images are able to convey or trigger specified emotions.

Background

Affective Computing

Research in affective computing is mainly focused on building systems that can respond and adapt to human emotions [4]. Such systems first need to be able to detect human emotions. For this reason, a great variety of sensors have been developed that can monitor physiological signs that are later utilized for recognizing emotions. The modalities of facial expressions, body gestures, and speech have also been used for recognizing human emotions.

When detecting emotions, it is most common that Paul Ekman's basic emotion theory [5] is utilized, suggesting that all emotions can be derived from a limited set of universal and innate basic emotions. Therefore, the following six basic emotions are considered: anger, disgust, fear, happiness, sadness, and surprise. It is also common that another seventh neutral emotional state is added. Additionally, there are cases where a few other emotions are considered, such as anxiety, excitement, calm, and lust, among others. More recently, two-dimensional models of emotion have gained interest. One very commonly used two-dimensional emotion model is the valence and arousal model [6]. This model proposes that all affective states can be understood as varying degrees of valence (a pleasure – displeasure continuum) and arousal (activation – deactivation).

To a large extent, affective computing research focuses on detecting rather than on generating or triggering emotions. A considerable body of research on affect generation involves synthesizing human-like expressions of emotion through facial features, speech, and gestures for virtual characters and robots [4]. Affective games are a sub-field of affective computing that studies how the gameplay can be adapted according to players' emotions and how emotions can be triggered [7]. Nevertheless, affective games currently adapt to or trigger emotions by design rather than with computational methods.

In conclusion, research on generating affective triggers is highly unexplored. Accordingly, interactive media artworks that utilize affective computing methods also mainly consider affect detection rather than affect generation.

For example, the work *Chameleon* (2008/2010) by Tina Gonsalves recognized the audience's emotional state, using a facial expression detection system, and classified it to one of the six basic emotions as defined by Ekman [5]. Then, the detected emotions were sent to the video engine that triggered videos from the new corpus Gonsalves created to empathize with the audience's emotional state [8]. Gonsalves created her own facial emotion dataset that was "*more dynamic and aesthetic, engaging and emotionally probing.*" Gonsalves' experience working with affective computing methods and visual emotion datasets led her to the conclusion that emotions expressed and monitored in laboratories for scientific research "*don't often correlate to the emotions that form the fabric of our everyday lives.*" She also notes: "*There seem to be limited emotions being explored, visually underwhelming databases being used, and the non-ecological settings such as the lab to test responses [...] using small groups of subjects with narrow representation, what does the knowledge that science is building about emotions actually mean?*".

Deep Learning Methods

Computational Creativity is a field that has lately regained much interest with the advent of Generative Adversarial Networks (GANs) [9], a deep learning method. If the problem of affect generation is to be considered, then the processes involved in GANs have to be explored. In music, there is the field of affective algorithmic composition (AAC) [10], where an intended affective response always informs the algorithm for music composition. There are many successful applications of GANs within the field of AAC. However, visual affect generation, that is, to generate new images that intend to convey or trigger specific emotions, is still unexplored.

GANs have already been explored by artists, for example, Anna Ridler [11] and Mario Klingemann [12], but not for visual affect generation. One of very few works in the literature that considers the generation of artworks that convey a specifically defined emotion is by David Alvarez-Melis and Judith Amores [13]. In this work, a GAN was

trained on 13,000 images of modern art paintings that were emotion-labeled. Alvarez-Melis and Amores concluded that their approach was able to generate artworks with high-level emotional features that agree with psychology literature; for example, red for anger, dark colors for sadness and fear, as well as images that resemble natural landscapes for joy.

GANs have already exhibited the ability to generate images that are hard to distinguish from "real" ones. One of the most well-known GANs is the one developed by NVIDIA to generate new face images that are hard to identify as images not of real people [14]. Additionally, approaches for synthesizing facial affect have also been presented in the literature [15].

However, in most cases, GANs have successfully generated images of objects or concepts that are quite specific in form and structure, e.g., human faces, dogs, landscapes, and others. As a result, the utilized training datasets are comprised of highly similar images. For example, the NVIDIA training dataset includes only photographs of human faces that are also automatically aligned and cropped.

Nevertheless, when higher-level concepts are considered, such as the whole notion of emotions, without being limited to facial expressions, it still remains a question of how to create a suitable training image dataset that could be later used with GANs to generate new affective images, i.e., images that convey or trigger a specified emotion.

Visual Emotion Datasets

Most datasets used for visual emotion analysis are targeted towards applications for affect detection. Even if the problem of visual affect generation is considered, a similar visual emotion dataset is also required for the system to learn how to generate affective images. For that purpose, in the following, the most commonly used visual emotion datasets are summarized. It should be noted that this discussion will not include datasets of facial expressions that are beyond the scope of the presented experiment *Forging Emotions*.

Emotion researchers have constructed quite a few visual emotion datasets. They commonly define specific categories of images according to their research questions and then hand-select images. The International Affective Picture System (IAPS) was designed to provide a standardized set of pictures for studying emotion and attention and was developed by the National Institute of Mental Health Center for Emotion and Attention at the University of Florida [16]. IAPS is the most widely used visual emotion dataset in hundreds of behavioral and neuroimaging studies. It includes over 1,000 images depicting people experiencing various emotions (e.g., sad, fearful, angry), erotic couples, funerals, dirty toilets, cityscapes, landscapes, wars and disasters, mutilated bodies, baby animals, and many more. Other visual emotion datasets constructed by emotion researchers are the Geneva Affective Picture Database (GAPED) [17] with 730 images and the Nencki Affective Picture System (NAPS) [18] with 1,256 images. In the GAPED dataset, images of spiders, snakes, and scenes of moral or legal violations were selected for negative images, whereas for positive images, mainly humans, animal babies, and landscapes were used. Images in the NAPS dataset belong to five broad categories: people, faces, animals, objects, and landscapes. The "object" category is a very broad class in which a wide range of clearly visible objects, foods, or vehicles were depicted without humans or animals present. Pictures in all categories included stimuli for different emotions. For example, images in the "people" category included alive, injured, or dead human bodies. In all the above-mentioned visual emotion datasets, images were evaluated on valence and arousal.

Computer scientists also have built visual emotion datasets. Mikels et al. [19] created the Subset A of IAPS (IAPSA) by selecting 395 pictures from IAPS and then categorizing them into eight discreet categories (anger, disgust, fear, sadness, amusement, awe, contentment, and excitement) by conducting a user study. Machajdik and Hanbury [20] created another dataset of 807 artistic photographs downloaded from DeviantArt, an online social community for artists and art enthusiasts. The same eight basic emotion categories were also used in this dataset. The associated emotion for each image was the label given by its owner on DeviantArt. A more recent dataset is the Open Affective Standardized Image Set (OASIS) [21]. It contains 900 images, collected using the Google Images search engine, depicting a broad spectrum of themes, including humans, animals, objects, and scenes. Each image was rated on valence and arousal by recruiting participants through Amazon's Mechanical Turk (MTurk).

You et al. [22] aimed at creating a large visual emotion dataset and remark that all the previously mentioned datasets are significantly smaller than those used for other computer vision tasks. For example, the ImageNet dataset [23] used for object recognition as well as image generation with GANs contains more than 14 million images. Hence, You et al. collected over 3 million images from Flickr and Instagram labeled with one of the eight basic emotions. Furthermore, they also employed MTurk to verify the emotion labels associated with images. Finally, the created dataset contains in total over 23,000 images with verified emotion labels, which currently is the largest visual emotion dataset available.

This discussion on visual emotion datasets can conclude that computer science researchers generally turn into online resources, and more often, to social media, to collect images associated with emotions with single-word queries. Then, most commonly, MTurk is employed so that many different people validate the emotion conveyed or triggered by each image. Thus, it seems that researchers in the field have almost reached a consensus on the most appropriate methodology, and what remains to be completed is to build a vast visual emotion dataset that would contain millions of images.

Forging Emotions

It is uncertain that the previously described visual emotion datasets can genuinely visualize how emotions are experienced or evoked. An emotion is not just a word, such as the ones used to query social media, but a network of associations. According to psychology research, each individual relates an emotional percept or event in many different ways to a multitude of past emotional experiences [24]. The basic idea is that, for example, the emotion of happiness is not just a word but a concept that can be represented by a network with nodes of past emotional experiences. Thus, the network of happiness could include nodes for the emotional experience of a child being born, a vacation, being with friends and family, and many more. Everyone experiences emotions differently, and thus emotional networks of associations are individual, i.e., each individual may have different emotional experiences related to happiness. However, according to psychology literature, emotional networks share a common basic structure for most people [24].

Forging Emotions aims to confront the idea that querying social media with a single word can result in images that genuinely visualize how emotions are experienced or evoked. Moreover, it seeks to question the process of employing MTurk to account for the subjectivity of emotions. For that purpose, two new image datasets were created by

querying Instagram with the hashtags #sad and #happy. The collected images were not verified in any way.

All the previously mentioned visual emotion datasets do not consider the emotion of happiness, although it was included in the six basic emotions originally introduced by Ekman. In social media behavior studies, it is often concluded that one always tries to appear attractive, happy, and clever [25]. In the context of the *Forging Emotions* experiment, it seems like a paradox not to explore the happy emotion while social media are utilized to understand emotions. The #happy dataset poses the question of whether this is the emotion that can be better understood from social media data or if shared emotional experiences on social media are authentic.

This experiment also aims to test whether new images can be composed that visualize and evoke the emotions of happiness and sadness, or in some manner can "forge emotions", which relates to commonly naming the generator component of a GAN a "forger." Thus, the experiment was named *Forging Emotions*.

GANs have been successfully applied for generating new images of human faces, dogs, landscapes, and many more. However, the criticism that follows the use of GANs is that they are not interpretable, and they are often considered black boxes. Consequently, interpreting and understanding what a GAN has learned is an active research topic within Explainable Artificial Intelligence (XAI) [26], which has gained much interest lately. In the recent work of Bau et al. [27], the aim was to understand if a GAN learns composition or if it purely memorizes pixel patterns. The conclusion was that GANs indeed learn aspects of composition and that certain neuron units have learned specific features of the taught domain.

Another exploration strategy for interpreting and understanding deep learning models is the black-box exploration. In this type of exploration, only the training dataset and the deep learning model's output are used to examine its behavior and provide insight into its interpretations [28]. This approach is similar to the one Ridler [11] describes in which she used GAN images as a mirror to her own drawing process.

In this respect, *Forging Emotions* will also perform a black-box exploration to understand what a GAN has learned when trained with a visual emotion dataset.

Experiments

The experiments were performed with the implementation, and the proposed architecture guidelines, for stable Deep Convolutional GANs (DCGANs) [29]. The training images were not pre-processed, except scaling them to the range of the tanh activation function [-1, 1]. All models were trained with mini-batch stochastic gradient descent (SGD) with a mini-batch size of 64 for 100,000 epochs. All weights were initialized from a zero-centered normal distribution with a standard deviation of 0.02. In the LeakyReLU, the slope of the leak was set to 0.2 in all models. The Adam optimizer was used with a learning rate of 0.0002. Finally, the momentum term β_1 was set to 0.5. The images were generated at a 64x64 pixel resolution. In all the following experiments, the DCGANs were trained with the same parameters and for the same number of epochs.

Forging Sadness

Initially, the image dataset created for the *Forging Emotions* experiment with 30,000 Instagram images that include the hashtag #sad was used to train the DCGAN. Then, new images were generated and are shown in Figure 1. The same procedure was followed for the dataset created

by You et al. [22] for the emotion of sadness, which included 2,635 images. The images generated in this case are shown in Figure 2.

It can be observed that all the generated images shown in both figures are, in some way, reminiscent of abstract paintings. In both cases, some images would seem like abstract human figures or, in other cases, abstract landscapes or cityscapes. In Figures 1 and 2, it can be noticed that there are more images with dark colors, which is in line with psychology literature that generally associates dark colors with unpleasant emotions. A distinct differentiation is that Figure 1 includes more images that look like text which is due to the different types of images included in the two utilized training datasets.

The dataset utilized for generating the images shown in Figure 2 was validated by humans and mainly consisted of images depicting humans with facial or body expressions of sadness. The dataset for sadness created by You et al. also included quite a few images of pets. Other types of images constitute only a tiny proportion of the dataset and include text images, graves or graveyards, dead flowers or plants, winter landscapes, etc. The You et al. dataset [22] included only 2,635 images for the emotion of sadness, and it is evident that a significantly larger dataset is required for the GAN to be able to generate less abstract images.

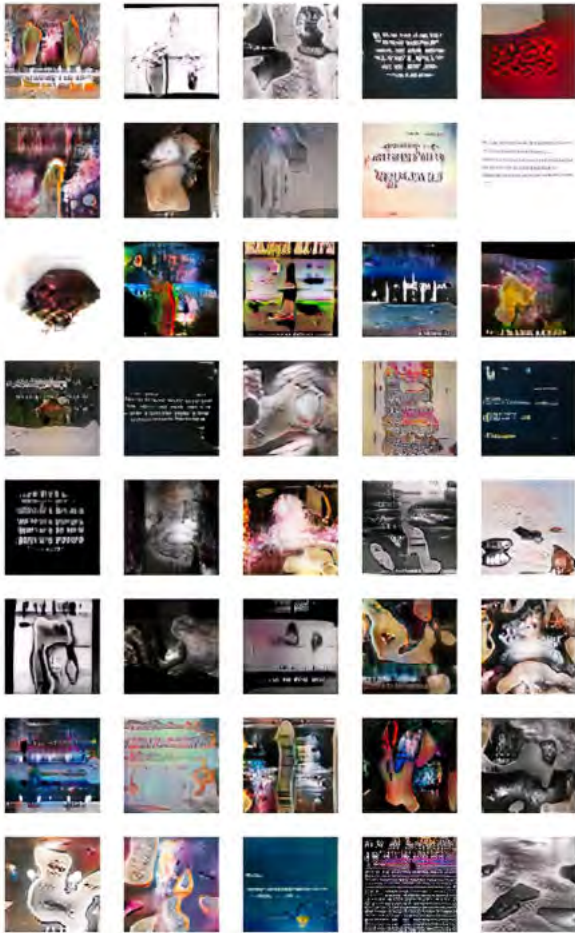

Figure 1: The DCGAN generated images when trained with 30,000 Instagram images with the hashtag #sad. (Full-size image available at <https://pasteboard.co/JKcqhxo.png>)

On the other hand, the image dataset collected for the *Forging Emotions* experiment included predominately text images. Our dataset also included many images depicting humans, pets, dead plants, and winter landscapes. Additionally, it included images of comics, movie stills, bad food, and other types of images that were not present in the dataset by You et al. [22]. Finally, since the sadness dataset

created for the *Forging Emotions* experiment was not validated, it included some images that were not associated with the emotion of sadness but rather with the meaning of the word sad for characterizing something as inadequate or unfashionable.

Nevertheless, it becomes evident that collecting social media images with single-word queries cannot guarantee that the whole range of how people experience emotions can be included. For example, we cannot find any images for sadness in either of the two considered datasets that depict, for instance, funerals, wars, disasters, or mutilated bodies, as was the case in the IAPS dataset created by emotion researchers. Moreover, it is most probable that such images would be removed, even if they were posted on social media, due to their policies in order.

In conclusion, although the employed validation method with MTurk ensures that some irrelevant pictures would be removed from the dataset, it cannot accommodate for the fact that several aspects of how sadness is experienced are missing. Social media users' behavior, along with emotion research, should be further studied to identify multiple image sources and the emotional networks of associations that constitute how emotions are experienced. Finally, significantly larger datasets should be built for training GANs.

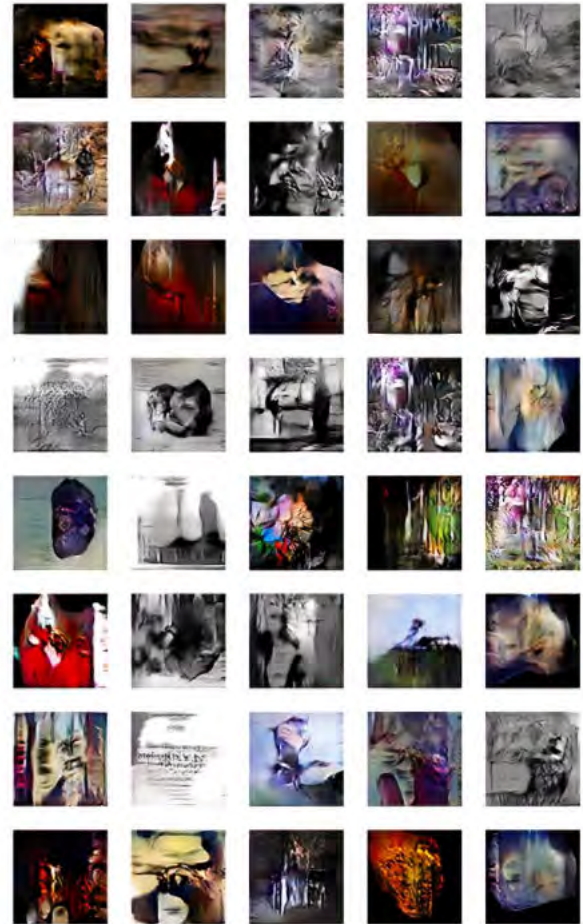

Figure 2: The DCGAN generated images when trained with the image dataset created by You et al. for sadness. (Full-size image available at <https://pasteboard.co/JKcpdeQ.png>)

Forging Happiness

Another DCGAN was trained using the image dataset created by collecting 30,000 Instagram images that include the hashtag #happy, and the generated images are shown in Figure 3.

Again, all generated images are reminiscent of abstract paintings, including abstract human figures, landscapes,

and cityscapes. Images in Figure 3 have noticeably brighter colors than those in Figures 1 and 2, which is also in line with psychology literature that generally associates bright colors with pleasant emotions.

Instagram users post a greater variety of images when they use the hashtag #happy. They also post many pictures depicting humans but similarly many images with luscious food, photos from vacations that include landscapes and cityscapes, images showing an object of desire, babies, and many more.

Even though the whole range of how people experience happiness is still not included in the collected images, what becomes more evident in this case is that it is questionable that the generated images can visualize or trigger the emotion of happiness. Generating images that merely correspond to basic psychology findings, e.g., bright colors like in the work of Alvarez-Melis and Amores [13], does not seem adequate for visual affect generation. For example, although the red color is generally associated with anger in psychology findings, this is not always the case. In an image depicting a natural landscape at sunset, the sky is often red, and it would trigger positive emotions for many people.

Figure 3: The DCGAN generated images when trained with 30,000 Instagram images with the hashtag #happy. (Full-size image available at <https://pasteboard.co/JKcrJO2.png>)

The two first images on the second row of Figure 3 quite clearly depict women posing. These images were generated because the #happy dataset included many images posted by women posing with their new clothes or in other cases posting selfie images to state that they are hap-

py for various reasons. Accordingly, the third image on the second row of Figure 3 depicts a natural landscape like the ones often posted on Instagram from vacations. However, as exhibited in the case of the *Forging Sadness* experiment, significantly larger datasets should be built for training GANs that include more aspects of how happiness is experienced.

More importantly, recent research efforts on understanding the structure of trained GAN could shed light on the different features learned from visual emotion datasets. This knowledge could be applied towards training compositional GANs that could create genuinely novel compositions and combine different elements from different types of images. Thus, the subject matter of generated images would be better directed for visually generating affect.

Conclusions

The experiment *Forging Emotions* was doomed to fail in its initial set goal to generate new images that convey or trigger the emotions of happiness and sadness. Nevertheless, its execution allowed us to draw two main conclusions and instigate research on the identified issues. First, the methodology used so far by researchers to build datasets for describing high-level concepts such as emotions is not sufficient. This conclusion is also in line with the comments artists made while working on affective computing methods; for example, the issue raised by Gonsalves on whether the datasets used in scientific research, especially in the case of emotions, can really "*correlate to the emotions that form the fabric of our everyday lives,*" remains unresolved. It seems that the collected images based on single-word queries can indeed generally be characterized as related to an emotion such as happy or sad, but not able to describe the full range of the emotional experience of happiness or sadness. It would appear as a more appropriate methodology to first explore a network of associations for an emotion that describes the emotional experience rather than just the name of an emotion. Additionally, a greater variety of online sources should be considered rather than only social media. Finally, the contribution of artists in the creation of visual emotion datasets would be most valuable.

The last conclusion of this experiment is that for visual affect generation, research efforts should be targeted towards better understanding the structure of trained GANs and compositional GANs. GANs, in many cases, are able to understand the different elements used to compose, for example, a scene. If visual emotion datasets are built according to emotional networks of associations, they will comprehensively visualize how each emotion is experienced. Then, methods and frameworks for understanding and interpreting GANs will shed light on the different features learned from visual emotion datasets. This knowledge could be applied to train GANs that can create genuinely novel compositions and combine different elements from different types of images. Thus, not only the colors but also the subject matter of generated images will be better directed for visually generating affect.

Author Biography

Amalia Foka (b. Greece) is a creative Artificial Intelligence researcher and educator who explores the intersection of computer science and art. Her work makes use of different artificial intelligence technologies and social media data to generate and study art. Her work has been presented and published internationally including the Leonardo Journal (MIT Press); WRO Media Art Biennale; EVA London and many more. She is currently an Assistant Professor in Computer Science: Multimedia Applications for the Arts at the School of Fine Arts, University of Ioannina, Greece, where she teaches courses on creative coding, creative interactive systems, and generative AI art. She holds a BEng in Computer Systems Engineering (1998) and an MSc in Advanced Control (1999) from the University of Manchester Institute of Science & Technology (UMIST) in the United Kingdom. She also holds a Ph.D. in Robotics (2005) from the Department of Computer Science of the University of Crete.

Spatial Photograms: Experimental Cyanotype Photography using 3D Scanning and Printing Technologies

Abstract

This paper discusses contemporary forms of photographic representation of space and, at the same time, new possibilities of making an objective spatial. Structured in two parts, it articulates an alternative model of photographic space in the form of a *Spatial Photogram*. We propose a novel photographic practice, based on traditional pre-photographic image-making and today's digital image methods.

In the first part, we analyze the cultural-artistic context of the historic developments in photography to articulate an objective image of space through comparing the movements of Functional Aesthetics and Neue Sachlichkeit (new objectivism) with the pre-photographic practices of camera-less photography – the photogram.

In the second part, we discuss the technical setup in the making of a *Spatial Photogram* focusing on comparing 3D printing and scanning methods, as well as the making of transfer tools between the digital methods and the chemical-based analogue cyanotype printing.

The result is a material-based image that introduces space as a density – a completely new method to articulate a representation of space in the context of photographic objectivism.

Keywords

Alternative Photography, Photography, 3D printing, 3D scanning, Cyanotype, Neue Sachlichkeit, Digital Craft

Introduction

'Photographs are a way of imprisoning reality...One can't possess reality, one can possess images--one can't possess the present but one can possess the past.'[1] We cannot possess a space, but we can make a representation of space – a photograph of that space. What we can have in a photograph of space is the visual experience and representation of that particular space.

In the first part of this research, we will contextualize the problem of spatial representation using photography and how historically, photography has developed methods to achieve objectivity towards the representation of space. We have structured this contextual critique into the elements of the camera – the aperture, the lens and the film. This part of the research articulates a conceptual framework to position the research in a lineage of experimental photography that aims to articulate the merit of art and science of photography.

In the second part, we will analyse the technical making of the spatial photogram, using 3D scanning and 3D printing to rearticulate the lens and aperture of the camera and cyanotype-based printing to work with a new and old type of medium. We demonstrate this new technique through two test pieces, both articulating the notion of a material-based image-making process, combining digital methods of contemporary image making with traditional chemical, analog methods.

Critical Context

The Aperture – Function Aesthetic

Functional Aesthetic is a concept *'Founded in reaction to soft-focus pictorialism and East Coast hegemony'* [2]. In particular, the group f.64, founded by Preston Holder and Willard Van Dyke in Oakland, California, are known for ultra-sharp photography as they shot with small apertures. The group promoted the notion of de-coupling the subjectivity of the image-maker to the space through diminishing the depth of field in the images.

Their photographs capture the sceneries with ultimate sharpness in what was coined then – an objectivist style. *'Objectivism focuses on the relation of the individual to a universe of objects, and the more or less subjective or objective attitude toward that relationship which the artist demonstrates.'* [3] And while this suggests the notion that the camera is used to create an objective image of scenery, the f.64 movement clearly stylized a view of nature through

idealizing angles and dropping horizon lines – reverting back to an inclusive Romantic acceptance of Nature [4]. The group f.64 focused only on the aperture as a tool to increase objectivity in the image-making, while at the same time using image manipulations such as contrast amplification of the print, or dodging shadows to create spectacular images that we cannot see with our naked eyes. And thus, the notion of objectivism, while, in contrast to the soft-focus pictorialism before in American landscape photography is correct, is confusing when discussing the notion of the true objectivism of the camera and the spatial image.

The Lens – Neue Sachlichkeit

‘Neue Sachlichkeit’ or new objectivity, a movement that started in the 1920s, is well known for rejecting expressionism, and articulating unsentimental, scientific representation of the world. Karl Blossfeldt, one of the founders, used special homemade cameras to dramatically magnify parts of plants, first as teaching tools and later, referencing the seminal work of Ernst Haeckel, a new form of aesthetic objects through gallery exhibitions and eventual publication of his version of Haeckel’s publication *Art Forms in Nature* [5].

Later, Bernd and Hilla Becher used special large format cameras, to avoid distortions of a normal lens when photographing industrial architectures of West Germany. The resulting images have transformed the photographic relationship to space as subject and object – in what Charlotte Cotton observes as the deadpan aesthetic: a dispassionate, patient, keenly sharp version of photography [6]. The relationship to Blossfeldt is clear, isolation of the object of study from context, removal of lens distortion, and any image enhancements – resulting what Sean O’Hagan, the photography critic for the British newspaper *The Guardian*, observes that “*the Bechers approached photography the way a botanist might approach the cataloguing of flora and fauna.*” [7].

The nature of photography with a lens is one of transformation of spatial representation. Even if deducted to the point of the deadpan aesthetics, it is not objective – might not need to be. How to remove the image perspective altogether, returning to Ernst Haeckel’s blueprints in the *Art-forms of Nature*?

The Film – Chemical Objectivity

In 1843, British photographer and botanist Anna Atkins made a series of cyanotypes of British algae [8]. The images show the silhouettes of the plants by placing the algae on a prepared cyanotype paper and exposing it to ultraviolet (UV) light. Not only do Atkin’s photograms preserve the silhouette of the plants, but also present some qualities such as the material density and translucency of the botanics. Her images, and cyanotype photography in general, a form of what Mike Ware calls alternative images [9], explore the

possibility of camera-less photography as a means to reconstruct a decentralized visualization through a controlled chemical reaction. The gradient and thus intensity of the cyanotype, either lightening or deepening the Prussian blue, articulates an objective chemical image closer to the notions of planar projections such as elevations in architecture.

Therefore, in the context of traditional lens-based photography, excluding extended photographic methods such as Stereoscopy, we put forward the hypothesis that space can be recorded objectively. Such a photographic representation of space can only be made without perspectival distortion or aesthetic manipulations, and thus cannot be made using lens-based photography. Instead an objective, constructed spatial representation is possible using cyanotype printing, if the space itself can be physicalized using 3D scanning and printing technologies. The result then can extend the comparison from two- to three-dimensionality – where the 3D scan and print today might still yield the decline of ontological originality from the actual object. [10]

Methods and Practices

As discussed, works from the f.64 group and Neue Sachlichkeit attempted to introduce spatial objectivity with cameras and failed on various levels – due to the subjectivity of the camera as such. At the same time, photographers such as Anna Atkins could objectively capture objects with camera-less photography. However these works can only be of physical objects, which act as a sort of lens and aperture at the same time, controlling the chemical image-making process. Thus, we offer that, if space itself is transformed into a physical object, with differentiating gradients of corresponding translucencies, a spatial version of the photogram, a Spatial Photogram can be created. Furthermore, seeing such a camera-less spatial image in the context of the notion of an objectified space as discussed by Sontag, we aim to create an objectivism that photographers from f.64 and Neue Sachlichkeit were not able to realise, as the technological developments of 3D scanning and 3D printing did not exist back then.

First, we used 3D scanning since it is the only way we can capture space digitally without distortion. Afterwards, we used 3D printing to articulate the digital 3D scanned data into a physical object. Therefore, the framework of this project is based on scanning an interior space, and the transformation of the 3D scanned data into a 3D printable model. The 3D printed model of the scanned space acted, similar to the algae in Anna Atkins’s practice, as a lens and aperture at the same time. This is due to the materiality of the model as well as the arrangements of the 3D data sets. In the following parts of the research, we will elaborate on the specification of this workflow and the particulars of the 3D print materials, the methods of digitally transforming the scanned space, and the chemical transfer methods we used and partially invented in this process.

3D Scan & Subdividing Space

The first task in the project was to find an appropriate way to create a digital, and later on, 3D printable data model. We experimented researched two 3D scanning methods. On the one hand, laser imaging, detection, and ranging (LiDAR) is a precise method to record a space, on the other photogrammetry using a series of photographs is a more cost efficient and versatile technology.

After comparing photogrammetry and LiDAR scanning, we found that although LiDAR scanning can achieve a high-quality surface model in a short period, the outline of the LiDAR scanned model is not as detailed as the one scanned with photogrammetry [11]. Considering the resolution of the scan, we chose photogrammetry as the method to 3D scan a domestic interior space (Fig.1).

Figure 1. A rendering of the scan of an interior. (© the author. Photo: author)

Figure 2. A rendering of the subtractive model in a diagonal orthographic view (right). (© the author. Photo: author)

After importing and preparing the scanned model, we built twelve cubic polys to subtract the scan with Boolean calculation for a negative cast of the scan (Fig.2). In the Boolean calculation, the mesh for subtraction (which is the scan in this case) must cut through the polygon to be subtracted (which is the blocks we built in this case). However, the height of the scan is uneven. It is impossible to subtract one big polygon with the scan. Therefore, we subtracted the scan with multiple polys to be able to create a sort of negative cast of the scanned space.

This method is inspired by the trapezoidal rule used to estimate the area of a definite integral in calculus. When a formula cannot be integrated, the trapezoidal rule helps estimate the value of the definite integral. Trapezoidal rule is a method to subdivide the area beneath the curve into different trapezoids. Then we could add the area of all trapezoids to get the approximate value of the definite integral. We appropriated this method to create a negative cast of the scan. In this method, the more blocks we use, the higher the accuracy of the final negative model. We decided to use twelve blocks in different heights for the Boolean calculation. After the calculation, we unified the height of the polygons and combined them.

3D Print & Materials

The second step, after preparing the 3D scan data, is 3D printing. The aim was to find a printing method and material that would allow us to create very thin and at the same time chemically stable, translucent 3D prints. Additionally, considering the use of UV light in cyanotype printing, the 3D print would need to be stable in UV light environments. Photosensitive polymer used for Digital Light Processing (DLP) or Stereolithography (SLA), one of the most commonly available methods, absorbs UV light continuously and degrades over time. Specifically, the polymers for SLA printing, such as thermoset acrylate (TSA) oxidizes and deteriorate after UV exposure, with *“the ether group appears to be the most sensitive to photooxidation, with a 50% loss after only 200h.”* [12] Seeing the degradation of the photosensitive materials used in DLP or SLA printing, we considered Selective Laser Sintering (SLS) printing as a method to print our model. However, the surface of an SLS printed object turned out to be too porous and rough, which negatively affected the printing result of the cyanotype. We found that compared to Digital Light Processing (DLP) or Stereolithography (SLA), the Fused Deposition Model (FDM) printed models with polylactide (PLA) filament are structurally stable under UV light exposure and at the same time, produced when using a very fine nozzle for the extrusion, a smooth surface that would not impact on the cyanotype print.

Since cyanotype is an analog photographic printing process, the results are dependent on the quality of the material and the light source. To ensure the stability of the experiment, we used only cyanotype-related chemicals from Bostick and Sullivan, and Fabriano's Artístico series watercolor paper as recommended in *Cyanotype: The Blueprint in Contemporary Practice*. [13] As the strength of the natural UV source – sunlight is not stable for printing, we used an artificial light source for the experiments. According to the scientific report from the University of Southern Queensland, UV light with 370nm wavelength is the weakest light for fully activating an unexposed cyanotype emulsion. [14] Although 330nm to 300nm UV light is the most effective light source for cyanotype printing, we chose UV light tubes emitting 360nm UV light in this cyanotype project – a choice that was dictated by the availability of UV light tubes in the market.

Calibration for material-based Images

In a traditional photogram, the images do not depict the correlation between the thickness of the object and the color intensity of the image. In order to discover the relationship between the thickness of the PLA model and the color intensity of the cyanotype print, we build a gradient map model from 0.1mm to 10mm, where the interval between each step is 0.1mm. The model contains 100 frames and 1 slope, which is bounded by four blocks to prevent refraction from the peripheries of the model. (Fig. 3)

Figure 3. 3D printed stencil in PLA for data collection (left), one of the cyanotypes printed with the PLA stencil for data collection. (right) (© the author. Photo: author)

20 minutes is the minimum exposure time to fully address the color intensity of the cyanotype with this stencil. An exposure under 20 minutes results in a pale print whereas over

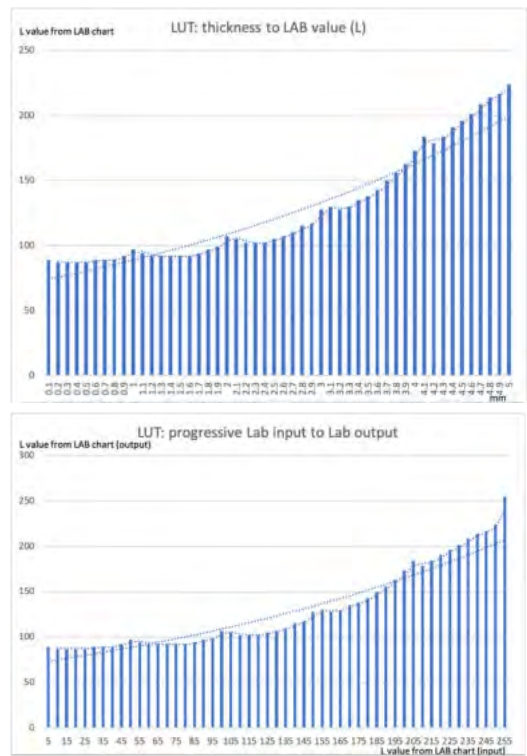

Figure 4. Top: Look-up Table: the input value L value in $L^*a^*b^*$ color space to the output value L value in $L^*a^*b^*$ color space. Bottom: Look-up Table: the thickness of the stencil in millimeter to L value in $L^*a^*b^*$ color space.

20 minutes has a similar result as a 20 minutes exposure. With all these presets, we printed 30 samples of cyanotype with this stencil to collect the data for establishing a look-up table (LUT) between the $L^*a^*b^*$ value (in CIELAB color space) and the thickness of the 3D print. [15] (Fig.4)

The reason we used $L^*a^*b^*$ values as an indicating unit is to establish a LUT that is applicable in Adobe Photoshop. Photoshop is the software we used to embed and apply the LUT to the image. By manipulating the image with the LUT, we were able to test the accuracy of the curve in terms of the thickness-color intensity relationship.

The LUTs can be used in two ways: to predict the outlook of the cyanotype printed with a PLA stencil, and to approximate the thickness of the PLA stencil according to the color intensity of the cyanotype. For the first use, which is what figure 4 shows, we can restore the contrast of the source image to the cyanotype by using the LUTs. As the tables show above, the thickness and the color intensity of the cyanotype are not in a linear relation. By embedding the LUT as a converter between the digital image and the stencil, the resulting cyanotype will become predictable. The second use, is a reversed version of the first use. If we know that the cyanotype is printed with a PLA stencil, we can estimate the thickness according to the LUT tables we established. Moreover, we can imagine the shape of the PLA print by the cyanotype since the cyanotype is the analog height map of the stencil in this situation.

Figure 5 Image source for the test of the LUT (left), PLA stencil for the test print (middle), A cyanotype test print with the PLA stencil. (© the author. Photo: author)

Testing

Having the LUTs, we retrieved the numerical correlation between the thickness of the PLA print and the color intensity of the cyanotype exposed with that print. This enabled us to develop a Photoshop curve, which is a graphic expression of the LUT between the $L^*a^*b^*$ input and $L^*a^*b^*$ output of an image in an RGB color space. The LUTs suggest how the thickness of the PLA printed stencil affects the color intensity of the cyanotype. In order to validate the LUT, we set up the first experiment, aiming to replicate an existing image as a cyanotype, by tracing the thickness of the print by the color of the cyanotype, and applying the LUT to an existing image with rich contrast as a curve to calibrate the contrast of the image. We set up the experiment to validate the hypothesis that if the cyanotype has a similar visual appeal to the original photo, the curve can convey the thickness-color intensity relationship successfully.

As the resulting images of the cyanotype test show, the LUT restores the contrast and the gradient of the source image well (Fig.5), though the cyanotype print is not as sharp as the source photo due to the depth of field. The thicker the stencil is, the blurrier the image is since the stencil we used is not designed for focusing light. Only the thin part of the stencil keeps the image sharp and clear. Although photograms are not as sharp as lens-based photos, it represents its subjects more chemically objective as any form of lens-based photo involves perspective, which distorts the appeal of the object. The photogram captures objects orthographically, which involves no distortion. Therefore, while photography is successful in terms of representing space, our approach is able to transform the volume of objects and spaces into the image since what we capture is the material density of the stencil – the material-based 3D-printed “lens”.

Spatial Photogram

Spatial photogram is a process in three phases, 3D scanning, 3D printing, and cyanotype printing. The following part is about the process to prepare the final print from 3D scanning to cyanotype printing.

After the Boolean calculation of the 3D scanned space, discussed in the chapter 3D scan – Subdividing Space, we proportionally scaled the digital model according to the cyanotype experiments with our LUT. We have found out that in our set-up, UV light cannot penetrate the PLA stencil if it is thicker than 5mm. Therefore, we scaled the model to a maximum height of 5mm to fully address the depth of the scan through the color intensity of the cyanotype. The images below are the photographic scans of the 3D-printed stencil. (Fig. 6)

Figure 6. Photographic scan of the PLA stencil for the final cyanotype a top-down view (left), and from a bottom-up view (right) (© the author. Photo: author)

Figure 7. Author, *Spatial Photogram*, 2021, a set of 2, cyanotype on watercolor paper, 8" x 10" (© the author. Photo: author)

In the last phase of the research, we exposed two cyanotypes with a 360 nm UV light source for 20 minutes each, and eventually achieved two prints from the two flat surfaces of the PLA stencil. (Fig. 7) The two prints are the photograms from one negative model of a 3D scan of interior space. Both prints articulate gradations of Prussian blue and blurry outlines due to the thickness of the 3D-printed stencil. The prints are exposed from two angles of the scan – one bottom-up and one top-down. This approach visualizes the depth in an orthographic way and thus visualizes the invisible but experiential subject – space. The perspective-free approach helps us estimate the dimension of the space via the color intensity of the cyanotype. The LUTs we proposed earlier suggests the correlation between the thickness of the model and the color intensity of the print. Therefore, reversely, we can reconstruct the volume of a particular area by using the LUTs and knowing the maximum height of the space.

We developed a method to understand the material depth to colour gradient. First, we scan the cyanotype print with a flatbed scanner to read the value of the color intensity using Photoshop. Then, we input the data to the LUTs and retrieve the respective output. Finally, we multiply the number according to the original depth of the scan. *Spatial Photogram* is therefore objective since it contains information that is not only perceptual but descriptive. As a result, we extended the conventional limitation of photography in capturing the volume accurately.

Conclusion

This paper starts from the cultural-artistic context of photography's journey to articulate an objective image of space. Based on these ideas, we developed and practice the idea of a spatial photogram with 3D scanning, 3D printing, and cyanotype as a material-based image. Like other forms of photography, the *Spatial Photogram* introduces a new method to perceive space. More importantly, *Spatial Photograms* help us envisage space, which is something we can sense but cannot see directly. As the spatial photogram works in an anachronistic method, combining state-of-the-art technologies with traditional, pre-photographic image-making processes, and thus is different when compared to lens-based photography and human eyes, it provides a radically new visual experience. When this feature is incorporated with the invisible nature of space, we can discourse a novel notion of space in photography.

Author(s) Biography(ies)

FONG Hin Nam is a Hong Kong-based media artist interested in exploring different forms of space with photography and other emerging imaging technologies. Obtaining a Master of Fine Arts degree from the School of Creative Media, City University of Hong Kong, Fong exhibits his works of art in various local and international exhibitions including the Chiang Mai Photo Festival 2020 and WMA Open Photo Contest Exhibition – Opportunity!

Tobias Klein works in the fields of Architecture, Art, Design and interactive Media Installation. His work generates a syncretism of contemporary CAD/CAM technologies with site and culturally specific design narratives, intuitive non-linear design processes, and historical cultural references. Before joining City University of Hong Kong in the role as interdisciplinary Associate Professor in the School of Creative Media, he was employed at the Architectural Association (2008-2014) and the Royal College of Art, (2007-2010), in both cases in the postgraduate level. The resulting works of his studio are exhibited internationally with examples being in the collection of the Antwerp Fashion Museum, the London Science Museum, the V&A, the Bellevue Arts Museum, Museum of Moscow and Vancouver. He is lecturing and published internationally with most recent articles focusing on the translation from craftsmanship to digital manufacturing.

Rituals of art and science to decompartment(mental)ize knowledge

Luca Forcucci, Bruno Herbelin

forcucci@tutanota.com | bruno.herbelin@epfl.ch

Abstract

We here explore the potential of rituals in order to more fully comprehend the subjective mechanisms of listening, leading to a broader understanding of phenomenal consciousness (why and how do I know that *I* am experiencing something?). The originality of the project resides in the blending of phenomenology, cognitive science, the sonic arts, and rituals studies. Rituals are explored in the context of a practice-led methodology between an artist and a cognitive scientist in order to decompartmentalize and possibly decolonize knowledge, namely shifting away from a purely Western techno-scientific perspective in order to embrace a plural vision involving indigenous epistemology. In this project, the sonic arts include music and sound in the arts, and focus specifically on the very act of listening. Rituals constitute structures for the lives of communities and societies, which we address more deeply from the perspective of sonic and cognitive research, so as to understand their roles and the epistemology emerging from them.

Keywords

Rituals, Sonic Arts, Cognitive Science, Hallucination, Mental Imagery, Visuals, Art Based Research, Practice-led Research, Art and Science Research, Interdisciplinarity.

Introduction

Little is known about the mechanisms of listening or on the finesse of sonic imagination as related to sonic phenomena. Nancy proposes that ‘it is always in the belly that we –man or woman– end up listening or start listening. The ear opens into the sonorous cave that we then become’ [1]. The earliest common memory of space among human beings might indeed possibly be the womb. Similarly, Schulze proposes materializing listening and rendering our senses corporeal [2]. Listening, the senses and the body should help in achieving a broader understanding of the structures of the self. According to Zahavi, ‘many scientists regard questions pertaining to the nature of phenomenal consciousness, the structure of the first-person perspective, and the status of the self to be among the few remaining major unsolved problems of modern science’ [3]. Focused listening induces mental imagery and it may then, as for visual mental imagery, include the whole body and involve the motor system [4; 5, 6; 7; 8; 9]. Listening (as opposed to

hearing) requires attention to and engagement within an environment, and relies on subjectivity and (self-)consciousness. In effect, ‘[mental] imagery not only engages the motor system, but also affects the body, much as can actual perceptual experience’ [10]. Dedicated listening is an active experience; it addresses the questions of the structure of the first-person perspective, makes room for a novel philosophy of combined auditory perception and sonic imagination [11; 12; 13], and requires engagement with an aural architecture [14] as perceived atmosphere, which necessarily involves the whole body. As for Massumi who relies ‘on the irreducibly bodily and autonomic nature of affect’ [15], the morphological quality and immersive potential of aural architectures, namely imagined and subjective architecture triggered by sound as atmospheres, unavoidably affect the body of the listener. Prinz even highlights the crucial idea that ‘conscious experience is not restricted to what is in my head but includes the environment around me, then the richness of experience is not an illusion’ [16]. Sonic imagination may widen understanding of the mechanisms of listening. Pauline Oliveros specifically proposed sound imagining in her sonic meditations [17]. However, the term ‘imagination’ too often relates to the visual aspect, and a new vocabulary needs to be developed for the sonic counterpart. Oliveros chose the term ‘auralization’, underlining that ‘[y]ou might begin to notice how your attention changes when you use auditory terms instead of visual terms to speak about sound’ [18]. Sonic imagination and auralization thus lead to the development of a new dimension in listening.

A combination of academic fields, artistic and scientific approaches (Western, and non-Western) of the experience of the self has already been expressed in technoetic and moist media [19], anthropology [20], the combination of neuroscience and suprasensory perception [21], and first-person accounts of the shamanistic perspective [22]. Blanke and Dieguez stress that ‘approaches and traditions often considered as outside the reach of science, such as (...) shamanism, mysticism, religious rituals, and the use of mind-altering drugs, the study of altered states of bodily consciousness holds the potential to offer important scientific insights about the brain processes involved in creating our everyday experience of the self’ [23]. For instance, the combination of EEG measurements within

Ayahuasca rituals was investigated for the first time in April 2019 by a team of scientists [24]. Such an approach is still in its infancy, but already raises many questions, including ethical ones, and might benefit from insights from the field of the humanities, as is proposed here. Watson-Jones et al. call for a combination of cognitive science and anthropology ‘to understand how individuals in diverse cultures incorporate both natural and supernatural explanations for events’ [25] and, as stated by Astuti and Bloch, ‘anthropologists and psychologists are willing to look both ways and learn to respect, speak, and read each other’s language’ [26]. Rituals, defined by Tambiah as ‘patterned and ordered sequences of words and acts, often expressed in multiple media’ [27], are central here. For Schilbrack, ‘in the study of rituals, then, phenomenology can provide a dialogical partner for those approaches that treat ritual as cultural inscription and do not take into account the materiality of the lived body’ [28]. This research needs to be addressed now, because the field and the literature of sound studies have grown considerably in the last decades, yet little is as yet known of the mechanisms of listening and of the finesse of the sonic imagination.

Research Methodology and Approach

The scope of this paper as related to the project shall also provide new data for cognition and perception in the context of art, phenomenal consciousness, artificial intelligence, and augmented and mixed realities. Such pervasive fields are now mostly approached from a techno-scientific and Western perspective. Humanities, art, and indigenous epistemology and knowledge, which ‘is generated from careful observation of the ecosystem and natural phenomena, observed by many people for millennia’ [29], introduce new questions, and new responses. They thus enrich research by providing a pluralist, widely encompassing vision; and by including indigenous perspectives in A.I., it may even widen perspectives and lead instead to Extended Intelligence (E.I) [30], Extended Reality (E.R.), and Extended Self (E.S.). The innovative aspects of the interdisciplinary project move beyond the state-of-the art and push it further by proposing a unique combination of fields, such as ritual studies, anthropology, phenomenology, cognitive science, and the sonic arts. Such an approach allows for the mechanisms of listening and questions about phenomenal consciousness to be addressed from a sonic perspective by fusing theoretical writing with sonic artworks as research-creation. It also counterbalances a dominant visual, Western, techno-scientific perspective.

Our approach for decompartmentalizing knowledge, namely by creating bridges, emphasizing on the interdisciplinarity nature generated by art and science collaboration, and looking outside well established Western academic methodologies, focuses on the rituals involved within such collaboration through a nomad lab as mobile and multi-sited ethnography [31]. The focus resides on

fieldwork, phenomenology, cognitive science and research-creation. More specifically, at the intersection of sonic arts and cognitive neuroscience, we explore how a scientific experimental approach can take place within the venue where the artwork is installed. The focus resides in the research process and is not limited by an outcome defined in advance. The artistic research process combines our experience in the sonic arts and our scientific expertise in the cognitive neuroscience of perception to explore the mutual interactions between visual and auditory stimulations for the mental elaboration of illusory or hallucinatory precepts. In the visual domain, illusions (when you perceive an object but you misperceive one or more of its properties) have traditionally fascinated the audience and have been extensively studied by the Gestalt and in psychophysics as a tool to understand perception. Hallucinations (when you have an experience as of an object but there is no object that you actually perceive) on the contrary are associated with a form of dementia, often mistaken for psychiatric delusions or delirium. In contrast, our approach is based on recent accounts on the psychological mechanisms of hallucinations [32] and debates on their phenomenological foundations [33] suggesting that the boundary between illusion and hallucination might not be so strict, the neural mechanisms of hallucinations sharing with illusions the need for the brain to interpret perceptually insufficient information, to ‘find meaning in noise’. Pareidolia (when you perceive an object in place of others) are examples of the intermediate between an optical illusion and a hallucination. Interestingly, although they are common (e.g. seeing a human face in the shape of clouds), they have only recently been linked to the evaluation of hallucinatory tendencies [34]. Visual illusions and hallucinations thus take place in a continuum of visual misperceptions, and we believe this space can be explored artistically and creatively, avoiding the common association made between hallucination and either drug use or mental illness. In practice, we explore the possibility to trigger the true experience of perceiving nonexistent objects or complex scenes (i.e. the actual conscious sensation of having perceived) by combining specifically composed sonic and visual stimuli.

The implementation of this process and the physical setup supporting it could take various forms, from the projection of visuals during a concert to the construction of a semi-permanent multimedia installation. In all cases, the objective is to accompany the audience to reach a state of dedicated listening, leading to a focused attention to the experienced sensations and perceptions, in order to magnify mental imagery. To leave room for such ‘auralization’ [35], visuals should therefore not entirely capture the attention of the audience. We explore ways to merge or alternate the stimuli (e.g. presenting visuals at first as an invitation for mental imagery), and specifically address the role of rituals for reaching this goal.

Merging rituals of art and science

The artwork is an electroacoustic musical composition developed during an artistic residency at the Helvetic Circle in Genoa, Italy. The central element of the composition is the organ situated in the church above the residence. The work was conceived in the present moment without a written score, and after long walks in the surrounding nature. The church contains an intrinsic architectural sonic spatial identity. The recordings of the organ and its reverberations in the architectural space were then sampled, reworked, and implemented into a software allowing live manipulation in order to be played in any future concert venue. The addition of these sonic spaces, those initially recorded, those of the future concert venues, and those present in the mental imagery of the listener during the concert, shall lead to a sonic moiré, a polyphony of spaces. The conceptual idea of the sonic moiré is an auditory perception of several layers of space and comparable to that which emerges visually from Marcel Duchamp's rotoreliefs. Such perception exists between the work and the spectator, and here between the work and the listener. The sonic moiré changes according to the typologies of each concert venue, and its ultimate goal is to produce an illusion of cinematic experience for the mind of the listener. Moreover, for the first concert involving the current experimental setup described below, a pianist was presented with a graphic score of the composition, on the base of which she developed a live composition on a prepared piano along live electronics and the sampled organ.

Performance outline

For the first public performance of *The Room Above*, the rituals from the scenic arts and from the experimental laboratory work in cognitive sciences were combined and balanced to satisfy the expectations of the audience attending a concert, while triggering their curiosity and priming them to the encountering of mental imagery. On the one hand, the scenography and the succession of events followed the classic ritual for attending a concert; finding your seats, waiting for the lights to dim, applauding the performers as they get on stage, etc. On the other hand, the visuals displayed on a large projection screen at the back of the scene (11 x 7m, see Fig.1) provided information related to another ritual; spectators are addressed as participants to a psychophysical experimentation. First, a welcome screen presented the objectives of this research and informed attendees that they will be asked to fill a questionnaire at the end. Second, an ethical statement was presented to remind them that their participation is on a voluntary basis and that “This study is undertaken in accordance with the ethical standards as defined in the Declaration of Helsinki”, as per the requirements for conducting behavioral research on humans. As the concert started, each musical movement was then introduced with a title displayed on screen, as it would be for an experimental bloc in the laboratory. A final acknowledgement screen was then shown at the end of the

Figure 1. Concert settings for the pilot experiment (top) and screenshots of the visuals for the three musical movements/ experimental blocs.

experiment and invited participants to fill a questionnaire (QR-code linked to an online form they can fill on a mobile phone).

of the mind linked to listening and perception mechanisms by integrating the scientific lab into the artwork, and by combining the methodology of art research with science research in order to develop novel routes for original questions and answers.

Here, we report how the merging of rituals from the sonic arts and from experimental psychology could already provide space for extending the audience's expectations and encouraging an active role from the 'participants' attending a music concert. In appearance, both rituals were distinct, relying on different mediums. This complementarity, together with the attention drawn upon visual perception and mental imagery, are intended to lead the spectators to exercise their ability to explore deeper their perceptual abilities. The voluntary interruption of the visuals in the middle of a musical movement then leaves them with a purely sonic experience, and with an absence that their mind would spontaneously compensate for. More refinements are needed to better orchestrate this process (precise timing, improved communication about experimental research, raising expectations before the show, etc.), but preliminary observations provided encouraging results.

The overall ambition of this art and science collaboration is to decompartmentalize these two approaches of the study of the conscious (and active) experience of perception. The scientific and technological innovation associated with the realization of the project will then be valorized by the sharing of open source software and hardware, and by linking it back to neuroscience research, may it be by offering new perspectives on how to conduct studies on a large audience, or by providing insightful data on rich and unique experiences. In that sense, the rituals of experimental science would, in a way comparable to the rituals for knowledge acquisition in indigenous cultures, get re-appropriated by the general public.

Authors Biographies

Luca Forcucci, artist, scholar and guest professor, observes the perceptive properties of the first person experience through art installations, electroacoustic compositions, videos, photography and writing. His research investigates mental imagery of sonic architectures. The artworks have received numerous prizes and are held worldwide. Forcucci's nomad research lab, UBQTLAB.ORG, produces talks and podcasts. He is chair of Laser Nomad, as part of the LASER series of Leonardo / ISATS. He achieved a PhD in Sonic Arts at De Montfort University.

Bruno Herbelin is senior researcher in virtual reality and cognitive neuroscience in the laboratory of Prof. O. Blanke at École Polytechnique Fédérale de Lausanne (EPFL), Switzerland. He was deputy director of the EPFL Center for Neuroprosthetics (2012-2019), and Assistant Professor at the Medialogy Department of Aalborg University, Denmark (2005-2009). He obtained his PhD at EPFL School of Computer and Communications in 2005 for his research work on virtual reality exposure therapy.

Speakers, More Speakers!!!^{1,2} – Developing Interactive, Distributed, Smartphone-Based, Immersive Experiences for Music and Art

Anna Forgette, Bill Manaris, Meghan Gillikin, and Samantha Ramsden

Computer Science Department
College of Charleston, USA

forgetteak@g.cofc.edu, manarisb@cofc.edu, gillikinme@g.cofc.edu, ramdensl@g.cofc.edu

Abstract

We describe a multi-speaker, smartphone-based environment for developing interactive, distributed music and art applications, installations, and experiences. This system facilitates audience engagement through participation via personal smartphones, potentially connecting with traditional computing devices via the Internet without additional software or special configurations. The proposed approach has been inspired and motivated in part by the COVID-19 pandemic and builds on earlier works and technology. It demonstrates a design approach that is more efficient and provides a new avenue for music composers and artists to design highly distributed, participatory, immersive music and art experiences, utilizing various input sensors and actuators available in today's smartphones. These include individual smartphone accelerometers, video cameras, and – of course – speakers. The use of smartphones also provides for relatively precise geolocation through GPS or simple social engineering approaches, such as using dedicated QR codes for different locations (e.g., seats in an auditorium). This allows for composing experiences to be rendered in the same room / auditorium, highly distributed across the Internet, or a combination of both. The paper presents the technological background and describes three case studies of such experiences, in an attempt to demonstrate the approach and inspire new avenues for artistic creativity and expression towards highly immersive, participatory installations / performances of music and art works for the 21st century.

Keywords

Interactive music and art, distributed music and art composition, smartphone-based interface, human-computer interaction, generative music, mobile device control, real-time communication, music performance, audience participation.

Introduction

We present a multi-speaker, multi-screen, smartphone-based environment for developing interactive, distributed music and art applications, installations, and experiences. This environment allows arbitrary network connections to be established among numerous smartphones and other

Figure 1. One of the authors demonstrating our smartphone-based, sound spatialization system in a simulated, multi-speaker laboratory environment.

computing devices (e.g., laptops) to support synchronized delivery and performance of sound and visual materials. This environment also supports design of arbitrary interactive experiences utilizing smartphone touchscreen, video camera, and microphone input, as well as movement captured via smartphone accelerometers (e.g., see Figure 1).

This work has been inspired by the realization that the ongoing pandemic has emphasized a pre-pandemic societal shift in how people communicate and share information – including how they experience, consume, and potentially generate artistic, musical, gaming, and other audiovisual materials via smartphones (such as Zoom, and other related technologies). We believe this shift is here to stay. This has tremendous implications for the average future artist and how they choose to make their work available to vast audiences.³

¹ Funded in part by the US National Science Foundation and the US National Endowment for the Arts (CUE-1935143 and CNS-2139786).

² Also “screens, more screens!!!” – in part inspired by Goethe’s (famous) last words (see <https://www.loc.gov/pictures/item/00652178>).

³ A related example is the shift that streaming services (such as Pandora, Spotify, and YouTube) have made to the delivery, consumption, and – most important – economy of musical compositions and performances.

The average person already owns, carries, and operates at least one smartphone device on a continuous daily basis. These devices are extremely powerful in capturing data and in delivering audio visual material. However, in most cases, due to pre-existing momentum and concerns for protecting copyrighted or otherwise exclusive artistic material, we are all being shielded from using our devices (and the potential they afford) in designing new artistic and musical experiences and performances. Most of us have experienced being asked to silence our smartphones, turn them off, or put them away (as experienced by one of the authors at a recent Brian Eno concert under the Acropolis in Athens, Greece).⁴

We believe the time has come for composers and artists to embrace this new smartphone-based technology – as with other technologies before it – and utilize it meaningfully, in music and art works, installations, and performances.

Our approach utilizes standard and custom-built JavaScript libraries, which allow to seamlessly connect with other pre-existing libraries and tools, including as Ableton Live, Iannix, Isadora, JythonMusic, and PureData, among others, using Open Sound Control and MIDI messages. This flexibility to bring together such powerful and expressive components facilitates rendering of artistic, musical, and other material, designing / building of immersive experiences, installations, and performances, and including audience participation through smartphone input and output.

We demonstrate this approach discussing three such experiences, namely

- a recreation of Iannis Xenakis’s avant-garde piece, “Concret PH”, created originally for the Philips Pavilion in 1958 [1];
- a Zen-like, meditative, music interactive experience, called “Be the Wind”, which renders binaural wind-chime and other restorative sounds, in a distributed fashion with participation from the audience; and
- a fractal-based, sound spatialization piece, called “On the Fractal Nature of Being”, which invites audience members to interact via movement – collecting accelerometer and video data from their smartphones – to generate a dynamic fractal design on a main screen and an evolving, generative soundscape, utilizing musical input from live instruments interspersed through the audience.

While the current paper focuses mainly on designing smartphone-based, participatory music and art experiences / installations, it should be emphasized that this work also applies to designing other kinds of art experiences, including kinetic sculpture, dance, and theatrical experiences and performances, among others.

Background

Audiences in most traditional art and music performances in the West are often considered as mere “receivers” of the performance [2]. In other words, they are not expected to contribute in any way to the creative act occurring before them. Yet, the very presence of an audience in the space does have an effect on the performance. For instance, there are always some low-level forms of participation involved in artistic endeavors (moving around a gallery space, filling in gaps in information, applauding, etc.). This observation led new media theorist, Lev Manovich to argue in “The Language of New Media” that all art is, indeed, interactive [3].

In music, even something as simple as physical gesture can be an integral part of music ensembles and allow for interaction among music participants [4]. The level of interactivity though varies and is usually confined only to the music performers.

Computing systems have opened new avenues for designing explicit interactivity within newer artistic and musical experiences. There are many examples, such as Waite’s Church Belles [5], whose focus is to explore how to provide an effective means of audience participation and interaction.

Another development is peer-to-peer systems, which have found success in this area. Peer-to-peer systems gained popularity between 1999 and 2001 with the wide proliferation of the file-sharing system Napster [6]. The wide acceptance and understanding of the system led to the creation of interactive music works using Napster and related technologies. One such example is the system built by Tanaka, which allowed collaborative music composition on personal digital assistants (PDAs) across short distances [7].

Interactive music creation and performance has continued to evolve, and, as technology has improved, musicians have been able to interact over greater distances. Network Music Performance (NMP) systems, which allow real-time music performance from different locations, are great examples of this as they break the traditional localized geographical barriers of music performance and composition [8]. For instance, Benson et al. discuss SoundMorpheus, a system supporting distributed musical performances, via Myo-armbands to capture motion, and control aspects of music performance, via user arm movements and interaction [9].

An interesting development is the *Web Real-Time Communication* (WebRTC) protocol and related APIs. This has made it possible to design meaningful artistic collaborations across great distances. Such systems include Lind’s Soundtrap [10], a music studio which allows for digitally collaborative music composition; and Ramsay and Paradiso’s GroupLoop [11], a web-based collaborative audio feedback control system, among others.

⁴ A perfect, yet missed opportunity, as Brian Eno with Peter Chilver have been creating avant-garde experiences for music and art, distributed as smartphone apps, for over a decade.

The WebRTC protocol and APIs have permitted peer-to-peer systems to become more user friendly, providing functionality for audio, visual, and data sharing from device-to-device across networks, thus breaking geographical barriers. An interesting example comes from Chaves, who describes the overarching goals of such a system, stating that he wishes to create “[a] networked performance in which a ‘wireless imagination’ engages the listening subjects in different spatial, temporal, and social poetics” [12].

In terms of using smartphones for building music and art experiences, the work of Brian Eno and Peter Chilvers’ Bloom [13], among others, stands out. This innovative and truly inspired (and inspiring) smartphone app uses a game-like environment to encourage users to make music and visual art, in the form of raindrops, by tapping on the smartphone screen.

Dekel and Dekel’s MoGMI [14] also demonstrates the ability to transform the smartphone into a musical instrument, this time using physical gestures and accelerometer data, as the control mechanism.

The smartphone has also been used to gather accelerometer data in Jean, Broll, Stein, and Lédeczi’s work [15].

Many installations, such as Manaris, et al. “Diving into Infinity”, use body movements, tracked by Kinect and other related sensors, as the means of interaction with an artistic piece [16].

Of all related work, CoSiMa’s Soundworks environment is one closer to what we are presenting herein [17]. Soundworks supports artists in developing smartphone-based experiences, which allow users to collaborate and generate various sounds via touch and the movement of their smartphones. However, having experimented with the framework, we found it to be difficult to install and use, mainly due to the lack of documentation. Still, this is a piece of inspiring, pioneering work in this area.

Finally, Carson’s *immaterial.cloud* [18] brings elements of all this technology together, allowing users to break geographical barriers and collaborate with one another on a musical piece using WebRTC’s data connections. The architecture of our environment is similar to that of Carson’s but extends it in important ways, making it more generic, modular, and thus more easily adaptable to new applications. This allows the development of more varied, complex experiences, by creating a well-documented, easy-to-understand environment.

System Architecture

Our system allows the development of smartphone-based interactive music and art installations. One of its main advantages is that it supports an arbitrary number of audiovisual channels (i.e., intendent, individual experiences), which can be as large as the number of available smartphones (and networked laptops, tablets, etc.). This is accomplished by providing individual URLs, created specifically to serve

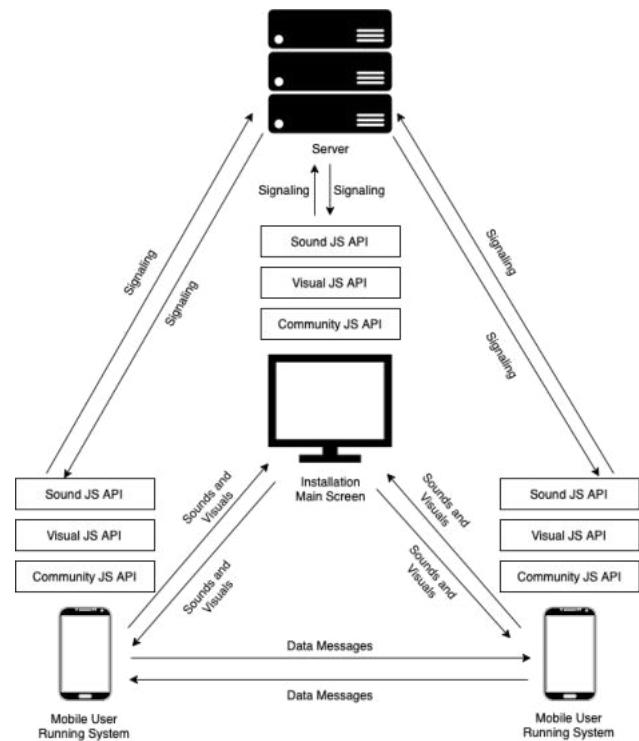

Figure 2. The various components and APIs comprising our system architecture.

different (or identical) resources, such as sounds or images, to the participating devices.

When conceptualizing our system architecture, our goal was to provide a means to engage users in interactive digital music and artistic experiences and performances. Based on earlier work, and current technological capabilities (e.g., WebRTC, WebAudio, etc.), it became clear that a web application would provide the best framework to support everything we were seeking.

In particular, web applications make music and art experiences easily accessible to participants’ smartphones (and other related devices, including tablets and laptops) **without having to download** any specialized software. This is by far the most enabling aspect of this design decision; users just need to point their devices to a particular URL (which may be different for different users to provide multi-channel, or even multi-role, engagement with the experience itself). Accessing a URL is a common task that all users of smartphone devices know how to accomplish – i.e., typing a URL, and scanning a QR code.

This approach also supports granular / cloud sound stochastic experiences, where the actual location of the sound is not as important, but instead the variety / multiplicity of sounds is what “creates” the experience.

Moreover, this system design allows for mixed-types of experiences, i.e., where there is a special role – via a dedicated URL known to only one person – who can act as an

on-stage performer / DJ / maestro of experience, deciding which sounds to be played at a particular time, adjusting timbres, volumes, and potentially sound panning / spatializations / diffusion patterns, thus providing overall navigation of the experience as it unfolds, based on a particular composition, or experience design.

System Elements

Our system architecture consists of two main components – a server, and various client modules.

- The server component stores various pieces of code and assets (sounds, visuals, etc.) comprising the experience. It is usually very minimal, with the only goal of serving the right content to the right client (in the case of a multiple user-role experience, such as maestro on stage vs. audience participants), or the same content to all clients (in the case of a single user-role experience). Additionally, it supports messaging for bi- or multi-directional communication between user clients, allowing for a wide variety of interaction / participation designs.
- As mentioned above, the user client component is able to run on mobile (or other) devices within the safe space (no downloads) of modern web browsers. This module generates / renders the artistic and musical component of for the experience / performance, receives input (if any) from the user, and communicates with other components, as orchestrated by the experience design.

The server and client components communicate with each other through (wired or wireless) Internet connections. This is accomplished via the WebRTC protocol. As mentioned earlier, this allows users to interact with one another, and to render audio and visual artifacts in real time (as allowed or dictated by the composition or experience design).

Implementation

The server component is built in Python or JavaScript. The user client component is built in HTML5 and JavaScript. This infrastructure is truly lightweight and does not require any installation or special configuration, as it comes pre-installed in all major web browsers.

When the participant / user visits the corresponding website established for the experience, the client software begins to run inside the browser's secure environment (also, see next section discussing security of the approach). The client opens a WebRTC data connection via the server to all other clients (user devices) connected to the server. This allows for controlled interaction / communication / synchronization between all devices and the server, while running the particular experience. The types of messages exchanged, and their frequency depends on the artistic experience design.

Currently, it is expected that the artistic experience designer is well-versed in both art and programming. However, our approach makes both development and

deployment much easier than with earlier approaches, as it standardizes and hides unnecessary complexity behind well-defined APIs. This is similar to the approach used in the JythonMusic environment [19], an environment for music and art experiences developed in Python, which has also been a design inspiration for our system.

Our system improves on JythonMusic, as it makes running experiences (as well as communication / synchronization between devices) transparent to the end-user (i.e., no software to download, and no specific configurations to be performed prior to running the experience).

This is a significant advantage / improvement, as it makes such experiences much more usable, accessible, and potentially more appreciated by average end users, who simply enter an experience by browsing to a website. Everything else automatically happens, as they navigate the user interface provided to them by the experience. In a later section, we discuss three such experiences, as examples / case studies.

APIs for Building Experiences

At the heart of this new artistic experience design framework, we incorporate several JavaScript libraries / APIs, some of which are pre-existing, and others have been created by us to handle / hide unnecessary complexity and make designing music and art experiences easier, compared to existing systems. Since the system is implemented in JavaScript, a developer may incorporate additional libraries / APIs (not mentioned here) to access additional desired functionality. Below, we present our system's APIs based on the functionality they provide.

Connectivity

- *Community.js* – this is a custom API which allows user clients to register themselves, when they come online, and connect to other clients. It provides functions to register a client via a custom ID, to get a list of registered clients (users) from the server, to broadcast to all clients (or some of them, having a certain ID pattern), to send messages to a specific client (using an existing client's ID), and to receive messages from another client.

This API utilizes part of a cloud-hosted Community server, for client registration. Once registered, however, users may initiate connections to other users and communicate directly and securely (without overburdening the cloud server). This is particularly important for musical experiences where timing and low latency are important. This approach allows for truly distributed, potentially massive experiences to be designed and deployed.

This functionality has been implemented utilizing the pre-existing *PeerJS* library,⁵ which simplifies WebRTC peer-to-peer connections and allows users to broker data, video, and audio stream connections to other remote users.

Designers of various performances/experiences are able to specify how to best connect users, and what type of data messages to send through these established connection channels, in order to create compelling and interesting participatory experiences.

Sound

For adding sound capabilities, we utilize the following:

- *AudioSample.js* – this is a custom API which allows user clients to use existing sound samples as instruments. While there are other more powerful, lower-level APIs (mentioned below), we developed this one for convenience, as it handles the majority of design situations we have experienced.⁶ It provides functions to load an audio sample (supports a variety of formats, including MP3, WAV, and AIF – 16, 24 and 32 bit PCM, and 32-bit float formats), to play the complete sound or a subset of it, to loop the complete sound or a subset of it, to stop the sound playing, to pause, and then (as needed) resume the sound playing, to set the pitch (in MIDI – 0 to 127) of sound, to set the frequency (in Hz), and to set volume, panning, etc.

For additional functionality, we have explored the following pre-existing libraries: *Howler.js* – a web audio library which provides functionality for playback of multiple sounds, control over fading, rate, volume, and seeking, in addition to 3D spatial sound or stereo panning.⁷ *Tone.js* – a web audio library for creating synthesized music interactively.⁸

Visual

For visual design, we mainly utilize *p5.js*, a porting of the MIT Processing system into JavaScript. *p5.js* is used already by artists to create interactive, 2D and 3D graphical applications (including drawing shapes, creating complex animations, accessing / reacting to mouse and touch events, loading images, etc.).⁹

Interaction

For user interface building, we utilize regular HTML5 UI building functionality. We also use *NexusUI.js*, a collection of HTML5 interfaces and JavaScript functions to assist with

⁵ See <https://peerjs.com>.

⁶ This is motivated by the 80/20 design rule, i.e., identify a set of functions (20%) that handle 80% of use cases, delegating the remaining, rarer ones to more complicated approaches, thus gaining in convenience and ease / simplicity of use.

⁷ See <https://howlerjs.com>.

building of interactive web audio instruments in the browser.¹⁰ Finally, we use *Hammer.js*, an open-source library for capturing and recognizing gestures made by touch, mouse, and pointer events. This provides functionality to recognize the various user touch events, including *tap*, *double-tap*, *press*, *pan*, *swipe*, *pinch*, and *rotate*.

In terms of additional input, we can also access accelerometer, microphone, and camera data through available Web API functionality. This allows to design a wide variety of interesting and versatile smartphone interactive experiences.

Security of Installation

Finally, and perhaps most importantly, our approach is extremely secure, through the strong, intended layer of security protection provided by modern web browsers. This creates a *barrier* between:

- a. the physical device hardware (and its contents, such as existing photos or personal contacts); and
- b. the software rendering the actual artistic or musical experience.

This is very important and cannot be overstated.

Any extra access required / desired for the experience (such as accessing the user's camera¹² or the device accelerometer, for example) must be explicitly approved by the device user. The browser security enforces this, and there is no way around it.

This way, the artistic experience designer can separate themselves from hacking concerns and from maintaining their software according to the latest security updates and directives; instead they may focus on artistic concerns and content creation (sound, images, interaction, etc.).

Managing security is delegated to the developers of modern web browsers, which are updated by the end user as part of maintaining the security of their own device(s).

To summarize, this division of concerns (artistic vs. security / software maintenance) is significant.

Case Studies – Artistic Experiences

This section discusses briefly (due to space limitations) three artistic experiences designed using our system.

Iannis Xenakis, “Concret PH” – A Retelling

Iannis Xenakis was a pioneer in using early computers to create music. He coined the term *stochastic music* (from the

⁸ See <https://tonejs.github.io>.

⁹ See <https://p5js.org>.

¹⁰ See <https://nexus-js.github.io/ui>.

¹² Which is very different from accessing the device's camera roll / existing photos, for example.

Greek word *stochos* (“στόχος”), or target), to describe music that evolves over time within certain statistical tendencies and densities, and has points of origin and destination. Xenakis created stochastic music to react to chaotic, purely random properties of 12-tone, or serialist music [1]. He believed that the listener may be aesthetically overwhelmed by the complexity of serialist music (which, while deterministic in its rules of creation, by definition, over time sounds utterly chaotic (i.e., uniformly distributed), as if generated using a random number generator in modern computer programming [19].

Xenakis proposed that mathematics of probability could be used to produce a compositional technique that is more controllable. This compositional technique could then be used to produce more aesthetically pleasing music, as he went on to demonstrate [1].

Reconstructing the Piece

This is a recreation of Iannis Xenakis’s avant-garde piece, “Concret PH”, an early and influential example of stochastic music. It was created to be played at the Philips Pavilion in the 1958 World’s Fair in Brussels [23].¹³ Unfortunately, the Pavilion was soon demolished, so there is no way to experience this piece as was originally conceived.

“Concret PH” (and stochastic music in general) may sound random at the local level - i.e., at the level of a single symphonic orchestra musician or, in our case, at the level of an individual’s smartphone speakers. However, when listened to as a whole at the global level - i.e., the sounds of the whole orchestra or, in our case, the sounds emanating across all the speakers of smartphones in the audience – the music exhibits movement and direction through unfolding waves, or areas of concentration in pitch, volume, and panning (among others). Although the music may initially sound random, when observed over time and more carefully, it exhibits some of the same qualities as listening to, say, falling rain, which has Zipfian (or power-law, non-random) proportions [20]. It should be noted that these proportions are also observed in more traditionally composed music (such as classical and jazz music, for instance) [21, 22].

The piece is performed mainly via audience smartphones, with an additional main screen presence (see Fig. 3). It unfolds over time and is relatively short (about 3 minutes).

In the original, Xenakis used a recording of burning charcoal, partitioned into one-second fragments, and then pitch-shifted and overlaid, to create a semblance of harmony or polyphony, thus generating a granular, ever-unfolding continuous sound texture. The piece was performed through approximately 400 loudspeakers in the Philips Pavilion arranged (due to technical limitations of the time) in five clusters and 10 channels (sound routes) [23].

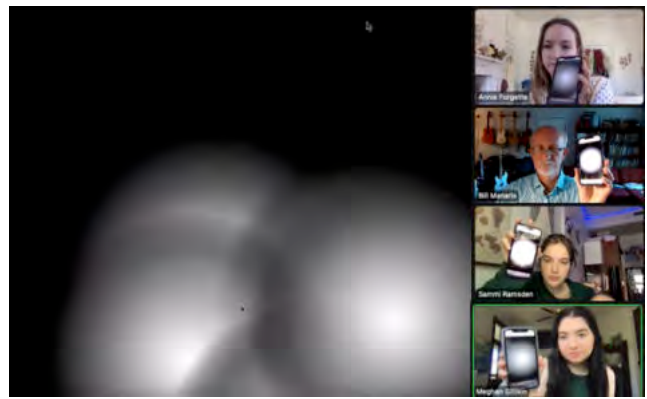

Figure 3. The four authors testing “Concret PH” (right). Sound and visuals are disturbed among all connected smartphones, including a main screen experience (left).

In our reconstruction, we use all participating smartphone speakers in the audience. We reconstructed the piece by sampling the background sound from the original (as found on YouTube¹⁴), and recreating the aural density using Python code written in JythonMusic.¹⁵ This produced a score, which was then manually inserted in the JavaScript client code of our framework to drive the sound of the participants’ smartphones.

Our reconstruction utilizes a probability density function controlled by the number of available (or connected) smartphones, adjustable in real-time. This forces the sonic outcome to remain approximately the same, regardless of how many smartphones are participating. The piece can be experienced with as little as one smartphone, or distributed over numerous smartphones – as many as connected to the experience, gradually approximating the sonic characteristics of the original. Our experience also utilizes the *visual* JavaScript API (described above) to visualize each sound playing from individual smartphone speakers, as well as the global, communal soundscape created by the culmination of all the smartphone speakers (see Figure 3).

The smartphone piece was premiered at the University of Maryland, College Park, USA on April 8, 2022. Participants were asked to move freely through the space, while their smartphones produced sound and visuals. In some regards, the ability to move freely resembled the movement of people inside the Philips Pavilion in 1958. A recording of the performance, captured via a 3D binaural microphone, is available here - <https://bit.ly/concretPH1>.¹⁶

¹³ This building was designed by architect Le Corbusier, who employed Xenakis as an architect and mathematician at the time.

“Be the Wind” – A Case Study

This experience is similar to the Xenakis’s “Concret PH”, except it adds user interaction. Instead of the audience passively listening to sounds unfolding over all participating smartphones, audience members can also decide when sounds are generated by tapping on their smartphone screens (see Figure 4).

Unlike “Concret PH”, which was influenced by Xenakis’ 1944 Greek Civil War experience, where he almost died in an explosion from a British tank shell, the goal of this experience is to be restorative in nature.

Through integration design and choice of sound materials, users are encouraged to engage in a slow, deliberate, meditative experience. The sound material consists of high-resolution, binaural audio recordings of a high-quality wind chime (tuned in C minor), as well as a field recorded sound of a running river and various recordings of bird calls.

Using these audio samples, the score is constructed in a way similar to “Concrete PH” using a probability density function. Users may contribute sounds to the collective experience by tapping on their smartphone, or they may simply sit back and listen to other people’s sound contributions. Harmonies emerge, and go away, as people contribute material. This smartphone experience will be premiered at the Music Library of Greece in May 2022. A recording of it will be available at <http://manaris.org/research>.

“On the Fractal Nature of Being” – A Case Study

Fractals are a fascinating natural phenomenon. Their mathematical intricacies and iterative or recursive self-similarity remind us of the complex underlying interconnectedness of the world around us. This immersive, smartphone-based artistic experience aims to capture the essence of fractals and evoke reflection on the intricate and meaningful ways in which we are all interconnected.

Similarly to “Be the Wind”, this piece involves a peer-to-peer network, connecting each smartphone in the audience to a larger main screen in the installation space. The audience members have the opportunity to alter and change the main screen by interacting with their own individual device. The system utilizes the built-in accelerometer capabilities of the smartphones to gather data on how each audience member is moving. Camera data are also collected from the smartphones to capture the most prevalent colors in the areas surrounding each user.

Using a recursive fractal design, natural images are displayed on the main screen. At the smallest recursive level, each main screen image is controlled by an individual user’s smartphone input. As a user moves their device, their corresponding image moves on the main screen, matching their movement, and causing a chain reaction of movement within the fractal design, which shifts and “breathes”.

Additionally, the color of each image on the main screen reflects the main color “seen” by each smartphone camera. As a user moves their device, and the camera captures

Figure 4. Interacting with “Be the Wind.” Users tap on smartphone to generate a specific wind-chime pitch, utilizing binaural recordings of a high-quality wind chime tuned in C minor (*left*). Images chosen from a set of restorative, natural images are displayed on both the smartphone and shared experience (*right*).

different colors, the corresponding image on the main screen changes to match that color. This change is then propagated in real-time to all higher-level images, thus reflecting the colors captured from each camera in the audience, and creating a fractal collage that is an ever-changing representation of this communal experience.

In terms of sound, the piece utilizes live instruments, including a piano, a theorbo, a cello, and a bassoon. These instruments are performing improvised musical material from a series of harmonies emanating from 371 Bach chorales (based on earlier work presented in [24]). The participants’ smartphones utilize elements of the sounds generated from these live instruments (recorded earlier), distributing them in real-time throughout the performance space.

The piece is controlled using several density functions similar to the one used in Xenakis’ “Concret PH”, utilizing excerpts of recordings from the live instruments. Together, the sounds create a cloud structure that navigates the harmonic progression of the piece. Live instrument performers and smartphone participants come together through interaction, movement, and deep listening. The piece lasts approximately 12 minutes. It will be premiered at the Music Library of Greece in May 2022. A recording will be available at <http://manaris.org/research>.

Conclusion

During at least the last decade, artists and musicians have begun experimenting with various online delivery mechanisms and smartphone technologies. At the same time, computer game designers have engaged fully with such media, resulting in numerous, highly popular / successful online games and game platforms, such as World of Warcraft (WoW), Minecraft, Fortnite, and many others. Such experiences have allowed people from across the globe to come together and experience joint game play.

We propose that similar experiences may be created with appropriate musical or artistic goals, as the technology is

readily available to support this. This involves a multi-speaker, smartphone-based environment, which supports the development of interactive, distributed music and art applications, installations, and experiences. This approach allows audience members to become themselves performers, simply by entering a URL into a browser, or scanning a QR code. The goal herein has been to report on how such a platform can support the design and deployment of evocative artistic experiences combining sound, visual art, meaningful and accessible user interfaces.

This is especially important now, given the complicated nature of designing artistic and music compositions and live performances during a global pandemic (with country-wide lockdowns in various nations or cities, and the canceling of medium- to large-crowd events, including exhibits and performances in museums, theatres, and music halls / auditoria, at the time of this writing). While this has seriously affected traditional music composition and art installations and performances, we hope that the work presented herein (as well as approaches similar to it), will provide a viable, innovative alternative, in terms of economies of scale, and delivery platforms / physical spaces, to deliver artistic and musical content well into the 21st century.

Acknowledgements

This work has been partially funded by the US National Science Foundation and the US National Endowment for the Arts (CUE-1935143 and CNS-2139786). Nick Moore has provided significant assistance in various ways, including testing of the experiences reported herein.

Transforming Practices: a practice-based research approach to teaching emerging media at undergraduate level

Dr Christopher Fry and Dr Julie Marsh

Westminster School of Arts, University of Westminster

London, UK

C.Fry@westminster.ac.uk, J.Marsh@westminster.ac.uk

Abstract

This paper suggests how a ‘research-oriented’ and ‘research-based’ approach can help undergraduate students engage creatively with new and emerging media technologies, as well as creating a critical and less disciplinary focused approach. It also proposes a way in which arts practice, and specifically practice-led research, can inform pedagogy, improving satisfaction for tutors and students alike.

The authors reflect on their experience of modifying the module ‘Media Frontiers’ on a media arts undergraduate degree programme, presented as a case study. It sets out how the changes made transformed students’ means of engaging with emerging media technologies and developing new artistic insights.

Keywords

Research-orientated, research-based, undergraduate, learning, teaching, media practice, research environment, emerging media, media technologies, new media

Introduction

This paper suggests how a ‘research-oriented’ and ‘research-based’ approach can help undergraduate students engage creatively with new and emerging media technologies. This approach emerged as a result of changes made to address specific issues on an undergraduate module. However, the solution, which drew on the authors’ experience as practice-based researchers, could be of use to wider interdisciplinary arts teaching. In particular, it could be a way of arming media graduates with key skills needed for an increasingly interdisciplinary media landscape that requires critical approaches to developing new ways of working.

The module ‘Media Frontiers’ aims to engage students with emerging technologies, asking them to explore and experiment with their potential for expanding arts practice. However, students were seemingly reluctant to take the necessary risks and to adopt an experimental approach that this requires. Rather than a body of work, they were often overly focused on a single final finished outcome. This limited the scope for engaging with the possibilities for new technologies, and often led to conservative or conventional outcomes. Alternatively, responses would simply consist of technical tests or demonstrations that didn’t address the creative possibilities of the chosen media technologies.

While being experts in the use of current media technologies, when confronted with the challenge of creating new ways of making, they lacked confidence and strategies. To address this, the authors drew on their experience of practice-led research, using this as a way of changing students’ approach to and engagement with new technologies. The structure offered by a research-led approach freed students from their preconceptions not only of what the module required but also their relationship with media practices and technologies.

This involved adopting a ‘research-oriented’ and also ‘research-based’ approach to the module where emphasis was placed on process work rather than a final outcome [1,2]. Students were asked to develop their own research questions and adopt an exploratory approach to creative practice, in order to challenge their preconceptions and prior experiences. It also promoted a learning environment rewarding for both students and tutors.

Previous versions of the module had been structured around different media disciplines reflecting a model of undergraduate teaching that is based around providing subject or discipline specific skills. However, as a course whose specialism is interdisciplinarity, a research-oriented approach, with its emphasis on process and knowledge creation [3], is more appropriate. It may also be a better way of providing students with the skills needed for the contemporary media landscape.

Many studies have looked to link the *quality* of research and the *quality* of teaching – often concluding that the link is difficult to prove conclusively [4, 5]. In this reflection we will be focusing on the impact of research on students’ learning and attitude to practice, as well as staff motivation and enjoyment of teaching. We will summarise the key benefits reported by students and staff as well as reflecting on the suitability of this approach in the context of the current media arts landscape.

Background

The BA(Hons) Contemporary Media Practice is an interdisciplinary media arts course in the Westminster School of Arts, University of Westminster. Students produce work in and across a range of media areas including still and moving image, installation, sound arts, interactive and emerging media. It also offers opportunities to work with disciplines

outside the arts through cross-university modules. These allow for collaboration with students from across the University and in particular courses from the Science, Architecture and Computer Science schools. As a specialist interdisciplinary media arts course, it looks to draw on contemporary practice and research to inform and update its curriculum. The course is also very well placed to draw on and make links between research and teaching because of its close links to the CREAM research centre at the University of Westminster. The majority of the course teaching team are actively engaged in practice-based research, including the authors. Being practice-based researchers in the field of interdisciplinary arts informed how we looked to make connections between teaching and research.

In the second year of this three-year degree programme, students undertake the practice module 'Media Frontiers'. This module asks them to identify and explore emerging media practices, producing and documenting practical experimentation with different techniques and technologies. Students have in the past worked with augmented reality, virtual reality, code art, tangible and physical computing as well as experimental approaches to photography and moving image. In previous runs of the module, students struggled with the exploratory nature of the module and were unsure about how to approach the project. They particularly struggled to see how different pieces of work and experiments might build on each other and might be something other than individual, technical tests. They were final outcome oriented and often unwilling to take risks, concerned about 'failing', in their eyes, to produce a successful 'finished' result. Rather than working across media as the brief asked them to, they would often be conservative in their approach and use of existing media practices. This was at odds with the aims and learning objectives for the module which emphasise experimentation. Discussions with other members of the teaching team and external examiners identified a mismatch between the stated aims of the module and what students were producing. This set in motion the development of the changes described here.

The solution to the issues we had identified lay in shifting the students' understanding from 'research as knowledge accumulation' to 'research as knowledge creation' [6], and also, from practice as the demonstration of knowledge to practice as a means of generating knowledge. This shift was achieved by creating greater links between practice and research, and in particular drawing on the tutors' own research practice.

Challenges presented by the ubiquity of digital media

It has been well and widely noted that the media landscape has changed from an era of media audiences as consumers to audiences as producers; a landscape described variously as 'convergence', 'participatory' or 'networked' culture [7, 8]. As Jenkins and others have argued, in such a 'participatory culture' the forefront of media practice is likely to

emerge as much from "bottom-up by decisions made in teenagers' bedrooms" as it does from industry [9]. Increasingly, undergraduate students find themselves at the forefront of media developments. And yet the very ubiquity of media and media production means that students may not be best placed to gain a critical perspective.

In this light it could be that at least some of the issues we initially identified were caused by a lack of critical distance that we had not previously anticipated. Our experiences of teaching 'Media Frontiers' has shown that, while undoubtedly expert users of media systems, they can struggle to locate or understand them in their wider context. This becomes especially noticeable when they are asked to develop new ways of working with media. It is as though they are constrained by a perception of their role as a 'producer of content'. This seems to be at odds with the way we typically think about participatory culture which tends to emphasise empowerment. The ubiquity of digital media may be contributing to its obfuscation. Digital media, as Berry notes in relation to computation itself, "is increasingly not seen, obscured or ignored by virtue of its everydayness." [10].

What this, and our experiences of teaching 'Media Frontiers' would suggest, is that we may require new ways of learning about media practice. In this context our approach, which places emphasis on critiquing practice through an engagement with a process of questioning, draws on the 'Digital Humanities' [11]. The Digital Humanities are, Berry argues, uniquely positioned to contribute to "pedagogies to teach computational technologies, allowing students to see the computation in our culture." [12]. Just as particular tools and critical perspective may be needed to 'see' and understand computation, so the ubiquity of contemporary media may require a similar set of critical skills. A research-oriented and based approach to teaching media practice, which promotes a questioning of practices and a testing of processes, may be one way of providing these skills.

The arguments for connecting research and teaching

A connection between research and teaching is often assumed or claimed, although exactly how can be difficult to establish [13]. The benefits of research for teaching are elusive – a meta-analysis of 58 articles by Hattie and Marsh suggested that there is no correlation between quality of teaching and research, describing the relationship as "an enduring myth" [14]. One study from 1993 even concluded that it can have a negative impact, and that "a college whose faculty is research-orientated increases student dissatisfaction" [15]. More important for this discussion than trying to prove a connection between teaching and research is the possibility that linking them can be beneficial for staff motivation and satisfaction. As Brown has noted, while linking your research to teaching may not be necessary in order to be a 'good' teacher, it can bring significant benefits, not least unifying the dual roles of researcher and teacher [16].

Regardless of any measurable connection between research and teaching, improvements in staff satisfaction and motivation are well documented [17].

At an institutional level, research-informed approaches to undergraduate and postgraduate study are widely seen as highly important. A survey by Jenkins [18] notes numerous reports and government papers stating the importance of the relationship between teaching and research. However, the ways and extent to which they are connected remains variable across different disciplines [19] and levels of study [20, 21]. It can also be linked to institutional priorities and public profile. A Russell Group report in 2014 stated that research-intensive environments bringing together research and teaching offer significant benefits and can help take students' "thinking to a new level and develop skills they need for a wide range of careers" [22]. This would imply that research informed teaching can provide graduates with a competitive advantage, and one that Russell Group institutions feel they are well placed to provide. We would like to challenge any tacit assumption that only self-identifying 'research-intensive' institutions should promote the benefits of research for their students. Also, rather than an add on or 'added value' that extends teaching, we propose that it can be a key part of developing students' approaches to learning and particularly at undergraduate level.

It can be assumed that research informed teaching is more appropriate for post-graduate teaching, the 'academic maturity' of students seen as a key factor in their ability to benefit from research informed teaching [23]. However, rather than being a prerequisite for research informed approaches, these may be able to develop students' 'academic maturity'. This involves focusing on how introducing research processes can change approaches to learning rather than their participation in research projects. At undergraduate level, the goal can be seen as generating inquiry which reveals something new to the learner rather than the 'original contribution' expected of post-graduate research [24].

Arts subjects are well placed to adopt research informed approaches to teaching owing to their focus on process-based work. Healey notes that inquiry led disciplines can more easily make connections to research than some sciences. The argument is that so called 'hard' disciplines tend to focus on acquiring uncontested knowledge, where 'soft' disciplines are more likely to be "constructive and interpretive" [25]. Winters argues that the approaches to incorporating research that focus on process are of most value to art and design pedagogy. Furthermore, arming students with research processes and approaches may be particularly useful for those entering interdisciplinary contexts and working across disciplines [26].

It is important to recognise that links between research and teaching exist across all universities, including those documented by Healey [27], and we make no claim to being the first or best example. But we would note that the links between research and teaching are not as common or as visible as they might be, and this is an opportunity to highlight the importance and to argue for its continued support.

Research-based and research-oriented approaches

Part of the reason that links between teaching and research are not more common could be different understandings of what research-informed teaching looks like and the variety of ways in which the two might be linked. A study at the University of Birmingham concluded that, despite extensive links between teaching and research, this was not widely recognised by students. They also observed that even staff may not have a good understanding of what research-informed teaching actually is [28].

Varying by discipline and teaching context, a range of approaches exist for creating links between teaching and research. These can be broadly mapped and have been described as the research teaching nexus. Healey et al. [29] building on the work of Griffiths [30], identify four models for the 'research-teaching nexus':

- **Research-led** - structured around teaching current subject content - traditional transmission model
- **Research-tutored** - emphasises learning focused on students writing and discussing essays and papers
- **Research-based** - curriculum emphasises students undertaking enquiry-based learning
- **Research-oriented** - curriculum emphasises teaching processes of knowledge construction in the subject

The last two place the greatest emphasis on processes and problem solving. They are also most closely aligned with the exploratory nature of the module and our own backgrounds in practice-based research. They are less concerned with content and more with processes and students' approach to learning.

The change of approach in 'Media Frontiers' can best be seen as a combination of what Healey et al term 'research-oriented' and 'research-based' approaches [31]. Our approach combined a 'research-oriented' approach, "where students learn about research processes" and staff also try to "engender a research ethos through their teaching" [32]. And a 'research-based' approach where students learn as researchers largely through inquiry-based activities. Here practice is the method of inquiry and the insights from making, reflecting and evaluating are fed back directly into the artefact itself.

Changes made to the module and delivery

Several changes were made to the design and delivery of the module in order to introduce research and research processes and also to support a research ethos and culture. This initially came about as an intuitive response to the

difficulties students were having. Our instinct as practice-based researchers was to ask students what they wanted to find out through their experiments which led naturally to asking them if they could express this as a research question. This subtle shift reframed the purpose of the practical work from learning about specific techniques and processes to how these processes might be applied to create new understandings. It encouraged ‘creative play’ as part of cycles of reflection and exploration as a means of discovering new artistic insights, resulting in greater autonomy for students in selecting research interests. The key changes involved:

- Asking students for research questions
- Workshops to introduce students to current staff research and encourage creative play
- Using a dedicated website as a virtual research environment

Research Questions and Exploratory Approach

Students were asked to develop their own research questions and to adopt an exploratory approach to practice, which challenged their preconceptions of what media practice is for and how it might be approached. They were asked to produce a series of pieces, rather than a ‘finished’ final outcome and greater emphasis was placed on the importance of experimentation and risk taking. They were also encouraged to share their process with their peers by documenting their work using a dedicated site which acted as a virtual studio and research environment.

The students were asked to develop and refine their research question/s throughout the project development. These initial questions were used to frame students’ interest and inquiry. The practical experiments in turn created new discovery-oriented questions that help refine the focus of the project. Reflecting on and reformulating the research question became a central point for assessing the appropriateness of the decisions taken. This approach also provided a critical distance for the students to reflect and question the process and outcomes in relation to the research question, as opposed to their ‘idea’. This distance was also used within tutorial support, allowing staff to critique the work in relation to the approaches and processes as opposed to the students’ outcome.

At the start of the module staff were encouraged to present their own research practice and discuss their research questions with students. The variety of staff interests and research processes helped students see the different methods and approaches that can be taken, within a critical framework. Staff were also encouraged to incorporate their own research methodologies into workshop teaching, which provided a way of bridging the gap between research and practice for both staff and students.

Workshops

We implemented a series of workshops to introduce students to current research topics and new technologies, as well as a possible path for them to explore their own field of interest. We invited module staff and visiting lecturers who were

engaged in practice-based research to develop a workshop that explored a particular theme of their research and practice, this included graduates from the course who are currently studying a practice-based PhD. These workshops encouraged experimentation, creative play and creative thinking across disciplines, promoting ‘divergent thinking’ to help students to come up with multiple solutions to open-ended, unscripted problems. Previous workshops had tended to focus on delivering technical skills. While they may have been contextualised through reference to existing practice, they were not as explicitly linked to current research questions.

Virtual Research Environment

An online platform was used as a virtual studio and research environment. Previously each student maintained a separate blog for their documentation and these were usually only seen by tutors. By using the platform, all the blogs were in one place and could be seen and commented on by peers and staff. The aim was to support student-led learning and to continue to foster a research ethos outside of contact teaching. Previously the quality and depth of documentation varied among students which may have been due to it being treated as a record after the fact rather than an important tool for reflection and discovery. By making the documentation more visible we aimed to place greater importance on it and on the processes it documented. Staff could comment on blogs between contact teaching while in tutorials it could be viewed and added to. The transparency and sharing of research were intended to better reflect the expectations for research practice, framed as a tool rather than a requirement for the module.

Findings and Discussion

Evaluation Method

We designed a mixed-methods approach to evaluate the initiative, involving the use of written student feedback and direct observations made by academics delivering the module. Anonymous student feedback was collected in the final week of the module via the Student Module Evaluation Survey. This is a standard course evaluation feedback tool developed by the University of Westminster. The forms include a scoring scale of satisfaction with various elements of the module and teaching staff from 5 - Definitely agree through to 1 - Definitely disagree. It also includes a text box to comment upon the following areas: Teaching and Academic Support, Resource and Learning Environment, Assessment and Overall Satisfaction. Students were also asked to respond to the questions: What did you most like about this module? and What did you least like about this module? We received feedback from 76% of the cohort undertaking the module. In addition to the written feedback, academics delivering the module observed and interacted with the student groups to provide feedback from their professional perspective.

Impact of Changes on Students

Student feedback was positive, particularly in questions relating to intellectual stimulation and receiving helpful feedback. Students reported that 85% agreed that ‘the module is intellectually stimulating’, 96% agreed that ‘staff are good at explaining things’ and 89% agreed that it ‘challenged them to do their best work’.

The qualitative written feedback responses were as follows:

The module was stimulating and pushed me to achieve the best outcomes.

The module took me out of my comfort zone and encouraged me to explore through practical making and experimentation.

However, some students noted that the lack of prescribed direction at the start of the module was hard at first and they would have benefitted from clearer expectations. When asked how the module could be improved the majority of responses stated ‘nothing’ with only one recommendation provided in the text box:

The lack of direction was difficult at the start, could we be shown more examples from previous students work?

In was also noted that students positively valued staff’s enhanced enthusiasm, credibility and currency of knowledge translated through the module. This would seem to support the data of Lindsay et al. [33] in suggesting that student attitudes can be enhanced by interactions with teaching staff that share concerns and enquiry derived from the discipline.

External examiners also noted that ‘Media Frontiers’ has allowed more exploratory and investigative approaches, adding depth to the student work and learning. Rather than producing separate technical tests, students were now producing connected pieces with clearly stated aims. This allowed them to evaluate their own work, according to the terms they had determined rather than looking only to staff for feedback. Things that didn’t work became points of learning and potential for development which reduced the fear of ‘failure’ that students had previously experienced.

There were still a number of students who initially struggled to develop research questions that had creative worth. However, these students were especially helped by being able to see other students’ questions and practice through the virtual learning environment. Students initially had fears about sharing their ‘research’ with others, showing their ‘research as the accumulation of knowledge’ mind-set. Once they understood that their practice was ‘generating knowledge’ and that it was the process that we were interested in, they valued being able to share their process with their peers, particularly in group tutorials. Having a shared environment helped to reinforce the research ethos and the

idea of research as knowledge generation. This was probably the clearest indicator of a shift in their mind-set.

The change in the students’ attitude to learning became apparent especially in group tutorials and critiques. Rather than a clear distinction between the role of student and lecturer, discussions were driven by a shared sense of enquiry. The staff role became far closer to that of more experienced researcher advising students rather than primarily as a source of knowledge. In this way a community of enquiry developed in which staff and students were ‘co-learners’ [34].

Impact of Changes on Staff

The benefits of staff research for student motivation and satisfaction has been noted [35]. However, the sharing of practice can also have a positive impact on tutors [36]. Staff reported an increase in motivation as they were encouraged to explore their own research methods and processes with students and other staff members, unifying the role of teacher and researcher. They were also encouraged to share research concerns and processes with other faculty members, building a sense of solidarity, shared interest and facilitating future collaboration. The module provided an opportunity for staff to reflect on their research and rearticulate it for a different audience, which led to new research outputs.

An unexpected consequence of sharing research was a change in how staff see themselves. The recognition from both students and colleagues provided a sense of worth and confidence in the value of their expertise to the course. However, it is important to note that this may not be appropriate for all academic staff who might not want to share or feed their research into their teaching delivery; it is also important to avoid marginalising staff who are not currently research active.

Conclusion

This paper has set out to show some of the benefits of linking teaching and research in the context of undergraduate media arts practice. A wide range of approaches for combining research and teaching exist, varying across disciplines, and the benefits of such approaches have been widely discussed and debated. However, despite a long history, linking research and teaching appears to remain an exception rather than a norm, particularly at undergraduate level. The approach used in this case study involved sharing staff research with students, introducing them to research processes through workshops and fostering a research ethos, supported by a virtual research environment. Not only did this see student performance and satisfaction improve but an environment was created that was also rewarding for staff. While there are other ways that we might have introduced students to research and research processes, drawing on our own research-based practices had several benefits not least creating a more holistic work experience by combining teaching and research. This allowed both roles to be equally appreciated and valued and saw them as complimentary

rather than separate, something that was not typically experienced before. The research environment fostered by sharing research through the workshops and supported by the virtual learning environment, created a different dynamic between students and staff. Being viewed more as fellow researchers rather than simply as teachers changed the nature of discussions in tutorials and allowed students to take a greater role in guiding and also evaluating their own work. Despite what might be perceived as a lack of ‘academic maturity’ as a cohort of undergraduate students, they responded positively with feedback suggesting, for some, a ‘transformational’ effect on their practice.

While the changes made were initially intended to solve specific issues encountered on a particular module, it became clear that the research skills students were acquiring

have a significant value for their ongoing development as practitioners. The critical and reflective skills, together with an enquiry-based approach to practice, are well suited to a media landscape where the ubiquity of media can prevent a deeper understanding of them. It changed the students from being producers of content within existing media structures to practitioners increasingly capable of critiquing and re-deploying existing media in the pursuit of new practice. This has raised further questions that need addressing about how contemporary media practices might best be taught. In particular, further research is needed to explore whether research-informed approaches to teaching contemporary and interdisciplinary media practice should become the principle means.

Authors Biographies

Christopher Fry is a researcher at the Centre for Research and Education in Art and Media (CREAM), University of Westminster, UK, where he also teaches practice and theory on the BA Contemporary Media Practice. He completed a practice-led PhD in 2008 entitled 'Perceiving Experience: accounting for the role of the audience in the construction of pervasive and locative artworks' at the Wimbledon School of Art. His current research continues to examine relationships with digital and interactive media, employing drawing as a means of bridging between the digital and the analog.

Julie Marsh is a senior lecturer and researcher at CREAM in Westminster School of Arts. Julie is a specialist in interdisciplinary practice, exploring the intersections between film, installation, performance and site-specificity. Her research is engaged with collaborative and knowledge-led approaches to field research, from moving image to emergent technologies. Through the exploration of real and representational space she investigates how technical machines can perform site, creating critical experiences for audiences that open debate and question social spaces. She has exhibited internationally, most recently as part of the *Three British Mosques at Venice Architecture Biennale* (2021).

Making a Manual: The Manual for the Curation and Display of Interactive New Media Art

Rene G. Cepeda

University of Sunderland, UNARTE

Puebla, Mexico

renegecepeda@me.com

Abstract

The Manual for the Curation and Display of Interactive New Media Art is a creative commons living document aimed at assisting curators and exhibition designers, particularly non specialist curators seeking to engage with interactive new media art. This paper will explain the design philosophy of the manual as well as the methodologies employed.

Keywords

New Media Art, Interaction, Curation, Exhibition Design, Methodologies

Introduction

The Manual for the Curation of Interactive New Media Art was the resulting product of a doctoral research program at the University of Sunderland. This project aimed to create a manual for non-specialized curators and designers interested in working with interactive new media art but may lack basic knowledge on the form. In this paper I will explain the rationale behind the design of the manual itself as well as the methodology and methods used in deriving intersubjective data from a variety of practitioners and sources.

Contextual Review

While manuals for art curation are nothing new, manuals for new media are to this day much scarcer. My research has led me to the conclusion that one of the biggest issues with manuals of new media of any kind, is how fast technology moves, making these documents obsolete within a period of three to five years. For example, the *MITES Manual* by Clive Gillman focuses mostly on video and audio art, and features sections on technologies no longer used in contemporary practice. [1]

While recommendations on technologies such as laser discs (a technology by then already obsolete), PAL and NTSC or the suitability of composite vs coaxial cables in

video setups may be useful for objects created before 2002, for contemporary practice lack of recommendations on streaming, HD formats, VR video and live streaming makes the manual insufficient. This very situation repeats itself over and over again as formats come and go. A second cause for this lack of manuals for new media curation, was the relatively small group of academics that engaged with the form until very recently, as well as the ghettoization of the form within institutional spaces. [2]

Curatorial Context

During the survey of curatorial sources several trends became evident. As mentioned above, the limited number of academics cited, with an even smaller circle of authors being most prominent, amongst these we find Christiane Paul, Steve Dietz, Beryl Graham, Sarah Cook, and Jon Ippolito. [3] For this project, the literature was expanded to include other authors not cited as often, journal articles, and blogs of prominent curators, as well as doctoral theses.

While performing the literature review it also became evident that certain recommendations made in the past such as the expectation of privacy while browsing the web have changed due to recent social and technological shifts. [4]

Finally, pre-pandemic, while interest in curation had been steadily increasing, resources beyond scattered efforts such as the Node Centre's *Curating New Media Art: Process, Interaction, Virtuality* and the University of Salford's module on new media curation were limited and often only accessible to those enrolled in such institutions. Since then, interest in new media curation has risen and the manual has been positively received by the community. [5] [6]

Finally, to this day, literature directly engaging with interactive new media is limited, often being subsumed within the larger field of new media art. This means, that for certain aspects of the manual such as practical curatorial and exhibition concerns, sources had to be sought from adjacent fields such as science museums,

commercial exhibition design and the video game industry as these fields have a more open engagement with interactivity than art historical sources.

Research Questions and Aims

With the aim of creating a comprehensive manual for curating and exhibiting interactive new media art, it was necessary to determine what issues the manual would address and how they could be tackled in the form of a manual.

- What are the challenges curators and institutions encounter when working with interactive new media art?
- How can interactive new media art exhibitions be designed and curated to ensure an exhibition is accessible, usable, and fulfils a curatorial purpose while preserving the artistic integrity of artworks?
- How can these concerns be addressed through a best practice manual?

It is also important to emphasize that the manual's scope was purposefully limited to interactive new media art as this specific aspect has been traditionally ignored or engaged with in a problematic manner, from works being displayed in inaccessible or user-unfriendly ways to up to complete deactivation where the work is rendered inert, and its meaning is lost. [7]

Thus, the resulting manual became a repository of knowledge aimed at non-specialists while also being of use to more experienced curators and designers who may require help engaging with certain aspects of new media art.

As the project progressed, it became evident that part of the reason literature was so limited also had to do with memory making of past exhibitions which limited the ways a curator may learn from the experiences of others. Thus, the manual expanded to include recommendations on how to preserve the history of an exhibition in a way that would benefit future researchers, designers and curators.

It is also important to highlight the fact that while the term curation covers a vast amount of knowledge, from acquiring and cataloguing to research to exhibition design amongst other aspects, in this manual it refers specifically to research and exhibition planning, while the exhibition design aspect does expand to cover all relevant aspects of the discipline within the context of interactive new media art exhibitions.

Methodology

The methodology developed for creating the manual was designed in a way that could first, determine if the manual was something the field required, second, find prior examples of manuals in the field and identify gaps in knowledge, third, as acquiring objective knowledge from the creative practices of curators and designers in a variety of institutions is not possible, it was necessary to develop a method to derive knowledge from their experiences.

The resulting methodology utilized interviews, oral stories, and international case studies to identify potential teachings that could be generalized for use in a manual. These were then tested by comparing them to exhibitions in the United Kingdom, United States, and Mexico to determine their validity in real-world applications.

Practice based research

During the research steps of this project, it became apparent that curators in particular are hesitant to share their findings and opinions while speaking on record. [8] Gray and Malins tell us "creative practitioners tend to treat their know-how as either a trade secret or as not important enough to document.", during the course of this research it became evident the later conclusion may be more accurate, although there also exists a feeling that curation is so unique and individual, that no recommendation would ever be suitable, one last factor was speaking on record, meaning interviewees would be hesitant to offer a recommendation or opinion in an official manner. [9]

Curiously enough, often after the interviews happened, during more casual moments such as lunch or during idle chat, practitioners would be much more candid and open to share their thoughts, for this reason, oral histories became a very important aspect of this work.

As was mentioned in the methodology introduction, creative practices are not objective and depend on the context and experiences of both the practitioner as well as the context of the space. A modified version of Gray and Malins' reflective practice methodology was developed in order to create intersubjective learnings that were general enough to be suitable to a variety of contexts. [10] The methodology presented in *Visualizing Research* is meant to be used by artists and other creatives themselves to reflect on their own practice and find if not subjective data to report as research in order to give legitimacy to their claims at least find intersubjective data that may be validated through its constant occurrence in practice over

time. [11] For the manual, I became a form of facilitator in this process of self-reflection and collecting the knowledge generated in this way. This facilitation comes through my own personal experience as a designer, curator and exhibition designer, which gives me the ability to filter out, to a certain degree, faulty assumption and make editorial choices regarding the discoveries made through the research process.

After repeating this process several times with different practitioners, I was able to identify the common threads which by virtue of recurring between different practitioners, were candidates for consideration as intersubjective data that could be applied in wider context. To further validate this information, it was double checked with other practitioners, now as a general question, and through observation in a practical context, i.e., exhibitions and memories of past exhibitions, with the hopes of furthering the validity of the manual's claims. Should one of these recommendations not be supported by practical data, they were rejected, and further analysis was done to identify other intersubjective data that may have led to its recurrence between practitioners. After this third step it could be safely rejected as a persistent malpractice (bad habit) or reinterpreted in a way that was validated in practice.

Literature

The literature used to support this research included established new media texts, such as *Rethinking Curation*, *Digital Art*, and *Aesthetics of Interaction in Digital Art*, as well as blogs and journal articles of experts in the field such as Steve Dietz, Jon Ippolito, Sarah Cook, and Annet Dekker, to name a few. [12][13][14] However, in the specific field of new media there exists a lack of practical recommendations when it comes to installation and the practical consequences of a work being interactive. For this reason, literature research was expanded to include sources in the wider field of museum studies and exhibition design. A few books were of particular use for this very reason, including *Dinosaurs and Dioramas*, *Exhibition Design Second Edition*, and *Exhibition Design*. [15][16][17] These books cover aspects of interactivity that can be easily translated into new media art as long as one keeps in mind the special treatment that artworks deserve over educational kiosks and commercial products. Such considerations include the fact some works cannot be duplicated, or that not all artworks are meant to be easily accessible and that those difficulties may, in fact, be the entire purpose of the work, or the tendency of

cultural institutions to deactivate works in the name of conservation concerns.

Finally, case studies published by curators such as Helen Stuckey's *Play on Display* and Beryl Graham's *Serious Games* were used as was mentioned above as means to verify the findings made in this research. [18][19]

Case Studies

In order to gather more information on curation and exhibition in the real world, two case studies were carried out. The first study was done at the Laboratorio Arte Alameda (LAA) located in Mexico City and is one if not the only space dedicated solely to new media art where the exhibition *Circuito Alameda* (2018) a monographic exhibition of Brazilian artist Gilberto Prado and curated by Argentinian curator Jorge La Ferla was being installed at the time of the study. A second case study took place at FACT (Foundation for Art and Creative Technology) where the exhibition *REAL WORK* (2018) was underway and the initial planning of *you feel me_* (2019) by curator Helen Starr was taking place. These two institutions were chosen because they are focused on new media art and as such their methods have been developed specifically for working with new media art.

An important factor to choosing Laboratorio Arte Alameda was its documentation center, the Centro de Documentación Priamo Lozada (Priamo Lozada Documentation Center) and its existence outside of traditional western institutions which allowed me to witness and document the difference in approach between western institutions and individuals, and non-western ones. FACT on the other hand was chosen due to its international recognition, the existence of a prior relationship with the institution on my part and offers an interesting contrast to LAA with a lack of a dedicated archive for exhibitions.

Output

The main output of this research is the website <http://inmamanual.wordpress.com>, a living creative commons document that can be actively updated to address changes in technologies and remain up to date unlike many of its predecessors that have over time become obsolete. This manual is free of charge to distribute and reproduce, however, modifications have to be submitted to the author for analysis and validation prior to being implemented. The submission process

consists of utilizing the platform's comment feature or through the author's email. Any contributions will be properly credited and if approved, integrated into the manual. The decision to make the manual a creative commons document was done in order to allow wider distribution and accessibility, again offsetting the limitations of printed manuals and facilitate its use in education settings as well as cultural institutions without the traditional fair use limits imposed on sharing books and documents within an educational setting (e.g., may only reproduce one chapter or 10% of a work for lectures and lessons).

The manual itself is divided into three sections: Curation, Exhibition Design and Memory Making, each section is further divided into subsections. This was meant to facilitate reading of the manual in a modular manner, liberating the reader from the necessity of reading the entire manual sequentially. In fact, this modularity is meant to allow referencing only the sections the reader requires without depending on prior sections for context.

Curation

Curation begins this process by providing context for what is meant as interactive new media art and later heading into crucial concepts that make Interactive New Media Art different from other art media. These include Steve Dietz' three behaviors that characterize new media art [20] and expand on them to better explain the behaviors to non-experts. I also expand on Dietz' and Manovich's definition of interactivity as a means to taxonomize interaction on a scale that ranges from no human centered interactivity to full interaction. [21] The manual also expands on Christiane Paul's Neomateriality to recognize the physical forces that code can exert in the physical world as well as the physicality of certain artworks and thus counter claims that all new media art is either ethereal or abstract with no space requirements. [22] Derived from this, the subsection labelled 2.2.5 Location, also expands on definitions of site specificity expanding it to include virtual sites as locations that due to context or infrastructure make certain works virtual-site-specific. Such sites include video game worlds, social media platforms and remote servers without which works would be deactivated. Other issues such as shared ownership between multiple stakeholders and the audience are also covered in the manual as well as the challenges of conservation of works meant to be played with and how to separate interface from the artwork with the intention of facilitating the presentation of interactive

works and circumvent conservation issues. Other basic concerns covered include time in artworks that may go on forever, require long interaction times, works that depend on time zones distinct to their current location to function and works who may become activated outside of opening hours, all this with the intention of facilitating the planning stages. Finally, the midsection of the curation chapter addresses two more aspects of new media art that affect the upcoming planning stages. Instability refers to new media art's instability which translates in works changing and multiplying either through variations to fit new venues or spaces or teams changing and by undergoing significant alterations in the way of versions. [23] The other aspect covered is reproducibility, specifically the potential for certain artworks to be multiplied or duplicated for ease of access and enhanced interactivity particularly in networked works.

Once the particular aspects of new media were discussed the manual moves on to address labelling, this section is of particular note as it was developed in conjunction with Jon Ippolito and combines his research in *Death by Wall* Label and my own conclusions derived from case studies and interviews. [24] The resulting hybrid (digital/analog) system allows accrediting an expanded group of stakeholders in the work including designers, programmers, musicians and any other individual involved in a work. It also recognizes both the work and its parts as well as the specific form they take within an exhibition and generating a genealogy of the work and its versions and variations. All this data turns the label from a simple document into a full-fledged asset for documentation.

Marketing and tone are also discussed and presents alternatives to technological fetishism, how to engage with new media art beyond the novelty and the importance of being open with new media artists injecting their work into the branding and image of an institution and how to negotiate such interactions in order to both retain institutional integrity while allowing the art to retain its poetics.

The final section of the curation chapter is dedicated to the practical matters of planning, from determining bookings, interaction with complex pieces, resolving issues of compatibility and considering porting certain works that may no longer be compatible with current technology usability and concludes with a suggested workflow that may be adapted and modified to suit any institutional methodologies.

Exhibition Design

This section, the largest of the three, deals with issues of exhibition design starting with the importance of collaboration between curatorial and design teams and with other departments as well. This is important for new media art as its interdisciplinary nature guarantees that different teams in an institution will have experience and knowledge curatorial teams alone may not have, thus ensuring a richer experience for the audience. This knowledge may be practical or theoretical such as understanding the limitations of certain computer systems or identifying aspects of the artwork that may be missed by someone not trained in a certain discipline such as software development, to cite one example. The manual then rescues conversations started in the curation section such as time and space but from the perspective of exhibition design and how such concepts limit and expand creative possibilities.

The next section deals with more practical matters of installation such as hanging, maintenance during the exhibition, power, light and environment control, and media rights before moving to specific recommendations for distinct types of new media such as net art, livestreaming, VR, Video Games, AI and Robotics amongst others. These recommendations, drawn from the intersubjective data derived from case studies, interviews and direct observation are not meant to be the final word on how to curate and exhibit specific new media art, but rather present methods and suggestions that have been proven to work and which may then be adapted by the reader to their needs. The section ends with a discussion on kiosks, their design, accessibility and their potential not only as displays of the works but facilitators for interaction. It also presents lessons learned from various types of institutions on how to make these kiosks durable and efficient.

Memory

The last section of the manual, Memory, addresses two concerns in memory making. First, preserving exhibition histories through thorough documentation and second, beginning a process of documentation for artworks which can then be extended through an institution's regular channels for documentation and preservation. The manual encourages this process of memory making as during the research phase, it became evident few new media exhibitions are thoroughly documented and those that are, in most cases, photographs of the space and the hanging, floor plans, and literature on the exhibition are all that is

preserved [25]. While this is suitable for more static and traditional exhibitions, in the case of new media art it is necessary to track much more, including modifications done to the works to suit them to a space, preserve evidence of specific variations, such as the work being presented as a VR experience instead of as a web browser 3D space as was the case for Gilberto Prado's *Desertesejo* (2000/2014/2018) a work that could not have been recreated after the original assets were lost if not for the thorough documentation kept from previous exhibitions as well as the artist's own notes. [26]

Following that example, the manual presents a variation of the Variable Media Questionnaire and the Laboratorio Arte Alameda's own analogue documentation method to create a hybrid archive that preserves both digital and analogue memory including design notes, work modifications, stakeholders, hardware utilized, sketches, known issues, exhibition walkthroughs, and public interactions and impressions. [27][28] It should be pointed out that the manual does not expect all suggested steps be taken but rather, that one should make an effort to meet as many of the suggested steps as possible and within budget. The manual also presents a method for documenting artworks themselves, including the artists' intentions for the work, reasoning for modifications, interviews with the artist and other creators involved, other stake holders in the process as well as who can provide technical support on the works, related media that is not a part of the work but related to it, its environment, interactions and other literature related to the work.

Finally, the manual makes recommendations for the actual storage of said data including constant monitoring of digital data, migration to new formats as older formats become obsolete, and the creation of physical copies. The manual then ends with a list of other resources for the preservation of new media that delve into the subject more thoroughly.

Conclusion

The Manual For The Curation And Display Of Interactive New Media art required a thorough survey of current curatorial practice, specifically in the field of interactive new media art, which has historically been underrepresented in literature. This multidisciplinary survey was combined with interviews and oral histories collected and then cross-referenced with two case studies, one conducted at the Laboratorio Arte Alameda in Mexico and the other at FACT in the United Kingdom. This then provided the necessary information that, when combined

with the author's own personal experience, allowed for the creation of a manual that provides the combined knowledge of curators and designers from around the world and through Grey and Malins' methodology is given credibility and intersubjective validity. [29]

Furthermore, the manual also contributes to curatorial knowledge by expanding the taxonomies of space to include virtual-site-specificity, time in relationship to interaction and its effects on curation, reproducibility of artworks for the purpose of display, and memory making methods to preserve exhibitions and artworks for future reference and restoration purposes.

Areas for future research for this manual include expanding the manual to include all forms of new media art, continue research on the subjects covered in the manual, and amend and grow the text as technology changes. This will ensure the document's continued relevance. Finally, the manual can be developed into a series of workshops, publications and lead to consulting relationships with institutions that are interested in implementing the manual either in full or in part.

Ultimately, the manual's purpose is to function as a resource for anyone who is interested in creating exhibitions and in this way increase the reach of interactive new media art in not only the artworld but also the wider public sphere.

Abstract

Image apprehension is a dynamic biological process where our brain receives data and converts it according to previous memories. To experience and understand images, we take simultaneously the role of observers and subjects in action. Our perception is embodied and situated in a world that can be both real and virtual. We receive images all around us and we anticipate movements and project our actions in the world. The role of interaction and plasticity in live-wired and embodied experiences, together with augmented technologies, are shaping and expanding human perception. Anna Unterholzner's and Diana Carvalho's artworks explore invisible and expanded imagery to reflect about arts-based research as knowledge creation, production, and dissemination.

Keywords

Invisible Images, Complexity, Mediated Aesthetics, Expanded Imagery.

Introduction: The Role of Interaction and Plasticity in Live-wired and Embodied Experiences

According to David Eagleman, the delicate structure of the brain reflects the environment, and our overall experience influences almost all brain measurable details, from the molecular scale to global cerebral anatomy. [1] We have the possibility of "feeling our own body's invisible states like

tension, pulsations, and the state of the microbiome, thus elevating unconscious signals to the realm of consciousness". [2] In the same idea of how invisible data turn into visible bits of feelings, emotions, and sensations, Eagleman states that the amount of movement in the world, for example, the stability of the ground, the vision that passes through us when we move our legs, the colouring of lines, none of this is determined by our genetics, our experience calibrates it. Anything we stare at becomes invisible. Good information must be updated; "the system ignores things that do not change". [3] Changing states are difficult to grasp and perception is a fluid dynamic system that artists tend to interpret to grasp world complexity.

Any image that "remains perfectly fixed in a position on the retina will become invisible because our brains care about change and all-important information comes from things in flux". [4] Juan Luis Arsuaga, [5] following Julian Huxley, considers that what characterizes human beings is a double tendency: towards migration (leaving the region where they were born) and towards exogamy (reproduction outside the group in which they were born). Thus, human migrations created great geographical differences between populations and crosses between various genetic lines gave rise to the variety of the Homo Sapiens species that has no possible comparison in the animal kingdom. Specialization reduces the ecological niche, and it is versatility that increases it. Our genes are units which extract information from the environment. Humans develop in line with the environment through their family, social and community

¹ This research was previously presented by invitation at the International Congress Carelessness, Instituto de Estudos Filosóficos, Faculdade de Letras da Universidade de Coimbra, October, 21, 2021.

relationships. Genes are also mechanisms of experience that expand rather than restrict our possibilities.

For Eagleman, the following question arises: “Are there parts of the world that are invisible to us and that should be evident? Successful adaptation makes regular features invisible because the body system predicts and generalizes data from the world and makes it invisible by ignoring it with the purpose of saving energy”. [6] This useful brain magic “maintains the system composed, balanced, and ready to make changes”. [7] To understand brain’s magic and how it contrasts with, for example, artificial neural networks, we must understand real and biological memory. In our brains, different interaction scales work together through innovations. The faster layers pass information to the slower ones. These convey balance and structure faster. Following Eagleman, “the power and resilience of a culture comes not from any one level of the system but from the interaction between them”. [8] According to Arsuaga, today there are four fundamental and invisible forces in physics: gravity, the electromagnetic force, the strong nuclear force, and the weak nuclear force. [5]

The digital revolution has so completely changed every aspect of our lives that it is sometimes hard not to think in metaphors. The plasticity of our biological system tells us that what we learn is represented in terms of what we already know, it interacts with our previous memories. “Each experience is foundational, everything new is understood from the older exchanges, and memory is a function of everything that went before it”. [9] Eagleman suggests that unlike a computer, the ‘instructions’ for piloting the machine are not a file; they are linked to everything that has happened before in your life. Interaction and plasticity are key concepts to understand brain activities. That is, “the brain needs to have different systems with different learning speeds: one for extracting generalities from the environment (slow learning) and another one for episodic memory (fast learning)”. [9] The more we learn new things, the more we can absorb the next fact related to it, and the more we are able to predict possible futures.

There is an intriguing variation in human experience in the eye, mind, and memories relationship that we are just starting to understand. According to Carl Zimmer, scientists are finding new ways to probe two not-so-rare conditions to better understand the links between vision, perception, and memory. [10] These two not so rare conditions were named Aphantasia, or the inability to visualize, a condition also known as image-free thinking², and Hyperphantasia, hyper-vivid mental imagery, a condition that might reveal “how our imaginations shape the world we perceive and make us who we are”. [11]

The so-called “Default Mode Network” (DMN) is worthy of mention within the brain’s neural processes of the inattentive or invisible. The activity within this network dismantles information that is regarded as going beyond whether one gives attention or strong focus/care to a task (when the brain is in a “wakeful” rest) and may include detailed experiences during an active task as well. [12] The network interplays with three main regions of our brains: the medial prefrontal cortex, the posterior cingulate cortex, and the angular gyrus. This means that the network is activated most of the time during tasks such as daydreaming, memories about the past, planning the future, empathising with others or, for instance, thinking about others. [12] Surprisingly, the DMN is highly activated when one has a strongly moving aesthetic experience³ with a visual artwork. [13]

Interestingly, this would mean that the suppression of the activity of the DMN in a focused state is released in the case

or a self-referential process of an external object. [13] Even though the exact role of the DMN within aesthetic experiences is still not clear, the information that it contains about the appeal for artworks suggests that within a strong aesthetic experience, non-perceptual aspects play a role. [13] These findings and interlaced processes highlight the connection between the role of our own experiences in non-attentive states and the self-relevance and self-referential processes of these experiences when being moved intensely by works of art. In turn, Ana Peraica considers that “the truth-claim of post-digital photography is framed by the fact that humans cannot produce objective knowledge, even when using machines. Only machines can be objective, with their non-subjective, nonhuman artificial intelligence”. [14] Embodied experience is, according to Peraica, fundamental to our understanding of the world we are living in. Human beings.

Gouveia [15], in her understanding of digital arts and gaming aesthetics had the same approach when considering live-wired cognitive knowledge as a place of embodied mind and body convergence. Based on Damásio’s integrative mind and body connected approach and Maturana’s and Varela’s biological perspective, [16, 17] where human beings are also environment-dependent, Gouveia [15] highlighted the role of interaction in human experience and cognition. Memories are not stored in a file cabinet. They are rebuilt when triggered by the appropriate associations, suggests Franklin. [18] Bodies “learn without awareness, as do cities, because learning is not just being aware of information, it is also receiving information and knowing where to find it; it relates to our ability to recognize and respond to changing patterns”. [19] Without cell interaction the blueprint of our genetic code would be unnecessary. Hans Jonas considers that only if the concept of “life” includes the interaction between organism and environment can it be said that “life gives rise to the species”. [20] The natural selection of the environment and the organism’s random variations or mutations enhance variability and trigger evolutionary mechanisms.

We can create an interior replica of the outside world, in which objects are represented by images (not necessarily visual), organized into categories such as space and time. We don’t know what is out there besides the internal image we develop from our behaviour combining the possible images coming from our experiences and memories. [5]

How Augmented Technologies Are Shaping and Expanding Human Perception

Technological devices enhance human vision, but they are still far from creating embodied subjective experiences like live-wired human memories. According to Peraica, [14] in line with Eagleman, we deal with two types of spaces, “an absolute space that consists of those parts of space that are experienced by the viewer as well as those part[s] of space that are non-experienced”. [14] Both spaces coexist, but one is given a priori, and the other is apprehended by the human perception in the fly movement of living. As Peraica states “new techniques of image making have been developed which bypass the limitations of a human-based point and angle of view, which relies today not upon the integration of multiple viewpoints but rather their computation.” [21] The drone machine-like aerial bird’s eye view changed the previous paradigm of view translating it into a machine-like or nonhuman apprehension that “cannot discriminate between the objects, people, or things which are being perceived.” [21] Peraica suggests that “[i]n parallel to artistic

² For a better understanding of this condition please see <https://aphantasia.com/> (accessed 27.07.21).

³ Noting that this is not the case with merely pleasing or not pleasing aesthetic experiences.

countersurveillance using actual drones, some artists also map drone positions from land, making visible what is otherwise invisible: the very presence and activity of drones in our societies”. [21] Thus, “[c]ombining images from various times with maps, and merging them algorithmically, it creates a total image which is more fiction than document”. [21] For that reason, the question arises, “what shall we dream when everything shows visible? We’ll dream of being blind”. [21] Mediated types of vision oblige us to think about complex systems and how our reality is interconnected with computational thinking. According to Richard Coyne, digital code creates space as a convenient fiction, a rubric that assimilates all concepts. [22] The concept of space, like the concept of consciousness, which BLIND REVIEW has also tried to demystify or deconstruct through Maturana and Varela, António Damásio, Stan Franklin, among others, is a container that covers a diverse set of phenomena. [22] Consciousness was thought of as intention, knowledge, autonomy, “individual self” and contemplation. Space is furnished by perspective, geometrized, standard rules and sets of coordinates.

The spatiality that information technologies – cyberspace and virtual reality – build is composed of ambiguous and distorted narratives where desire plays an important role. Real time exists and moves inexorably forward, events follow one another, and everything is subject to temporal authority. Unlike reality, in digital narratives time goes back and reconfigures itself, events are organized according to the subject’s actions. Regardless of whether these actions are linear, the subject composes the story from their interpretations and their experiences, and this story can be radically non-linear. The human being should assert itself as existence and desire. A philosophy of life must deal with the organism as its objective form but also with its interpretation in the self-reflection of the human being. Hans Jonas, in harmony with Stan Franklin, introduces the action effort as the founding characteristic of the experience.

James Bridle advocates for a real systemic literacy which somehow rescues our ability to experience, to gain agency through the physical and mental space around us with the purpose to “understand and think our place in the world, and our relation to one another and to machines”. [23] According to Bridle, “[c]omputation replaces conscious thought. We think more and more like the machine, or we do not think at all”. [24] Our obsession to process the world through computation makes it even harder to grasp and turns data into complex hyperobjects denying the bonds of time, place, and individual experience that characterise our inability to think about the challenges of the new dark age. For this artist and researcher, rescuing the Homo Ludens⁴ can be instrumental to avoid “arranging the world from the perspective of the machine” because it “renders it computationally efficient, but makes it completely incomprehensible to humans. And moreover, it accelerates their oppression. The current aesthetic and technological obscurity require, according to Bridle, certain modes of resistance to avoid such powerful invisibility. [25]

Shoshana Zuboff, in the book *The Age of Surveillance Capitalism*, adverts about our knowledge that our lives have unique value, but nevertheless we are treated as invisible and disposable. Today the sense of invisibility is widespread and common and if we want to make our future digital, we should avoid focusing on technologies instead of ideas. [26] Maybe familiar categories are not the best way to label unprecedented phenomena such as surveillance capitalism and we must research recent trends properly to avoid

rendering invisible what is going on without further scrutiny.

The increase of opacity and unpredictability can be transformed by the human ability to understand and interpret complex systems, but currently the cynical perspective⁵ “where everybody knows what’s going on, and nobody can do anything about it” remains. The cynical perspective insists on a kind of blind view where “everything is illuminated, but nothing is seen”. [27] A world of ghosts, zombies, and easy preys of conspiracy theory coexist with “[s]cientific and political knowledge” that “cannot escape the horizon of their own experience any more than embodied ones can, but it doesn’t mean that they are not looking at the same thing and thinking ways to articulate it”. [27] Those who live in grey zones avoiding binary and black and white perspectives can build islands of shared embodied experience.

Complex World Poly Perspectives

The passion for truth obscures the ambiguous relationship between fact and fiction and separates what is not separable. Memories and histories are interconnected instances, and only those who believe in ideological purities can still encourage simplified versions of the world. Ana Peraica criticizes the dualism between place and space, considering that it turns out to be quite limiting when we take into account the recurrent opposition between real and virtual space.

Inspired by Henri Lefebvre’s definition of abstract space and its relation to real space, Peraica “includes the historic, military, urban, and economic narratives within these spaces which in turn can make abstract spaces more complex and thus, at least to a limited extent, more real”.⁶ [28] According to the author, “contemporary media epistemology suggests that we do perceive virtual space as if it is real. And we do not disregard the knowledge that is being transmitted. Rather, we live in both virtual and real space simultaneously. Thus, W.J.T. Mitchell distinguished between the virtual space that is transferred by a medium and the unmediated ‘feeling’ of a place in reality. That is to say space is epistemological while place is phenomenological, space is conceived while place is perceived. Yet, today space that is constructed around place, or digital space, is perceived as being integral to our life experience as well”. [28]

According to Walter Benjamin, “[i]n great historical epochs, with the form of collective existence of humanity, the mode of its sensory perception changes. The way in which man’s sensory perception is organized – the medium in which it occurs – is conditioned not only naturally but also historically”. [29] In this way, the alternative realities fabricated by digital technology enable other regimes of sensory perception, which are continuously activated by machines that allow the disconnection of the “tangible” real. For that reason, some artworks turn the invisible into visible bits and pieces of data enhancing, according to Castro, “this close relationship between the visible and the invisible, between the possible and the virtual (...) that modern technology has facilitated.” [30] In this fashion the work of art is a silent “saying” that projects or makes possibilities happen giving rise to visible deeds. [30]

In space and place perception it seems that we already experience a fusion between the ontological and epistemological dimensions. For earlier proto-scientific

⁴ For a better understanding of this concept please see Huizinga, J., (1955 [1938]), *Homo Ludens*, The Beacon Press, Boston.

⁵ For a better understanding of this idea please see Sloterdijk, P., (2011 [1983]). *Critique of Cynical Reason [Crítica da Razão Cínica]*, Relógio de D’Água Editores, Lisboa.

⁶ Supported by Lefebvre’s distinctions between the conceived and the perceived space, or the merge between the ontological and the epistemological, Peraica considers two life dimensions, namely, the represented and the lived one.

thinkers, adverts Dennett, there is no distinction between the manifest image, a type of everyday life ontology, and the scientific image, or the ontology of science. Both images were connected and intermingled “in a single ancestral world of “what everyone knows” that included all the local fauna and flora and weapons and tools and dwellings and social roles, but also goblins and gods and miasmas and spells that could jinx your life or guarantee your hunting success”. [31] Assemblage and detournement techniques are familiar in artistic subjective environments and movements, where artists merge several strategies to create alternative possible versions of incorporated digital and real lives. Peraica quotes in her book, for example, the 19th century first polyperspective experiments from the Pictorialists, who montaged several photographs together in order to produce complex stories such as simulating the existence of ghosts. [21] Dennett also considers how competence without comprehension is ubiquitous in human life, from human action to animals and bacteria. [32] We tend to overlook it.

It was with Cézanne that, for the first time, the filling of preconceived forms with matter was dealt with consciously. [33] Sensory perception in Cézanne’s time was activated to reproduce, through drawing and painting, images extracted from reality that perception managed to capture. “By being able to impose on the same matter two or three shapes simultaneously, it is possible to show, for example, the same apple from different perspectives. This was taken to the apex by Cubism: it was about showing the preconceived geometric shapes (interlocking), in them, the matter serves exclusively to let the shapes appear”. [33] But what would Cézanne do if mastered the use of animation and digital design technologies? Maybe the same thing he did with his brush and paints – he would be drawing an apple from different perspectives, only on a computer screen.

Western culture promoted, according to the Korean philosopher Byung-Chul Han, an unsustainable split between pleasure and knowledge. Complex systems cannot sustain these simple dichotomies, binaries and grand narratives, and more entertainment and more game play doesn’t automatically mean less aesthetic quality. A rejection of entertainment or play can lead to an atrophy of the aesthetic. [34] In tune with Ana Peraica, Byung-Chul Han and James Bridle, we can consider that we are living in a complex world that cannot be reduced or unified without flows and constant changes and, as Peraica states, we can no longer believe in a given perspective system where “the viewer accepts the position which someone else has created, identifies with it, and accepts its gaze, even if that gaze is misogynistic or racist (...)”. [35] Machines and their ability of logic must not be turned into gods by contemporary surveillance. Human beings provide information about themselves unconditionally in social networks and, in machine gaze, every bit of information count (body height and weight, number of steps walked, home furniture disposition, type of supermarket purchases, among other shares on social networks). Sharing this information rises algorithmic knowledge and power and may defeat subjective thinking.

Peter Sloterdijk adverts how one can describe the course of European history up to the 20th century threshold as a procession of apparently dead imaginaries that dedicated themselves to the life of theory in its different forms. [36] The author criticizes the Platonic duality that condemned the West to an emotional impoverishment of all relations with the world and, as Sloterdijk considers, haunted scientific and philosophical thought to this day. The author suggests that “we look at other richer forms of knowledge that survived, for example, in poetry, in the arts, in language, in myths and other creative activities”. [36] Artistical objects are wild objects⁷ which suggest weird⁸ connections and liaisons, evoke ancestry, and promote intertextuality.

Artistic signs have only meaning because “they do not refer to any real object, they do not have a real referent”. [37] According to the distinction between Semiotic and Symbolic modalities, explained by Julia Kristeva, there are two types of texts: genotext and phenotext. In the genotext we find Semiotic processes but also the advent of the Symbolic, we see the different components and faculties and their dispositions and divisions in the body, as well as the surroundings of the ecological and social system that surrounds it, that is, the pre-edipal objects and relationships with the parents. Although this text can be found in language, the genotext is not linguistic but rather a process that articulates ephemeral structures. The author uses the term phenotext to explain language used to communicate, which is described in terms of competence and performance. The phenotext is always divided and separated and is not reduced to the Semiotic process that works in the genotext. It is a structure that can, for example, be generated “in the sense of a grammar that obeys communication rules and presupposes a subject of enunciation”. [38] Certainly, inspired by theories of genetics Julia Kristeva claims that the human body is also a process. The dismembered body is no longer able to regroup, set itself in motion, or function biologically and physiologically unless it is included in a practice that incorporates the process of meaning. Without this practice, the body as a process is disjointed. On the one hand, outside of the process, identity is inorganic, paralyzed, dead. On the other hand, within the process, when confronted with borders and laws, “the subject in process discovers them and makes them present through its practice”. [38]

For Kristeva by identifying knowledge with nature or nature with knowledge, metaphysics avoids thinking of the subject as a producer of the symbolic function. Concrete operations involve a practical relationship with objects, their destruction, organization, etc. This connection with the environment is also knowledge modifies the apprehended object with evident results and transformations. These concrete operations of the body in the environment include sensory and motor actions that are not based on imitations but rather on operations per se. The denial of this unity that places the object as exterior/separated from the body transforms the body into absence, sign. The subject is apprehended as not having a real reference, as if she/he were disembodied. [38] We can consider that this aspect of bodily performance, as an integral part of a system between subject and world, not only inherits Merleau-Ponty’s ideas⁹, but also

⁷ Please see AA.VV. (2012), *Objectos Selvagens*. Ed: Godofredo Pereira, Guimarães 2012, Edições Imprensa Nacional Casa da Moeda.

⁸ In her presentation and dialogue with the artist Tomás Saraceno, Vinciane Despret refers to artistic knowledge dissemination and production as the ability to establish weird connections. Please see

Festival Hors Pistes 16e édition, en intégralité en ligne du 1er février au 14 février 2021 about Images ecologies [L’écologie des images] available here: <https://www.centrepompidou.fr/fr/horspistes2021>

⁹ For a better understanding of this idea please see Merleau-Ponty, M., (1945), *Phénoménologie de la Perception*, Éditions Gallimard, Paris.

integrates biology and bodily materiality through phenomenology in the study of the process of meaning. A disembodied perspective is a convenient fiction to turn the body into a sign, an external entity becomes a symbol with no flesh and body fluids.

Arts do not show consistency through their uniformity but rather through a creative life invested with change, movement, flexibility, and dexterity. Only a harmonious relationship between ancestral life and knowledge enables innovation and empowerment. [39] According to Maturana and Varela, "(...) we don't see the "space" of the world, we live in our visual field; we don't see the "colours" of the world, we live in our chromatic space. (...) as we come to know this world, we will always discover that we cannot separate our history from actions – biological and social – from which it appears to us" [40] and "(...) Bringing up a world is the throbbing dimension of knowledge and is associated with the deepest roots of our cognitive being, no matter how solid our experience. (...) There is no discontinuity between the social, the human and its biological roots". [40] Artists work in this imaginary space of potentialities, and in our contemporary world, it means to be immersed in databases¹⁰ and computational power. In this mixed environment the separation or the opposition between the real and the digital does not make any sense.

According to Mark Coeckelbergh, there "probably never even was a separate sphere or such an opposition between virtual and real in the first place, and it has never been sensible to make the online/offline distinction, at least if that distinction is supposed to have ontological significance. We have always been 'postdigital' from the beginning of the so-called digital revolution. When we are using the Internet and 'online' media and technologies, "we do not leave our bodies at home" [41], and neither are we separate from others or from the so-called external or offline reality; from a phenomenological and non-dualist point of view, our use of these media and technologies should be understood in terms of living experience that is embodied, social, and real. Platonic and modern dualisms are still very influential, but we can at least try to think in a way that goes beyond a dualist platonic split of the world into real and unreal". [41] When we experience still images, we interact with them in an interpretative manner, we relate to them with previous experiences and memories, with our own full body. When we interact with procedural images, those available in gaming, interactive experiences, and installations, we respond actively to these bits of information. All these processes are dynamic and convey our mind and body. We involve our brain, our senses, emotions, and memories in apprehending the space of possible imaginaries.

Anna Unterholzner's and Diana Carvalho's Artworks

Anna Unterholzner focuses on transdisciplinary art and design territories that merge arts and emotions, neuroaesthetics, gaming, interactive media, and gender equity. Since October 2019 she attends the Ph.D. in Fine Arts at the Multimedia Art department at the Faculty of Fines Arts, Lisbon University, under the supervision of professor Patrícia Gouveia and works experimentally.

¹⁰For an overview of the mixed contemporary artistic environment with databases please see Quintán's master thesis by project: Quintáns, P., (2020), *Entre Imagens e Bases de Dados: Percursos e Poéticas Possíveis*. Available here: <https://repositorio.ul.pt/handle/10451/45898> (accessed 15.07.21)

¹¹ Merleau-Ponty, M., (1962 [1945]), *Phénoménologie de la Perception*, Editions Gallimard, Paris. Available here: <https://archive.org/details/merleaupontyphenomenologyofperception/page/n255/mode/2up> (accessed 25.07.21).

In an ongoing project that reflects about the interplay of colour perception and emotional development in different stages of life and body, small textile works were created by Unterholzner. The ongoing project started by depicting the feeling of pleasure and dis-pleasure of a baby by stitches of the body's silhouette on silk textile and silk paint. A next version shows coloured and painted rougher fabric of four emotional states (fear, anger, happiness, and sadness) in early childhood. The project will go on by the use of other materials reflecting about the understanding of our perception, body, and emotions, or as Merleau-Ponty said in his *Phenomenology of Perception*, "my body as field is the fabric into which all objects are woven, and it is, at least in relation to the perceived world, the general instrument of my comprehension".¹¹ [42]

Another project in process of Unterholzner displays microscopic photographs and short movies of fruit. This project engages in a reflection of two of our senses, namely smell (olfaction) and taste (gustation). These creations attempt to explore the changes of the interiority and exteriority of food and the contact with them. The general topic of this project is our abilities of taste and smell and the question about how to look at something in a scientific way or in an aesthetic way. Linked to this project we can name Felice Frankel¹², who connects science, photography, education and design, and the author Jorge Luis Borges, who once stated that "the taste of an apple (states Berkeley) lies in the contact of the fruit with a palate, not in the fruit itself: in a similar way (we would say) poetry lies in the meeting of the poem and the reader, not in the lines of symbols printed on the pages of a book. What is essential is the aesthetic act, the thrill, the almost physical emotion that comes with reading."¹³ [43]

A further experimental reflection of Anna Unterholzner is one on flowing energy through the body while experiencing an emotion created by paintings and augmented reality. The small postcard-size paintings consist of different colour compositions made by acrylic and resin pouring technique. The spectator can perceive the paintings with the mere eye or through the lens of a camera of a digital device. When doing the latter, the painting will re-liquify again and move in various ways, reflecting about our fluids moving physically through the body while being moved psychologically and on the meantime about the perception of a static painting and a moving image.

Diana Carvalho works in transmedia art practices that reflect the use of analogue and digital technologies in contemporary art with a focus on photography and mix media installations and environments. Since October 2019 she attends the Ph.D. in Fine Arts at the Multimedia Art Department at the Faculty of Fine Arts, University of Lisbon, under the supervision of professor Patrícia Gouveia. Diana Carvalho attended the residency *Paralaxe*¹⁴ (2020-21) and presented the developed work¹⁵ under this residency in the exhibition named *Whether the Weather* (2021). Diana Carvalho's work explores the exterior space from an interior one challenging the observation point of view through images. Throughout her artistic practice, Carvalho has been exploring issues related to the nature of the image as a way of communicating or showing that which is not present, mainly through media such as photography and drawing, crossing analogue and digital processes, and as means to understand how research processes may be developed through artistic practice.

The work developed in this residency started off by the observation of the University of Porto (IGUP) placed in Vila Nova de Gaia. This was done with the aim to integrate processes of contemporary artistic practice by making use of this specific scientific research place, including its geography, as an object of visual study. Due to the geographical conditions presented by the terrain, a question arose: why would someone climb to the top of a

¹⁴According to the event website: "The term parallax comes from the Greek parallaxis which means change. Frequently used in the scientific context, it refers to the apparent difference in the location of an object from different points of observation. A word that denounces the failure in the rigor of self-centered and watertight perception and that, therefore, establishes itself as a metric system

through the triangulation, crossing and analysis of the same thing from different points of view" (2021). More information available here: <https://www.paralaxe.space/>

hill? Perhaps to have a certain distance, as Goethe points out in “Italian Journey” [44], or to experience what André Malraux’s posits in his Imaginary Museum,¹⁶ as a suggestion on how to look at the landscape and the amount of images that are made possible through the IGUP’s observation point. From this, the work developed over the course of three months emerged as a kind of visual map built from collected images, that was initially created from a general point of view but later a particular one, linked to Diana Carvalho’s personal experience of the place. The landscape itself was perceived as being a constructed image [45], one of an illusory nature, an ordering of the visible through our cultural references, leaving aside the conception of landscape as an equivalent of nature and as a poetic representation of the world.

From this reflection, it was asserted that the set of images collected during the first part of the residency could be defined by the following ideas: wind / geometries / landscape overlays / meteorological observatory / background sounds / architectural elements scales / aimless perspectives / garden paths that go nowhere. After selected and analyzed, the collected images gave rise to three sets of categories, defined by their content: i., views comprised of the garden’s meteorological measuring devices; ii., objects or fragments not resulting from the IGUP’s scientific research; and iii., the point of view from an inside space over an exterior one, through the frame of a window. The final part of the residency work, which is hereby presented, was built reflecting the possibilities of the studio-based research practice, in the relationship between image and territory, which has become inseparable from the project.

Conclusion

Supported by the assumption that there is a merge between the conceived and the perceived in analogue and digital spaces. An inseparable connection between an ontological and epistemological dimension or perspective, we can consider that image apprehension is a dynamic biological process where our brain receives data and converts it according to previous world experiences and memories.

Anna Unterholzner’s and Diana Carvalho’s artworks, in their explorations and research about invisible and expanded imagery, reflect about arts-based research as knowledge creation, production and dissemination pointing to the phenomenological integration between conceived space mind maps and the perceived place of reality. In that fashion, we can consider that the merge between the ontological and the epistemological life dimensions, namely the possibility of identifying simultaneously knowledge with nature and nature with knowledge, as Kristeva once proposed, is the only way to think about the subject as a creator and producer of the symbolic function and of meaningful artistic proposals.

We echo Benjamin Bratton’s words: “[i]f Philosophy and the Humanities are to claim due legitimacy for present and future challenges, the collective conception of another positive biopolitics –based in the reality of our shared technical and biological circumstances–is absolutely essential”. [46] Humans will survive only if they use resources with rationality, inclusion, and care, transforming the present into a possible sustainable future. Arts, aesthetics, and philosophy can be the territory to articulate possibilities for that possible future.

Author(s) Biography(ies)

Anna Unterholzner attends the Ph.D. in Fine Arts (Multimedia Art Department) at the Fine Arts Faculty at Lisbon University, Portugal. She completed her Master's degree in Modern and Contemporary European Philosophy in 2019 at the Luxembourg University and received her Bachelor's degree in Economics and Social Sciences in 2016 at the Vienna University of Economics and Business, Austria. She is currently a research collaborator at Interactive Technologies Institute ITI/LARsyS, Laboratory for Robotics and Engineering Systems, IST. Anna Unterholzner's research focuses on transdisciplinary art and design territories that merge arts and emotions, neuroaesthetics, gaming, interactive media, and gender equity.

Diana Carvalho (Lisbon, 1986), lives and works in Lisbon. She holds a degree in Painting (2009) and a Master in Contemporary Artistic Practices (2012) from the Faculty of Fine Arts of the University of Porto, Portugal, and she is currently a PhD student in Fine Arts (Multimedia Art Department) at the Faculty of Fine Arts of the University of Lisbon, with a studentship funded by FCT – Portuguese national funding agency for science, research and technology. Currently she is a researcher collaborator at ITI/LARsyS research center. Her work has been shown since 2009 in solo and group exhibitions. In 2012 she was awarded the prize BES Revelation (8th edition). In 2020 she held the art residency Paralaxe in Porto and has been participated in other art residencies in Clermont-Ferrand, Budapest, Porto and Lisbon from 2017 onwards.

Luciana Lima has a PhD in Psychology from the Faculty of Psychology and Educational Sciences of the University of Porto. Luciana Lima is currently doing post-doctoral studies at the Multimedia Department at the Faculty of Fine Arts of the University of Lisbon with a scholarship from ARDITI, ITI – Interactive Technologies Institute / LARSyS, Laboratory for Robotics and Engineering Systems, IST. She is an effective member of the Portuguese Psychologists Association and her current research interests focus on the intersection between gender, digital games, and gaming culture. Luciana Lima research focus the hegemony of games as interactive and artistic media and their social impacts, with an emphasis on gender equality. Author's institutional e-mail: luciana-lima@edu.ulisboa.pt * Author's personal email: lufacime@hotmail.com

Patrícia Gouveia is Associate Professor at Lisbon University Fine Arts Faculty [Faculdade de Belas-Artes da Universidade de Lisboa]. Integrated member of ITI – Interactive Technologies Institute / LARSyS, Laboratory for Robotics and Engineering Systems, IST. Co-curator of the Playmode exhibition (Brazil: CCBB Belo Horizonte, CCBB Rio de Janeiro, CCBB São Paulo and CCBB Brasília 2019_2023) and Portugal: (MAAT Lisbon 2016-2019). Works in Transmedia Arts and Design since the nineties. Her research focus on playable media, gaming, interactive fiction and digital arts as a place of convergence between cinema, music, games, arts and design. The Cabinet of Wolfgang von Kempelen: AI Art and Creative Agency

Dejan Grba

Artist, researcher, and scholar
Belgrade, Serbia
dejangrba@gmail.com

Abstract

The aim of this paper is to expand the existing critical discourse of AI art with new perspectives which can be used to examine the creative attributes of emerging practices and to assess their cultural significance and sociopolitical impact. It discusses AI art projects that explore creative agency and associated topics such as authorship, authenticity, intellectual property, and labor. The focus is on works that exemplify poetic complexity and manifest the epistemic or political ambiguities indicative of AI science, technology, and business. By comparing, acknowledging, and contextualizing their accomplishments and shortcomings, the paper outlines the possible directions to advance the field.

Keywords

AI Art, Anthropomorphism, Artificial Intelligence, Authorship, Creative Agency, Creativity, Machine Learning.

Introduction

From a small community of computer artists who experimented with artificial intelligence (AI) in the 1970s, AI art has expanded, gained visibility, and attained cultural relevance since the second half of the 2010s. Contemporary AI art includes practices based on diverse creative approaches to, and various degrees of technical involvement with, the increasingly affordable machine learning (ML) architectures such as Deep Learning (DL). Its topics, methodologies, presentational formats, and implications are closely related with a range of disciplines engaged in AI research, development, and application. AI art is affected by epistemic uncertainties, conceptual challenges, conflicted paradigms, discursive issues, ethical, and sociopolitical problems in AI science and industry. Similar to other new media art disciplines, AI art has had an ambivalent relationship with the mainstream contemporary artworld (MCA), marked by selective marginalization and occasional exploitation. [1]

Its interdependence with AI infrastructures, technologies, and socio-economic trends, exposes AI art to a critical consideration within a broader cultural context. The existing literature comprises several studies of AI art and implicitly relevant works. For example, Mitchell [2], as well as Marcus and Davis [3], provide a conceptual, technological, and sociocultural critique of AI research. Kearns and Roth [4] and Pasquinelli [5] address the ethical, socio-

political, and cultural consequences of the AI's conceptual and technical issues, and inherent biases. Miller [6] includes AI art in his examination of creativity, and Źylińska [7] opens a discussion of AI's influence on visual arts and culture. Cetinić and She [8] provide an overview of AI research that takes art as a subject matter, outline the practical and theoretical aspects of AI art, and anthologize the related publications. Zeilinger [9] investigates the tactical and posthumanist values of AI art. I address the ambiguities that AI art shares with AI-related creative disciplines [10], the AI art's entanglements and cultural integration [11], and the dynamics of contemporary AI art. [12]

In this paper, I discuss AI art practices that explore the notions of creative agency, authenticity, authorship, intellectual property, and labor. I address the conceptual, expressive, and ethical aspects of these practices, focusing on works that exemplify poetic complexity and manifest the epistemic or political ambiguities indicative of AI science, technology, and business. By tracing these ambiguities I outline the possible directions to tackle the challenges and advance the field. The aim of this paper is to expand the existing critical discourse of AI art with new perspectives for understanding the conceptual and contextual nature of ML as a medium in the age when the arts, together with science and technology, are becoming increasingly responsible for changing ecologies, shaping cultural values, and political normalization.¹

Features

The poetic scope of AI art derives from computer art and generative art, and is primarily informed by the various phenomenological aspects of sub-symbolic ML systems. Themes such as creative agency, authorship, originality, and intellectual property are widely attractive to AI artists, popular with the media, and fascinating to the audience. The malleability of these notions was central to modernism and postmodernism, and artists have been addressing them with computational tools since the 1960s, so this recent surge of interest is probably due to a combination of the

¹ The paper's title references *The Cabinet of Dr. Caligari* (1920), a classic German Expressionist film about irrational and cruel machinations of authoritarian systems, and Wolfgang von Kempelen, the 18th century inventor of a fake chess-playing automaton called *Mechanical Turk*, with a human operator hidden in its cabinet stand.

novelty of DL, its processual opacity, and its informational or formal effects. However, artistic exploration of this territory has been challenged by the AI's most pervasive ambiguity—anthropomorphism.

Anthropomorphism manifests in various forms. One is a tendency to assign human cognitive or behavioral features to non-human entities or phenomena, which is often difficult to identify and sometimes has undesired consequences. It is complicated by the corporate AI's crowdsourcing of cheap, invisible, and underrecognized human labor for tasks such as dataset interpretation, classification, or annotation. [13][14] A converse form of anthropomorphic fallacy is to conflate the artists' creative agency with cumulative human creativity embedded in their tools, which simultaneously deprives artists of their own inventiveness, and lifts the responsibility off their creative acts. It often exploits the trope of the ever "blurring line between artist [ghost] and machine" [15], and involves experiments that are supposed to establish "who is the [real] artist" or "what art is better" by manipulating the preferential conditions of human subjects tasked with evaluating human- and machine-produced artefacts. [16][17] Such experiments are largely naïve or manipulative because they presume, and instruct the subjects, that their test material *is* art while omitting two fundamental distinctions: *who* considers whether something is an artwork, and *why*. [18] They disregard that *art is artificial by definition*, and ignore well-informed notions about the complex relationship between creative agency, authorship, and technology. [19][20][21]

The Elusive Artist

Pioneering AI artist Harold Cohen had an ambiguous relationship with machinic creative agency and flirted with anthropomorphic rhetoric about his life-long project *AARON* (1973-2016) which experimented with translating and extrapolating some components of human visual decision-making into a robotic drawing/painting system. [22] Not surprisingly, the most popular contemporary AI art belongs to the saccharine reiterations of Cohen's approach, in which artists "teach" their robots how to paint, such as Pindar Van Arman's *Painting Robots* (2006-) or Joanne Hastie's *Abstractions (Tech Art Paintings)* (2017-). [23][24] These projects "serendipitously" merge technically competent execution with weekend painter's enthusiasm, dilettante aesthetics, conceptual ineptness, and ignorance of art-historical context. The meaning of the word "art" collapses into banal, camera-driven visualizations, rendered and presented with amateurish self-confidence. Anthropomorphism is advocated within the art-academic domain as well, for example by Simon Colton's verbiage about his software project *The Painting Fool* (2012) that "will one day be taken seriously as a creative artist in its own right." It aims to dramatically expand the "artistic range" of Cohen's *AARON* by introducing the interface that could be trained by different human artists to critically appraise its own work, and (in future versions) the work of other artists. [25]

Fewer artists address the subtlety of this topical range. One of them is Adam Basanta. In his installation *All We'd*

Ever Need Is One Another (2018), a custom software randomizes the settings of two mutually facing flatbed scanners so that in every scanning cycle each captures a slightly altered mix of the facing scanner's light and its own unfocused scanning light reflected off the facing scanner. The perceptual hashing algorithms then compare each scan to the images in a large database assembled by scraping images and image metadata from freely accessible online repositories of existing artworks. If the comparison value between the scan and its most similar database image exceeds 83% based on the parameters such as aspect ratio, composition, shape, and color distribution, the software declares a "match", selects the scan for printing, and labels it with the matching image metadata. [26] When it selected and labeled one of the scans as *85.81% match: Amel Chamandy 'Your World Without Paper', 2009*, Canadian artist Amel Chamandy initiated a legal action about the intellectual property rights against Basanta because of the reference to her photograph although Basanta's print is not for sale, and he apparently does not use it for direct commercial gains by any other means. *All We'd Ever Need...* disturbs the concepts of authorship, originality, and intellectual property by legitimately and consistently applying the functional logic of ML, while the intricacies of the lawsuit it triggered exemplify the intellectual and ethical issues of our tendency to crystalize the commercial rights of human creativity. [27] It links the notion of "autonomously creative" AI with appropriation strategies but couples its playful production setup with a tangible referencing system. This allows it to go beyond "preaching to the choir" with a satirical or cynical reaffirmation of cultural trends, towards engaging (and provoking) mainstream artists, their agents, collectors, and audience. It effectively critiques the chronic rigidity of intellectual property conventions in general, and particularly the emerging modes of crypto-based art monetization.

Basanta's and other artists' exemplar works such as Nao Tokui's *Imaginary Landscape* and *Imaginary Soundwalk* (both 2018) [28], or Anna Ridler's *Myriad (Tulips)* (2018) and *Mosaic Virus* (2019) [29], approach AI both as a criticizable technology and a sociopolitical complex, and recognize the variable abstraction of technologically entangled authorship. They demonstrate that crucial aesthetic factors such as decision-making, assessment, and selection are human-driven and socially embedded regardless of the level of complexity or counter-intuitiveness of the tools we use for effectuating these factors. They remind us that our notion of art is a dynamic, evolving, bio-influenced, and sociopolitically contextualized relational property which needs continuous cultivation.

Performative Aesthetizations

Performance artists who enjoy corporate AI sponsorship tend to emphasize dubious human-centered notions of creative agency through sleekly anesthetized mutations of earlier avant-garde practices. For example, Sougwen Chung's projects, such as *Drawing Operations Unit: Generation 2* (2017, supported by Bell Labs) [30], draw a

comparison with Roman Verostko’s algorist compositions from the 1980s and 1990s. [31] Whereas Verostko discreetly encapsulates his formal experiments into a relationship between a pen-plotter and its material circumstances, Chung uses the theatricality of her homo-robotic collaboration as a “spiritualizing force” to mystify the manual drawing process—which is by nature highly improvisational and technologically interactive.

Similarly, Huang Yi’s robotic choreography *HUANG YI & KUKA* (2015-, sponsored by KUKA) [32] spectacularizes the metaphors of harmonious human-machine interaction and mediates them safely to the passive spectators, while the referential Stelarc’s performances since 1976, such as *Ping Body* (1996), emphasize the existential angst and uncertainty of shared participatory responsibilities between the artist, the technology, and the audience who all have a certain degree of manipulative influence on each other. [33] Also sponsored by KUKA, Nigel John Stanford’s musical performances, such as *Automatica: Robots vs. Music* (2017) [34], can be viewed as encores of Einstürzende Neubauten’s concerts from the 1980s “spiced up” for tech-savvy cultural amnesiacs. [35] Rehearsed beyond the point of self-refutation, Stanford’s “improvisations” stand in as formally polished but experientially attenuated echoes of Einstürzende’s rugged guilty pleasures in sonic disruption.

With high production values and aesthetics palatable to a contemporary audience, these AI-driven acts largely evade the unfavorable comparisons with their precursors and serve as marketing instruments for their corporate sponsors by promoting vague notions of a robotically-enhanced consumerist lifestyle. Their persuasiveness relies on our innate anthropocentrism, myopic retrospection, and susceptibility to spectacles.

The Uncanny Landscapes

The exploration of anthropomorphism in AI art often involves the uncanny appearance of artificial entities. Uncanniness is the occasional experience of perceiving a familiar object or event as unsettling, eerie, or taboo. It can be triggered in close interaction with AI-driven imitations of human physical or behavioral patterns. [36]

Some artists approach it by extracting human-like meaningfulness from the machinic textual conversation, for example in Jonas Eltes’ *Lost in Computation* (2017) [37] with reference to Ken Feingold’s installations such as *If, Then, What If*, and *Sinking Feeling* (all 2001). [38] In these works, natural language processing systems provide semantically plausible but ultimately senseless continuation of narrative episodes which allude to the flimsiness of the Turing test and serve as (vocalized) metaphors for our lives. They extend the experience of uncanny awkwardness into the absurdity of miscommunication and the overall superficiality of the systems tasked to emulate human exchange.

Ross Goodwin and Oscar Sharp used this type of slippage to disrupt the cinematic stereotypes in their short film *Sun-spring* (2016). Trained with the 1980s and 1990s sci-fi movie screenplays found on the Internet, Goodwin’s ML software generated the screenplay and the directions for Sharp

to produce *Sun-spring*. [39] The film brims with awkward lines and plot inconsistencies but qualified with the top 10 entries of the Sci-Fi London film festival’s 48-Hour Film Challenge. *Sun-spring* reverses the logic of movie search algorithms and playfully mimics contemporary Hollywood’s screenwriting strategies largely based on regurgitating successful themes and narratives from earlier films. [40] By regurgitating *Sun-spring*’s concept and methodology two years later, Alexander Reben produced *Five Dollars Can Save the Planet* (2018), “the world’s first TED talk written by an A.I. and presented by a cyborg.” A YouTube comment by MTiffany fairly deems it “Just as coherent, relevant, and informative as any other TED talk.” [41]

Ironically, projects that combine uncanniness with our apophenic perception in order to “humanize” AI often contribute to diverting attention from pertinent sociopolitical issues. For example, with *JFK Unsilenced: The Greatest Speech Never Made* (commissioned by the Times, 2018), Rothco agency aimed at contemplative uncanniness by exploiting the emotional impact of sound to reference the romanticized image of John F. Kennedy. [42] Based upon the analysis of recorded speeches and interviews, Kennedy’s voice was deepfaked in a delivery of his address planned for the Dallas Trade Mart on 22 November 1963. The voice sounds familiar, but its cadence is uneven, so the uncanniness relies mainly on the *context* of the speech that the young president never had a chance to give. However, even with perfect vocal emulation, this exercise could never come close to matching the eeriness and deeply problematic political context of Kennedy’s televised speech on 22 October 1962 about the Cuban missile crisis in which sheer good luck prevented multilateral confusion, incompetence, ignorance, and insanity of principal human actors from pushing the world into a nuclear disaster. [43]

Visual deepfakes, such as Mario Klingemann’s *Alternative Face* (2017) [44] or Libby Heaney’s *Resurrection (TOTB)* (2019) [45], approach uncanniness by simultaneously emphasizing and betraying the persuasiveness of statistically rendered human-like forms. This strategy was prefigured conceptually and procedurally by Sven König’s *sCrAmBIEd?HaCkZ!* (2006) that used psychoacoustic techniques for continuous real-time audiovisual synthesis from an arbitrary sample pool of stored video material to mimic any sound input. [46] Perhaps this innovative project has been largely forgotten because König pitched it to the VJ scene instead of using it to develop his own artworks that establish meaningful relations between stored videos and input audio. Along with the sophistication of his technique, König’s expressive mismatch may have anticipated some issues of contemporary AI art.

The Mechanical Turkness

The sociopolitical aspects of anthropomorphism can be effectively addressed by artworks that expose human roles and forms of labor behind the “agency” or performative efficacy of corporate AI. For example, Derek Curry and Jennifer Gradecki’s project *Crowd-Sourced Intelligence Agency (CSIA)* (2015-) offers a vivid educational journey

through problems, assumptions, or oversights inherent with ML-powered dataveillance practices. [47] It centers around an online app that partially replicates an Open Source Intelligence (OSINT) system, and allows the visitors to assume the role of data security analysts by monitoring and analyzing their friends' Twitter messages, or by testing the "delicacy" of their own messages before posting them. The app features an automated Bayesian classifier designed by the artists and a crowdsourced classifier trained on a participant-labeled data from over 14,000 tweets, which improves its accuracy by the visitors' feedback on its previous outputs. *CSIA* includes a library of public resources about the analytic and decision-making processes of intelligence agencies: tech manuals, research reports, academic papers, leaked documents, and Freedom of Information Act files. This relational architecture offers an active learning experience enhanced by the transgressive affects of playful "policing" in order to see how the decontextualization of metadata and the inherent ML inaccuracies can distort our judgment. It also serves as a gentle reminder of our complicity in the politically problematic aspects of applied AI through conformity, lack of involvement, or non-action.

Similarly, in RyBN and Marie Lechner's project *Human Computers* (2016-2019), multilayered media archaeology of human labor in computation since the 18th century offers revelatory insights into the use of human beings as components of large computational architectures. [48] It shows that many AI applications have in fact been simulacra, mostly operated by echelons of underpaid workers, which corporate AI euphemistically calls "artificial Artificial Intelligence" (AAI) or "pseudo-AI". This foundational cynicism of corporate AI also indicates that its development imposes an exploitative framework of cybernetic labor management. A sub-project of *Human Computers*, titled *AAI Chess* (2018), was an online chess app with three all-human playing modes: human vs human, human vs Amazon MTurker, and MTurker vs MTurker. Two years later, Jeff Thompson "replayed" *AAI Chess* with his performance *Human Computers* (2020) in which the audience members were tasked to manually resolve a digital image file (Google StreetView screenshot of the gallery) from its binary form into a grid of pixels. With 67 calculations per pixel, the complete human-powered image assembly takes approximately eight hours. [49] Here, the visitors' enactment of automated operations asserts how a combination of complexity and speed in pervasive technologies makes them difficult to understand and manage by an individual.

By wittily "exploiting" human labor to emulate the features of AI systems, these projects remind us that the "Turk" in AI is still not mechanical or artificial enough, it resists "emancipation", and it is not easy to make it more "autonomous". Their self-referential critique also points to the ethically questionable use of crowdsourcing in art practices, exemplified by earlier Aaron Koblin's projects *The Sheep Market* (2006), *10,000 Cents* (2008), and *Bicycle Built for Two Thousand* (with Daniel Massey 2009). [50]

However, artistic attempts to approach computational creativity through active open-sourced participation can be

equally undermined by muddled anthropomorphic notions. Seeing ML as a tool that "captures our shared cognitive endowments", and "collective unconscious or imagination" [51], Gene Kogan initiated a crowd-sourced ML project *Abraham* in 2019 with a goal to redefine agency, autonomy, authenticity, and originality in computational art. In the initial two parts of the incomplete four-part introduction, Kogan describes *Abraham* as "a project to create an autonomous artificial artist, a decentralized AI who generates art", and provides an elaborate, semantically correct but conceptually derisive, discussion of this idea. [52]

Issues

These examples show that, through success or failure, AI art expands the idea of technologically entangled creativity, and that conscious consideration of the notion of creativity is a prerequisite for human creative endeavors. They also point to the human fallacies and biases, cultural constraints, and sociopolitical ambiguities, which manifest in the conceptual, methodological, ethical, and educational domains of AI art. By identifying, acknowledging, and understanding these issues, artists can refine their creative approaches and find new ways to intervene critically and productively in the AI-influenced social reality.

Conceptual

AI research struggles with encoding crucial aspects of human cognition—such as intuitive knowledge, abstraction, and analogy making—into machine intelligence. [53][54] Similarly, the conceptual realm of contemporary AI art is most deficient in interesting intuitions, meaningful abstractions, and imaginative analogies. The field particularly lacks projects that use AI systems as means to actualize strong concepts that effectively address wider perspectives or deeper issues of human existence. The lack of conceptual sophistication also manifests as a disproportion between the artists' computational dexterity, their eloquence in articulating relevant ideas, and their competence with broader artistic, cultural, or historical contexts.

AI art tends to be technologically self-referential as many works rely on tautological or circular concepts or themes based on the artists' ideas about ML. Various notions of bio-detached and socially unembedded creative agency permeate both AI art production and its popular representation through confused, ambiguous, or openly mystifying rhetoric about "machinic artistry". They promote a pseudo-romantic quest for human-flavored creative "essence" within ML systems (and AI in general) instead of demystifying them as sociopolitical apparatuses which have little to do with creativity per se, and are better understood as sophisticated tools for statistical analysis. [55]

Complex devices such as computers and software only represent the cumulative human creativity invested in their design, but the artists' self-awareness, reasoning, abstraction, conceptualization, generalization, and analogy-making in dealing with these tools inform the cogency of their

works. Their idiosyncratic mental abilities, senses, emotions, passions, obsessions, and incentives determine how they interact with the world and make their art. These qualities and aspects should be in the forefront of AI artmaking. Conversely, a responsible approach to AI art requires a clear understanding that—while different forms of creative intelligence are possible and explorable—computers, robots, or algorithms are not artists because they do not embody human social embeddedness, cognitive capabilities, skills, quirks, and, most importantly, *human motivations for making art*. [56][57] Art is a human dispositive within anthropological and sociocultural perspectives, so motivations for expressing creativity through artmaking are partially driven by the evolutionary competitive ambition; among its many functions, art is a socially-constructed system for displaying mating fitness (intelligence, proteanism, wit) and for exhibiting or gaining social status. [58] Therefore, it is crucial to acknowledge that the poetic qualities of our artefacts are inherently instrumentalizable as virtue signaling means.

Cognitive

Technocratic or technofetishist mentalities have been haunting computational arts since their outset [59], and continue to affect AI art. [60] Production, perception, and reception of the arts have always been evolving in a complex symbiosis with technological and sociopolitical trends [61], so AI artists—as well as the media and the cultural sector which represent them—should be critically aware of these entanglements. The poetics of AI art will remain a facile reflection of its technological reality as long as artists keep constraining their notions of expressive cogency to a prima facie relationship with technology.

Successful AI art projects utilize their entanglements self-consciously, as the conceptual, tactical, and existentially inherent features within a broader context of digital culture. However, the complexity, interdependence, and pace of change make digital tools difficult to keep under artistic control. Most notably, the breadth of procedural literacy and coding skills required for elaborate AI art production tend to shape the artists' poetic reasoning, exploration, and learning by directing their creative focus toward mathematics and programming. [62] In general, the engineering approach is usually a welcome enrichment of the "traditional" artistic mindset, but when it takes priority over other poetic factors, it reduces the scope of artists' critical engagement and the impact of their works.

AI artworks that aim at a tactical or critical approach toward creative agency and expressive authenticity are also affected by academism [63] which exposes them to recuperation due to the lack of methodological clarity, formal cogency, or experiential impact. Solidly conceived and well-motivated tactical concepts are sometimes rendered as dry, humorless, unengaging, critically ineffective, or counter-effective works. Together with a few other projects discussed in this paper, Tom White's *Perception Engines* (2018 and 2021) [64] and Ben Bogard's *Zombie Formalist* (2021) [65] exemplify this issue. [66]

Ethical

Artists have faced the challenges of ethical integrity conflicting with professional well-being throughout uneasy coevolution between the open-endedness of artistic proteanism, and the ambiguous flux of discourses, criteria, and hierarchies in the artworld and scholarship. Reputation games in art community are driven by fluid social networks, cliques, coteries, and intrigues, directed by unstable loyalties or affiliations, and shaped by fancy, fashion, and authority appeal. Their capricious dynamics tend to reduce merit to a temporal figure of speech while upholding cultural hegemonies, institutional privileges, and profit-driven power games. Such volatile vocational milieu—combined with inherently high production demands and intrinsic need for endorsement by corporate AI, MCA, or academia—makes AI artists particularly liable to becoming intentionally or subconsciously manipulative, to compromising their creativity, and to softening their critical edge. [67] If they strive for integrity, all actors in AI art should be able to recognize these systemically noisy professional value systems, assess them objectively, and correct them.

AI art reflects the artists' motivations and ethical decisions in making their works and building their careers within a context of zeitgeist-relative interferences between the arts, science/technology, cultural trends, and sociopolitical vectors. [68] Regardless of their modes of involvement with broader issues of AI ethics, artists are responsible for their own roles in shaping cultural values and political normalization. Most artists, authors, and cultural operators prefer to ignore this sensitive territory for the sake of professional survival, which may seem obvious but in fact, draws a higher order of ethical implications. As long as this territory is protected by hypocrisy and vanity, the cognitive value of art criticism will remain inferior and complacent to diminishing the transformative potentials of the arts.

Prospects

The expressive, intellectual, and ethical implications of AI art have been relevant primarily as reflections of the AI's challenges, shortcomings, and ambiguities, but the diversity and criticality of the field have been improving as the initial hype is toning down, and more artists start to explore ML. They can establish insights into all important aspects of the AI-influenced world through meaningful relationships with the issues, contingencies, and advances of AI technology. [69] In order to engage the audience with a lasting impact, AI artists need to balance their motivational sincerity and ideational cogency with procedural skills, and maintain a critical outlook on their poetic devices.

Competences

The ethos of maturely calibrated competencies deserves cultivation through playfulness, bricolage, technical and conceptual hacking, and imaginative discovery that characterizes other areas of emerging media art. This requires a realization that art happens not simply by adding material

configurations that no one has witnessed before, but by integrating organized matter into complex human interactions that help us understand the world differently, make us better, or give us a chance to become better. AI artists need stronger criteria for poetic thinking, and better multidisciplinary knowledge of historical, theoretical, cultural, and political contexts in which they produce and present their works. [70] They should catalyze their procedural proficiencies by systematic training in related non-computational art disciplines, so they can appreciate the cognitive and physical demands of creative work in a broader existential sense. By raising the awareness of technocentrism in their practices, AI artists can also promote the necessary changes in STEAM education.

Creativity

Corporate media, some art institutions, and artists misrepresent AI algorithms as “artists”, and uncritically sensationalize shallowly anthropomorphic AI art. By debasing artistically crucial cognitive abilities which constantly evolve in humans, they legitimize the regressive, intellectually offensive, and politically dangerous cultural ignorance. AI artworks that glamorize narrow concepts of creativity sustain the notions of monolithic authorship rather than advocating for heterogeneous or conjugated actualization of the expressive agency. Intentionally or unintentionally, they reinforce the anthropocentric models of creativity which benefit the problematic culture of proprietary mental labor. [71] As AI art diversifies, these compound aspects are becoming increasingly evident and addressed more clearly. However, the future poetic scope of AI art may be limited by conservative initiatives for imposing legal instruments which would keep the creative decisions under centralized profit-motivated control. The responsibility for tackling these issues lies not only with the artists, but also with scientists, entrepreneurs, cultural agents, and the public.

To address the allurements of exploitatively incentivized creativity (for its own sake) [72], artists should articulate and respect their methodologies as heterogeneous productive frameworks which inform the audience by stirring inquisitiveness and critical thinking, stimulating imagination, and encouraging progressive action. Within this context, there is an underexplored analogy between the normalization of children’s creative idiosyncrasies through socialization and the artists’ conscious or intuitive compliance to cultural trends. [73] By directing their transgressiveness beyond amusement or showmanship, AI artists can turn their wit and versatility into exemplars of meaningful resistance to the social imperatives and existential bleakness. [74]

Commitment

The socio-technical entanglements of AI art with corporate AI, MCA, and academia may support the forthcoming art projects, but also attenuate their criticality and expedite recuperation. A straightforward way for artists to tackle this precarious relationship is to not prioritize their careers

over their art, be open to taking genuine risks, and pursue systematic support with skepticism toward institutional rationales for art sponsorship. The key requirement of avant-garde art is a deep, constructive dedication to evolving potentially hazardous ideas and finding effective ways to share them with the thinking audience. It takes exceptional curiosity, inventiveness, and enthusiasm to do any creative work without anticipating affirmation, compensation, or success, and artists cannot maintain such costly order of priorities indefinitely. Therefore, both the public and the institutions should rise above their unspoken but unrealistic and ultimately cruel expectation that an artist should continuously deliver significant works.

In a broader prospect, the frameworks of contemporary art, science/technology, and education can provide significant incentives for the unbiased development and representation of AI art, thus enhancing the exploration of AI; but they need thorough reconsideration and reconceptualization in order to be self-critically adaptable for absorbing the knowledge and value systems that emerge from various relevant disciplines. [75] This requires close cooperation between artists, institutional representatives, and the public in exposing the political hegemonies, and criticizing the coercive evaluation criteria imposed by the artworld, academia, politics, economy, and the media.

Critique

The tactical impact can be improved by examining the cultural and sociopolitical contexts of AI technology and business, and by deeper probing, understanding, and problematizing the underlining concepts of intelligence, creativity, expressive agency, intellectual labor, and ownership. The flexibility and mutability of these concepts are inherent to sociocultural dynamics, and technologies such as ML or blockchain can be used to reconfigure them in interesting ways but challenge them less drastically than it is widely presumed. [76] By demystifying seemingly radical capabilities of their tools, AI artists can leverage questions of authorship and authenticity as critical assets with wide political significance. Empowered by the destabilizing value of humor, responsible treatment of these assets can build new insights about human nature and provide meaningful posthumanist perspectives. [77][78]

AI art also requires appreciation models for experientially, intellectually, and emotionally competent spectatorship keyed to an artworks’ demands. [79][80] This paper’s outlook on the creative agency in AI art aims to expand the exploratory discourse with new critical perspectives for understanding the nature of ML as an artistic medium. It concerns the accomplishments, shortcomings, and ambiguities across the AI art-related disciplines, and facilitates comparative insights into their sociopolitical, cultural, and historical contexts. As AI art diversifies, these critical perspectives can be taken to identify and study the creative attributes of emerging practices in order to assess their cultural significance and sociopolitical impact.

Nam June Paik's Bibimbap Aesthetics as a Korean Reinterpretation of the Gesamtkunstwerk

Byeongwon Ha

University of South Carolina

Columbia, SC U.S.

bh33@mailbox.sc.edu

Abstract

Nam June Paik often describes his mixed media based on *bibimbap aesthetics*. Bibimbap is a Korean traditional rice dish, which incorporates diverse side dishes as toppings. The discrete beautiful topping pattern on bibimbap becomes a whole new entity by mixing them together. Like bibimbap, Nam June Paik's art shows creative combinations among a variety of media. Paik's bibimbap aesthetics is a Korean reinterpretation of the Gesamtkunstwerk, or total work of art. This paper explores Paik's artistic transition from non-mixed media to bibimbap aesthetics as a Korean version of the Gesamtkunstwerk.

Keywords

Nam June Paik, Gesamtkunstwerk, bibimbap, viral aesthetics, medium specificity, John Cage

Introduction

In 1967, Nam June Paik published the essay "Electronics, Arts, and Bibimbap," for Korean readers. [1] In his writing, bibimbap aesthetics was a creative tool for approaching the emerging phenomenon of mixed media in contemporary art. Bibimbap is a Korean traditional food, which combines rice, an egg, meat, and a variety of vegetables. The term *bibimbap* is a compound word: bibim (mixing) and bap (rice). It literally means "mixed rice with something." Bibimbap does not include objects, and it is open work with variations based on locations and seasonal products. The aesthetic image of bibimbap is replaced with a harmonious flavor which comes out through a blending process with red pepper paste and a hint of sesame oil. Paik thought that bibimbap showed Koreans' preference to a harmonious combination with heterogeneous materials. However, in 1956, when Paik had just arrived in Munich to pursue a PhD in musicology, he followed serialism, the opposite of mixed media. Paik studied and practiced serialism, or twelve-tone technique, developed by Arnold Schoenberg, which uses every tones equally without duplicates until they all are used. In other words, serialism is a medium-specific idea, which explores how not to trespass other media but to focus on the fundamental quality of music, or tonality, itself.

Nam June Paik's Desire Toward Serialism

While studying in West Germany in 1957, Paik thought that "New Music was the center of all arts movements and Germany was the center of the New Music." [2] In addition, Paik was excited that "all arts movements" explored how to be abstract in a medium-specific way as serialism composers had already pursued. [3] For example, Jackson Pollock explored colors, or pigments without concrete figures to make painting an autonomy medium. In this medium-specific atmosphere, Paik examined serialism as the most progressive art form. Art critic Gotthold Ephraim Lessing described medium specificity as the suppression of qualities of other art forms and the autonomy of each medium. In *Laocoön*, Lessing explores how to distinguish one medium from another. For example, he thought that in poetry we had the wrathful Jupiter, who hurled the thunderbolt. However, in visual art, Jupiter was simply an austere figure. Unlike the poetry about *Laocoön*, Lessing emphasized that in the *Laocoön* sculpture, anguish must be softened into sadness and screams must be reduced to sighs because they would deform the countenance to a repulsive degree. [4] In the same context, Johann Joachim Winckelmann argued in his writing "On the Imitation of the Painting and Sculpture of the Greeks" that extremes become so unnatural that sedate grandeur in Greek sculpture can be attacked unlike Greek writings. [5] This idea led to art critic Clement Greenberg's support for purity in art. In his essay, "Towards a Newer Laocoön," he emphasized purging literature from painting to achieve absolute autonomy. Greenberg emphasized an abstract art as an art of 'pure form,' and "purity in art consists in the acceptance, willing acceptance, of the limitations of the medium of the specific art." [6] Serialism shared purist art based on medium specificity with the Greenbergian idea. Paik's bachelor's major was art history and aesthetics at the University of Tokyo. It is natural that Paik was aware of the topic of medium specificity. Specifically, Paik mentioned Winckelmann in his essay "afterlude to the EXPOSITION of EXPERIMENTAL TELEVISION 1963 March. Galerie Parnass" to discuss nobility and simplicity in the Greek art. [7] In his Korean newspaper article "The Music of 20th Century (1958)," Paik introduced Korean readers to the four qualities of modern art from Professor Hans Sedlmayr: the

intention toward purity (abstractionism), geometrical construction (functionalism), absurdity (surrealism), and longing for the primitive (expressionism). [8] These qualities originally came from Professor Sedlmayr's book *Die Revolution der Modernen Kunst* (1955). In his book, Sedlmayr explained that purity is not affected from structures or elements of other arts. He emphasized that this absolute concept is not for art but chemistry in the field of science. Moreover, he negatively regarded extreme purist painting as unstable, indeterminate, meaningless, or non-objective art. [9] Unlike his professor, Paik supported the purist music style as the most progressive art form. In addition, Paik used the current topic in art to reinforce serialism.

Close Encounter with John Cage

Serialism explored to be pure by using each tone equally and be mathematical by creating algorithmic patterns regardless of traditional harmonies. Without the contributions of performers, early electronic music generates pure and mathematical sounds with electronic devices such as an oscillator. It is natural that Paik's interest in music moved from serialism to electronic music. In between this transition, Paik was interested in collage-based music, *musique concrète* for a short time. However, after visiting the pioneer of *musique concrète* Pierre Schaeffer's music studio in Paris, Paik decided to make electronic music in West Germany. [10] Paik was fascinated by electronic music as an updated version of purist music generated by electronic devices. This also shows the transition from mathematical to parametric, to algorithmic, and electronic elements in music. This chronological trajectory coincides with the development from twelve-tone music to electronic music. [11]

After attending John Cage's lectures and performances at the 1958 Darmstadt Summer Course, Paik thoroughly updated the idea of contemporary music that he pursued. He first attended Cage's *Variations I, Music for Two Pianos, Winter Music, and Duo for Pianist II* on September 3, 1958. Subsequently, Paik took Cage's lecture on *Music of Changes* on September 6, 1958. Finally, he attended Cage's *Indeterminacy* on September 8, 1958. In Cage's presentations, Paik found new possibilities of music based on chance and indeterminacy. These approaches are opposite to precise music: serialism and electronic music that Paik focused on. Cage's music allowed Paik to escape from the respect he had been educated to have for the European musical tradition. [12] Specifically, Paik was overwhelmed by Cage's theatrical music, and Paik's electronic music, which was once the core medium of his art, became a peripheral part of his music. Paik reinterpreted Cage's theatrical music as action music. Inspired by Cage's lectures, Paik experimented with aggressive performances, which made a crashing sound like shooting a bullet through a glass. [13] In a letter to Cage, Paik described his work-in-progress.

I use here: Colour Projector. Film 2-3 screens. Strip tease. Boxer. Hen (alive). 6 years girl. Light-piano. Motorcycle

and of course sounds. One TV. // 'whole art' in the meaning of Mr. R. Wagner. [14]

Paik incorporated a variety of media from performers to electronic devices. R. Wagner's whole art is a rough translation of the German term *Gesamtkunstwerk*, which was developed by Richard Wagner.

The Gesamtkunstwerk

The Romantic composer Richard Wagner emphasized the *Gesamtkunstwerk* as the theoretical basis for artistic synthesis in his essay "The Art-Work of the Future" (1849). He insisted that, "by uniting separate branches of art, artists can create common art." [15] Unlike the title of his essay, "The Art-Work of the Future," the *Gesamtkunstwerk* paradoxically came from a tragic drama, a mass religious event, unified works with dance, music and poetry in the art of ancient Greece. His desirable outcome as the *Gesamtkunstwerk* was the theatrical stage, or the Drama with reciprocal agreements among the other arts. [16] It is natural that Paik paid attention to the *Gesamtkunstwerk* after encountering Cage's theatrical music.

The German term, *Gesamtkunstwerk*, is derived from the archaic verb *samenen*, which means 'to assemble, gather, collect,' so Oliver Schefer stresses that the translation of *gesamt* as "total" in English and French is not exact. [17] However, it is true that Wagner himself emphasized a totalizing perspective: to achieve the highest artwork, the separate artists from different media must quell each selfish, harmful outgrowth from the whole. [18] In addition, American artist Randall Packer analyzed the *Gesamtkunstwerk* inspired Bauhaus and Fluxus by dissolving boundaries between art and life as well as disciplines. [19] In this regard, the *Gesamtkunstwerk* is a recurrent idea to return to mixed media that people did not logically or academically distinguish a medium with the others yet and explored to find a harmonious combination between media.

Likewise, Anke Finger and Danielle Follett further argued that the *Gesamtkunstwerk* could be divided into three different levels: aesthetic, political, and metaphysical. [20] Paik's idea about the *Gesamtkunstwerk* coincides with the mixture of the first and the second levels of it. First, the aesthetic level is the blending of diverse arts and genres as in multimedia, operatic, and synesthetic creations. Second, the political level is the interactive transgression of the concrete boundary between art and life. In this regard, the *Gesamtkunstwerk* seems to inspire the emerging avant-garde art with artistic synthesis. Even though most progressive art movements, including dada, break the boundary between art and life, they maintain their position in art institutions. However, Joseph Beuys's idea that everyone is an artist who is an active participator within a society, and the concept of Fluxus members including Paik, which breaks the boundary between art and life, invited art to a daily life instead of galleries or museums. In the idea of the *Gesamtkunstwerk*, Paik developed his original idea from the letter to Cage with a motorcycle in the second version of

Hommage à John Cage (1958) and a live hen in *Symphony for 20 Rooms* (1961) as well as electronic televisions in *Exposition of Music – Electronic Television* (1963). This concept was reinforced by Richard Wagner’s Gesamtkunstwerk, which was opposite to purity in art. The Gesamtkunstwerk was a significant seed to developing Paik’s progressive art.

The Viral Aesthetics

In Paik’s essay “Electronics, Arts, and Bibimbap,” he explained that bibimbap aesthetics was a creative tool to make new art form, or mixed media, as the cutting-edge method to mix art with electronics, art with life, and music with noise. Paik published this article in December of 1967. While writing the article, Paik had been inventing his own video synthesizer (1969) with the Japanese engineer Shuya Abe. His video synthesizer was a visual version of bibimbap, which manipulated and mixed up diverse images in real time.

Bibimbap aesthetics can be intertwined with “viral aesthetics” which art historian David Joselit coined. Viral aesthetics is similar to the result from the invasion of a virus into certain ecology. It does not aim to overturn its host but infect it as the Paik/Abe Synthesizer degrades and distorts the image of mass media. In other words, the aesthetics does not reject the origin of the host but manipulates it. [21] Joselit connected Paik’s video art based on the synthesizer with American novelist Williams S. Burroughs’s manipulation of language via a tape recorder. Burroughs thought that when the established lines of association in mass media are cut, the associational links are broken. By altering muttered lines of the mass media with a tape recorder, he used it as a kind of political virus. Joselit insisted, that although Paik and Burroughs’ manipulations are similar to Duchamp’s ready-made, which untied the signifier from the signified, Paik and Burroughs tied their works to a political purpose. [22] Paik’s viral images bridged a gap not only between art and technology but also art and life with noisy/distorted video sources.

Like a harmony of bibimbap, Paik’s video manipulations show collage-based images with diverse materials.

Bibimbap as a Style of Art

In Paik’s Korean essay, he mentioned bibimbap as an artistic concept. Bibimbap is a Korean traditional food, which consists of rice and a variety of toppings such as soybean sprout, radish salad, and an egg. Bibimbap does not have any restrictive rules for materials. Available ingredients based on a location make variations of bibimbap. This provides not only a fascinating visual pattern but also an orchestrating taste in different ways. Paik defined bibimbap as neither bean sprouts, mushrooms, spinach nor herbs. If the vegetables in the dish try to stand out, the true taste cannot come out. [23] This idea is identified with Wagner’s Gesamtkunstwerk. Paik focused on two qualities of bibimbap: mixture and combination. With bibimbap aesthetics, Paik interpreted bibimbap spirit as a main idea, which blurs a boundary between different realms. He mentioned three main approaches with bibimbap aesthetics: Norbert Wiener’s cybernetics, Alan Kaprow’s happenings, and John Cage’s noise music.

First, as Paik’s essay “Electronics, Arts, and Bibimbap” indicates, he mainly focused on the emergence of electronic art and mentioned cybernetics to analyze this phenomenon. Wiener’s cybernetics explores an effective communication between a machine and a human. Paik survived in mainstream art by making a blurred boundary between them.

Cybernetics, the science of pure relations, or relationship itself, has its origin in karma. . . .
The Buddhists also say
Karma is samsara
Relationship is metempsychosis [24]

Paik’s writing above can be reinterpreted in the realm of digital interactive art. Cybernetics, which represents the relationship between human and machine with the control system, fundamentally supports defining interactive art. In 1947, Norbert Wiener coined the term cybernetics from the Greek word kubernetes, or “steersman.” According to Edward Shanken, “The scientific discipline of cybernetics emerged out of attempts to regulate the flow of information in feedback loops in order to predict, control, and automate the behavior of mechanical and biological systems.” [25] In the same context, Katja Kwastek insists that cybernetics opens up new perspectives on processes of interaction. [26] In a mixed communication between a human and a machine, Paik emphasized that cybernetics allowed a machine to understand human’s communication, not vice versa. Paik’s idea on cybernetics not only indicates his philosophy on interactive art, human-centered perspective to cybernetics in his first solo exhibition, *Exposition of Music – Electronic Television* in 1963 but also suggests the creative video manipulation system, or his video synthesizer, which allows the

artist to interact with electronic interface to make electronic art. [27]

Next, Kaprow's happenings blurs a boundary between art and life. His happenings invited audiences to specific situations, and they interacted with specific environments while interrogating a clear boundary between art and life. As a co-founder of Fluxus, a main figure of *Originale*, or the theatrical music performance organized by Karlheinz Stockhausen, and an independent musician, Nam June Paik had already experimented with the same question in his performances such as *Etude for Pianoforte* (1960), *Entwicklungshilfe* (1961), and *One for Violin Solo* (1962). Since Paik interacted with audiences in a violent way, he was named a "cultural terrorist" by Allan Kaprow. In his action music, Paik decided to break the boundary not only between several media, but also between performers and audiences. He often trespassed a clear boundary between the audience and performers on the stage by cutting the necktie of John Cage who sit as an audience member in *Etude for Pianoforte* and by encouraging the audience to disturb an opera during the performance in *Entwicklungshilfe*.

Finally, Cage's music shows a blurred boundary between music and noise in his theatrical music, Cage equally focused on any sounds from any materials. There were no preferences in between music and noise. For example, in *Water Walk* (1959), Cage used everyday materials such as a bathtub, a pot, and a toy as well as the piano. Specifically, he did not play the piano but hit the body of the piano or directly touch the strings in the piano. Furthermore, John Cage utilized several electric/electronic devices all in *Variations VII* (1966). In real time, Cage made sounds with telephone lines, radio receivers, and square generators. In this regard, Cage did not distinguish noise with music in *Variations VII*. In the end, by blurring boundaries between art and technology, his music contributed to redefine an idea on music. This performance was part of the historical theater event *9 Evenings: Theatre and Engineering* organized by *Experiments in Art and Technology (E. A. T)*. The Cage's performance returns to cybernetics and happenings ideas. In the same context, Paik's "whole art" in his letter to Cage shows art-and-technology with everyday materials. In this regard, those creators' mixing approaches are intertwined with Paik's bibimbap aesthetics.

Conclusion

Paik's collage philosophy not only mixed diverse media but also trespassed a boundary between art and life as well as between art and technology. This coincides with the different levels of the Gesamtkunstwerk. After pursuing the opposite side of mixed media in music, or serialism, Paik focused on the Gesamtkunstwerk to develop a variety of his own mixed media. In "Electronics, Arts, and Bibimbap," he did not have to mention the German term anymore since he inherently had a unique genetic approach, or Bibimbap Aesthetics.

Machine Learning-based Approaches in Biometric Data Art

Yoon Chung Han

San José State University

San José, CA USA

younchung.han@sjsu.edu

Abstract

This paper explores issues of bias on biometric data and anxieties about identifications through audiovisual interpretations of the biometric data artworks. As seen in previous historical approaches, many people have been concerned about the reading of race, character, and narratives into genetic traces. Recent history and current trends in biometrics show that biometric data relates to statistical prediction, and bias is an inevitable part of biometrics. The bias has been observed in my previous exhibitions from spectators who experienced their biometric-driven audiovisual outcome. The artist created an experimental version of the two biometric data artworks using machine learning (ML) methods of artificial intelligence (AI) to investigate the bias on biometrics. The AI-driven interface analyzes the input data, improves predictions, and extracts visual features based on sample data. Two biometric data (iris and fingerprint) are used in the artworks, and an informal user study is discussed. This project investigates the possible artistic approaches in using biometric data and attempts to find unbiased solutions for biometric data interpretations.

Keywords

Machine learning, biometric data, data art, data visualization

Introduction

Biometric data has become one of the most crucial data in our lives. The personalized information hidden in the biometric data has been used for various identification systems and applications. Each different biometric data contains unique visual features such as colors, patterns, and lines. Feature extractions have been the most significant part of biometric data identifications. However, there are many cases of identity fraud, identity theft, and bias in identifications, which show that personal digital records are frequently and easily used in the wrong ways. Will the system confirm our identities to prove “who we really are?”

The questions raised by the biometric data are: what can we read and learn about ourselves with the data? Do they represent our identities incorrect and secure ways? Are they simply superficial copies of our identities or one of the many methods used to index each person using biometric data

Figure 1. Two biometric data artworks: an exhibited view of *Eyes* (top), and an exhibited view of *Digiti Sonus* (bottom). ©

images such as numbers? And the most critical question is, “Is there any bias and misinterpretation in the analysis of the biometric data?”

I have been creating a series of biometric data artworks since 2012. Two of my biometric data artworks *Eyes* [1] and *Digiti Sonus* [2] showed novel ways of using the biometric data as art materials and revealing hidden information about

the biometric data as arts-engineering projects. The unique visual features of iris and fingerprint data were transformed into audiovisual outcomes in the two artworks. Every participant can use their own distinctive biometric data as input data, which creates a unique and personalized outcome. Figure 1 shows the exhibited views of the two artworks.

Although the works successfully demonstrated unique artistic experiences in many art/design exhibitions, the spectators have raised questions: "Why does my eye/fingerprint sound like this?" For example, users with dark brown eyes mostly listen to the lower-frequency sound in the artwork *Eyes*. Brighter blue eyes result in creating high-pitch sound based on the mapping between color value and audio frequency. Besides the question about the relationship between eye color and sound, spectators also asked about the relationship between fingerprint lines and sound. It brought my attention to the data mapping between visuals and sound, biometrics and audiovisual interpretations, and revealed anxieties about race. What is the proper data mapping for an inclusive art experience? How can we make non-biased data mapping when using biometric data or personalized data? The spectators also preferred to see detailed information about their biometric data and additional visual features on the screen. They wanted to know the "Behind-the-scenes" information, the relationship with other people's biometric data, and how it is used to create data sonification.

This paper explores discussions about a biometric data visualization and sonification system that extracts visual features of biometric data using machine learning methods and explores issues of the bias on the biometric data and the relationship between user expectation and results. Interviews and answers from questionnaires about the comparison between biometric data and audiovisual works are discussed. This project aims to investigate the meaning of biometric data in these days and find possible unbiased solutions for data sonification and subjectivity in the artistic experience.

Anthropometry and Identification of Biometrics

Biometric data has become one of the most crucial data in our lives. The personalized information hidden in the biometric data has been used for various identification systems and applications. Each different biometric data contains unique visual features such as colors, patterns, and lines. However, this is not the new technology for identification. Although DNA testing, face recognition, and fingerprint scans were not available in the early nineteenth century, similar techniques and the same modern concerns about bias, privacy, and incursions on free existed. Phrenologists and craniometrics believed that heredity, race, ethnicity, and character could be read in the shapes and sizes of human skulls. [3] Francis Galton attempted to create a system for

groups of people based on heredity via composite photography. [4] He captured an arbitrary number of individual portraits of chosen groups of people and controlled exposure time to the portrait images. Francis Galton believed that "Composite Portrait" can categorize individuals into different types, such as "criminal types." It was an extension of the statistical techniques of averages and correlation. [5] His approach was one of the first thirty implementations of convolution factor analysis and neural networks. It repeatedly occurs in the area of popular science. Anthropometry was intended to investigate the predictability of relationships between biometric and moral and intellectual traits of humankind. [5] The American Centers for Disease Control and Prevention describe Anthropometry as a "science that defines physical measures of a person's size, form, and functional capacities." [6] The Belgian statistician Adolphe Quetelet was the pioneer on anthropometry with his own statistical database, which can be referred to as the first stage of what we today call data mining and big data. [7] However, Quetelet focused on the "unity of the human species," which he believed could be most clearly seen by distributing different traits. This is a very different manner from later biometricians. [7] Quetelet's overall idea led to the modern concept of normality and the universality of racial categorization. It shows that biometric data relates to statistical prediction, and bias is an inevitable part of biometrics. It has continued in the recent history and current trends in biometrics.

Art is always trying to reveal the artist's personal truth, and social or political voice. Many artists use traces, imprints, and indexes of bodies to reveal hidden narratives, truths, and identification of ourselves in society using the physical traces based on the early modern identification system's semiotic approaches. It is also my attempt to create an interactive system that allows audience members to recognize who they are. Artistic approaches to revealing meaningful narratives beyond the photocopied images of the biometric data with new digital technologies could give potential answers to the biometric failures and point out the current issues of biometric technologies in society these days. I believe biometric data artworks can address the current problems of generalization, bias, and protest against the misuse of biometric data and suggest a possibility of reconsidering the issue for the audience.

Bias on Machine Learning and Biometrics

As Galton's anthropometric projects had already convinced people to share their biological information, biometric data collection, and its misuse have become enormous in our everyday life. Like how Quetelet attempted to create a neutral and generalized system, modern technology and algorithms, especially machine learning methods, have made identification systems that use biometric data wildly biased.

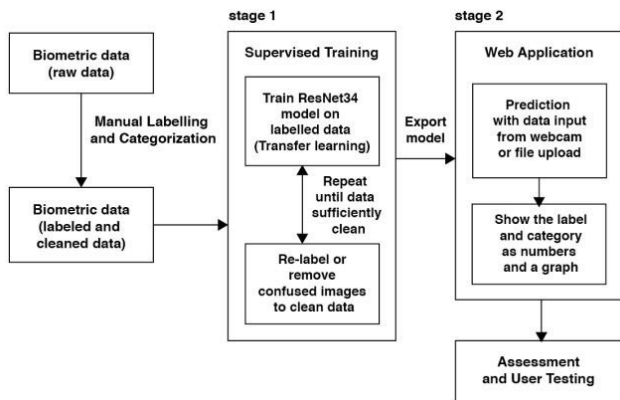

Figure 2. The overall process for visual feature extractions of the biometric data.

For instance, Google’s facial recognition software misidentified African-Americans as “gorillas” in their automated photo-categorization software. [8] Many types of research have revealed that machine learning technologies create an unfair treatment for specific populations. The issue of racial bias in its applications with artificial intelligence has been critical and not resolved yet. Algorithmic biases explicitly and implicitly harm racial groups and lead to forms of discrimination. [9]

Interactive media artworks created by machine learning or related technologies might have similar issues to the spectators due to the limited scope of data acquired and implicit decisions on the experience design. Mapping the data to unfair or incorrect audiovisual outcomes and miscommunication between the interface and spectators might create confusion or disturbing art experiences. Automated interfaces with emerging technologies have a higher chance of significantly creating those issues without enough research and evaluations. I wanted to explore the issues addressed above through my artworks and examine any possible solutions or address awareness of the problems to spectators. Furthermore, through this artistic practice, my intention was to use the abilities of artificial intelligence to understand the categorization and identification on biometrics in an artistic and creative way by adding data sonification methods.

Machine learning is not new in the fields of arts and design. Many artists have started using machine learning to explore various new approaches to artistic expression works by Anadol [10], Ji, and Wakefields [11]. Despite this approach’s remarkable recent successes, it must still be a clear understanding of what intelligence is, how it works, and how to make it work properly is lacking. Biometrics is the perfect dataset that is numerous, unique, and never changing. However, in the process of visualizing and sonifying the biometric data, the issue of genetic and racial bias should be resolved with more research and feedback from the

spectators. I leverage machine learning methods to learn from a large set of data images and extract features to support the existing artwork to help users understand. In previous exhibitions of two artworks *Eyes* and *Digiti Sonus*, most people wanted to know two essential pieces of information: 1) what colors of eyes and patterns of fingerprints they have in detail, and 2) how the data is transformed to sound. The updated version of the two artworks described in this article will demonstrate how machine learning can help map biometric data to sound and how the spectators think about the outcome with more detailed info.

Design Approaches

Figure 2 shows the overall process for visual feature extractions, applications, and assessments. Biometric image data is acquired in agreement with the users going through the machine learning process, and categorization and detailed biometric data labels are exported. The exported outcome is used for both data visualization and sonification, in which users can experience and share their thoughts. Mapping data to sonification is tweaked over time based on feedback from users for better results.

Two biometric data (iris and fingerprint) used in this research include unique visual features that need to be extracted with different approaches. There were two approaches for the iris color analysis; the first approach was to use image processing to extract the most dominant colors from pixel data and make a list with color code and domination rate. The second approach uses machine learning methods that analyze all other previously acquired eye images and show the eye color in real-time. For fingerprint analysis, the previous research focused on extracting minutiae, brightness, size, and fingerprint position [2] without the types of fingerprint patterns, while this updated version focuses on machine learning.

Figure 3. Five examples of iris data and analyzed color results. Raw data (top), cropped circle images (middle) and lists of most dominant color values (bottom).

Figure 4. Raw iris data (above) and extracted dominant colors from the iris data (below)

Dataset

Both iris and fingerprint data were acquired during previous user studies and art exhibitions with all participants' permission. The data is entirely anonymous without any personal information such as name, gender, or address. The iris images were divided into four categories (Blue, Blue-Green, Brown, and Light-Brown/amber) manually. I also manually sorted out the fingerprint data into three categories (three patterns – arch, loop, and whorl) [12]. In the previous version of the application, I used various visual features of iris data such as eye colors, brightness, size, and patterns. However, the colors are the most critical data that directly impacts the art installation's audiovisual results. The other data controlled the extra components in the outcome. Furthermore, I wanted to use the colors as the main source to investigate the visual metaphor of racial bias that spectators could explore in this artwork. Therefore, I decided to focus on analyzing and extracting the color values at a deeper level. Figure 3 shows the five examples of iris data and analyzed color results.

Color Extractions from Iris

I used various visual features of iris data, such as eye colors, brightness, size, and patterns. However, the colors are the most critical data that directly impacts the art installation's audiovisual results. The other data controlled the extra

components in the outcome. Therefore, I decided to focus on analyzing and extracting the color values at a deeper level. There are many distinctive eye colors and different ways of categorizing human eye colors, such as the martin scale [13]. The most relevant epidemiologic and genetic research uses simple, three category scales (blue/mixt/brown) [14]. The other most common colors are blue, green, brown, black, amber, or hazel/mixed. Unique colors such as grey, violet, and red can be regarded as mixed colors.

As the first approach to extract the color values from the eyes, I used the image processing methods. Figure 3 shows the steps of the process to extract the dominant colors of each iris data. I detected the pupil and iris circles and cropped only the iris circle area using the Hough transform [15]. Image processing techniques such as segmentation, normalization, and feature encoding were employed to extract the eye's digitized image's unique colors. I analyzed all the image pixels' color values and ranked the most dominant colors as a list of color codes and domination values. As the pupil is always in the black color, I removed the pure black color. Figure 3 shows the lists of extracted colors from five iris data samples. I could categorize the dataset into four colored groups (blue, blue-green, light brown/amber, and brown) applied to the next approach developed using machine learning classification methods. Figure 4 shows the raw iris data achieved from previous users studies and extracted dominant colors from the iris data.

Figure 5. Previous fingerprint analysis with minutiae, position, size, and mean brightness (left) and three patterns of fingerprints (arch, loop, and whorl).

Pattern Analysis of Fingerprint Images

Fingerprints are one of the unique biometric patterns on the human body. In the previous application, five distinct visual features were extracted for the art application. However, with machine learning methods, the types of patterns are focused, analyzed, and pulled. Fingerprint pattern types are categorized into three groups: arch, loop, and whorl [16]. Figure 5 shows minutiae as red dots on the fingerprint image on the left and examples of the three patterns of fingerprints on the right. Pattern types are the most visible and significant features used for various purposes. In the artwork *Digiti Sonus*, the pattern types determine the frequency range in the data sonification. Therefore, extracted pattern types will be crucial to enhance the quality of experience and range of contents.

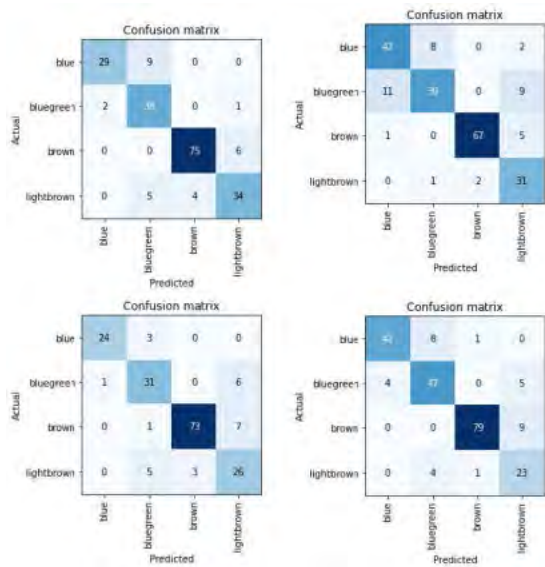

Figure 6. Four confusion matrices with iris data. The matrix on the bottom-right has better results and higher success rates than the other matrix on the top-left.

Implementation

The most straightforward approach for eye color detection would be to use a convolutional neural network that has been pre-trained to recognize the difference between common objects. It is accurate at identifying the critical differences between eye colors. Mimicking the Fast AI [17]'s image classification modules proved useful since it provided the ability to use a pre-trained model called ResNet34 [18], which has already been trained to classify millions of images from the ImageNet database containing everyday objects. The coding environment used was Google Colab [19]. The chosen coding language was Python, and some of the libraries used were PyTorch [20], TorchVision, and NumPy. These were used to create a convolutional neural network based on ResNet34.

In the process of training the model, the interpretation of the classification was created using fast.ai methods, including the confusion matrix. The confusion matrix (figure 6) is a grid that plots the actual category of an image with the predicted category. Numbers in the diagonal represent correct predictions, and other numbers represent errors. The error images were usually unclear or dark, or the iris's core part was not captured. The images from the dataset could be miscategorized, which needs to be re-labeled to make the model more accurate and create a cleaner, adequately labeled dataset. Smaller numbers in the confusion matrix represent a more precise model.

Observing the confusion matrix and cleaning the data, this training process was repeated over several iterations, increasing the eye color model's accuracy from ~82% up to

86-88%. This is shown in the table, where the error rate drops to 0.1466 in 4 epochs. The fingerprint classification model confused many loop and arch images, and some of these are shown in Figure 7. After cleaning these images, the confusion matrix shows the total number of images confused between the two categories dropped to 8 from 11. The accuracy went up to 90% at the last result, where the error rate drops to 0.140, meaning that the model is 90% accurate at the end, as the results are shown in figure 8 in two ML-based applications. Although this process may be performed several more times, the data was deemed sufficiently clean for the project after referring to other models.

User Testing

I developed a customized web application using HTML, CSS, and JavaScript to test the results. The application transferred the learning algorithms to train models fast and effectively. I input the cleaned data and labeled data from the previous process, and the model trained and exported the results. Additional functionality (file upload and a bar graph) was added to visualize the accuracy of an eye color/fingerprint prediction.

Figure 7. Iris images and fingerprint images miscategorized and caused errors in the system.

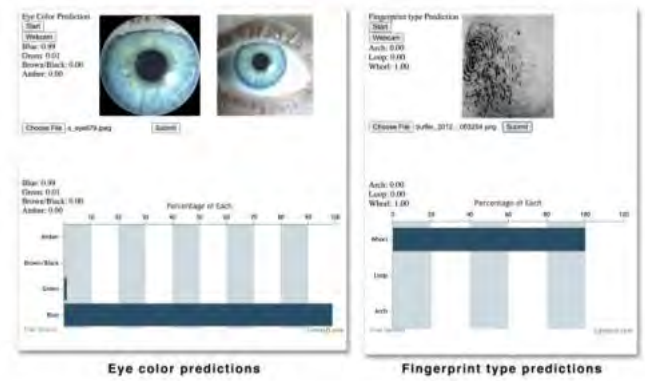

Figure 8. Two ML-based applications: eye color predictions and their results (left) and fingerprint type predictions and its result (right)

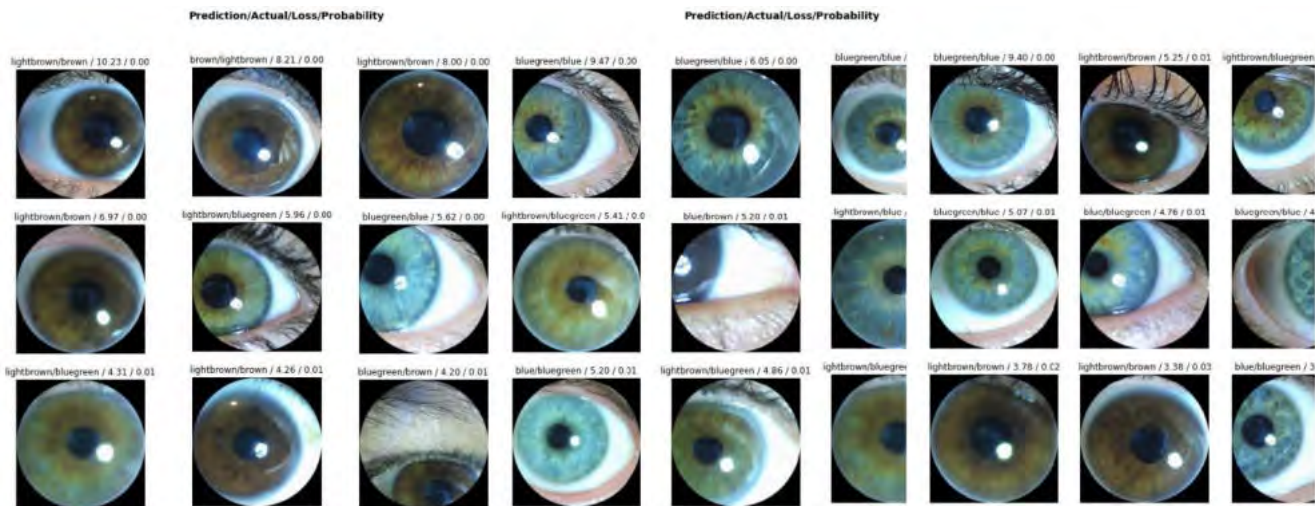

Figure 9. Predicted colors and error rates extracted from the analysis of the raw iris data. The extracted colors and rate were used for data sonification.

Detailed numbers of data are added to support the understanding of the process. Figure 9 shows how the application works with the real-time camera captured and then predicted colors and error rates extracted from the iris data are displayed. The data is transformed to sound software (Max 6) for data sonification, and users can listen to the sound.

In December 2020, I tested the application with fifteen participants, who mostly have a background in arts, design, or engineering. I explained this project's goals, and the purpose of the application and asked questions about the overall art experience and the relationship between sound and image. The participants first experienced the original artworks, observed the audiovisual results of his/her data and other data, and ran this application to learn the detailed information about their biometric data.

In the survey, the first question was, "Do you think the relationship between the image and sound is clear?" Of the people I surveyed, 80% of the participants answered that they could easily connect their eyes to the sound. One user said, "The brightness and color of the eyes and fingerprint images matched to the sound very well in comparison with the sound of the other data." 80% of the participants had five blue eyes, five brown/black eyes, one green eye, and one amber eye. However, 20% of the participants mentioned that "It is not highly clear to connect the images and the sound very well" They had one green eye and two amber eyes. One user mentioned that "My amber eye color is in a medium tone, but the sound seems quite low and dark." This comment reflects that the audio frequency (approximately 300 Hz to 1800 Hz) used for the medium tone eye color falls in a subjective territory for each person. Unlike the iris data-based application, to the first question, 60% of the users answered that it was not clear to understand the relationship

between the fingerprint patterns and the sound. The four patterns were mapped to the different melodic sound determined by the position and complexity of the line formation. Unlike the eye colors, the patterns were less impactful to link to the sound due to the complicated patterns.

In the other question, "Do you think the sound is biased based on the biometric data and races?" 40% of the participants who experienced the iris-based application mentioned that they thought the data mapping was based on a presumable bias. A comment from one respondent was, "Lower frequency sound for the dark/black eyes and higher frequency sound for the blue eyes might be a possible issue of racism. The implicit decision on the data mapping should be addressed." However, 50% of the participants answered "no" to the question. One user mentioned, "Based on the color intensity and brightness, the higher pitch to the brighter color and lower pitch to the dark color makes sense to me. It was quite clear to understand the linkage between the sound and the visuals" There were varied answers and feedback related to the bias in eye sound, according to the interview. In contrast, 90% of the participants who experienced the fingerprint-based application said no to the question. It shows that the fingerprint images seem not strongly connected to the races in comparison with the eyes.

The last question about the detailed info presented on the screen, 93% of the participants mentioned that the visuals helped connect sound and biometric data. Furthermore, they noted that the number of eye colors and fingerprint patterns helped to recognize the comparison with other eyes and fingerprints. However, there were very similar eye colors (dark browns), and the sound and data were almost identical. Some of the feedback included showing how similar their eyes and fingerprints can be compared to others in detail. A

user also suggested an automatic capture system to achieve eye and fingerprint images to make the process faster and easier.

Discussion and Future Work

Based on comments from participants in the user study, it was interesting to hear various voices from the users about their thoughts on the implicit bias on the eye colors, the relationship between visuals and sound, and the difference between fingerprint and iris. The most interesting response was about the preferred eye colors and sound. According to various studies, eye color preferences are based on assumptions about personality, cultural ideals, rarity, and sexual imprinting. Researchers found that people subconsciously assume other people with brown eyes are more trustworthy due to facial structures accompanying the brown eyes. [21] Another factor is based on cultural ideals. Cultural influences affect what people desire (e.g., blond-haired, blue-eyed' person emphasized in movies and the media for decades). Another interesting factor in controlling the preferences on eye colors is sexual imprinting; human romantic partners tend to have similar visual traits driven by their families' or parents' visual traits. [22] Various artworks such as "Eyewalker" [23] and "Opto-isolator" [24] explored eye gazing, level of awareness, and eye colors in conjunction with technology. The eyes are a strong symbol and a metaphor for personalities as a visual trait. It also leads to communication and interaction between people. Based on the facts, it was interesting to observe the preferences on eye colors from the participants in my art installation and the user study. Most participants mentioned "beautiful" many times when the 3D animated blue eye was projected on a wall. It made me ponder where the bias started from initially. Is it from our decisions? Or are we trained? Did the machine follow our choices and get trained based on our preferences? In my study, machine learning methods could only retrieve the results from collected statistical information but couldn't talk deeply about the reasoning behind people's preferences and choices. Furthermore, data mapping from visual features to audio parameters in this artwork didn't target the audience members with highly personalized choices due to its predetermined mapping system. More freedom and choices on data mapping and sonification could create more personalized artistic experiences. The possible bias embedded in the data sonification should be more investigated by testing with more users and data. The frequency of the sound might be too simple a parameter to examine the gauge of the bias issue. More personalized choices and diverse styles on sound determined by machine learning can be one further direction to investigate. The various scenarios with different approaches for the following versions are potentials of this project.

I envision my approach to be applied to multiple domains in both arts and engineering and foster future research about

finding unbiased ways of using biometric data. Since Quetelet and Galton, the biased statistical vocabulary and methodologies have been developed and applied to various applications. And it has impacted people's preferences and decisions in a feedback loop system. Whatever the solution, it would seem that we need to understand the roots of systematic bias. And more investigation on modern statistical analysis that was built upon racial thinking should be recognized and reconsidered. I believe the next big thing is further recognition of non-biased thinking through a focus on the unity and individuality of all humanity rather than quantitative measurements and statistical analysis. This applies to the current modern technologies, and system designs and artworks that utilize the human body as input data. A deeper understanding of individuality and subjectivity will result in a more personalized artistic experience.

As future work, the applications will be more developed with further exploration on data mapping and user preferences on sonification. The machine-learning-based application will be embedded in the future version of the two artworks. It will include spectators' choices and preferences rather than adding their biometric data itself. Over time, the artwork can generate a less disturbing and more personalized art experience for spectators based on their input data in a feedback system. As a continuing project, other biometric data such as the face, veins, or signature will be analyzed and used to expand the range of case studies and discover hidden narratives in different types of biometric data. It will contribute to the open-ended development of the biometric data-driven system and show potential to be developed further by providing insights to other artists, designers, and creators interested in using biometric data and other human body data.

Acknowledgements

I would like to thank the participants who helped the informal user study for all their great feedback. This research is supported by the 2020-2021 Dean's Professional Development Grant at the San José State University.

Author’s Biography

Yoon Chung Han is an interaction designer, multimedia artist, and researcher. Her researches include data visualization, biometric data visualization and sonification, a new interface for musical expression, and multimodal sensory user experience design. Her recent research focus was on multimodal interactions using body data, in particular on creating a personalized experience in media arts using biometric data visualization and sonification. Her works have been presented in many international exhibitions, conferences, and academic journals such as ACM SIGGRAPH, Japan media arts festival, ZKM, NIME, ISEA, IEEE VIS, ACM CHI, and Leonardo Art Journal. She holds a Ph.D. at the Media Arts and Technology, UC Santa Barbara, and currently is an Assistant Professor in Graphic Design at the Department of Design in the San Jose State University.

Dr Theo Harper

Northumberland, UK // info@theoharper.com

Abstract

By holding on to the idea of ‘origin’, understood in my research as hand-printing clay, I aim to rethink our interactions with technology and automated making. During the past three years, I have been exploring the relationship between hand-coiling clay and 3D printing. Hand-printing uses hand-extruded clay that, with skill, creates long hanging ropes that are pressed together. The movement is highly laboured and repetitive. It is this difference in the physical making experience, against the digital one that my research explores.

Keywords

Clay, Movement, Computer Aided Design, 3D printing (3DP), Hand-printing clay (HPC), Digital, Touch, Robotics, Innovation, Sculpture

Figure 1; Photogrammetry scan hand-printing-clay, Theo Harper, 2021

3D Printing Backwards

The ethical development of these technological parameters is paramount, as our entire made environment is created through interactions with computers. The stakes are environmental, geological, and political. As computers connect with making machines it is important to address issues within the automated future we are facing and have begun to live with (Bennett 2010, Vallgård, A. 2009, Ingold, etal).

Figure 2; A generic sedentary design practice not in contact with physical material

Examples include robotics and advanced manufacturing tools that rely on top-down desk-based instructions generated by a select few. This clay-first perspective on making seeks to realise a deeper understanding of the materials and processes involved in our daily lives and to describe the hybrid materiality we are part of. This approach is made possible by working with computer programmers to create disruptive innovations that affect the framework of how our fabricated environment is designed. In so doing, it is possible to ‘3D print in reverse’, allowing the digital to be touched.

In this article I describe how 3DP clay has served as a learning tool and conduit for a new digital expansion in my practice. I describe a way of making digital sculpture that directly originates from an experienced physical place through the blended interaction with clay and new technologies. The projects that I will describe are based at Grymsdyke Farm, the European Ceramics Work Centre (EKWC) and my home studio, expressing this hybridity in the form of hand-printed clay, digital models, robotically printed and 3DP clay and ceramics

Pressing between the lines

Throughout the development of this three-year research project, I have maintained a connection to the process of hand-printing clay. This work embodies what Richard Sennett refers to as an ‘extended rhythm...that allows the craftsman to develop specific skills and rituals—duties performed again and again’ (Richard Sennett, *The Craftsman*, 2008). It is also something that can be measured by using various sensory technologies, such as 3d scanning and movement tracking.

Figure 3; Hand-printing-clay in action, link to time-lapse <https://vimeo.com/512429824> ,studio, 2021

My relationship to HPC was already well formed before I had seen the ceramic 3DP working (developed first by Studio Unfold and others, 2009). My body and closeness to the clay is removed and replaced by an automated machine.

Figure 4; 3D scanning in motion, studio, 2021

I assumed I owned my experience but now I was observing it, watching it play out in front of me. This provided the motivation to understand the processes involved in printing an object. These stages in order are normally: CAD; SLICER; 3DP.

Figure 5; Guard, 3D printed ceramics, 21x12x27 (EKWC, 2021)

This led to me thinking about the sensory body changing through time and how that could affect the handmade object. As living beings, we (as well as animals and plants) make connections with our material environment through experience that manifests, often in hindsight, as meaning. On 28th May 2019 I interviewed Nicolas Pope whose practice takes a similar form to my own sculptural strand (figure 2) but is devoid of any technological mediation.

Figure 6; Yahweh and the Seraphim (1995), Glazed and lustered ceramic Height: 430 cm | 169 in Installation view, Stedelijk Museum, Amsterdam, 1995

Early on in Pope’s interview, he remarks that he has Parkinson’s Disease and that it is very hard to control his actions; something he says is interesting in terms of the hand and material, as he is losing control of his own body. He values the mistakes in the work, something a machine cannot do.

“I am joyful when I go wrong. But if I purposefully try to go wrong, it becomes false. Its why Parkinson’s is so great, I’m going wrong all the time.” (Pope, transcript, 2019, p4)

I asked Pope how his forms come to be: do they come from the material or are they pre-designed?

“The forms created come from an entanglement of concepts, materials and forms that are put together when a group of pieces start to make sense. The work comes from the material as much as it comes from the person making it.” (Pope, 2019)

This is a statement that makes sense when I think about my own form making. Because of Pope’s ceramicist background, clay has always been his first-choice material and it has remained central to his way of working. Pope mentioned a simple but important point when we were trying to determine the value of the ceramic 3D printer, which is the regularity of the printed object and how its lines were not defined by touch but by the tool of the instrument:

“It’s very well made, without hesitation, without mistakes. I value mistakes. A lot of finger work is apparent. Finger work is really nice!” (Pope, 2019)

The most valuable and relevant insights from the interview are of Pope seeing himself as the instrument of making sculpture and drawings. He speaks of his own body being used by his instruction but also that he is not fully aware of the forms he wants to make and just going with the ‘flow’ (Csikszentmihalyi, *The Psychology of Discovery and Invention*, 2013). The body in his case is in decline, or ‘has the shakes’, which he sees as introducing the benefit of chance into his drawings. This is an irregularity which he likes – within the constructs he puts around himself. A robotic or mechanical process does not age the same way as an organic body. Its actions can be replayed in the same way 1,000 years from now if well-maintained and given the same code to follow. But Pope’s is a changing body that exists within a finite time frame.

“I have no choice for Parkinson’s. My computers got fucked up. My antivirus is not working.” (Pope, 2019)

Figure 7; Hands, Touch, Clay

Our bodies perform an astonishing assortment of actions (Barbera Tversky, *Mind in Motion, How Action Shapes Thought*, 2019). The movements involved in this investigation alone include moving to stand, to kneel, to sit, walk, type, click the mouse, look up, look down, pull clay, coil clay, press clay, move clay, and operate various tools that in turn require their own movements to operate. These movements are broad outlines; they all require other movements within them, and they all operate in digital and physical space. These gestures without the physicality of clay are made digital in the world of computer-aided design. Algorithms have been created to twist and pull digital form in simulated space. They have been built to express actions on design ideas and use only small, isolated movements of mouse clicks and key board shortcuts rather than the physicality needed to bring handmade things into the world. The next section offers a working solution to this sedentary way of interacting with computers so that my practice can better join these two opposing contexts.

Hand-printing-clay and movement capture

Figure 8; Magnetic movement tracking sensors, <https://polhemus.com/applications/electromagnetics/>

The intent of this practical exploration is to bring in a material connection to digital sculpture at the CAD stage. I intend to capture the experience of making using an electromagnetic tracking device, gathering layered movement data, essentially turning myself into a 3D scanner.

By taking this approach I will be fusing the sculptural/material experience into the digital record. I hope that the digital object could then originate from a deeper, felt and more experienced place that can then utilise all of the spiralling possibilities afforded by digital fabrication. The 3D scanning methods I have used previously have required too many separate processes that can cause friction with one another across these physical and digital material boundaries.

Figure 9; Prototype 01, Movement tracking set up, link to demo <https://vimeo.com/413878714> (Grymsdyke farm ,2020)

They can slow down the flow of working. The emergence of robotics in the creative industries is revolutionising how things are designed and made. They are transforming the culture of the spaces they inhabit (Willman, Block, Hutter, Byrne, *Robotic Fabrication in Architecture, Art, and Design*, 2018).

Figure 10; Printing clay using robotics, link to demo <https://vimeo.com/413878905> (Grymsdyke farm, 2020)

Another popular perspective, or feeling, is that automation and universality of mark-making within 3D printing is standardising the objects it creates by following the rules set out by the machine's author and different slicing programs. It allows everything to be measurable and quantifiable. The mistake can even be repeated! (Paul Virilio, *The Original Accident*, 2005).

If the aim is to get closer to the experience of the material and the bodily performance of making itself, then movement sensors could be the best way of recording the experience as well as the emergence of the sculpture.

Figure 11; Together Crown, robotically printed, ceramic, derived from multiple 3D scans of the hand-printed origin, 35x48x120 cm, (Theo Harper, 2021)

In other CAD platforms that I am aware of, where a clay-type simulation is visualised, there is no possibility of linking it with the actual physical material itself. Creating a better interaction between the physical and digital spaces requires a lot of development. I required coders and specific hardware usually used in the domains of science and surgery. This blended practice, using the programming knowledge of Vicente Holler and Yingying Ying, who both wrote the Python script in response to my making and verbal directions, via a text editor plug in for Grasshopper (a Rhinoceros 3D platform) that understands each point in motion captured by the tracker to draw the clay lines in digital space. Essentially, I was turned into a 3D scanner by

utilising hand-printing movements and the natural additive process of the emergent sculpture to build the digital model.

Figure 12; Prototype 02, movement tracking hand-printed-clay, studio, UK, 2021

The unique position of HPC is that the practitioner is involved in the movement of creating the object whilst in contact with clay. The hands are involved in the emergence of the sculpture and so can be recorded by the tracking device (figures 3 and 4). This closer integration differs from the previously used 3D scanning devices because it utilises the hand-printing movement as it interacts with clay. Observing the digital and material artefacts gives me confidence that the layered recording of these tacit movements captures the experience of making the sculpture in a fuller way than simply scanning the surface of the object. The simulated artefact has infinitely more surface detail than that of a scanned version and records internal surfaces, which reinforces the importance of this process as something that is unique, and different from 3D scanning.

When planning the project for EKWC, I found that the Grasshopper plugin (an algorithmic visual scripting programme) had unfortunately been corrupted, and all the work that Vicente had done coding these developments was lost. It meant that I had to repeat the process with a different tracking system but also collaborate with a different person capable of coding in Python script as Vicente was not available. All this had to be done at distance which created further parameters in terms of communication, responsiveness, and flow.

Figure 13; Isolated movement of one hand-printed clay line, studio, UK, 2021

From my studio I began spending time working on capturing the hand-printing data to collect

enough information to build the grasshopper script. This sculptural form (figure 8) was first defined by the need to create internal shapes as well as external shapes and to understand the capability of the prototype to track through clay walls. Figures 5, 6 and 9 show the mesh-generating process. In figure 8 you can see an isolated section of the data showing the wavy motion which visualises how I hand-print the clay onto the line beneath it. The algorithms created by the programmers measure the movement between a set of distance parameters that correspond to the pressure my thumb put on the clay. All other unwanted movements fall outside of the parameters and are automatically deleted. It means that nothing, but the HPC will be recorded.

This much more analytical process makes me acutely conscious of how I am interacting with the clay and the computer in tandem. There is a hyper-awareness of my making actions while engaged with two types of record. Defining my actions created small changes in the surfaces of the sculpture and affected the overall form as it did when 3D scanning some of my work leading up to this exploration.

Figure 14; 3D digital record of clay movement, studio, UK, 2021

The additive nature of clay printing is especially good at translating into the digital space as it is in reversal. The coding algorithms consider the downward pressure of the thumb and the surface of the initial lines of clay so they can be pressed flat onto the surface of the 'ground' both in the physical and non-physical realms of materiality. The final mesh shows the entire layered experience of constructing the sculpture (figure 9). Internal and external spaces that could not have been achieved from scanning the sculpture are shown to be effective using this method of 'movement scanning'. The movements that have changed the visual appearance of the digital clay are actions that are attached to the making experience and are ones that I see as beneficial in how the digital object can be expressed. After it was used, the clay was reclaimed.

Figure 15; Digitally printed emergent clay form at 1/20th of the scale, nylon, studio, UK, 2021

The clay has been through changes beyond this sculpture and will continue to go through changes as it is used again to record sculptural movement. The clay allows for instantaneous change and reaction that is reciprocal for the human senses. The digital object is then able to be printed at much smaller scales with very intricate details, compressing the physical movements recorded from the clay origin (figure 10).

EKWC-Putting methods into practice

I could now put this into practice at EKWC to produce a large-scale hand-printed origin that is tracked from start to finish. The following images describe the process and the capabilities of this unique way of reciprocally producing both a physical and digital record of my movement.

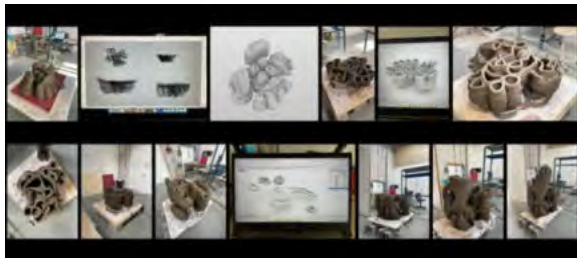

Figure 16; Process into practice, building a full-scale hand-printed sculpture, EKWC, 2021.

Based on the measurements of the hand and the clay coil, the movements specific to this way of making have enabled a more meaningful digital record to take place, meaning that is, 'incorporated and lived rather than simply intellectually understood' (Juhani Pallasmaa, *The Thinking Hand*, 2012). In future projects this could be expanded on exponentially if given to other practitioners to work with who's practice can be

measured through repeated movements. It would allow a unique response to cad design based on human interaction with clay.

Figure 17; Derived from the clay origin, Digital 3D render, EKWC, 2021.

For my sculpture this blended way of thinking about material has enabled the internal structure to be recorded as it is experienced, which has resulted in an unusual formal digital development that is different from standard scanning devices. It will no doubt have interesting future fabrication consequences, utilising CNC, 3D printing and robotics.

Figure 18; Nylon prints, taken from the movement data, studio, 2021

Figure 19; CNC milling the captured lines of movement and hand-printing back into the polystyrene mold (with thanks to Sander Albas and EKWC, 2021)

Figure 20; Jest, Derived from the Origin, Ceramic, 74 x 65x 79, Theo Harper, EKWC, 2021

The unexpected capture of other repeated movements that are not visible on the physical origin could also be a source of future inspiration that can guide this developing language in both the digital and physical realms.

The focus on detailing the movements of hand-printing clay has led to a hyper-awareness of the actions that I am involved in. Some of the parameters have altered the way that I make the sculpture, sometimes having to change the direction of movement so that I don't have to change hands, so that everything can be recorded. This explicit example of how technology can define a direction of thought through mediated instruction is another important reason for needing to understand these systems from the inside out.

Summary

This approach intends to change the direction of travel for CAD: not following the direction of a desk-based beginning, but with a connection to the material and labour that is essential in bringing something physical into the world. It enables a connection we need to get back, that helps promote

care and understanding for what is produced. The fields of fine art, fabrication, design, architecture, craft, and human-computer interaction can benefit from this research, with crossovers occurring in many other academic disciplines. This project gives practical examples of integrating varying levels of hand-making into the space of Rhino CAD (multidisciplinary platform) and the 3D printing process. This way of linking movement to an ageing and forever-changing body can also affect the language that machines produce, to be less perfect and more attuned with our living origin.

Figure 21; Origin, Ceramic, 128x 88 x78, EKWC, Theo Harper, 2021

Acknowledgements

3D printing backwards has only been possible with funding from AHRC UK. It has been enabled by computer programmers Vincente Soler (UK) and Yingying Ying (University of Michigan US). Making workshops Grymsdyke farm (UK) and EKWC (Netherlands). The conduit hardware that I have used to make the digital sculptures was supplied by Target 3D and Polhemus Electromagnetic Tracking (EMT), Rhino 3D (CAD program) and Clay 3D Printers LUTUM and WASP. This research was conducted whilst on the CDT research program, a PhD partnership between Northumbria University and the University of Sunderland.

Biography

Theo is an artist and researcher based in Northumberland. His practice spans site-specific installation, sculpture, video, and photography. Clay always at the centre; Theo interrogates material and processes, intuitively inventing ways to release an expressive making narrative. It is a constant inquiry: Born out of repetitive, time consuming and layered techniques. By mastering different making systems, it is possible to break apart pre-existing realities.

Theo studied sculpture at the Royal College of Art, London. He has shown work nationally and internationally and taken part in various residencies. Alongside gallery-based exhibitions he has organized various projects that include a permanent installation in a terraced house, London (2013-16), a cliff polishing in Cornwall (2014) and more recently taken part in a three-month residency at EKWC in the Netherlands. Theo has been working on a AHRC funded PhD that he has completed in April 2022.

Splitting Defense: A Methodological Journey into the Material Basis of Practice-Based Research

Michael Heidt

GeDIS, University of Kassel / HCI Research Group, Anhalt University
Kassel / Köthen, Germany
michael.heidt@hs-anhalt.de and

Elli Kuruş

Independent Artist
Leipzig, Germany
info@ellikurush.com

Abstract

This text details a practice-based research project which was partially materialised within the art-installation *Splitting Defense*. Splitting defense is a mixed media artwork, comprising an audio narrative embedded within a physical installation. It places the recipient into the realm of a future society, remembering the horrors of the present. While evoking a languorous sense of belonging to the future, it casts an eerie light on current practices of feeling, empathising, caring, ignoring, and dividing. The artwork thus playfully engages topics such as gendered patterns of valuing and devaluing phenomena of emotional labour.

Keywords

Practice-based research, new materialism, diffraction, digital installation art

Introduction

This text talks about the relationship of a project of practice-based research [8, 14] and its partial materialization in the form of an art installation. The respective research project inquired into the status of affective economies in relationship to the question of value. The artwork *Splitting Defense*¹, created by collective artist Elli Kuruş², negotiates these questions in the form of a speculative narrative.

The text will first describe some of the methodological peculiarities inherent within the practice-based approach adopted. Subsequently, it briefly describes the collective context of the artwork's production before launching into an account of the work itself and the readings it affords.

Aporias of Practice-Based Research

As a reflective process, practice-based research constitutes a deeply paradoxical endeavour. It has to continuously reinvent itself in order to do justice to its object while at the same time remaining consistent enough to sustain an intelligible process of inquiry. It is a methodology without method, dependent on a delicate balancing act at every turn of its application.

Resultingly, practice-based research constitutes something of a methodological peculiarity, especially in the context of

creative practice. It does not provide any recipes or guidelines, nor does it prescribe procedures to be followed. It is neither toolkit nor framework.

The troubles of practice-based research multiply as soon as it is employed in a sphere such as art-making. Artworks do not require a method, on the contrary, their very nature always also resists the application of repetitive procedures. Insisting on a playful surplus, conceptions of art as autonomous practice sit uneasily with any constricting set of methodological demands.

The passionate indifference of methodology and artwork extends to the level of materiality: Tautologically, a body of theory and a material artwork occupy different planes of being: They cannot touch. Artworks do not read theory, they do not possess a library card and cannot subscribe to neural.it or the British Journal of Aesthetics. Theories on the other hand do not frequent galleries, exhibitions, or museums. In order to establish any form of relationship they are always dependent on the presence of an "external" apparatus.

Even if we possess a dearth of methodological knowledge of how to construct these devices of relating, fortuitous accidents and serendipity hint at the possibility of their creation. Theories do seem to have the ability to inform processes of art making, their signifiers keep seeping into the form of artworks. Likewise, artworks do possess certain provocative capabilities, attracting readings and interpretations.

Perhaps the notion of practice-based research as a device for *reflection* itself is to blame for our troubles. A methodological alternative presents itself in the notion of diffraction, a category highlighting the importance of phenomena of embodiment and material intra-actions [2]. Neither completely disavowing the subject as a surface phenomenon nor constructing its objects from a position of analytic detachment, it highlights the material community of signifiers with the phenomena they want to speak about.

If we follow this path, there indeed are countless ways to organise the congress and crosspollination of material works and theory. One of these approaches is discussed here in the form of utilising the artwork as a diffractive apparatus. It tries to utilise works produced as elements within a material-discursive network. The remainder of this text describes an experiment of this kind by retracing the entanglement of theory and artefact in the art installation *Splitting Defense*.

In the following, the artwork is first described in relation-

¹http://ellikurush.com/?page_id=659

²<http://ellikurush.com/>

ship to the collective process that produced it.

The Poietic Process – Antagonistic Negotiations

Works within Elli typically emerge through a process of continuous contestation, collaborative making, antagonistic reframing and productive misunderstanding. There frequently is no consensus regarding interpretation, character, or intent of works. Furthermore, the boundaries between works themselves will often be contested.

Any process of description is further complicated by the iterative history of the work's development. Both physical components and the audio narrative existed in multiple forms and variations, their development lay in the hands of different members of Elli. Respective elements were combined into exhibited form in a process of negotiation in which participant's intentions created a network of productive tension.

On the level of production, Splitting Defense was made as bipartite entity, consisting of audio narrative and physical installation. Processes of creation of the audio narrative and physical installation were communicatively insulated against each other during the majority of respective making processes.

Furthermore, it has to be stressed that, due to the collective nature of the work, no perspective can claim an authoritative status. There exists no privileged position within Elli itself, discussions are not consensus based and usually do not result in shared views or interpretations. Ultimately, Elli's communications cannot claim any special authority in relationship to the work. They simply originate from a perspective that is materially implicated in the work's production.

The Artwork – Splitting Defense

The installation is created by joining an audio-narrative and a physical structure.

Audio Narrative

The audio narrative addresses the listener as a member of a future society. From this perspective, the narrative tells the story of a lost prehistoric civilization whose remnants pose an unspecified threat to the narrated moment.

The listener is guided through the narrative by a spirit, embodied as whispering voice. The basic setting is that of an initiation ritual; the listener is addressed as a disciple ready to join the ranks of "wise women". This rite of passage, however, calls for a journey through the perilous territory of the *split*: a spiritually and mentally challenging trial which exposes the disciple to the horrors of the past.

Following this short introduction, the listener is led through a set of chapters highlighting various aspects of the split. The spirit guides the listener by modulating sounds heard in the background. Furthermore, every chapter is associated with its own base-frequency.

In order to reconstruct the lost prehistoric society, its way of life is related to specific patterns or weaves. These constitute modes of intertwining and separating ways of thinking, feeling, building, constructing, caring, ignoring, repressing, seeing, exerting, and relaxing. The narrative subsequently plays with various references to mental practices alluded to

by virtue of respective audio samples. The "economic cortex" is described as an encompassing agent that imposes a certain order, trying to separate strands of the weave.

An uncanny characteristic of the split is its tendency to organise the world into binaries: Paid / Unpaid, Public / Private, Conscious / Unconscious, Domestic / Professional, . . . These exert a separating, splicing influence on the pre-split fabric, thereby complicating the weave. On a sensory-auditory level, remembrance of the split is manifested by shifts regarding the stereo-balance of samples within the experience.

The narrative ends with the downfall of the lost society as it ultimately weaves itself to death. In a final spell of disorientation, the split closes and the listener has completed the trial.

Endemic throughout the narrative is a sense of anxiety that past dynamics, the violent history might again inflict itself on the present, thereby destroying the fundamentals of the post-split society. The inner workings of the future society are not explained further. The spirit merely hints at the mortal dangers posed by the split, while the urgency of the message is transported more by tone of voice than through explicit narration.

Physical Installation

The physical installation is shown in Figure 1. Intended to be read as reconstruction of contemporary artefacts by a future society, it consists of mundane technological artefacts arranged in a way that seeks to present them as part of an unfamiliar setting.

It is composed of a tripod, circuit board, bluetooth receiver, a Raspberry Pi computer, headphones with electrodes, a fluffy cushion, and wiring. The tripod evokes the form of a tent, thereby engendering associations of shelter and providing a space for visitors to feel safe while listening to the narrative. The wiring repeats the trope of the weave: Woven wire is arranged through craft techniques such as macramé and braiding. The circuit board is placed on the floor under the tripod and connected to the wiring. Audio signals are supplied by a small bluetooth receiver, fixed at the tripod canopy's underside, thus remaining invisible from most viewing angles. The sender is realised as a Raspberry Pi single board computer running customised software and placed out of sight. Headphones are equipped with saline-based wet-contact electrodes. This inclusion of neural sensing equipment hints at the topic of detecting and valuing patterns of emotional labour.

Methodology – The Artwork as Diffractive Device

By their very nature, artworks are multi-purpose devices. You can look at them, dream about them – they successfully operate as paperweights, mood-stabilizing agents, distractions, theatrical props, or investment opportunities. This text, rather restrictively, is interested in a different feature of the artwork, in its capacity as a diffractive device, giving rise to a family of readings.

In accordance with this approach, signifiers are channeled through the artwork, giving rise to specific patterns of expe-

Figure 1: Splitting Defense - Installation View

riencing, feeling, and thinking. The work thus co-produces patterns that otherwise would not be observable, while their appearance also depends on the influx of intellectual and experiential particles.

Crucially, the composite work leaves semantic gaps through which discursive elements ceaselessly pass. Patterns observed depend both on the theory used to create a particular diffractive patterns and the material characteristics of the work itself. The work thus intra-acts with semantic materials to give rise to a family of readings which is described in the following section.

Emerging Patterns – An Affective Economy of Discourse and Material

Psychoanalytic Reverberations

Psychoanalytic literature provides us with an intra-psycho account of the activity of *splitting* in the form of object-relations theory [10]. The eponymous Splitting Defense marks the attempt of consciousness to separate two unrec- oncilable impressions.

It also implicitly points to the manifold precarious psycho- logical formations produced by the capitalist system.

Just as capitalism cannot simultaneously account for the presence of production of value and the reproductive prac- tices which sustain it, splitting defense points to a conscious- ness unable to account for a contradiction. The term conse- quently can be read as “defense through splitting” and “def- ense from splitting”.

New Materialist Overtones

A recurring motif within material-discursive networks are new materialist [5] ones.

The narrative tries to entangle the temporal positions of social analysis, utopian speculation, and immediate experience. It selectively foregrounds the recipient’s body through ASMR [3] effects. There is a pervasive lust for the creation of entan- glements, for intertwining and confronting seemingly disaf- fected analysis with the immediacy of corporeal experience.

However, “new materialisms” were by no means the only materialisms injected into the diffractive situation. In fact, considerable attention was given to their (negatively) dialectical siblings:

Value Diremption Theory – The Commodity and its Other

The trope of the “split” is intellectually implicated in the the- ory of value diremption.

Value diremption theory is a heterodox Marxism indebted to value critical discourse as espoused by groups *krisis*³ and *EXIT*⁴. Created by German theorist Roswitha Scholz, it can be conceived as dialectical-materialist response to feminisms basing themselves on post-structuralist discourse [13]. Inter- estingly, the community of value critics subjected them- selves to a split of their own when tensions within *krisis* lead to a schism, creating value critical rivalries between

krisis/EXIT! adherents (which in themselves constitute a mi- nority within the rapidly dwindling community of Marxists). One of the more famous publications of the group (pre split) is the “Manifesto against Labour”⁵.

Scholz analyses capitalism as a social edifice which for its functioning depends on a patriarchal system of distributing and selectively obscuring practices of labour. Certain labour practices (such as emotional work) have to be constantly dis- avowed while at the same time their presence is vital for the system’s survival [12]. Within a gendered regimen of divi- sion of labour, these devalued activities are projected onto a hidden “female” reproductive domain, which is ideologically excluded from the sphere of work proper. Respective invis- ibilising effects are masked by patriarchal discourse which exclusively focusses on the surface level of the commodity form.

Value diremption theory is special in the sense that, un- like many Marxisms (value critical or not), it does not install its own version of a privileged phallogocentric [4] position. Any exclusive focus on the orthodox concept of commodity inevitably reproduces not only gendered power relations but misses the crucial dialectical relation through which value re- produces itself. The category of value itself can only be re- constructed in the context of a dialectical relationship towards its dirempted other. Consequently, the analysis of value is not intellectually privileged over theorization of its diremption. Resultingly, neither scientific, rational discourse, nor every- day experience and empathy are able to claim a privileged position regarding practices of social analysis.

A material phenomenon such as a social-media platform cannot be understood without analysing the network of cor- porate structures, ad-revenues, the constant reutilisation of value produced by users. At the same time, it cannot be un- derstood without giving voice to the passions and experiences circulating through its communicative channels.

Indeed, adopting the position of an artwork that speaks in unsettling tongues while at the same time mobilizing the an- alytic functions of discourse might constitute a fitting narra- tor position when speaking of value diremption. After all, endeavouring to speak of the Other in the medium of phi- losophy, science, or theory always traps the speaker within a performative self-contradiction [7]. Conversely, it could be argued how any theoretical account of the Other neces- sarily remains incomplete, as the medium of theory under capitalistic-patriarchal conditions necessarily implies an an- drocentric tendency.

Diffraction Pattern – Materialisms in Dialogue

The most interesting patterns might indeed be observed when examining the series of readings in its totality, as an encom- passing material-discursive network, thereby putting different materialisms in dialogue with each other:

The artefact thus becomes visible as site of entanglement where different materialisms meet, attract, repel, and inter- lock. Crucially, we perceive the omissions, and semantic dark spots left by any one individual reading.

³<http://www.krisis.org/>

⁴<https://www.exit-online.org/>

⁵<http://www.krisis.org/1999/manifesto-against-labour/>

The work ceaselessly labours to complicate the relationship between voice and soundscape. Detached analytic and immediately bodily implicated elements intra-act with each other, displace each other, at times entering into precarious equilibrium before re-emerging within processes of cordial antagonism. Constructed as a diffractive device, it creates a tableau of signifiers shifting against each other while possessing internal relations and structure.

The presence of auditory antagonisms within the work can easily be deciphered as reference to social discords if the receiver should be so predisposed. Furthermore, Splitting Defense can be read as liquidation of value-criticism in the form of post-semantic play with signifiers. The recurring motive of 'binaries' alludes to the digital character of computer networks, forming a web of their own while escalating the affective engagement of their users [9].

The work's intermittently disorienting effects hence point to the irreducibility of a material analysis of capitalist societies which does not proceed in recourse to self-identical principles but has to account for the ambivalence of social phenomena.

Over time, the work becomes suffused with the categories and associations of the theories it draws on. Simultaneously, theory changes in the process of materialization, losing its illusory autonomy when becoming an element within an artwork which projects its own logic and inner dynamics.

Diffractive Practice – Diffraction as Methodological Element within Practice-Based Research

In order to playfully entangle discourse and artwork, the practice-based process has to continuously formulate new strategies to relate theory and artefact. A recurring model within this constant practice of relating is that of playful intercourse with theory:

The material body of theory is opposed to that of the art object. These initially have nothing in common – it is the mutual alienness of materials, the pleasant shock of incommensurability which affords a tantalizing quality to the process. Gradually, their bodies begin to displace each other, effecting different shapes, forms, and pressures. Their elements enter into a succession of configurations while assimilation or merging remains impossible. It is an activity that knows no immediate goals or strategies outside of itself.

The ensuing process thus accentuates the shifting position of nodes of heightened excitability, turns its attentions towards semantic cavities in the form of omissions and ellipses. Consequently, it is the intellectual experience, the joy derived from playfully assuming speculative or analytical stances that unlocks the work, diffracting theories into a multiplicity of perspectives and incentives for interpretation.

Within these constructed material-discursive networks, practices of reception can be conceptualised as processes of differential sensitisation. Artworks begin to provide a manifestation of intellectual elements that subsequently become available to sensory experience. The receiver is neither a distanced observer of the artwork, nor an equitable part of it. She becomes materially reconfigured [6] through her en-

counter with the work, obtaining novel sensibilities for the work's communications. The singularity of any given body and its sensibilities effects the singularity of every process of reception.

Conclusion

Confronting theory and artwork in the context of diffractive experiments might ultimately perturb both. It can trouble our image of an artwork, leave us in doubt about the dominion of theory. Theories might crack under the weight of objects; objects might melt under the unforgiving gaze of theory. If we are lucky, however, they might also start invading each other, forming surprising constellations of material interpenetration.

A body of theory might choose to join itself to an alien assemblage of matter, thereby allowing both to exercise their specific agencies: Theory possesses the power to connect the site of the artwork to the illimitable sphere of social experience. Artworks can act as recalcitrant models of theory, allowing its concepts to be embodied while simultaneously insisting on the irreducible individuality of concrete experience.

In the context of the specific practice-based experiment discussed in this text, one of the most fortuitous consequences might be for the receiver to start suspecting the economic order and the patterns of emotional labour practices that go with it.

All travails of analysis should, however, never distract from playful and immediate engagement with the artefact. If we allow ourselves to be invaded, if we start listening, it creates a field of comforts, suspicions, disappointments, gives rise to disorientation and curiosity. After all, it is the result of desires, of desires to contradict, to narrate, to pervert, and to embrace.

Authors’ Biographies

Michael Heidt likes to situate his practice at the intersection of poetic code creation and critical-reflective theory production. He has conducted practice-based research endeavours informed by fields such as philosophy, media art, and electronic writing. Project foci range from software-based inquiry into microbiological populations to speculative inquiry into the potentials of distributed ledger technologies to foster post-scarcity economies. An ongoing focus of Michael’s research is complexity, which he has applied as intellectual lens motivating research engagements with biological systems, interaction systems, and distributed systems. Michael was a visiting scholar at Simon Fraser University’s School of Interactive Arts and Technology, is an alumnus of German Academic Scholarship Foundation, of DFG’s research training group crossWorlds, and of Andrea von Braun Foundation. Currently, he is conducting the project CoGS at Anhalt University while being an affiliated researcher at University of Kassel’s Gender/Diversity in Informatics Systems group.

Elli Kuruş is a Leipzig-based collective artist, 44% complete. Her practice spans research-based and speculative approaches that converge into installations, videos, drawings, and various performative practices engaging the audience. Investigating the agency of the things around her, she critically examines the development of media and technology, reading the present as material history.

SONUS MARIS

Dr Nigel Helyer

Sonic Objects; Sonic Architecture & Macquarie University
Sydney, Australia
sonique1@icloud.com

Abstract

Sonus Maris is a collaborative creative-research project at the Water Research Laboratory, Sydney Australia (University of New South Wales) which is developing a series of artworks that attempt to manifest the underlying dynamics and complex interaction of natural climate and oceanic systems. Employing visual and telemetric data from satellites as well as on the ground observations and ariel surveying the research team aim to generate sophisticated sonification and visualisation that offer a palpable and visceral experience of the long-term flows and patterns as well as of the singularities that make up the world around us.

Keywords

Art and Science, Environmental-art, Bio-art, Sonification, Visualisation, Sound-art, Sound-sculpture, Earth-observation, Climate-systems, Hydrology.

Introduction

Whilst the focus of this paper is upon the current creative-research project *Sonus Maris*, undertaken with the Water Research Laboratory of the University of New South Wales (Australia) it is placed within the context of a series of prior art and science projects which have endeavoured to reveal aspects of the environment and biosphere that are normally unavailable to our senses.

Works such as *Under the Icecap*, a long-term collaboration with the Institute for Marine and Antarctic Studies (University of Tasmania) that sonify and visualise bio-logging data collected from the deep under-ices dives of Southern Elephant Seals in Antarctica. *VoxAura* and *Take a Deep Breath; Breathless* reveal the subtle chemical variations in water and air quality respectively. And the ongoing *Oratorio for a Million Souls* project generates both real-time mixes and musical scores, based upon data-bee-hives installed in special bee listening architectures constructed in German and Dutch botanical gardens. These projects are the conceptual and developmental pathways for the current works.

*Sonus-Maris*¹ started life as a short artist in residence with the Water Research Laboratory in which the artist created a prototype sonic sculpture that made palpable the interactions of wave and tide action upon the deposition and erosion of sand along the axis of a famous Sydney surf beach called Narrabeen. The work took the

form of four giant Chaldini Plates driven by powerful audio transducers that delivered musical scores derived from data. Happily, the collaboration proved successful and the relationship has now flourished into a long-term creative art and science research project.

Sonus Maris, Version No.1 a context.

The Brain is wider than the Sky
For put them side by side

The one the other will contain
With ease and You, beside

The Brain is deeper than the sea
For hold them Blue to Blue
The one the other will absorb
As Sponges, Buckets do

The Brain is just the weight of God
For, Heft them, Pound for Pound
And they will differ, if they do
As Syllable from Sound.

Emily Dickinson, The Brain is wider than the Sky (1862)

Figure 1. *Sonus Maris* 2019, prototype installation (© Nigel Helyer).

¹. <http://www.sonicobjects.com/index.php/2019/12/16/sonus-maris/>

We are neurologically predisposed to seek patterns in our surroundings: in fact, pattern recognition is our core cognitive ability, vital to our evolution and survival as a species, as it affords the capacity for prediction.

In life as in art, we take delight in the symmetries, growth patterns and morphologies of the natural world as through them we recognise our formation. However, there is a constant flux between, on one hand, the regularity, or predictability of a pattern and on the other, the instability or turbulence that might threaten to render it indecipherable - to walk this tightrope between order and chaos is one of the central techniques of art, to distil clarity from chaos is the purpose of science.

In 1917 the Russian Formalist writer Viktor Shklovsky made a distinction between poetry and prose, coining the term *Ostranerie* (or Defamiliarisation) a device for making strange, to render a common thing in an unfamiliar manner or context to create a fresh perception of it. This trope of making strange with language has recurred throughout the twentieth century, surfacing in Freud's notion of the Unheimliche (the uncanny), Berthold Brecht's *Verfremdungseffekt* (the estrangement effect) and Jaques Derrida's *Différance* (which hovers somewhere between difference and deferment).

The probabilistic learning that pattern recognition develops is extremely useful in the prosaic world—it is the way we navigate our daily lives. However, in creative practice, we always require a twist to a narrative, a dissonant metaphor in a joke, or an unpredictable note to conclude a melodic series. This is the sweet spot, the point at which our expectations of regularity in a pattern are disrupted—but not too much, just enough to throw the brain into mild confusion. It is the fissure, the reveal, the punchline that reflects on the narrative arc and plays with our assumptions.

Science is based upon empirical evidence, it observes and carefully quantifies the complex phenomena that surround us in an attempt to make sense of chaos. At the small end of the scale, each wave that crashes onto the beach at Narrabeen creates a turbulent swirl of sediment, multiplied thousands of times in each storm. The scientists and engineers of the Water Research Laboratory understand these individual events as nonlinear interactions which are difficult, if not impossible to interpret or predict. However, they have been monitoring the shifting shoreline at Narrabeen for over 43 years and from this long-term view, it is possible to identify an accumulative effect in which the sand volume rotates between the northern and southern end of the beach in cycles that range between two to seven years. When considered in conjunction with wave and storm data an overarching mechanism driven by climate emerges - it is such a point of view that operates along the axis of the particular to the general that allows us to see the 'wood from the trees.'

A step back - How to make palpable the invisible?

Precursor 1. - *Under the Icecap*.

Science is constrained by Objectivity and Impartiality and perhaps Art is constrained by Subjectivity.

Our Bio-Sonic journey begins by heading toward the South Pole and the Sub-Antarctic Islands. *Under the Icecap* is a long-term Art and Science collaboration² that links scientific bio-logging data and GIS techniques with interactive acoustic cartography to develop a series of Audio-Portraits that extend the conceptual and intuitive grasp of extremely abstract bio-logging data.

The bye-line for the Institute of Marine and Antarctic Studies is "Turning Nature into Knowledge." The *Under the IceCap* project supplies a second line "Turning Knowledge into Culture" encapsulating a powerful Art and Science synthesis and simultaneously raising the expectation but also the risk of the endeavour. The primary aim of the project is to produce creative works which are compelling and affective, but which can simultaneously be works of scientific utility; that hopefully tap into both sides of the brain! The key focus is to illuminate the relationship of the environmental knowledge generated from Antarctic bio-logging data with the Anthropogenic changes in the biosphere.

The collaborators realised that the extensive and extremely complex datasets collected by southern elephant seals (*Mirounga leonina*) represent a considerable interpretive challenge and provided the opportunity for a hybrid art and science exploration of new methods and forms for manifesting the data and to develop novel forms of public awareness and debate about the oceanographic and climatic data that the seals collect. Our aim is focused on developing techniques for visualising and sonifying the complex bio-logging data collected by southern elephant seals on their deep dives under the Antarctic Ice shelves and their long southern ocean transits.

We explore new ways to make these data-sets palpable, manifesting them as a series of experimental music concerts and visual and sonified installations with the express intention of illuminating the fundamental connection between human activities and planetary dynamics. The intention that drives our methodology is that the artistic and scientific paradigms which intersect in *Under the Icecap* form the basis of a robust and productive trans-disciplinary collaboration. The word collaboration is widely and often incorrectly used in art & science projects, typically one discipline being subservient to the other. However, the emphasis within *Under the Icecap* is to design an open, consensual and collective creative research process, that balances and complements the knowledge bases, motivations and target audiences of the art and science disciplines involved. Within a scientific context, such bio-logging data is most frequently

2 Artist Dr Nigel Helyer (Sonic Objects; Sonic Architecture) and Marine Scientist Dr Mary-Anne Lea (Institute for Marine and Antarctic Studies at the University of Tasmania).

Figure 2. Bio-logging 2012, data rendered as animated maps and graphical scores in a live performance (© Nigel Helyer).

consigned to two-dimensional graphs each of which contains a limited range of variables, making a wholistic gestalt improbable, if not impossible to achieve. Searching for a more flexible approach we imagined a situation in which each of the many variables could be dynamically put into play, examined in real-time and generate on the fly responses - a kind of neural network.

Our solution, musicians! Our decision to interpret environmental data via an aural process is based upon a hunch that musicians have the best pattern-recognition wet-ware around and that our aural sensibility is in fact more finely tuned to detect minor variations in pattern and recognise subliminal differences, than our visual sense.

The large multi-factorial data sets are re-conceptualised in two ways. Firstly, using sophisticated cartographic software, we generate animated 3D maps of the data traces of individual elephant seals for large scale data-projection.

Using the same data we also generate various forms of graphical scores and again render these as dynamic projection works. These are then presented in parallel to a quartet of professional musicians in a live concert context where they are asked to respond individually and/or collectively to the material (there have been many structural variations on this method).

Naturally, the elephant (seal) in the room is the scientific allergy to a subjective, and non-repeatable response which some may consider renders the enterprise interesting but ultimately un-scientific. A somewhat cheeky rejoinder might be that statistical data is, in and of itself, an artefact and that its analysis is even more so. Does the bio-logging data in any manner resemble the

experience of a southern elephant seal feeding two Kilometres deep beneath an ice shelf at a pressure of one hundred and ninety-four atmospheres? As the British Prime Minister Disraeli once said -

“There are three kinds of lies;
lies, damned lies and statistics!”

Precursor 2. - *VoxAura; The River Sings.*

Our blood has the same salinity as the Ocean, a reminder of the origin of all life on the planet and a warning that we share our well-being with our vast and indifferent mother.

As terrestrial dwellers, it is easy to overlook the fact that we inhabit an essentially two-dimensional space

Figure 3. VoxAura, 2011, Turku, Finland. (© Nigel Helyer).

that has surface area but scant depth. By contrast, the marine world is three dimensional, its depths accounting for 99% of the Biosphere and its surface accounting for 70% of the planet's area. The ocean forms the principal inter-face for chemical exchange with the atmosphere, absorbing carbon dioxide and releasing oxygen – it is the pump that drives climate and regulates the air that we breathe.

Like other semi-enclosed bodies of water, the Baltic is brackish, its waters less saline than our tears. The River Aura flows through the port city of Turku, past the maze of low granite islands that form the Finnish archipelago and into the Baltic, carrying with it a mixture of chemical nutrients and effluents that simultaneously drive the annual algal bloom and degrade the complexity and fecundity of marine ecosystems. Put simply the Baltic has lost its clarity and its fish but has gained the reputation as the most polluted sea in the world.

*VoxAura; the River Sings*³ suggests that we pay attention to these complex issues that ultimately control our destiny by listening to the chemical composition of the Baltic.

The project consists of two vessels, moored on either side of Turku's Theatre Bridge, equipped with speakers which broadcast a soundscape. The first of these plays material from a large archive of sound recordings which evoke the maritime traditions and marine environment of the Baltic; whilst the second transforms this material, allowing us to 'listen' to water quality data that is constantly collected by two trans-Baltic ships and downloaded to the work. The project's computer system takes variables from this data, such as position, depth, temperature, salinity, turbidity and pH, using them as musical parameters to transform the source audio (which is playing simultaneously on the first vessel) producing an ethereal 'data music' as a metaphor for, or analogue of the chemical composition of the sea.

Precursor 3. - *Take a Deep Breath; Breathless.*

This work investigates the sonification of environmental data and how the resulting sound works can be installed into a public or architectural situation to create new forms of sonic space in which it is possible to experience, examine and reflect upon the complexities and consequences of our political and economic actions in an increasingly chaotic world.

Conceptually the work is similar to *VoxAura* in that it is structured in two parts, one originating in a social and cultural context, the other ecological and environmental. The work aims to integrate and interrogate the relationship between these spheres, and present them in an outdoor urban environment and/or public architectural space.

Figure 4. Take a Deep Breath-Breathless, street recording (© Cecelia Cmielewski).

*Take a Deep Breath; Breathless*⁴ concerns the atmosphere, the breath and the act of breathing. Breathing as meditation, as respiration, failing breath in respiratory diseases, the breathy sounds of our voices, of song and flute – ultimately the metaphor of breath as life itself.

During his sojourn in Delhi, the artist recorded a large audio library that embraced a wide range of ambient, vocal, environmental and musical sounds, in effect creating an AudioPortrait of the physical and social environment.

Atmospheric data was sourced directly from the City's environmental monitoring system providing a constant and somewhat alarming stream of digital information on the levels of pollutants in the Delhi atmosphere. Ironically, during the project New Delhi experienced the worst air pollution on record, driving home the point in a dramatic but unpleasant manner.

From a technical perspective the system consists of two components ~ firstly a large audio library that is capable of being updated via wifi – the second element is a correspondingly large library of environmental data sets which can be accessed either in real-time (online) or updated via wifi regularly. The system computer selects a sound file and data file at random and convolves them to render two stereo audio streams to the speaker array which was installed in the gallery space of the Portuguese Embassy's Cultural Centre.

As in *VoxAura*, one stereo pair of speakers plays the unadulterated audio file whilst the other plays the harmonic data-music that simultaneously renders some of the data structure, but which also has a sonic imprint of the audio original.

⁴ *Take a Deep Breath; Breathless* was commissioned by the Sound Reasons, Sonic Cities Festival 2012 and took place in Delhi, India. https://www.sonicobjects.com/index.php/2014/06/29/breathless_take_a_deep_breath

Precursor 4. - Oratorio for a Million Souls.

*Oratorio for a Million Souls*⁵ is a public art project that spans three physical locations and was designed to contribute directly to the debate around issues of biodiversity and the population collapse of bird and insect species in Europe. The decision to work with bees developed from a long-standing interest in the cultural metaphors that have historically been associated with colonial insects (especially honeybees).

Figure 5. Oratorio for a Million Souls (2018 ~ 2022) B-Rhapsodie concert in the de Kriedhof Botanical Gardens. (© Nigel Helyer).

The organisation of the hive with its epigenetic formation of social ranks and the strict division of labour have long been used as a template for human social and political regimes. Characterised as obedient, efficient and with a selfless devotion to the common cause, bee society has been a paradigm vaunted by autocracies and monarchies for centuries; only recently has research demonstrated the remarkable level of consensual decision making that rewrites the old hierarchical stereotypes. The second strand of interest is focused upon the complex abilities of communication, navigation and collective problem solving that are performed not by each individual, but as a network – the *hive-mind* an entirely different paradigm a ‘rule from above’ model. The level of parallel processing and complex communications evolved by bees over 100 million years render the hive a true *Super-Organism*.

It was in this context that the *Oratorio for a Million Souls*⁶ developed three bee-listening architectures sited in European botanical gardens, each structure equipped with two sensor hives. As the work is extensively described in the proceedings of ISEA2019⁷ here the focus is on the creation of musical scores, which function externally to the public artworks per se. The score was based upon two streams of real-time audio from the sensor

hives; one from miniature DPA microphones embedded in the entry and exit ports of each hive and a second stream from custom-built contact microphones placed deep within the hive itself. The audio content was complemented by data extracted from a series of hive exit and entry sensors that provided a picture of the diurnal activities of bee colonies, which generally correspond to external temperature and light levels. The audio recordings were employed to establish a tonal palette that was subsequently quantized into an even-tempered scale. The bee movement data was parsed into a rhythmic and temporal framework, giving the score its overarching structure. In contrast to the more stochastic processes of the previous works, once the ground rules were established, the musical form took on a life of its own, bound by the parameters derived from the original hive audio and data.

The resulting scores were, from the perspective of the three large brass and wind ensembles, quite unconventional and challenging to play. The performative challenge was amplified by the technical and logistical difficulties in synchronising the three-part score via an audio-visual satellite link-up that connected the botanical garden in Buitenpost (Netherlands) with gardens in Emden and Oldenburg (Germany).

The outcome of the debut performance which launched the overall project, was a success, despite the inclement weather which drizzled into the mouths of Tubas and Bass Saxophones – a tribute to the hive-mind of the musicians, conductors; sound engineers and cultural producers – it seems that we may have learnt something from the bees!

***Sonus Maris*, Version No.2 - Work in Progress.**

The current *Sonus Maris* collaboration, which is in its developmental stage, initially places its attention upon the extraordinary coastal environment in which the art and science team live. The Eastern Seaboard of Australia is the greenest and most fertile part of the continent (and naturally the most populated). Measured South to North the coastline is approximately 4000 kilometres and supports a wide variety of coastal waterways.

These include tidal creeks (35%), wave-dominated estuaries (17%), tide-dominated estuaries (11%), wave-dominated deltas (10%), tide-dominated deltas (9%) and strand plains (5%), with the remaining 13% comprising drowned river valleys, bays, coastal lakes, lagoons and creeks. Many of these coastal freshwater resources are only intermittently open to the sea and are termed *Intermittently closed or open lakes and lagoons* (ICOLLs) and these are our current focus of interest. Australia is home to 305 (21%) of 1477 globally mapped ICOLL systems.

5. Commissioned by the European Capital of Culture, Leeuwarden, Netherlands 2018.

Figure 6. A coastal river system with a narrow opening to the sea, New South Wales east coast ((© WRL).

The principal research collaborator at the lab, Valentin Heimhuber is an environmental researcher & engineer working on the integrated management of river systems, wetlands, and estuaries in the context of climate change and the pressures of population growth. His work focuses on the use of large satellite datasets and machine learning to develop new tools for the improved management of water resources and water-dependent ecosystems. Valentin is particularly interested in using data to find the right balance between human and environmental water requirements in catchments, rivers and coastlines.

Valentin has developed an algorithm *InletTracker*⁸ that draws upon more than three decades of public-domain satellite imagery (Landsat 5, 7 and 8 and Sentinel-2). His new analytical tool can reconstruct the dynamics of ICOLLs by retro-analysing the relatively low-resolution satellite images to identify the flow patterns and frequencies of these water bodies, thus providing a historical perspective that demonstrates the cyclical nature of interactions between fresh-water and salt-water bodies. *InletTracker* reveals when and how they open and close to the ocean and this data can then be correlated with the associated climatic and oceanic data to illustrate a complex web of environmental interactions, which may hopefully indicate future behaviours under the influence of a changing climate.

The ingenuity of *InletTracker* (a Google Earth Engine enabled python tool) is that it functions to recreate observational data of environmental events that were not previously intentionally observed or recorded. The system uses a novel least-cost pathfinding approach to trace inlet channels along and across the barrier/berm, and then analyses the resulting transects to infer the minimum channel width and whether an inlet is open or closed. The tool is simple to use and provides data on the location and shape of entrance channels, their width at the throat and their status (open or closed to the ocean).

The principal drivers of such interactions are; terrestrial rainfall; fluvial action; wave and tidal action;

Figure 7. Preparation of the original Landsat capsule (© public domain).

atmospheric pressure and associated storm events. All of which combine to set in motion a constant but irregular cycle of opening and closing water bodies, which have implications for coastal integrity and human habitation and coastal land use.

As in all of the pre-cursor projects, the dominant concern is how to manifest such complex data in a way that makes it palpable, visceral and emotionally engaging. How can these complex webs of information become something that illuminates the fundamental connection between our human activities and planetary dynamics as it spins out of control? My initial and immediate response was to imagine the complex web of climatic and oceanographic interactions as a form of musical instrument—perhaps an organ, voicing and modulating as the environmental unconditions fluctuate.

How to begin a conversation?

Following this musical metaphor, we have selected the flows of six ICOLL water bodies to create an organic musical score; an instrument conceived on a geophysical scale. The soundscape (or score) will be accompanied by rich data visualisations and inter-mixed with actual

⁸. The *InletTracker* <<https://github.com/VHeimhuber/InletTracker>>

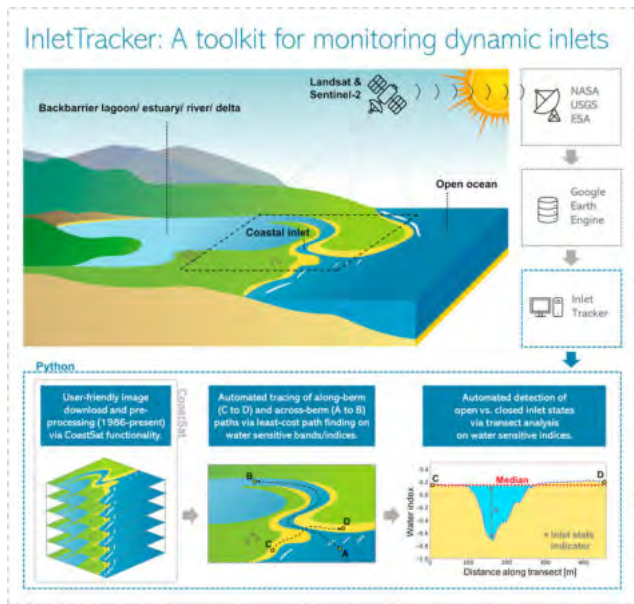

Figure 8. An InletTracker schematic.
(© Valentino Heimhuber).

environmental recordings using a variety of visual technologies (video, LIDAR, particle modelling etc) as well as acoustic ecology microphony techniques.

The intention is to establish an indexical relationship between the data and the musical structure, similar to *Under the IceCap*, where the data itself ‘authored’ the mappings and graphical scores, with the oceanic data providing strict relationships between, for example, depth pressure, temperature, salinity and turbidity, none of which were influenced by subjective interpretation.

Likewise, we envisage that the new *Sonus Maris* project will bring together the environmental flows of coastal lagoons and estuaries as they debouch into the Tasman Sea in a manner that will directly translate the observed data into a soundscape, but one that has not passed through a conspicuous layer of (subjective) interpretation (beyond the process of establishing the parameters for assigning sounds and their properties to the various data sets). Here the sonic output will be structured directly by the InletTracker data, itself, generated through an analysis of the pixels present in Landsat images.

The project is scheduled to debut in December 2022 in Sydney, Australia at the 37th International Conference on Coastal Engineering as a large-format data projection with options for both digital sound and a version with a live musical performance of the data structures. The project will also generate a touring exhibition and a dedicated website.

To conclude.

Concern for the environment has become a central political and artistic issue in the contemporary world. Environmental science and climate change science now perform crucial roles in analysing, and forecasting, the (increasingly precarious) state of the global environment. Siân Ede, in his book “Art and Science,” has proposed that ‘the fragile environment’ might well become ‘the most crucial matter for the future concerns of both artists and scientists.’⁹

However, the broader public (and political) realisation that art and science can form powerful and symbiotic relationships with benefits that extend into all aspects of social, economic and cultural life has been a long time coming.

*‘L’art c’est al science faite chair’*¹⁰

‘Art is science embodied’ these words by the French poet Jean Cocteau written in 1918 neatly encapsulate a perspective in which art and science are imagined as two expressions—as two voices of the same spirit of enquiry, but perhaps delivered in a different register. Cocteau’s short phrase employs the French word ‘chair,’ in English quite literally ‘flesh,’ emphasising that art brings science into the visceral world as a palpable experience, and by so doing it can become something that we can relate to directly—a narrative behind the data! It is this embodiment of curiosity, of knowledge, and sheer wonder that the melding of art and science is all about.

Artist Biography.

Dr Nigel Helyer (aka DrSonique) is a contemporary sculptor and sound artist whose work links Art and Science to embrace the environment; identity and cultural history. He has an international reputation for his large scale sound sculptures, environmental artworks and interactive bio-art projects that prompt the community to engage with their cultural histories, identity and sense of place; inviting us to examine the abstract conditions of our world and our complex relationships to it. Nigel is the director of SonicObjects; Sonic Architecture <<http://www.sonicobjects.com>> an Honorary Professor in the school of Media, Music, Communications and Cultural Studies at Macquarie University, Australia <<https://www.mq.edu.au/faculty-of-arts/departments-and-schools/department-of-media-communications-creative-arts-language-and-literature>> and is currently the Artist in Residence at the Water Research Laboratory, The University of New South Wales, Australia <<https://www.wrl.unsw.edu.au/>>

Knowledge Cultures in New Media Art

Rama Hoetzlein

Digital Media Design
Florida Gulf Coast University
Fort Myers, Florida
rhoetzlein@fgcu.edu

Abstract

New Media Art reflects the dramatic creative and cultural shifts in science and technology of the past century. With these shifts the multitude of forms of art-making have expanded to include a wide range of ideas and techniques. Following several decades of new contributions this plurality of expression has resisted monolithic or curatorial approaches to organization along the lines of media.

This paper defines knowledge cultures as flexible, overlapping, non-exclusive, ideological sub-groups and seeks to identify such groups within the practice and theory of New Media Art. While practicing groups may be associated with specific media such as games, 3D printing, or artificial intelligence, we seek to identify knowledge groups by their explicit, hidden or shared ideological principles.

Keywords

art and technology, knowledge cultures, post-medium, post-modernism, pluralism, curation

Introduction

The field of New Media Arts (NMA) does not have any single point of origin but has evolved from a variety of practices engaging with new technologies. Approaches to organizing NMA, such as Christiane Paul's *New Media in Art*, have grouped works and artists according to media practices. [1] Tribe and Jana define NMA according to a variety of themes such as computer art, collaboration, open sourcing, surveillance and hacktivism. [2] These themes are loose incomparable sets. For example, computer art is technique, collaboration is a social activity, and open sourcing is a decentralized licensing strategy. While these words convey various practices an understanding of New Media Arts as a collection of themes tends of collapse ideologies of meaning.

In the context of academic disciplines, New Media Art may be defined as a form of "knowledge production." Beyond aesthetic considerations, Borgdorff draws from Kant and Adorno to compare art to other disciplines generally. [3]

"Art's epistemic character resides in its ability to offer the very reflection on who we are, on where we stand, that is obscured from sight by the discursive and conceptual procedures of scientific rationality."

Such comparisons are academic in the sense that they establish the uniqueness of art with respect to science or engineering but do not delve into ideology or meaning of specific movements, or of New Media Art in particular. A superficial view of NMA as a "production of knowledge" suggests an accumulation of ideas for its own sake.

We seek to explore the knowledge cultures present within NMA and how these inter-relate, evolve and define the discipline. Of particular interest are those knowledge cultures and ideologies which are embedded or assumed by current practices.

Cultures of Practice

That the practice of New Media Arts has resulted in new sub-cultures is a natural outcome of the media on which it is based. Manovich identifies this in the *Language of New Media*. [4]

"The computerization of culture not only leads to the emergence of new cultural forms such as computer games and virtual worlds; it redefines existing ones such as photography and cinema."

Whereas the phrase 'cultural forms' is not explicitly defined we take it to mean a format (or media) produced by culture. New media leads not only to cultural *forms* but to new sub-cultures of people around those forms. The computer game is a new cultural form yet also a people who make, play and create videos games.

Such is the state of New Media Art that novel sub-cultures abound. Artists organize around database art, data visualization, computer games, virtual reality, artificial intelligence, and many other media which have emerged in the past few decades. We may view these as sub-cultures of practice which are loosely organized, fluid and constantly changing.

With the identification of media as one foundation of New Media Arts efforts were made to form modern collections accordingly. Oliver Grau proposes a digital and "scholarly archive" to document the works of NMA and the humanities

generally, similar to such archives in other fields. [5] He acknowledges that an archival database would require a unified effort among institutions, artists and conservators. Such efforts are already undertaken by publishers [6]. However these are not collated uniformly with other publishers while also discounting works solely shown in galleries, museums or solo venues. Despite the challenges of a unified archive such a system would be of significant benefit to the field.

A digital archive of media artworks might collect the authors, visual records, or even the works themselves, yet without further analysis the ideas that motivate each work may again be collapsed or lost within a literal database. An archival database of NMA would be a research tool and this paper is not concerned with the curation of collections per se, but with the identification of ideologies embedded in New Media artworks.

For our purposes we may define a *knowledge culture* as a fluid, non-mutually exclusive sub-culture or group of people (artists or otherwise) with a particular ideology. Within this definition, a “culture of practice” is a group that identifies itself according to a given media, such as video game creation or internet art. The aspect of non-exclusivity is helpful since any particular artist or work might belong to multiple knowledge cultures simultaneously.

Social or Explicit Cultures

Explicit Cultures

Certain artists focus on an explicit value system driving their works to a greater degree than form. One such example is Ecological art defined here by Aaron Ellison and David Borden.

“Ecological art is purposeful and often prescriptive: the intended actions and directions for activists are clear.” [7] Their work *Warning Warming* consists of a series of large hemlock timber triangles painted in yellow, red and black to indicate the average global temperature from 1880 to 2001, with carbon dioxide emissions on the opposite side. The artists seek to engage the viewer in ecological activism and ask questions such as: “Can it [ecological art] also provoke emotional responses that inspire immediate action or long-term activism?” [8]

An intriguing aspect of this work is that operates fluidly between sculpture, public art and data visualization. Its purpose is guided by a shared vision among ecological art toward environmental activism. Whereas cultures of practice (e.g. database art) may evolve from their media the presence of an explicit value or ideology defines a *social culture* of knowledge. This is not to say that the choices of media are irrelevant but that the intentions are explicit beyond merely “experimenting with the media”. These social cultures of art grow from an immediate or perceived human need that the artists are compelled to address.

Contemporary artists frequently participate in multiple value cultures. The artist Shu Lea Cheang is a pioneer in video, cyberfeminist and internet art. Her work *Brandon*

(1998-1999) focuses on the murder of a trans man, Brandon Teena, and was the first web-based commissioned artwork by the Guggenheim Museum of New York. [9] The explicit value structure in feminist art is observed by Lucy Lippard in Framing Feminism where “[feminist art] is neither a style nor a movement but instead a value system, a revolutionary strategy, a way of life.” [10]

More recently Cheang’s work *Composting the Net* (2012) takes the recorded legacy of online communities such as IDC and Spectre – lists of artists & works – and turns them into digital pixels, thus “poetically, composting them.” [11] The culture of internet ecology questions the Internet as a digital landfill of accumulated information.

An explicit social culture is a type of knowledge culture that defines its shared value structure and membership a priori. Members are those that support the value system while they may also simultaneously participate in multiple cultures such as Cheang’s cyberfeminist work (*Brandon*) and works in internet ecology (*Composting the Net*).

Non-Explicit Cultures

An explicit shared culture may not always be defined or present in socially meaningful works. In the video game *Vietnam Romance* by Eddo Stern, players experience the Vietnam War as a “mash-up” of cultural artifacts creating a colorful contrast between the players nostalgia with the surrounding military activity. [12] This work functions as a commentary on war and loss of history.

The video game *Papers, Please* by Lucas Pope takes place in a fictional Eastern Bloc country with the player as an immigration officer at a migration checkpoint, with actions “mostly confined to shuffling papers and confirming or denying someone’s entry into Arstotzkan.” [13] The game thus creates an uncomfortable power struggle in the player as their duty and its impacts escalate.

Vietnam Romance and *Papers, Please* are related in their role as political criticism – this is their social culture. Even so, Eddo Stern is often described within the culture of practice as a video game artist since this is a medium he works with frequently. Social cultures may be defined informally, non-explicitly, around groups of artists with similar ideological themes (e.g. war, ecology, environment, feminism), *in addition* to any identity with practice or media.

Non-explicit cultures are loosely defined by shared interests among artists that may or may not know one another. Social cultures, as a consequence of meaningful work, and whether they are explicit or non-explicit, *transcend* media and cultures of practice.

Mainstream Contemporary Art

A well-established knowledge culture can be found in mainstream contemporary art (MCA), whose values are summarized by Edward Shanken. MCA is the “primary arbiter of artistic quality and value through its control of the market.”

[14] The ideology of MCA thus equates, among other ideas, with money and market capitalism. Shanken sets up a dichotomy between MCA and NMA along the lines of the technological divide introduced by Claire Bishop and goes on to criticize MCA for being technically illiterate. [15]

“mainstream discourses typically dismiss NMA based on its technological form or immateriality, without fully appreciating its theoretical richness.”

The issues of capitalism and technological innovation are not easily resolved. At times Shanken appears to contradict himself, for example when speaking of MCA’s ability to “commodify relatively ephemeral art forms” such as video, while later stating that MCA “remains tightly tethered to more or less collectible objects.” [16] The one constant in mainstream contemporary art, however, is the continuing value structure of art as a marketable good.

Three Technological Sub-Cultures

In evaluating the relationship between MCA and NMA, Shanken reveals multiple ideological relationships with technology. By setting aside market-driven discussions we can extract these value systems as follows.

- Techno-philic – many artists and people embrace a technological future, or at least one in which technology plays a prominent, positive role, as for example in *La Plissure du Text* referred to by Shanken.
- Techno-critical – some cultures within New Media Art are meta-critical, embracing technology while simultaneously reflecting on it “in a manner that self-reflexively demonstrates how new media is deeply imbricated in modes of knowledge production.” [15] Shanken describes this as the best of NMA.
- Techno-phobic – some cultures are against technology, either explicitly or indirectly. Shanken questions Bishop for posing the Digital Divide without having exposure to NMA: “could a contemporary art historian/critic be taken seriously if s/he stated that performance or video or installation lay beyond their expertise?” [17] As a critic of NMA a better question is how Bishop became interested in confronting the “digitization of our existence” in the first place.

Artworks within a techno-philic culture may be described as innovative but not necessarily reflective on its limits. Those which are techno-phobic are generally not new media artists themselves if their dismissal of technology is complete. Artists which adopt new media must at least embrace it in practice and thus become techno-critical at a minimum.

The confusion in Shanken arises because MCA, while always a capitalist value system, is not one people with a singular technological outlook but a multitude of sub-cultures consisting of curators, directors and institutions which may be techno-philic, techno-critical or techno-phobic.

Case Study: Artificial Intelligence and GANs

A recent techno-philic culture that has gained rapid acceptance in mainstream contemporary art is *artificial intelligence*. In 2018 the work “Edmond de Belamy, from *La Famille de Belamy*” was created by a generative adversarial

network (GAN) developed by the French art collective *Obvious* and sold for \$432,500 at Christie’s New York. [18]

The monetary values of MCA shift instantaneously with shifting demand. Aaron Hertzman (Adobe) attempts to describe this rapid rise in popularity with the concept of *visual indeterminacy*. [19]

“Visual indeterminacy describes images which appear to depict real scenes, but, on closer examination, defy coherent spatial interpretation. GAN models seem to be predisposed to producing indeterminate images, and indeterminacy is a key feature of much modern representational art.”

Hertzmann misses the fact that GAN-generated artwork is more properly defined as NMA and thus better compared with other AI-based art forms. Nonetheless his description might explain how mainstream art has rapidly adopted this style.

New Media Artists have been producing important works in AI since the 1950s. Michael Noll developed algorithmic drawings with compositions similar to Mondrian. [20] As members of the *Algorists*, a culture dedicated to algorithm-as-art, Noll, Verostko, Hebert, Mohr, Nike and others have been exhibiting works in galleries and museums for decades. In 1968 Harold Cohen developed AARON, a program that could produce child-like drawings of people and gardens. As a work of symbolic-AI in art, while not a learning-style AI like GANs, it is nonetheless an early example of machines creating captivating visual imagery.

Artificial intelligence, as an art form, has developed many knowledge sub-cultures. Works that are accepted by mainstream art are difficult to ascertain on a conceptual basis alone. The AI artworks of Refik Anadol have been featured in prominent venues globally. His recent project, *Quantum Memories* “utilizes the most cutting-edge, Google AI publicly available quantum computation research data and algorithms to explore the possibility of a parallel world.” [21] Interestingly, given the description provided, this AI is likely not a GAN since the presentation of the work is abstract, more akin to abstract expressionism than to modern representational art. One might make the case that AIs which can mimic *any* style of early modern art are destined for acceptance by mainstream contemporary art.

Also important is that any note of techno-criticality, or self-reflection on the limits or dangers of AI technology, is absent in this work by Anadol. Thus it remains firmly within the techno-philic culture surrounding affirmative trends in artificial intelligence.

Post-Modernism

What other knowledge cultures are embedded within New Media Arts today? We have surveyed those of shared cultural practice (media), those of social ideology (explicit or non-explicit values), those of the art world (market value) and those based on future technological outlook. To appreciate NMA more deeply is to address cultural ideologies

which may be assumed, or embedded, within the culture of new media art itself.

One may begin by appreciating that New Media Art developed on the heels of post-modernism. It is not coincidental that new media art arose at the same time that media theorists such as Jean-François Lyotard were reflecting on the condition of post-modernism. [22]

“Simplifying to the extreme, I define postmodern as incredulity toward metanarratives. This incredulity is undoubtedly a product of progress in the sciences: but that progress in turn presupposes it.”

Scientific progress is intertwined with the modern condition, as it is with new media art. Lyotard understands science, in part, as “searching for and ‘inventing’ counterexamples, in other words, the unintelligible.” [23] Only within a plurality of hypotheses can one seek the more correct one.

Distance and Objectivity

Within the digital humanities, the post-modern condition is reinterpreted by Franco Moretti as a distinction between close and distant reading. [24]

“Distant reading: where distance, let me repeat it, is a *condition of knowledge* [sic]: it allows you to focus on units that are much smaller or much larger than the text: devices, themes, tropes—or genres and systems. And if, between the very small and the very large, the text itself disappears, well, it is one of those cases when one can justifiably say, less is more.”

This distance is an intentional space between the reader and narrative. Distant reading examines text as fragments of knowledge, similar to or derived from the methods of science in questioning a multitude of hypothesis of manageable size. The premise is that *distance* confers *objectivity* via comparison, with fragmentation as a by-product of tried-and-failed ideas.

Under the system of science all untried ideas are equally valid for Lyotard recognizes that “science does not expand by means of the positivism of efficiency.” [23] Human intuitions that might move more ‘efficiently’ toward readily viable ideas are suppressed as every hypothesis is valid until tried (bias being undesirable). Thus science proceeds slowly with repeatable, testable, comparable ideas.

How do the scientific conditions of post-modernism influence the knowledge cultures of New Media Art? Previous methods of narrative, artistic movement and cultural dialog become passé. The tenants of science must be reframed for adoption. Within NMA there are no hypotheses, only artworks, and therefore the scientific theory of objective testing translates poorly to art. Duchamp began the experiment of art as idea and since then each conceptual work must be evaluated on its own merits. The lack of an objectifiable (comparative) metric for works of art, combined with the literal technological outcomes of science, has resulted in an explosion of viable forms and meanings.

Fragmentation and the End of Art

The accumulation of information was anticipated by Paul Virilio and Vannevar Bush. [25]

“There is a growing mountain of research. But there is increased evidence that we are being bogged down today as specialization extends. The investigator is staggered by the findings and conclusions of thousands of other workers.”

The art object fits within this accumulation ever since the appearance of the readymade. For Danto this signifies the ‘end of art’ since it can no longer be distinguished from everyday objects [26]. Vassiliou reflects on NMA to conclude that “Danto’s theory for the ‘end of art’ seems to withstand the advent of digital media.” Within his reasoning, NMA does not “escape” from or “distinguish” itself from common objects, nor from the “institutional norms of art.” [27] One must concede that NMA, through a proliferation of media forms, appears to support this fragmentation.

The ‘end of art’ is the end of the artistic object as an institutional form, with NMA forging new pathways for distribution. Additionally, the pluralism of NMA is not equivalent only to a growth of information (or objects) for the lack of scientific metrics in art also undermines a unified sense of purpose. Nonetheless, scientific theorists (non-artists) continue to pleasantly make the case for a scientific understanding of art pluralism. For example, Magnus & Uidhir, offer “species concept pluralism — a well-explored position in philosophy of biology — provides a model for art concept pluralism” [28]. The problem is that art objects are not comparable the way biological species are. Unlike species which are naturally (physically) comparable, meaning in art depends on the ideology of knowledge cultures of both the creator *and* the viewer.

In science, the direction forward is guided by nature (reality). In art, every direction is viable. Thus the ‘end of art’ is not only the end of the art object, or artistic creation, but the end of the artist — one who guides our reflections on where humanity stands. Fragmentation leads to the loss of sense of the *artistic self*; a unified ideological direction forward in art is no longer achievable.

The knowledge culture of fragmentation is the acceptance of pluralism; an ideology that any object, any media, even any idea may be the subject of art. Hence the proliferation of art-science-engineering crossover disciplines such as biological art, database art, and AI-based art.

Pluralism

Object pluralism, presently discussed, may be distinguished from social pluralism, i.e. diversity and inclusion. Both are embraced by venues of NMA despite the increasing difficulty of defining artworks along thematic categories.

A practical experiment will demonstrate the challenges of pluralism. Choose five artworks at random, preferably using a computer to ensure randomness, from the pages of the International Symposium on Electronic Art (ISEA) catalog for any year. See the footnote for an example ¹. A knowledge culture in favor of pluralism would argue that each work found deserves equal attention without bias. Pluralism in NMA accepts the premise that all art experiments are of value; immeasurable until tested.

The issue raised is the curation of New Media Art. A culture of pluralism must accept Bourriaud's criteria for the evaluation of art. [29]

"...this 'arena of exchange', must be judged on the basis of aesthetic criteria, in other words, by analyzing the coherence of this form and then the symbolic value of the 'world' it suggests to us..."

Criteria for new media art in a pluralist framework is judged according to internal self-consistency. Absent are any preferences toward a larger significance or meaning, and, since they are lacking in Lyotard's "efficiency," are intended to be unbiased selections. Thematically, and in current practice, the efficiency in selection is achieved by venue according to the historicity and evolution of currently selected knowledge cultures (e.g. AI, database art, etc.) and to a significant degree on industry and market trends.

Knowledge cultures of NMA may view pluralism positively or negatively. Those in favor of pluralism accept that all works are deserving of equal attention in accordance with the tenants of scientific non-bias and based on the self-consistent merits of the work. Arguments against pluralism are currently more rare, but must be founded on the notion that art is not science – there will never be a universal arbiter of creative truth (as nature is to science) as the vast range of ideas is too overwhelming to receive our equal attention. Therefore we must ask: *what do we value?*

There can be no singular answer in a global culture – hence the embedded condition of pluralism. A recent plea which calls for a culture of non-pluralism can be found in Alexandra Bal's "Sentience as The Antidote to Our Frenzied Mediated Selves." [30]

"Contemporary western tools of perception have adapted to a human consciousness that exists in hybrid techno-

natural spaces... We exist in a frenzy of online social performances and simulated realities, constantly moving from one network node to another."

Bal recounts the history of Western science as the arbiter of our sentient selves and our subsequent "disembodiment" with the world. Her conclusion is that, with respect to our social products and activities, the final metric of humanity – to which pluralism is a detriment – is our ecological and environmental relationship to the planet.

Pluralism, defined here as the selection of artworks based solely on self-consistency (e.g. quality, coherence), is an outcome of the global embedded knowledge culture of the scientific and industrial revolution. The result is a vast range of works whose value structures overlap with other disciplines.

Post-Medium and Remix Culture

Some extremes of pluralism are described by Rosalind Krauss as "post-medium." [31]

"As medium specificity fell out of fashion, it seemed retrograde for artists to attempt it or for critics to praise it. Art had, it seemed, entered a 'post-medium condition' in which the inauthentic seemed more daring and up-to-date than the exploration of limits and materials."

Post-medium is established by Krauss by its opposite; hold-out artists that make use of 'technical supports', specific non-traditional media, to avoid the post-modern condition of medium irrelevance. Shanken is critical of Krauss by noting that she "misses the richness" of artists who join together multiple media [14].

Interestingly, similar observations on the loss of medium specificity are made by Manovich in his description of deep remixability. [32]

"But software is like various species within the common ecology—in this case, a shared computer environment. Once 'released,' they start interacting, mutating, and making hybrids. The invisible revolution that took place in the second part of the 1990s can therefore be understood as *the period of systematic hybridization between different software originally designed to be used by professionals working in different media.* [sic]"

Manovich describes those engaged in remix as forming a "remix culture", in our parlance a knowledge culture based on the resampling of content and the intermixing of media. Remix culture is one cause of the post-medium condition.

Whereas post-modernism introduces the notion that *any* object (readymade) may be taken as medium, Vassiliou observed that the response of New Media Art was to adopt the *media of technology* as the new normal form – code, database, VR/AR, internet, etc. The post-medium condition takes this exchange further by eliminating the boundaries of media altogether – remix culture is the lack of medium specificity.

Post-medium fits naturally within the pluralist paradigm, for the "interaction, mutating, and making hybrids" is easily adopted by scientific hypothesis-generative thinking.

1 The random art selection experiment was conducted with the following Processing code (see processing.org):

```
for (int n=0; n<5; n++) println ( (int) random(0,300) );
```

For example, results from a single run gave five randomized page numbers in the ISEA 2016 Catalog:

#1, p.212, Julien Ottavi & Jenny Pickett, *Electromagnetic Spectrum Research* – explores "inaudible sounds" recorded by VLF (very low frequency), especially the hum of manmade devices such as electrical pylons, to discover musical complexity.

#2, p.136, Sandra Heinz, *Haitus* – pull cords trigger a dark patch within a grid of 6x3 light panels, with gaps and random behavior that give a "dust", glitch-like aesthetic.

#3, p.160 Jinku Kim, "*..What Is Seen was Not Made Out of What was Visible.*" – sound, which creates a physical vibration of air molecules, is visualized as geometric patterns on an oscilloscope, giving a "hyper-tactile" experience.

#4, p.26, Nurit Bar-Shai, *Objectivity: Soundscape* – applies lab techniques to visualize the "chemical tweets" of microorganisms as beautiful patterns.

#5, p.291, Rewa Wright, *An Algorithmic Life* – procedurally generated terrain rendered from a non-manifold geometry.

Pluralism, at its extreme, is no longer even a branching taxonomy of the evolution of distinct media but the boundless, multi-dimensional crossbreeding of media.

Modern Meta-Narratives

The ideological frameworks of the present are embedded deeply in the knowledge cultures of scientific thinking, distant reading, objective analysis, pluralism, and remix culture. The conditions of knowledge are not mere conveniences or temporary infatuations; they reflect the values of our times.

Each knowledge culture has adherents and detractors. For those technophiles who see no contradictions within the present global system, the contemporary knowledge cultures of NMA are a playground for novel experimentation. Reflected aptly in the documentary film *Surviving Progress* by Roy & Crooks, the science-driven technophile conceives the only relevant future for humanity is as a spacefaring civilization. [33]

However, many others are not convinced, citing our rapid global impact on the planet. Alexandra Bal summarizes these concerns. [30]

"Our challenge is not so much to seek ever more sophisticated technological solutions to existential and environmental problems, as it is to re-establish a moral, emotional, and perhaps spiritual, relationship with the biosphere: living with empathy and consciousness, with respect for the land, the plants, the animals, and people." If art merely offers a "reflection on where we stand", as Borgdorff suggests, then it has little to say on how we proceed to resolve conflicts between knowledge cultures. That would be the purview of politics and economics. NMA is arguably in a worse position to address such issues since it largely embraces the post-medium, scientific pluralism of the present.

We feel, however, that art can offer much more. Art, unlike science, is *not* bound to the terms of fragmentation and hypothesis testing – it has the capacity to coherently synthesize and integrate knowledge.

Within Lyotard's post-modernism there are self-contradictions. He states: "the grand narrative has lost its credibility," yet the argument for the condition of post-modernism is itself a meta-narrative. Perhaps he means the narrative promise of early modernism has shifted to means versus ends, in which "capitalism.. has eliminated the communist alternative and valorized the individual enjoyment of goods and services" [22], yet the ends of technology, that is its impacts and outcomes, are even more relevant now in our present global narrative. Perhaps meta-narratives are no longer linear; but they are not absent.

The meta-narratives of our times *are* the knowledge cultures of scientific fragmentation, pluralism, presumed objectivity and their paradoxical relationship to globalism and ecological disaster. These are recurring grand narratives that are neither regional nor temporary. From the perspective of NMA, regardless of the plurality of expression, these knowledge cultures are embedded in our present condition.

Balance and Post-Pluralism

A balanced relationship with nature requires that humanity have a global, structured, *organized* relationship to our environment. It must be at least sufficiently organized to be self-sustaining, conforming (to natural limits), self-limiting (of consumption), and non-wasteful. The structures of institutions, hierarchies and governments may or may not be needed – this is outside the scope of our discussion.

Herein lies the problem: We have yet to discover a structured organization for humanity that achieves this balance with nature while also allowing for a cultural pluralism of ideas and expression. Scientific thinking argues that pluralism is necessary for hypothesis testing. Yet pluralities of technologies, media, hypotheses, ideas and artworks compete directly for resources and energy. The production of NMA is a relatively small consumer of energy compared to the human creation and consumption of media generally.

Every individual is a creative actor in the world of social media; consuming resources to fuel their participation in a wide variety of overlapping knowledge cultures. NMA is a participant in that pluralism. However, *art is not bound to the terms of science*, and we believe that interesting future contributions of New Media Art reside in the capacity of art to synthesize and integrate knowledge.

We will avoid speculating what the future contributions of New Media Art may be, for one can hope they are still many and varied since knowledge cultures are not mutually exclusive: synthesis does not negate pluralism. Consistent with our analysis, we might instead observe that a knowledge culture of *synthesis* need not deconstruct (fragment through excess questioning), it need not propose hypotheses, nor conduct experiments, nor invent media types. It does not require "novelty" to legitimize itself but might instead draw from what exists to define similarity and consensus. A synthesis of knowledge objects such as the "digital archive" of Grau is interesting but how might we have a better understanding of ideological synthesis.

One of the most valuable aspects of New Media Art may be that a deep appreciation for media uniquely places it to formulate ideas or systems that address pluralism and social organization. At a minimum we can see that a pluralism of creativity (content/media) is not necessarily inconsistent with a sustaining, structured, relationship to nature since the former is only indirectly related to consumption.

Aside from individual efforts the challenge of pluralism requires us to address social discord and ideological differences. What restructuring of our media, devices and lives would enable collective actions to be defined more readily by our shared values? How are shared values discovered? What are the operations that allow us to combine or unify disjoint values? The post-modern condition would suggest that all methods and devices are tried – every application, every idea, every image – is equivalent in value and the whole of this space shall be tested. However, we question the scientific basis for post-modernism in art as self-contradictory. The culture of scientific thought is one approach to art but need not apply to the whole of art for which the contributions of creative synthesis and intuition may be of

greater value. A generic, efficient (non-exhaustive) metric, which is implied by this, is the evaluation of a given work on its ability to discover or unify shared cultural values.

One possible approach for artists working within a knowledge culture of synthesis would be to define, in real terms and more precisely, where our shared values lie. What systems or media could measure this more directly? From there the next, more difficult challenge is to imagine approaches that would enable these shared values to surface ubiquitously (i.e. regardless of politics). New lines of inquiry that might arise are: How should social media function? What would the internet look like if it were nature-sustainability ranked as opposed to popularity ranked? This reorientation of new media art is not a universal metric, but it need not be. We seek new ways of thinking beyond the knowledge cultures of our past. Outside the limitations of scientific thinking, but not lacking from it, these issues of value ideology in media and culture seem to be the kinds of problems that new media art is well positioned to address. The above dialogue is just one approach where a better grasp of embedded knowledge cultures might enable new directions in new media arts.

The knowledge cultures observed here are a reflection of the trends of science, technology and art over the past century, the goal of which was to make explicit the new meta-narratives of the post-modern/medium so that the future of new media art might avoid being bound to the same narratives.

Abstract

Throughout the 20th century and up to the present day, many artists have addressed the archive by questioning its function, classification systems, legitimacy, registration technologies or inclusion/exclusion protocols. Considering that within digital culture, AI has become a key factor for information management, this article explores how the use of these technologies in art is offering new perspectives to think about the archive, heritage and memory.

Within the meshwork of existing practices and approaches that operate creatively challenging traditional hierarchies and protocols of the archive, we will pull from two strings: 1) on the one hand, the group of appropriationist-type tactics that operate by activating new interpretations of already constituted archives; 2) on the other, those that propose the creation of new archives, generally dealing with scattered elements that were previously ignored or discarded.

We will delve into these two anarchival strategies [1] [2] by focusing on two case studies that address critically the filmic and audiovisual heritage: *Jan Bot: bringing film heritage to the algorithmic age* and the *Oráculo de Capturas de Pantalla (OCP)*. In both cases we will study the strategies by which other possibilities are opened up for history, and the place given to algorithms in their construction.

Archival-Art, Anarchivism, Algorithms, Generative Art, Participatory Practices, Performativity, Collective Memory, Audiovisual Heritage

Introduction

Archival practices have been of great interest to contemporary artists and curators since the 20th century. Its field of action has grown and expanded significantly, giving rise to the expression ‘archival turn’. This concept was coined by anthropologist Anne Stoler in the 1990s to describe the transition from archives as *spaces where research takes place* into archives as *objects of study*. Theorized in the field of art by intellectuals such as Hal Foster, Boris Groys or Anna Maria Guasch, this critical look at the archive has enabled an extension of the possibilities of understanding treasured documents, objects or sounds, questioning, problematizing or dislocating the meaning of traditional archives.

Within the vast archival art production, this study will focus on two trends –understood as horizons of possibility– that encompass part of the complex and tangled universe of creative production:

- 1) On the one hand, practices that work with already constituted corpuses, intervening their documents or articulating new performative approaches enabling their visualization and accessibility, emphasizing unpublished or critical aspects that were not obvious on a first instance.
- 2) On the other hand, we will highlight practices that deal with the creation of new collections or archives, taking as input heterogeneous materials –of an artistic nature or not. In this hybrid place, the knowledge of collectors, archivists and curators overlaps with those of artistic creation.

In this article we will ask ourselves specifically about the strategies used in both trends, with a special emphasis on artistic practices using digital media. To this end, we have chosen two eloquent cases within each of the aforementioned trends that, despite their differences, converge in their quest to activate filmic and audiovisual heritage in our digital present.

Based on these cases we will try to identify how machine learning or artificial intelligence has become an artistic tool addressing these strategies of appropriation and creation of archives from a performative, poetic and critical approach.

Archival Performativity

To better understand the artistic approaches using the notion of the archive, we must first define the concept of ‘performativity’. If we inquire into the origin of the word, we can refer to the philosophy of language and to the lectures given since 1955 at Harvard University by philosopher John L. Austin, where he proposed the existence of two types of statements: constative and performative. The former is used to describe reality and verify facts, while the latter is not limited exclusively to acts of speech, but also involves an action, producing the reality they describe regardless of their truth or falsehood. Since then, the concept of performativity has been widely used by cultural studies and gender studies, among which the work of Judith Butler stands out, who recovers this term to explain the theory that gender is not something given, fixed or stable, but rather it is produced on a series of repetitive –performative– acts that configure certain cultural roles attributed to the sexes. Considering this approach, and more broadly, the term performativity enables us to understand

identity not as something given or essential, but as a chain of social constructions that could be questioned and, therefore, deconstructed by the subject.

In connection to this, for a few decades now, the notion of 'performance' has surfaced not only as a practice, but also as a "theoretical category". Richard Schechner states that "everything and anything can be studied as performance" [3]. More recent approaches such as those of Software Studies or New Materialisms (among them and particularly the performative materialism of Karen Barad) have also used the concept of performativity. Through a performing approach it is possible to describe certain phenomena and practices enabling, precisely, an analysis of the recurrences and repetitions of patterns, approaching them in a disruptive way, disputing their constitutive discourses and meanings. In other words, as performativity is transmitted, taught and learned, it can also be interrupted, unlearned and subverted.

Likewise, in the artistic field, postmodern practices have made an effort to address individual and collective processes in a critical way, understanding social and even physical reality as a social construction. As Andrea Soto states, a performative approach allows us to overcome the question "what are images?" with "what do images do?" This means paying attention to the subjective relationships that images dynamically tie together, overcoming the logic of representation and the utopia of thinking that there can be objective presentations of the world. For this reason, Soto says that, "the performative function has to do with tearing apart time and hegemonic spaces, opening gaps for the unforeseen." [4]

In this context, the performativity of the archive would refer to the set of conventions (contents, categories, structuring) articulating it. Its artistic appropriation, through the displacement of its parts, interpretation, assembly and so on, would enable viewers to see these conventions, but also their possible alternative constructions. In line with the theories related to the 'archival turn', Simone Osthoff suggests that understanding the archive as performance would mark an "ontological change" in its approach, abandoning a conception of the archive as a mere "repository of documents" in order to understand it in terms of "dynamics and a generative production tool." [5]

Artistic performativity of the archives makes it possible to problematize the storage of traces of time, distancing it from its scientific and positivist perspective in order to conceive it in a fragmentary, open and discontinuous way, because, according to Walter Benjamin, "History is the subject of a structure whose site is not homogenous, empty time, but time filled by the presence of the now." [6] Performance always acquires the position of now.

Next, we will analyze how the performative practices of archival art –practices of reordering, recontextualization, assembly and fragmentation that have called into question the canonical or dominant accounts of the archive– become anarchival strategies. Specifically, we will discuss how they have been enhanced by the use of algorithms programmed by artificial intelligence.

Anarchival strategies

Anarchival strategies must be understood not as the opposite of the archive, but as a critical approach to the archive. Anarchiving is the attempt to discover and give visibility to the specific storage and preservation logics underlying each archive that have been naturalized, as well as the conditions of possibility in which it was established as such; but also, it means to create other universes, opening up new horizons of meaning. Anarchivism is, in the words of Andrés M.

Tello, "the nightmare of every social order that claims to be in force at a certain time and place" and continues:

... not only does it disturb the sleep of those who hold hierarchical and well-off positions at a specific historical moment, but it also alters the principles of legitimacy protected and socially arranged by institutional classifications and by means of everyday recording technologies of bodies, their routines and their affects. [7]

Technopoetics that are built around a reflection on the archive, opening up to a multiplicity of options and relationships, to new sensorialities and affectivities, are anarchival strategies by definition. Within this broad field of artistic practices, we will focus on the creative possibilities of generative (or algorithmic) art, with special emphasis on projects that involve a questioning of information recording technologies, archive management, and heritage visibility and preservation policies.

Taking as case studies two ongoing digital projects in which the use of algorithms has a central place –*Jan Bot* and *OCP*– we will analyze two crucial trends: from and towards the archive. It should be noted that the selected cases re-mediate the cinematographic practice based on culture and the digital archive.

Algorithms looking into cinema

The present study is built around the construction of two case studies that shed a light on divergent tendencies of the continuous space posed by the anarchival artistic-algorithmic practice.

The choice of two cases related to algorithmic art is not accidental. Generative art expresses a human-machine co-production that in other artistic practices is bypassed or minimized by a stance where the idea (the artist) holds a higher rank, imposing form on matter (supposedly passive). Vilém Flusser already analyzed the concept of co-production in the case of photography, between machine and artist:

... A comparison of the photographer's intention and the intention of the camera shows that there are points where both converge and others where they diverge. At the points of convergence, they work together; at the points of divergence, they conflict with one another. Every single photograph is the result, at one and the same time, of cooperation and of conflict between camera and photographer. [8]

Therefore, thinking in terms of cooperation implies giving materials and technologies (in our case, algorithms and their physical environments of execution) an active behavior, such as *natura naturans* (creative nature). In the words of Fernando Domínguez Rubio, "active and constitutive elements in the production of social forms, relationships and meanings". [9] If these are elements with a generating force, capable of other forms of action and other modes of registration, if it is true that they are not reducible to full human agency, then they must clearly be considered active elements in the anarchival practice.

In other words, it is the creators, together with the technologies being used, who can promote new forms of recording. Therefore, it is upon this human-machine assembly that we can glimpse at new forms of meaning and

recovery of the remains of the past; reconfiguring non-arborescent relationships, or de-hierarchizing existing ones; and even, conceiving other ways of discerning the outside and inside of the archive. Therefore, practicing memory.

Considering the agency distributed between humans and non-humans, the specific question underlying this present work is:

How are human-machine cooperation strategies configured in algorithmic art practices enabling new possibilities for the archive?

And then a series of related sub-questions:

What aspects of the archive are affected in the cases studied? (e.g., recording technologies, classifications, hierarchies, exclusions....?) Or, perhaps, do they display a radically new notion of the devices and the very act of archiving?

What is the social scope of these algorithmic artistic practices, and their capacity for mobilization and change?

In what ways is film heritage activated through the anarchival practices operated on it?

Disruptive Poetics: *Jan Bot*

Our first study case is *Jan Bot: bringing film heritage to the algorithmic age*, a project born in 2016, aimed at disseminating the heritage of a film museum by revitalizing its content, in tune with new interfaces based on artificial intelligence and the narrative tactics from social networks. *Jan Bot* addresses the film heritage of the Eye Filmmuseum (The Netherlands), dealing specifically with one section in particular, the Bits & Pieces Archive, created in 1989 by Eric Kuyper and Peter Delpout by collecting short silent film fragments of uncertain or unknown provenance. The idea of preserving celluloid or nitrate (the oldest material in cinema) is a trend that only emerged in the postwar period, mainly focused on the preservation of films that had a specific historical, documentary or artistic value. Thus, the idea of preserving and collecting movie clips without a title, date, or credits was a risky idea.

This treasured material, even after being restored and digitized, lacked its full information (title, genre, date) and was thus kept dormant in the museum's hard drives. Uploading it to the Internet not only implied a taxonomic challenge but also a communicational one: how does one offer this material to a non-specialist public and to new audiences? The audiovisual artists Pablo Núñez Palma and Bram Loogman began to work on this material by creating, through the use of artificial intelligence software demos the *Jan Bot* project. *Jan Bot* is a bot or computer program based on artificial intelligence designed to cross information between the film material of the Eye Filmmuseum and the trending topics in Google. The project, as we will see below, addresses cinematographic history based on what Walter Benjamin, at the beginning of the 20th century, called actualization [*vergegenwärtigung*]: bring it to the present.

In an interview with Pablo Núñez Palma, one of its authors, we were able to have access to the details of the project. Initially they began by indexing the film material. They digitized more than 12 hours of small fragments, whose

program, which identifies different scenes based on the difference between one frame and another. Thus, they separated all fragments automatically. Later they dedicated themselves to the production of metadata. For this they used the Clarify program, whose function is to take an image and assign a series of tags to it. The next stage consisted in connecting keywords from the Google Trends API to “inspire” *Jan Bot* in its search for footage from the film archive and thus generate the films.

As Pablo Núñez Palma explains:

... we wanted to update a film archive that is more than a 100 years old, bringing it to the present, making it relevant today. And the way we could do this was by creating films generated by *Jan Bot* inspired by current news events. [10]

For this end, they used Cortical software which takes Wikipedia indexing to generate associations between different types of words, establishing their “semantic footprint”, that is, the different meanings linked to the same word. At this stage, *Jan Bot* takes the summary of a news item, draws a semantic fingerprint from the sum of words that are part of the story, this is associated with a number and that number is connected with the sum of the semantic fingerprints of all the tags that were generated for a shot of the film archive. That is, once the key themes or concepts of the day are determined, a text and image analysis algorithm enables you to recover movie clips from the archive whose tags match the emerging theme. Based on this, short video edits (approximately 30-seconds long) are automatically generated using pre-editing algorithms, which in turn are published on www.jan.bot and distributed on Instagram and Twitter.

The format of this audiovisual remix was not random. The artists were interested in linking the tradition of experimental cinema with the aesthetics of new narratives produced by social networks. Since the appearance of Snapchat, short audiovisual stories created by users have become widespread. Other platforms such as Facebook, Instagram and TikTok have also adopted this model. The Story format sequentially compiles a series of videos whose order is determined by algorithms. And the result is a type of film that, if at first it doesn't make much sense to the human mind, it "reflects the reasoning of the algorithmic mind of a computer". [11]

What is interesting about the project is not merely the curatorial capacities of the algorithms when recombining images according to certain parameters, producing unique works each time, but, as Palma points out, the fact of how the recipient's aesthetics and expectations are modified by technological uses. In 2018, the author would say that fifteen years ago a format like the one used in *Jan Bot* would have been considered cryptic by the audience, but today, the Story is one of the most popular audiovisual formats on the Internet, proving that not only computers “learn” from our behavior, but we, humans, also learn from them. [12]

Throughout the project, Núñez Palma puttigh himself in the place of the spectator, was able to identify at least three types of films produced by *Jan Bot*. Films that have what he calls “algorithmic narratives” because although they do not present conventional stories, one can deduce in them some kind of meaning given by the apparently causal sequence of scenes, by the suspense and tensions

gestures, etc. On the contrary, other types of films seem to have no meaning but, in contrast to the trend inspiring them, they manage to acquire new meanings. And finally, those films that are simply abstract, whose effect is more perceptual than narrative, operating at a nonconscious level, where even the visual alterations produced by the deterioration of the material medium (color or texture) would grant it new attributes, enabling us to appreciate, incidentally, not only the history of cinema as a narrative historical document, but also the aesthetic traces of a technology of the gaze.

In short, the project goes beyond the function of a traditional archive, inviting us to reflect on the status of historical or artistic documents –their incorporation into the catalog– and, furthermore, inviting us to reflect on AI, offering the exercise of seeing through the machine. As Nuñez Palma states:

Generally, the way AI works is to pretend to be a human being in order to facilitate tasks, or to relieve humans from thinking. And what we wanted to do with Jan Bot was the opposite exercise. That is, the machine did a job and we, as humans, had to try to understand what this machine was doing. [13]

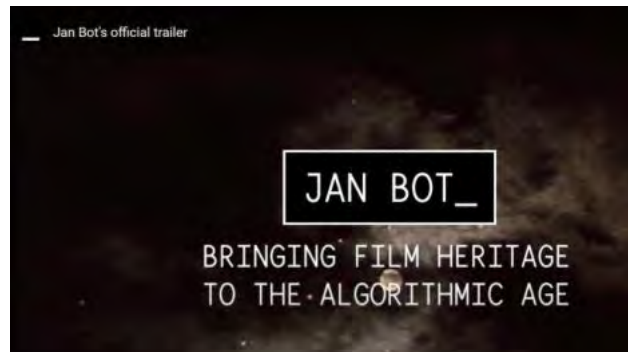

Image 1. Screenshot of the *Jan Bot: bringing film heritage to the algorithmic age* project trailer. See the full video at: <https://docbase.mit.edu/project/jan-bot/>

Indeed, one of the sources of inspiration for the project was a message in a “time capsule” that Jean Cocteau filmed in 1962, aimed at the young people of the year 2000. In his speech he addresses different topics and focuses on the uses and abuses of technology, stating that, “I certainly hope that you have not become robots, but on the contrary that you have become very humanized: that’s my hope”. [14]

For the artist, it is precisely this humanization through machine learning that *Jan Bot* aspires to. In his own words, he wishes that “by observing the visual piece that a machine generates, we can experience the work generated by a machine and we can also experience our own humanity, our way of seeing.” [15]

Creative poetics: OCP [Algorithms and Faith]

If in the previous section we examined *Jan Bot* as a paradigmatic case of projects oriented towards the archive, re-interpreting it through an algorithmic perspective, in this section –and regarding the *Oráculo de Capturas de Pantalla (OCP)* project– we will focus on other kinds of strategies: those of artists operating with the collection or appropriation of objects from different origins in order to create new collections.

One of the most eloquent references of this trend is found in the project by the controversial artist Marcel Broodthaers entitled *Musée d'Art Moderne, Département des Aigles, Section XIXème Siècle*, inaugurated in 1968. At a time when most intellectual circles denounced the transformation of culture into spectacle and that the avant-garde currents of the 1920s were being assimilated by institutions (museums and academies) and the market (galleries and auctions), Broodthaers opened a museum space in his own home with decorative objects and documents obtained at flea markets or from the street, all meticulously organized parodying the protocols and bureaucratic logic of institutions.

Artists such as Christian Boltanski, Annette Messager, Sophie Calle or Ydessa Hendeles are exponents who have become critical and poetic archivists. Exacerbated by the use of the Internet, as a monstrous catch-all, and nourished by the exuberant source of material it represents, archival art practices have spread everywhere. Such is the case of Olia Lialina and Dragan Espechied amassing GeoCities pages, thus turning a social practice into a true anarchiving, or Brian Mackern, who has been collecting since the 1990s gifs, banners and websites preloaders, or classic movie clips with which he has created his sound-visual artifacts called “soundtoys”. The collected sets of digital objects take on new meanings based on recontextualization operations involving juxtapositions, collages and remixes displayed in physical and virtual artworks/installations or in live stream concerts.

In this context of archival strategies for digital appropriation and recontextualization, in pursuit of the emergence of new meanings, we find Coni Rosman's *OCP* project (2020). Rosman's work combines audiovisual aspects (cinema, series, documentaries...), algorithms and faith crossed by the logics of the Web 3.0 era. Inspired by the I-Ching, Rosman's oracle stands as a digital, networked and interactive piece that seeks to give answers based on its interactors by answering their questions with a response in the form of a screenshot from a cinematographic work (or audiovisual, like a series, for example).

OCP works by inviting the participants to follow a series of steps: 1) Concentrate. 2) Ask a concise question. 3) Let yourself go by clicking the oracle button. 4) Analyze the image (screenshot) that is offered as a response. 5) Go deeper (“If you feel that you need to delve further, you can see the film, series or documentary from which this screenshot came from” can be read on the project's website) 6) Act.

A collection of screenshots is the foundation on which the oracle works. In Rosman's words “the screenshots are synchronous cuts in the diachronic axis of other stories (documentaries, films, series)”, adding, “all the sources are materials that are available online, re-appropriations of the contents of the virtual village, in tune with the practices of the Internet.” [16] The number of images it currently houses is “infinite.” Although the artist has started the collection (quoting dialogues from the films and subsequently, screenshots), the interactors are invited to expand the archive by donating new screenshots, adding a narration about their experience with them. These “offerings” become the project's database. This shift from the collection as an individual space to a collective environment has opened up new dimensions for the understanding of the project, which is currently being consulted 24 hours a day from different parts of the

reflected in the fact of inquiries "completely exceeds the capacities of human availability." [17]

This collective look at audiovisual art and the gestures of appropriation of images and their insertion in other stories, (both of those who make offerings and those who only consult the oracle) can be understood as a way of keeping film heritage alive, of practicing memory with these productions, but also of giving visibility through screenshots to films from regions whose productions don't have an ample distribution.

The social dimension of the project is reflected in each of its stages and its ambitions. The artist explains:

When carrying out a virtual work, I was interested in putting into play the practices of the Internet: community, collaboration, the virtual village and network construction. The 'offerings', which are a form of collaboration by the *OCP* Community, confirmed the idea that there are many collectors like us and that it is a shared practice. I observed a curious phenomenon: the same frames are sometimes repeated among the offerings, sent by different users. Which leads me to think that there is an '*OCP* gaze' facing audiovisual media (...). I like the game of thinking that there was a *OCP* way of relating to audiovisual stories that enables a way of perceiving those subtle messages within the great story. [18]

In addition to the project's website where the interaction with the oracle takes place, *OCP* has other channels for activating the collection: social networks (such as Instagram or Twitter) and the production of marketable objects (prints of the chosen screenshot).

Regarding the algorithm underlying the oracle and enabling the collection of screenshots to respond to the questions of the interactors, Coni Rosman doesn't reveal its operational logic, although she does insist that it doesn't take information from previous searches carried out by the users. Possibly, the reason behind this concealment is not to lose its essence, "the availability to believe in the magic of algorithms" (*OCP* website). Making the logic of the algorithm invisible is a poetic way of strengthening the enigmatic aspect by which one image is displayed and not another, but it also places an emphasis on perception: "the same screenshot in front of different questions can operate in different ways." [19]

OCP

Image 2. Screenshot published on the *OCP*'s Instagram account on March 1, 2021. Coni Rosman. Source: [instagram.com/ocp_oraculo](https://www.instagram.com/ocp_oraculo)

OCP is an art project that through the appropriation of images found on the Internet and the creation of a poetic and collective anarchic, is capable of activating the cinematographic heritage. It functions as a symptom of the time, as a space of convergence in the archive of dissimilar worlds and different times. It updates and acts out poetically and algorithmically the memory of audiovisual products.

Conclusions

The performative possibilities of the archive enable us to see how machines observe us looking at the world. What the concept of archive performativity tries to express is the possibility of approaching the set of documents, data or objects as a starting point that opens up to other stories and other forms of understanding of what the archive represents, contains or what it can become. The anarchival strategies analyzed in the *Jan Bot* and *OCP* projects undertake this task of disobedience to the Archive Law, questioning the transparency of the circumstances that gave it legitimacy or, at the very least, the order they impose. Both the remediation of the collection of silent film fragments from the Eye Filmmuseum in the first case, and the creation of a collection of screenshots in the second, mobilize new perceptions on cinematographic and audiovisual heritage.

Jan Bot and *OCP* show two tendencies regarding poetic-algorithmic cooperation: from the archive (performing the content of a previous collection) or towards the archive (generating a new collection, open to new inclusions in a collective way). In addition to showing different trends, these projects teach us divergent views on the role of algorithms. While in *Jan Bot* the logic behind the project is revealed (i.e., the parameters regulated by the algorithm), in *OCP* the algorithm is a black box, an unknown and "magical" operating space. *Jan Bot* presents an archive of silent films, connecting it directly with the trending topics of the day, while the *OCP* algorithm presents frames of movies and series, but it is oblivious to any ephemeral trend element, such as the specific previous searches carried out by those consulting the oracle.

In both cases, however, the projects result in products that pose an atypical approach to audiovisual heritage, which they challenge through the performance of the archive. The *Jan Bot* and *OCP* projects are exponents of what we could call Anarchival-Art practices. A group of artworks and artistic initiatives of a heterogeneous, experimental and sensitive nature, to the extent that they are able to activate new ways of looking at heritage and history by materially understanding and deconstructing the archive and the stories that run through it.

The divergences between the two case-studies constitute a clue that evidences that there is no single anarchival performance strategy, and that the present can open more than one possibility to history's revision. In fact, it is in the concurrence of the different ways of practicing the anarchic that each of these practices acquires its fullest meaning: in the meshwork and multiplicity. If plurality were to be extinguished, and anarchival strategies were to come together, we would be recreating once again the generalizing and unifying Archive Law. Therefore, dispersion is co-constituent of the anarchival sense. Thus, it is necessary to carefully examine the partial convergence of these, and many other projects, in the algorithmic logics of certain social networks (mainly Twitter and Instagram) as a possible "threat" to radicalism and anarchival poetics.

Regarding the scope of these practices, although there are some quantifiable aspects (for example, the number of visits to their respective websites), it is hard to ascertain to what extent—in its plurality and variety—they collectively impact on the emergence of new meanings for the archive. The doors opened up by their location on the Internet often surprise the creators themselves, as previously noted by Coni Rosman.

Finally, the artistic anarchiving has a poetic, critical and performative character. It enables both desired and unpredictable openings. The very idea of anarchiving implies to continue collecting and discovering with passion, deconstructing and reinventing, presenting and *presentifying* in a thousand ways, with the freedom of not knowing where all of this will lead us to.

Acknowledgements

The authors would like to thank the artists Coni Rosman and Pablo Nuñez de Palma for their time and their answers regarding their projects.

The series of educational modules for the subject "Archive, Documentation and Digital Conservation" commissioned by Dr. Ana Rodríguez Granell for the Open University of Catalonia are the basis of this research.

Vanina Hofman, PhD (Buenos Aires, 1978) works and lives in Barcelona. Lecturer at the History and Art History Department of the Universitat Rovira i Virgili (URV). She develops her work in a hybrid territory between academic research and cultural production. Her field of research lies in the intersections among Art, Science, Technology & Society. She is particularly interested in the processes involved in the construction of memory in contemporary culture, the archiving of media arts, the unconventional arts histories and the digital heritage. She has recently published the book *Divergent Practices of Media Arts Preservation. Remembering and Forgetting in the Digital Culture* (Prometeo Libros, 2019) based on previous fieldwork conducted in Argentina. She is part of the interdisciplinary Research Group SETOPANT (URV, Universitat Autònoma de Barcelona and Institut Català d'Arqueologia Clàssica).

Valentina Montero (Santiago de Chile, 1973). PhD in Advanced Artistic Production (University of Barcelona, 2015). Lives in Valparaíso and works in Santiago. Curator, educator and researcher. Her research, texts and exhibitions address the uses and appropriations of technologies and science in creative practices from a critical perspective. Currently is Associated Professor in Finis Terrae University; director of the Master's in Image Research-Creation at the same university, and professor in the Master's of Media Arts at the University of Chile. She also is director of PAM / Plataforma Arte y Medios and ANID / Fondecyt postdoctoral researcher.

A Sonic Exploration of Spanish Flamenco and the Whirling Dervishes of Turkey with Wearable Technology

Hedy Hurban

University of Plymouth, Plymouth, UK
hedy.hurban@plymouth.ac.uk

Abstract

Humans have gone to great lengths in recent years to augment their bodies with wearable technology using commercial devices such as smart phones, watches, and jewelry. Wearable technology has also been incrementally shaping the future of the performing and fine arts. This research explores creating a device that can be worn on clothing or costumes that performers can interact with as a digital musical instrument. This device can be used as an extension to the body with built-in sensor systems and haptic vibrations for producing sounds. The work draws from multidisciplinary practices including, sound and music, digital technology, costume design, body movement combined with traditional forms of cultural practices. Creating and expressing sounds using gestures and body movements can allow the performer/wearer to engage in a more interactive movement experience. The practices of Spanish Andalusian Flamenco and the Mevlevi Dervishes of Turkey are inspirations for creating a performance with these devices that will morph these styles by creating historical links through music and sound, body movements and gestures. These devices will track specific movements while emitting sound compositions that are related to music performed in these traditions. The experience will be an embodied one; a new way of performing with sound that can entrance both the wearer and the audience.

Keywords

Wearable technology, performance, sonic art, digital art, gesture recognition, cultural dance

Introduction

Wearable technology is incrementally changing the landscape of innovative designs in the fields of robotics engineering, medical and healthcare sectors, the military, commercial devices, and the performing arts. Applying technology to clothing for performative purpose opens the possibilities for speculative exploration. This could be using electronic circuits that operate on the body as mechanisms for producing several actions including emitting sounds by attributing gestures to them, controlling other factors such as lighting on stage, and transmitting tactile cues that inform the wearer that they have initiated an action. Haptic mechanisms contribute to the sensory experience where the performer initiates sound that provides feedback. These vibrations also mimic the reverberations felt when using physical instruments close to the body. By creating devices for costumes or attaching sensor systems on the body, performers can engage with interfaces that enhance their performance.

The focus of this research is to explore using existing technologies by developing systems or devices that can be embedded or attached to clothing which track and capture movements of the wearer and emit sounds. This amalgamation between science, technology and art combines the fluid, organic and at times abstract characteristics of the performing arts with the physical, tangible circuitry of hardware and computing. The inspiration for a performance piece using these sound costumes/devices is acquired from the rich cultural traditions of the Mevlevi Dervishes of Turkey and

Andalusian Spanish Flamenco. These two practices have had centuries-long traditions that have been deeply rooted and developed by merging and absorbing cultures to hone distinct practices that are recognizable the world over. The objective is to create costumes that have attached sensor systems which capture certain gestures or movements that are particular to both movement practices and augment them by allowing the performers to interact with the interfaces. The two forms have historical links both culturally and geographically which will be explored by morphing the two practices to create a new audio-visual wearable technology immersive experience. The potential implications can lead to the preservation of cultural heritage by digitizing these movements and cultivating new performance works as well as developing more streamlined systems that can be integrated into clothing in a sustainable and practical way.

1. Developments in Wearable Technology

In the post-modern contemporary world, humans have found themselves in a position where technology is becoming integrated with most everyday human functions. Wearable technology can be defined as a category of electronical devices that are attached to the body, embedded into textiles and fabrics, or even implanted onto the human skin. Seymour states that fashionable technology or wearable technology also has a purposeful function such as delivering computational data while creating meaningful design that is aesthetically pleasing. [1] Sazonov further describes wearable technology as having components such as small computers that provide feedback to the user through various ways of communication such as sensing and processing that information through to an application. [2]

The idea of human augmentation in wearables has been incremental over the last few decades but it is now becoming more of a reality. Raisamo et al comment that human augmentation is a means by which technology is somehow integrated using wearables especially, to enhance human capabilities or productivity. [3] It is arguable that humans have already augmented themselves to a certain degree by using and carrying portable devices such as smartphones and smartwatches that transmit and deliver information at the touch of a button. [4] Humans have for centuries been seeking ways of adding to or extending what is already on their bodies to minimize human labor but also to adorn themselves with useful gadgets and devices that enhanced their daily lives. [5] Some of these inventions include the wrist or pocket watch, and eyeglasses up until one of the first truly wearable pieces of technology that also transported music, the Sony Walkman. [5]

1.1 Wearable technology applications

Wearable technology roughly falls under three main categories: consumer devices, wearables for the health sector and health-related

applications, and textiles or skin-based applications that have been integrated with technology in some way. [6] Advancements in the health sector have provided the bulk of research being done in wearable technology but consumer products are increasingly becoming in higher demand with a market that is now flooded with a gadget for almost any need or purpose. Essentially, anything that can be attached to the body whether it is a ring, a hearing aid, glasses, socks, a watch, footwear, or jewelry, can be connected wirelessly.

Wearables are expanding into several different markets such as sports/fitness, military, security and defence, gaming, smart homes, as well as crowd sensing/interaction. With these areas targeting consumers that are not just for a niche market such as high fashion, the possibilities of integrating technology into clothing is inevitable. However, these above-mentioned applications and much of the research and reviews surrounding wearable technology, has a focus on the garment industry and less to do with the performing arts. Therefore, this research aims to develop and apply technology to clothing that provides an enhanced or augmented experience in the performing arts by integrating technology seamlessly onto garments.

2. Wearable Technology in Fashion, Costume and The Performing Arts

The world of fashionable wearable computing or using technology in the performing arts as it is known today may have started with the wearing of electrical diadems created by Gustav Trouvé for a dance/ballet performance of 'La Farandole' in Paris that was worn by ballet dancers in 1884. [7] Trouvé may have developed one of the first electrical interfaces- an example of wearable technology used in performances on stage. [8] These illuminated headbands were a key innovation of their time and paved the way to incorporating small-scale electronics by integrating them into clothing or for use on the body and in the performing arts milieu. [9] Costumes and fashion pieces that have been created for performing arts practices such as musical theatre, rock and pop shows or spectacles, have all begun to test the possibilities of how technology can be used to enhance garments and performances in this area.

Schneegass & Amft explain that in the last two decades, pop star performers and celebrities have been looking to enhance their on-stage performances with technology whether it be in the form of flashy LED lit costumes or perhaps even controlling certain aspects of the show's spectacle such as lighting or sound. [10] One of the more well-known artists to explore this intersection between fashion and technology has been Lady Gaga. In 2013, Studio XO and TechHaus (Lady Gaga's technology design team) collaborated to create the *Volantis* also known as the *Flying Dress* in which she was lifted off the ground. The dress was unveiled at the launch of her ArtPop album and is created with six battery powered rotors that can lift the wearer a few feet of the ground and propel them forwards. [11]

Wearable technology in the performing arts must be evaluated in all fields whether it be for the stage, musical performance or in cinema. In the world of fashion technology alone, there can be many subcategories such as art-related fashion tech, high fashion tech and/or just fashion technology. There are several crossovers as well such as designers who were trained as engineers or scientists who have collaborated with fashion designers to develop new ways of implementing technology into clothing while others are focused more on the performative or entertainment aspect of using technology in clothing, costume, or fashion.

2.1 Fashionable Wearables

Fashion designers have for the most part over the last three decades, embraced technology in one form or another, whether implementing technology in aspects of the fashion show such as lighting, projections, illusions, sound, and other effects as well as using technology as a medium for which to create fashionable garments from. Seymour remarks that the ideal partnership of scientists/engineers and fashion designers can result in creating truly functional and aesthetically beautiful wearable computing. [1] Fashion designers are not necessarily proficient in programming tech for use in their fashion tech design pieces therefore this union of fields is not only crucial to the output of truly operative smart garments but also inevitable. Perhaps it was the work of Turkish-born Hussein Chalayan that in the early 2000's broke ground in this area of fashion tech with his wildly innovative designs in his Spring/Summer collection of 2000 where he debuted his *Remote-Control Dress*. Sometimes referred to as the 'airplane dress' *Remote-Control* is a manifestation of Chalayan's concepts of combining architectural structures with the human body. [12]

CuteCircuit is a company founded by Francesca Rosella and Ryan Ganz out of London, UK. Many of CuteCircuit's designs have now become synonymous with wearable tech pop-fashion. The *Sound Shirt* is an immersive garment designed by the duo that uses haptics embedded in a garment that replicates the vibrations of instruments being played for the hearing impaired during a concert or performance. The shirt is totally wireless without any visible cables, it is lightweight and provides subtle vibrations from 30 high resolution haptic actuators. [13] The haptics provide an immersive experience for the wearer.

3. New Digital Musical Instruments; The performative Body

Several digital musical instruments have evolved recently in the field of wearable electronics for creating sounds or music. The Mi.Mu Gloves are an example how wearable technology can be used to create music for composition and performance [14]. The gloves use gesture recognition with which to generate synthesized sounds using dedicated software (Glover) that is designed for the user to program each gesture according to how they want to map sounds. Sawh remarks that the gloves were designed to make composing music easier for musicians during live performances where the gloves enable performers to be more hands-off on their instruments and more creative in virtual spaces. [15] Adam Stark who is the company's director and lead creative force says that the gloves are meant for people to express themselves through movement. [16]

The possibilities of creating devices for initiating music or sounds that accompany live performances or pre-recorded pieces which include theatre, dance, and musicals, reveal an exciting opportunity for exploration and development. Some pioneers in the field of using technology together with dance or performance include Merce Cunningham whose 1999 performance of *Biped* interlaced elements of dance alongside digital representations of the body on a screen behind the performers using motion tracking technology. [17] Birringer expressed that technology has changed the way in which relationships between humans and machines interact with one another in spaces providing new bodily boundaries yet in turn using technological advances in the theatrical arts as a significant tool for creation. [18] These digital tools can provide the potential to create and design unique pieces of work. One of the underlying interests of digitizing body movements is the scope for recording, preserving, and archiving them. This could also benefit the examining of

performance practices that have developed over centuries. Some of these deeply rooted traditions have become watered-down or lost over time therefore, re-imagining or augmenting them using wearable technology could uncover meanings behind significant body movements and gestures while placing them in a contemporary performance setting.

3.1 Digital Dervish

Part of the inspiration behind creating a performance piece using a wearable device is the sacred practice of the Whirling Dervishes or Mevlevi Order of Turkey. The Dervishes have had a long and ingrained history in Turkish culture for centuries. It is one of the oldest known dance/performances/spiritual practices in the world and has recently been proclaimed an intangible cultural heritage of humanity in 2005 through UNESCO¹. The practice of the *sema* which is the word for the sacred ritual that the Mevlevi order practice in their ‘turning’ performances, has rarely changed over the past several hundred years.

The most formative element in the way a Dervish moves adheres to the epithet that they ascribe to whirling or turning. The movement during a *sema* of continuous spheres sometimes for an hour, is the physical embodiment of the metaphysical connection between the ‘dancer’ and the Almighty Creator. It is the abandonment of all worldly attachments, and it is focused upon annihilating the temporal self through the recitation of *dhikr* or *zikr*. [19] It is not clear as to how or why the act of whirling began since during its early development, the *sema* was meant as a spiritual gathering for performing *dhikr* and to recite poetry or Qur’an in large groups above all else. There have been tales passed down through Mevlevi tradition that Mevlana (Rumi) walked past a goldsmith hammering and he felt compelled to start turning to the rhythm of the vibrations the metal made. [20] Feuerlicht remarks that the Mevlevi have argued that the *sema* is in fact not a dance because to some, dancing is frowned upon in Islam, but that they are turning and that everything including the clothing they wear has significant meaning. [20]

Some of the more prominent figures in current contemporary art circles globally who practice versions of the *sema* include performance artist Ziya Azazi, Sercan Çelik and Rana Ghorghani. Azazi has used technology to augment his practice and explores the repetitive nature of turning dervishes and concedes that there are not only mystical and meditative aspects to turning, but mental transformations that occur when one whirls. [21]

By contemporizing the tradition of the *sema* using wearable technology, it highlights historical traditions without the danger of removing the essential essence of the practice or by interfering with the metaphysical constructs of the form. The ideal performer will be one who open-minded about creating a contemporary version of the *sema* but who also adheres to the formal elements of the traditional practice. Many Dervishes who have been approached to trial these garments have declined since their intention is to preserve the *sema* in its original form without any need for adding technology, lighting, music, or visual effects.

The elements to be tracked and captured with the device the ‘Sound Drop’ (of which there are two) on the *Digital Dervish* dress (Figure 1) are the rotating patterns of the *tennure* or skirt of the Dervish, and the arm and hand movements. The breakdown of intended use and how each unit will be programmed can be seen in Table 1. These movements are of interest as they highlight the

gestures that are associated with the meaningful aspects of how a Dervish moves. The orbital patterns that are made by the circular skirt for example, could be revealed by amplifying the sound that is being emitted as the skirt comes into a fully turned position.

Costume	Unit 1	Unit 2
Digital Dervish	Function	Function
	<ul style="list-style-type: none"> tracks arm and wrist gestures can be turned on and off using touch sensor haptics and LED initiate when movement begins sound fades in volume depending on velocity 	<ul style="list-style-type: none"> tracks movement of skirt the more volume created by the skirt, the increase in volume of sound

Table 1: *Digital Dervish* units described in detail

Figure 1: Digital Dervish

3.2 Flamenco Sonic

While the practice of the Dervish is centuries old, traditional flamenco also has deep historical roots and a legacy that can be unpicked. Flamenco is an expression of song, story, dance, and instrumental music usually accompanied by a Spanish guitar (*toque*), vocals (*cante*) and dance (*baile*). [22] The practice of flamenco has also been recognized by UNESCO² as an intangible cultural heritage of humanity in 2010. Flamenco is a way of making the music a visual experience and in many cases, an emotional one for both the performer and the audience. Some of the most well-known flamenco dancers such as Carmen Amaya have dazzled the globe and introduced flamenco as a generically Spanish tradition. Although Carmen had a tiny frame, she commanded the stage and pounded the floorboards exhibiting her exceptional footwork – often referred to as the ‘Queen of Gypsies’. [23]

One theory suggests that the word ‘flamenco’ stems from two words ‘felah-mengus’ which some claim roughly translates to ‘wandering country person’ but many Arabic speaking people contradict this loose translation and meaning. [24] The word is often attributed to the association with the Gitano or Gypsy Roma that originally migrated from parts of Southern India through to Europe

² <https://ich.unesco.org/en/RL/flamenco-00363>

¹ <https://ich.unesco.org/en/RL/mevlevi-sema-ceremony-00100>

and the Anatolian Peninsula between the 5th and 10th centuries due to the flamboyant and expressive dance they practiced with costumes of short jackets and thin legs resembling the likes of flamingos. [25]

The traditional formal elements of flamenco can be broken down by examining the generational overlaps in cultural history. The origins of the practice are blurred; most flamenco is associated with the Andalusian region of Spain but it's roots may have come from further afield since the song traditions that influenced Gitano music in the Middle Ages were shaped by Islamic, Jewish, and Christian traditions. [22] According to Akombo flamenco can be attributed to Gypsy culture which dates back eight centuries and specifically to the descendants of the Moors in that region of modern-day Spain [26]. Totton suggests that the dance developed from the melting pot of cultures and descendants of Greek colonists, Sephardic Jews, Christians, and Phoenicians. [27] The music and form of narrative or storytelling began developing among these various cultures and the Gypsies who would perform with and amongst the Moors and the Jews shaped what we know as flamenco music today. [26] Leblon remarks that migrations from India through Persia of Gypsy people around the 5th century contributed to the development of the Romani language as well as the intermingling of musical cultures that they brought with themselves. [28] As well as developments in song and body movements practices, musical instruments such as the *tambura*, and the Persian *ney* or *nay* which is a reed instrument, were also experimented with throughout the Eastern and even Western European countries via the silk road. [28] Hayes writes that flamenco has become somewhat of a national identity of Spain and Spanish cultures, but the Gypsies have also claimed it as a form of civil rights activism due to its origins. [29]

Flamenco has garnered an incredibly visible sensibility in its form and associations that it has become recognizable almost the world over. Many iterations of flamenco have also been explored in many different cultures but in pop culture as well. Assimilating within other cultural practices, the dance formation, costume, and overall atmosphere of a flamenco performance has been seen in many different areas of film and television among others. The *Flamenco Sonic* dress will be outfitted with the *Sound Drop* device using two separate units as with the *Digital Dervish* dress. One device will be worn on the wrist and one at the ankle. Some of the more meaningful movements to be tracked are the subtle wrist twirling, and footwork that emphasize a certain beat or tempo. A description of how the devices are used is shown in Figure 2.

Figure 2: *Flamenco Sonic*

Table 2 describes the use of the devices to be worn on the *Flamenco Sonic* dress.

Table 2: Flamenco Sonic units described in detail

4. Morphing the Dervish and Flamenco with Wearable Technology

Interesting links and connections exist between the practice of the dervish and flamenco dance. There has been exciting cross pollination of music and dance styles and practices from the southern regions of Spain through to Turkey for centuries. These influences between cultures bring together possibilities for exploring new performances while enhancing them with technology.

Figure 3: *Digital Dervish* and *Flamenco Sonic* testing with *Sound Drop*

Figure 3 shows the two performers using and testing the device each with their own movement styles. Some of these possibilities lie within the musical forms of both Spanish flamenco and classical Turkish music. When flamenco is performed as a Bulería, the song can be very expressive and emotional often with elongated and drawn-out stanzas that carry on into exaggerated trills. It is the most fast-paced rhythmic form of flamenco using light-hearted banter, mockery, back and forth dialogue between singers, accompanied by Palmas (hand clapping) and guitar. [30] Similarly, many Mediterranean/Arabic song styles are performed using improvisational *maqam*, whether reciting Islamic prayers or poems, the melodic musical style is often interpreted as the musicians

perform made up of invented melodies that are adapted to pre-existing rhythms. [31] The *maqam*, which is prevalent in many Middle Eastern and Eastern Mediterranean countries such as Egypt, Iran, Iraq, Afghanistan, and Turkey among many others, forms a style of music that is not organized in the way for example, traditional ‘western style’ European Romantic music is performed. It is highly dependent upon the communication between singer and musician – the interplay of question and response, echoing each other without any structure and particularly characterized by techniques of improvisation.

The links between the two distinct practices will become clearer when the two performers begin to make contact. A fusion of music and movement will result in a performative piece using a bespoke device created to augment these practices in a contemporary performance setting. Some of the experimentation that has surfaced while exploring these links between the patterns made by dervish and flamenco movements as well as music, have been examined using motion capture technology. The possibility of integrating the physical device and the virtual space can inform how each mode of communication can exist together in a communal environment. Figure 4 shows how the same sound samples that are programmed to the *Sound Drop* can be used by taking a 3D model to explore sound creation in a virtual game engine using Unreal Engine and Vicon software. The goal is to create blocks of physical space that the virtual performer can enter which trigger sounds. This is a current area of exploration of possibilities with the *Sound Drop*.

Figure 4: Experimenting with motion capture technology.

4.1 The *Sound Drop*

The *Sound Drop* is created as a digital tool for augmenting body movement performances. The concept was to build a contained device that was completely wireless and communicates to a computer system via a stand-alone wi-fi network. There were several iterations of the device the first of which were compiling the components into sections and sewing them into fabric swatches to be then sewn as a patch onto a costume. It was found that after some testing, the sensors and battery within a fabric patch were inaccessible, and awkward. Further testing proved that a small device could be built using the 3D printing of a casing that was designed to house all the components which included an Adafruit Huzzah Feather with built-in wi-fi, a gyroscope/accelerometer, touch sensor, 3.7-volt Lithium-ion battery, as well as a haptic motor and twelve neo-pixel LED ring sensor. These are seen in Figure 5.

Figure 5: Components for *Sound Drop*

The *Sound Drop* fits inside the palm of the hand or onto other parts of the body via Velcro straps attached to the back of the casing. Various 3D printed versions using standard polyvinyl were created until an ABS-like translucent resin was used to test the model. It was found that the resin prototype proved to be the most suitable and robust design due to its slight pliability and smooth texture after being cured.

The *Sound Drop* is programmed to react to movements or gestures of a performer. The device reacts when a threshold is met whereby the LED neo-pixel ring is initiated along with the haptic motor. Currently, it is set to increase volume through increased velocity. It is turned on and off via a main control switch on the side of the device and can also be turned on or off via the touch pad sensor that lays underneath the neo pixel ring. The responsive interaction allows the performer to create subtle sounds that are programmed to each unit thereby layering sounds that accompany a pre-composed piece of music. The device works by using Max/MSP to read the incoming data of the microcontroller and processes the data to create variations on the pre-programmed sounds. The current sounds being used are representative of Turkish instruments traditionally used in classical Turkish music as well as sound samples of Spanish guitar and other instruments that have been electronically manipulated and are heard through a loud-speaker system. These sounds are interchangeable and can be used to reflect any style or genre of music making it versatile. A piece of music was composed in which the *Sound Drop* accompanies the piece with sounds that are related to it such as simple chords. The final design of the Sound Drop with lit up LEDs was printed in clear resin with the intention of having the components visible as a hybrid physical and digital object as seen in Figure 6.

Figure 6: The *Sound Drop*

Conclusion

This research has observed the developments in wearable technology over the last few decades and how these advancements contribute to the possibilities for use of wearable technology devices

to enhance or augment performance practices. The study has also adapted the historically rich traditions of Flamenco and the Whirling Dervishes of Turkey by intertwining them into a performance setting where a narrative can be used to bring the two practices together in an immersive audio-visual work that augments the traditions by using bespoke devices that track certain movements or gestures to which sound is attributed. These intersections of cultural performance practices can be further explored by investigating other global body movement/dance traditions. This study can also lead to the preservation of intangible cultural heritage by digitizing and capturing meaningful and significant movements.

The current research focuses on using machine learning to train a system whereby a set of up to four gestures will play four different sounds making the device variable. This can also lead to creating real-time sound synthesis based on gestures. These sounds are stored in a bank where they can be added to and accessed easily using Max/MSP. A web application is also being developed to streamline the process and usability of the device. Further work will investigate the use of the *Sound Drop* as a possible educational or therapeutic tool for learning and discovery by also integrating motion capture technology to develop interactive game engines. The device can be used as an extension of the body or a body instrument device that can accompany a live performance or pre-recorded piece of music. The prototype will be further developed to create a compact unit that can be more seamless and integrated into clothing/costumes or attached to various parts of the body.

Author Biography

Hedy Hurban is a designer of costumes, and a composer of electronic/electroacoustic music. She is currently working towards her PhD at University of Plymouth (U.K.) where she is designing musical body instruments. Hedy has taught across the globe including the Art Institute of Toronto, Canada, National Institute of Fashion Technology (NIFT) Hyderabad, India, Sehir University, Istanbul, Turkey and at the University of Plymouth. She has showcased her fashion collections at DSYN O4 (2004 Delhi, India) and has designed the costumes for the operas *Lampedusa* (2019 Plymouth, UK) and *The Mother of Fishes* (2020 Pittsburgh, USA). She has a BFA in Visual Arts from York University in Toronto and a ResM in Computer Music from the University of Plymouth (UK).

Robophilia and *Device Art* in Japan

Ricardo Iglesias García
Universidad Complutense Madrid
Madrid, Spain
ricardoi@ucm.es

Abstract

Japan has always exhibited a unique form of what can be described as robophilia. [1]

The peculiar characteristics of artistic creation in Japan and some Asian countries, in industrial developments in the field of engineering, computing, AI and robotics, and the existence of a culture of manga together with the idea of construction of prototypes from a certain artistic-commercial approach, raise the need to deal in depth with the development of robotic art in Japan, especially as a historical reference and as a vision of the future.

The permeability between art and design, so complexly posited in the West, does not suffer that categorical distinction in Japan, where the concept of Device Art opens the possibilities of aesthetic experimentation with new technologies towards industrial productions and, therefore, its approach to a public wider.

Keywords

Robotic Art, Technology, AI, Karakuri, Device Art, New Media Art

Introduction

The current Japanese revolution in industrial, social, and service robotics; the different anthropomorphic developments: assistance dolls, hostesses, dancers, and concert performers, etc., are well known due to their constant appearances in all the media. But the situation in which we find ourselves today is a reflection of the natural evolution produced in the world of automata since the middle of the 16th century. Historically, the concept of Japanese 'Art' (*Gei*) has a more transcendental and introspective sense, of interrelation between the individual and nature. It ranges from the most elaborate representations and objects to the simplest and most everyday actions. The principles of tranquility and calm achieved in the contemplative processes and in the performance of simple rituals such as, for example, the tea ceremony, the Geisha ritual (whose literal translation could be "performance artist") or the care and bonsai cultivation.

Japanese aesthetics, mediated by its philosophy and religion, seeks to find the meaning of life through art: beauty equals harmonious creativity. The realization of the work is presented as a poetic impulse, an almost spiritual

path, which has no purpose in itself. Beauty as an ontological category refers to the existence of all things: it consists in reaching the unitary sense with the rest of the material and immaterial world. It does not focus exclusively on the sensible qualities (in the external determinations of objects) but rather seeks an implicit communication with them. That is why oriental art is based mainly on suggestive qualities. It should not be perfect, but rather express a quality that leads to totality. It is intended to capture the essential through the part, which suggests the whole: the void is a complement to what exists. The radical separation between Art (with capital letters) and crafts, present in Western culture is not acceptable, because art and crafts are configured by the same spiritual substance.

The Edo Period and *Karakuri*

Around 1.600 the Edo period begins. It corresponds to the end of a period of fratricidal wars between the different clans of power: the imperial, the one formed by the regents (*shogun*), the feudal lords (*daimyō*) and the samurai warriors and gives way to the unification of Japan under the command of the Shogunate Tokugawa. Faced with commercial abuses by Westerners and the invasion of strongly proselytizing missionary congregations, the Tokugawa clan decided to impose strict control over the internal political structure (*sakoku*). All power is centralized in the city of Tokyo, the capital of the East, and any influence that comes from abroad is eliminated with the closing of the borders. This situation continued until 1868, when the Imperial Era began. A period of stability develops that will last 250 years.

During this stage of isolation, Japanese artisan technicians begin to develop their own technology, initially influenced by the Western one. They will have to refine the mechanisms to suit their culture: clocks (*wadokei*) must conform to the traditional Japanese division of time, where day and night were separated into six segments named after animals. The complexity of dividing and controlling the time segments, moreover, when they were not all the same, produced different and complex techniques and a very advanced development of the manufacturing and control of the gears. Quickly, this knowledge began to be used in the creation of different wooden automatons, the so-called *Karakuri*¹, which could be translated as 'mechanical devices to produce surprise in a person'. Its objective is the reproduction of

¹ Detailed information about *karakuri*. Accessed October 26, 2021, <http://www.karakuri.info>

daily actions within Japanese social life: religious or private rituals, theatricalization of historical events, indigenous dances, etc. According to its operation, a division was established into three large groups:

— *Butai Karakuri*, almost life-size, were used in the theater to stage historical events or ancient traditions, accompanying the actors in the representations. In 1662, the mechanic and watch and puppet specialist Takeda Omi opened the Takeda-Za Theater in Osaka as a space for experimental performance. The works of flesh and blood actors were combined with elaborate puppets and multiple automatons. Its great success with audiences throughout the country contributed to the development of the *Butai Karakuri* and the creation of numerous theaters with mechanical puppets.

— *Zashiki Karakuri* are smaller. Considered a luxury product by the feudal lords of the Edo Period, they are intended for the private and intimate space of the home. They perform actions that represent common life, such as serving, writing, playing an instrument, shooting arrows, etc. The best known are: the *ChaHakobi Ningyo* (figure 1), a semi-automatic servant who served tea to the feudal lord's guests, and the *Yumihiki Doji*, a dart-throwing archer. The operation of the first is both very simple and of great mechanical complexity. The counterweight of a cup of tea placed on a tray on his arms caused a movement of movement forward until he reached the guest, who when taking the cup of tea, stopped the mechanism. Once the liquid was consumed, when placing the cup back on the tray, its weight (in this case, less when it was empty) set the mechanism in motion again, but on another "programming": turn around to face the man. from the house and then walk towards him.

Figure 1. *ChaHakobi Ningyo*. © GFDL. British Museum

The original designs of its mechanism and construction have survived to this day thanks to the *Karakuri Zui Anthology* made by the great inventor, artist and engineer Hosokawa Honz Yorinao (1741-1796). The three-volume work also shows the designs and mechanisms of four kinds of watches (*wadokei*) and eight *Karakuri* models. The archer created by inventor Hisashige Tanaka, in the late Edo period, is able to take an arrow from his quiver,

place it on his small bow, and shoot it at a target. Tanaka is known as the "Japanese Thomas Edison", due to his many mechanical inventions, among which is a scribe who could draw Japanese characters. He contributed to the modernization of Japan by founding the telegraph company, developing Morse technology and the first telephones. His company will become today's Toshiba Electronics Corporation.

— *Dashi Karakuri* are large, luxuriously decorated wooden structures. They have three floors, with a small stage on each one. In the upper part, two or three automatons represent traditional legends or Japanese mythical tales, in the second a group of dolls acts as a

'choir' and in the lower part a group of musicians play the flute and drums as accompaniment. During religious festivities and ceremonies, the *Dashi Karakuri* were carried in procession. The tradition continues to this day in different events in Japan such as the Inuyama Festival, the Nagoya Festival, the Takayama Festival, the Gion Festival and, one of the most recognized, the Kamezaki Shiohi Festival.

In the different constructions of *Karakuri* we find the first peaceful (social) developments of interaction between automata and human beings. While the Western imaginary has been populated by servile, mechanical, almost monstrous beings who could escape the control of their creator to sow chaos and destruction, in the East a close relationship of trust is established, of belonging to the family and to the intimate and own world.

"The automaton puppet was a prototype of the robot that is said to be flourishing in industrial Japan today. In a sense, we can say that the Japanese learnt to tame the machine by means of the *kadakuri* puppet because they considered the puppet an extension and copy of the human figure, not as something sent by demons or animated by the divine. In a society where mechanical figures are thought to be pure material, people are always potentially suspicious that they may go beyond human control. [...] As playthings, the puppets did not threaten human competence or existence, they remained charming copies of the human figure. They were considered in a way like domestic animals." [2]

Another fundamental aspect that differentiates both worlds, and that is shown in a specific way in the sphere of art, as Machiko Kusahara will later propose, is an intense desire to fascinate, entertain, amuse and surprise with these creations, as opposed to theorizing technological and intellectual of the West.

After the success in 1924 at the *Tsukiji Little Theater* in Tokyo of the play *R.U.R. Rossum's Universal Robots* by the author Karel Čapek, where the word "robot" appears for the first time, begins the development of current Japanese robotics, from a more "humanistic" perspective in contact with Nature. The first modern Japanese robot, heir to the *Karakuri*, was built in 1928 by the biologist Makoto Nishimura for the public coronation festival of Emperor Hirohito. Baptized as *Gakutensoku* which means "learning from natural laws." He represents a human figure with golden skin, kind-looking and seated at an altar-desk. At more than 3.2 meters high, he had a complex compressed air system that allowed him to open and close his eyes, move his head, modify the features of his face outlining a smile, "breathe" and write. The image of *Gakutensoku* is closer to the representation of a great Buddha, than to the classic Western model of an aggressive metal robot. In 2008 it has been restored for the Science Museum in Osaka with a computer system that controls all its movements.

***Tetsuwan Atomu* and the 'Mechas'**

Starting in 1930, the figure of the robot began to be common in comic strips, popular stories, songs, business

developments and political documents. He was usually depicted as a nice, slim "man" who can communicate with people and especially with children. The stories of the father of Japanese science fiction, Juza Unno, about automatic machines will directly influence the creator of Astroboy. We cannot really talk about Japanese robotics, or understand its conceptual, industrial and artistic development without making a small note about the evolution of the concept of robot within popular manga culture.

The first manga representation of a robot corresponds to a little boy who learns, has his own will and wants to be the closest thing to a human, a kind of robotic Pinocchio. *Tetsuwan Atomu*, better known in the West as *Atom* or *Astroboy*, is considered the first manga to have a robot as its main character. Its creator Osamu Tezuka, currently considered the god of manga, studied medicine before dedicating himself to the world of graphic drawing and comics. Influenced by the aesthetics and dynamics of Walt Disney's animated films, his goal was to transfer that energy, mobility, and simplicity of lines to drawn comics. At first, he made different comics in which he tried a revolutionary form of quick cuts between the panels, which served to show dramatic close-ups and mix them with large wide shots. In 1951 the first comic of *Tetsuwan Atomu* appeared in *Shonen Magazine*: a humanized robot that helps the earth in an atomic conflict with an extraterrestrial civilization. In a later issue of the magazine, his birth is narrated: Doctor Tenma, a scientist from the Japanese Institute of Sciences, has created the robot in the image and likeness of his son, who died in an accident. It is a robot with a child's body and human feelings. It has artificial intelligence, X-ray sight, super-hearing, rockets in its boots and arms and, most importantly, a unique nuclear heart-reactor. In the development of his *Tetsuwan Atomu* saga, Tezuka shows his concern about the possibilities of the interaction between machines and human subjects, the pros and cons for the good of humanity, developing ideas and concepts extremely close to those proposed by Isaac Asimov in his Three Laws of Robotics.

Unlike what happens in many of Asimov's stories, Tezuka's robotic characters do not try to find ways to "break" the rules, but rather their robots have intellectual and moral free will, a condition that Asimovian characters do not have. Tezuka did not formulate any proper laws but established simple common sense ethical rules to govern the coexistence between robots and humans. "To put it simply, the difference between *Mighty Atom* and *Terminator* shows the differences between how Japanese and Westerners view robots. Westerners tend to have this sense of alarm or wariness. Japanese are unique in the world for their strong love and affinity for robots." [3] In addition to being a Manga hero, Atomu, whose name recalls Japan's traumatic experience with the atomic bomb, became Japan's Son, an ideal reflection for many families who lost their children in war, and a national icon, a symbol of scientific progress: "a peaceful future, where Japanese science and technology were advanced, and nuclear power was used for peaceful purposes." [4]

In 1956, at the age of 21, Mitsuteru Yokoyama published his science fiction manga *Tetsujin 28-go* in *Shonen Magazine*, known outside of Japan as *Ironman 28* or *Gigantor*. The robot's movement and actions are remotely controlled by the young Shotaro Kinta. "Aton and Iron Man are the ancestors of all subsequent Japanese fantasy robots, particularly two distinct genres seen today: truly autonomous robots and those that require human intervention for their operation." [5] He is the forerunner of the Mechas genre² (abbreviation of the Japanese *Meka* for the English word mechanical), a specialty of Mangas that exhibit robots, generally of great size and thought as defensive weapons to protect humanity, which are physically controlled by a human subject. A mecha can have a humanoid or zoomorphic appearance, be a kind of means of transport, a form of mobile weapon. Likewise, there are "fused" wicks, a variety of relatively smaller wicks that are assembled into a larger one or that can undergo transformations from one shape to another, to increase their deterrent power.

This genre quickly jumped into the realm of animation (Anime): cartoons for TV. From 1972 until today, more than thirty different series of Mechas have been created and reissued. The best known are: *Code Geass*, *Yatterman*, *Brain Powerd*, *Mobile Suit Gundam*, *Bokurano*, *Macross*, *Robotech*, *Super Sentai*, *Full Metal Panic!*, *Eureka 7*, *Daitarn 3*, *Martian Successor Nadesico*, *Burst Angel*, *Zoids*, *Neon Genesis Evangelion*, *Transformers* and, of course, the most famous of all *Mazinger Z*. The stereotype of the mecha pilot is a young, brave and active character. Normally the protagonist suffers an accidental encounter with his fuse or is a close relative of the creator who dies killed by enemies and before dying reveals the secret of the robot's construction. In 2013 (and the sequels) the Mecha anime genre received a western homage with the film *Pacific Rim* directed by Guillermo del Toro.

Mazinger Z (1970) by Go Nagai begins the saga of the Japanese super robot, with bright and primary colors, a mix between military equipment and samurai armor. For the first time, an integration between the machine and the individual is proposed. In the words of its author: "I wanted to create something different, and I thought it would be interesting to have a robot that you could drive, like a car." [6] The robot's brain is not a complex program, but a human being, the young orphan Koji Kabuto. Some researchers have pointed out a certain psychological problem within Japanese manga due to the continuous idealized representation of the image of the father; for the ever present initial conflict; by rejection of the individual in front of the machine, to end up assuming the role of hero; by the sublimation of the feminine; by the metaphorical use of the Great Robot (Meka-Corpo-Man) in front of the symbol of the Great Mother Earth and, finally, by the use of young adolescents as inexperienced or fusionable controllers with machines.

In 1979, the so-called realist school (*riaru-ha*) began with one of the anime that has most influenced the current Japanese youth culture and society: *Mobile Suit Gundam*³

² *Robot anime history* accessed October 26, 2021, <http://www.youtube.com/watch?v=KxntzjOvo8Q&feature=channel>

³ *Mobile Suit Gundam* accessed October 26, 2021, <http://www.gundamofficial.com/features/introduction.html>

by Yoshiyuki Tomino. The action is set in outer space, the manichean struggle between Good and Evil of the previous era evolves towards more complex and conflictive characters and characters. The robots are presented as combat suits-spaceships. At this point we can speak of exoskeletons, of giant structures that are driven and controlled by intrepid young men and fighters. The next step in evolution occurs in 1995 with *Neon Genesis Evangelion*.⁴ It shows the "existential union" between mechanical structures and their pilots: a new relationship between the organic and the inorganic, a relationship that in many cases becomes symbiotic and not exclusively due to proximity, continuity or mixture. Robots are losing their machine appearance, to become more and more evolutionary developments of the human subject

The evolution of robotic manga in Japanese culture, and by contagion in Western culture, is increasingly considered as a form of visual prediction of what is going to happen, or can happen in the future, a kind of Science Fiction in drawings, but at the same time it appears as a source of inspiration in the work of researchers and scientists. *Tetsuwan Atomu*, the robot child, reminds us of the legion of anthropomorphic robots born in the great Japanese industrial corporations: *Asimo* (Honda), *Qrio* (Sony), *Partner Robot* (Toyota), *Hoap 3* (Fujitsu), etc. *Doraemon*, without a doubt, could be a reflection, a little deformed, of the dogs *Aibo* (Sony), or the therapeutic seal *Paro*⁵. The different types of mechas have been transformed into sumo wrestling robots: *KHRI* (Kondo Kagaku), *Robofire*, *Chroino*, or in the robot Samurai *Kiyomori*⁶, developed by Waseda University and the Tmsuk company, and the evolved mechanical beings of *Neon Genesis Evangelion* in the humanoids of the engineer and professor Hiroshi Ishiguro. As Mark Gilson indicates "where will the future concepts in robotics come from? Keep watching the cartoons." [8]

Device Art for everyone

The curator Machiko Kusahara, in her article *Device Art: a New Form of Media Art from a Japanese Perspective*, introduces a new conceptual construction to redefine what we understand by interactive art, by media art, or by art and new media from a Japanese aesthetic. The new terminology used is *Device Art* "a form of media art that integrates art and technology as well as design, entertainment, and popular culture. Instead of regarding technology as a mere tool serving the art, as it is commonly seen, we propose a model in which technology is at the core of artworks." [9]

This definition is applied mainly to work carried out in Japan, but it can be extended to some countries in the rest of Asia, whose cultural and business traditions are different from the western one. The processes of interaction with the public are linked to new playful forms of entertainment. The creation of the artistic work may be accompanied by a parallel or subsequent commercial development. The union between art and "commercial" is not seen in such a negative way as it is

in the West. Japanese artists are interested in a "popular interactive art", if we can define it that way, and therefore expand its expansion beyond the usual exclusive circuits of galleries, museums and large exhibitions. This central point in their projects allows greater collaboration between artists, scientists, research centers and companies.

The western artistic community sometimes does not understand some of these premises, mainly the idea that art must be both entertainments, or it can be commercial. "Works that are highly appreciated in Japan are often criticized by Western art community for their lack of seriousness. These criticisms are often related to the entertainment factor in the works and their affirmative attitude towards technology." [10] The questions that Japanese critics and curators are asking are: Can artists present their work as software that runs on a popular gaming platform like Nintendo and still be considered art? Are the artistic pieces of the same quality, despite not being exhibited in spaces such as galleries or museums? Can they continue to be considered art despite not being in the "art market"? and your answer is: yes, yes, yes, of course. The distinction between the notion of Fine Arts, understood as the creation of a "Art PURE" and that of applied arts or "crafts" does not exist. Despite the Western desecration of Art, the loss of the aura of the unique and exclusive piece produced at the time of its technical reproducibility and the advances of the conceptual avant-gardes that have stopped placing the accent on the physical object itself to transferring the artistic experience to communication with the subject, in the West we still move on deep classical philosophical and aesthetic principles.

The term *device object*, which originally only refers to the tool with which a job is executed, has become a fundamental element in the realization of the new interactive robotics. The user's experiential level increases exponentially compared to the different uses of sensors, programming, materials, computers, cameras, connections ... in such a way that the device has become the body, the material of the piece, which produces a concrete experience and in its multiplication we can multiply the experience. In Japanese culture, it could be problematic to look for a separation between the tool and the sensation produced, when this has been precisely produced by a certain tool.

The importance of the concept and development of *Device Art* is confirmed by the Doctorate program Empowerment Informatics at Tsukuba University directed since 2014 by Professor Hiroo Iwata. Iwata himself provides a succinct and appropriate definition of the concept:

- (1) The device itself is content. The mechanism represents the theme of the piece. Content and tool are no longer separable.

⁴ *Neon Genesis Evangelion* accessed October 26, 2021, [http://en.wikipedia.org/wiki/Neon_Genesis_Evangelion_\(anime\)](http://en.wikipedia.org/wiki/Neon_Genesis_Evangelion_(anime))

⁶ *Samurai Kiyomori*. accessed October 26, 2021, <http://www.kiyomori.jp>

(2) Artworks are often playful and can sometimes be commercialized into devices or gadgets for use in everyday life.

(3) Refined design and playful features are traced back to the Japanese tradition of appreciating tools and materials. Traditional Japanese culture, such as the tea ceremony or flower arranging, uses sophisticated devices. These devices are the roots of device art. [11]

Maywa Denki is the best example of serial device artistic production. The artist Nobumichi Tosa (<http://www.maywadenki.com>) defines it as an *art unit*, which could be freely translated as “productive unit of art”. It works like an artistic company, a metaphorical imitation of his father's old electronics company, from which he takes his name (Maywa Denki). The conceptual approach, in an ironic and playful way, is closer to business standards than to artistic ones. Nobumichi Tosa (fiand all of his collaborators, whom he calls employees, wear a suit designed like the typical uniform of Japanese electrical shop workers in the late 1960s. These types of stores represent the small and medium-sized business that helped the Japanese economy grow after World War II, something like the Japanese version of the American dream.

Figure 2. Nobumichi Tosa.
©Ricardo Iglesias

The philosophy of his work is based on concepts 'copied' from the business world. Each piece created at *Maywa Denki* (figure 2) appears with the denominator of "product": a mixture of high-tech and low-tech that provides a unique visual aesthetic form. Recycled elements from old machines are reused in the creation of new parts with advanced programming. His live performances are called "product presentation". Each "product" is understood as a unique prototype within the production chain, representing the peak of a pyramid where the lower levels are industrial optimizations of the original developments, presented as objects for commercial sale with the motto: no product sales but secondary use profit. The “art production unit” that includes all kinds of mechanical, robotic, electronic, automaton, puppet and musical instrument gadgets, more or less controlled, has been divided into three production lines:

— *NAKI*, a series of mechanical objects and musical machines inspired by the skeleton of fish or some other characteristic of its own, such as the bidirectional eyes of

the *Oo-No-Me*, the *Na-Tate-Gato* electronic harp whose strings resemble thorns, the xylophone *Hou-Den-Na* with fish body, etc.

— *Tsukuba* (gadgets) is made up of recycled objects into original musical instruments, automatic puppets, modified guitars with remote control, etc.

— *Edelweiss* composed of different objects that suggest artistic and floral motifs. In operation for several years, it has now evolved into a more “classic” line: *Arclassy*.

Visually all the 'products' seem technologically very complicated, but one of the objectives of the company is that their operation is completely intuitive.

In 2004, the NTT-ICC Inter Communication Center in Tokyo organized the retrospective *Maywa Denki. The nonsencemachines*⁷ with more than three hundred objects distributed in ten spaces. The performance shows or “product presentations” are authentic robotic-mechanical-musician-visual paraphernalia, where the 'non-functioning' of the instruments is considered as one more variable element of the show. This fact allows Tosa to introduce a subtle critique of the industry (art industry) that considers the user (or the art viewer, if we continue with the analogy) as a technological illiterate, as an uneducated and simple recipient of mechanical objects (artistic) manufactured. Its intention is to directly show the product to its audience from two premises: maximum transparency of its operation and have fun together. A direct rejection of technological and intellectual curatorships, like “black box”.

As confirmation of the concepts exposed by the curator Kusahara, Tosa has developed a playful line of *toys*, where he applies the knowledge acquired and the techniques developed in the elaboration of *Maywa* objects to different series such as *KnockMan Family*, a set of small human figures who “play” music to the beat of their hearts; *Nao-Cord Series* - herringbone-shaped electric extension cords; *BitMan Series* small screens showing *BitMan* dancing; *Savao Series* show souvenirs etc. It is interesting, and it may seem paradoxical, to see how in any large electronic supermarket in Tokyo you can find some of Nobumichi Tosa's devices among hundreds of other commercial products and at the same time contemplate them inside urns with safety glass and control guards in major exhibitions such as the MuseumsQuartier in Vienna (2009): *Japan Media Art Festival*.

While Tosa's work exudes optimism, good humor and a certain technophilia, the artist Kenji Yanobe (<http://www.yanobe.com>) bases his work on a direct critique of an idealized approach to atomic energy, the uncontrolled influence of technological development in today's society and the ruins and waste generated by that same technology once it is obsolete. The negative experience produced before the abandoned spaces of the Japan World Exposition in 1970, as if it were a trip to an abandoned future full of rubble, marked his work from the beginning. The EXPO'70 in Osaka, as it is known, with more than 64 million visitors, consisted of a sample of all kinds of technological advances: innovative contributions to architecture and coexistence, sophisticated comprehensive communications systems,

⁷ *Maywa Denki. The nonsencemachines*. ICC. accessed October 26, 2021,

<https://www.ntticc.or.jp/en/exhibitions/2004/maywa-denki-the-nonsencemachines/>

new forms of transport and infrastructures, spaces multinteractivos, etc., (remember the participation of the two immersive American Pavilions). The EXPO'70 represented the "city of the future" (*miari no toshi*), from the infinite and peaceful possibilities of atomic energy. A year later, when the young Yanobe traveled it daily with his bicycle, there were only abandoned remains, the "ruins of the future" (*mirai no haikyo*).

His first pieces correspond to robotic sculptures that can be moved and controlled from the inside by a person, such as mechanical suits dressed by operator-pilots like those that appear in the manga *Mobile Suit Gundam*, but that function as a protective armor against an external attack or a nuclear disaster. *Tanking Machine* (1990) consists of a tank with physiological sodium chloride solution that is heated to the temperature of the human body that floats inside it, in a state of sensory deprivation. Covered with steel and lead plates, *Yellow Suit* (1991) is an atomic radiation protective equipment-suit built in the immediate aftermath of the Mihama nuclear catastrophe. The piece is accompanied by a counterweight that corresponds to an oxygen container, and also includes a version for dogs and a geiger counter. *Foot Soldier-Godzilla* (1991) is a platform that moves in the shape of godzilla feet. A "soldier" sitting on his top can control and direct his movements. movimientos.

In the following years, Yanobe built a whole series of vehicles and machinery with a strong post-apocalyptic aesthetic and a function that was both protective and intimidating. The manga figure Tetsuwan Atomu of Tezuka is a fundamental part of his aesthetic. It is used as a base concept in its criticism of idealism and the naive simplicity of the atomic-pacifist approach represented by the manga itself and assumed by Japanese society in a dogmatic and blind way. "In his reinterpretation of appearance and performance, Yanobe questions apparent innocence of robot's human-like appearance because it provides a kind of concealment or 'protection suit' to ward off criticism of the development of advanced technology." [12] *Atom Suit* (1997) is a yellow anti-radiation suit with lights, lead shields and a geiger counter. The spiky hairs of *Tetsuwan Atomu* are incorporated into the head. In 1997 he began his *Atom Suit Project*, which consists of a visit to different spaces: radioactive (Chernovyl, 1997), desert (1998) or abandoned (EXPO'70, 1998), dressed in the *Atom Suit* and for which he has developed other pieces as special vehicles and accessories.

Giant Torayan (2005) it is one of his best-known works. A child-robotic doll of more than 7 meters in height that sings, dances moving its arms and throws huge flames of fire, while it moves on a large mobile platform. The giant only reacts to orders given by children thanks to a control device, which uses an advanced voice recognition system to differentiate the tone of an adult from that of a child. The system has been developed by the Nagoya Institute of Technology. Despite the most critical aspects of him, he maintains a playful dynamic in his latest works, an approach between the world of children and technology. With the *Torayan series* (2004) he has developed, in the same way as Tosa, a whole commercial line of ventriloquist dolls dressed as *Atom Suit*, where he mixes infantile naivety and the

problems of the adult world (*mini Torayan, Torayan Head, Villa Torayan, Torayan Mask ...*).

With the same ironic-critical approach, the artist Momoyo Torimitsu also raises her different aesthetic productions (<http://www.momoyotorimitsu.com>). The piece *Miyata Jiro* (2001) is a robotic mechanism that represents, in a hyper-realistic way, the typical Japanese businessman crawling like a soldier through the streets of the main financial districts of cities such as New York, London, Paris, Amsterdam, Sydney and Rio. of Janeiro. Torimitsu, dressed as a nurse, walks behind him to meet her needs or show him the right way, change the battery, which she has curiously placed in the lower part of her back. "A satirical commentary on the humiliating conformity of Japanese 'salaryman' culture, the robot presents a cowed and hyperrealistic counterpoint to the camp heroic excesses of many robot performances." [13] In the 1960s, Japan entered a wild era of industrial and economic growth (*Japanese Miracle*) that involved the transformation of traditional oriental cultural parameters into a businessman culture, a business culture that will be characterized by new forms of entertainment. (TV, cinema and karaoke) and the compartmentalisation of physical spaces for entertainment and sex.

In subsequent installations and videos he has continued to delve into the conformity and humiliation of the "successful wage earner". *Inside Track* (2004) is a robotic installation where three top executives, one American (*Mark*), another North European (*Günter*) and the third Asian (*Lee*) crawl through the corridors of an office in a mad rush to be the first to reach the success. In *Horizons* (2004) they are one hundred miniature businessmen crawling like soldiers in combat on an abstract world map: a large area of artificial turf that includes mountains, seas, demarcations, cities, oil fields and other points of interest. Miniature entrepreneurs cross oceans and national borders in their ongoing battle for success, but wrecking the world in the process. The fear of a possible slavery of the human race, associated with dystopian literature where machines replace individuals, suffers a twist: human beings are already on their knees and are robotic servants of a global economic system.

The non-existent 'radical' separation between artistic work and manual development in traditional Japanese culture has allowed important industrial designers such as Shunji Yamanaka or Takeshi Ishiguro to develop pieces that can be viewed either as art or as design objects. Shunji Yamanaka has created an impressive robot: *Cyclops* (2001) (<http://www.lleedd.com/cyclops>) that updates the image of the mythical *Cyclops*. The work consists of a mechanical flexible spinal column (3.60 m high) from which one eye protrudes and two arms hang, slightly reminiscent of the figure of a human being. The spine has a flexibility similar to the spine of a human being and is made up of fifteen ball joints controlled by fifty artificial mechanical muscles that are moved with compressed air devices. The central computer controls the flexible and sinuous movements of the entire structure to direct and follow "with the eye" what it is contemplating. Its only "eye", a CCD camera connected to the computer, has optimized programming to analyze the environment and differentiate between moving human-sized objects. Eye contact in our society

corresponds to the first level of communication and intuitive understanding of the feelings of our fellow men. The visual contact established between the visitor and the Cyclops humanizes its construction and establishes affective bonds.

The artist considers that the psychological effect produced by the movement of the eye-cyclops can serve as a reference in the development and design of future intelligent organisms and creatures. The aim of the project is to confront the audience with a creature whose behavior resembles a living being, even when its spatial displacement is limited. The Cyclops cannot follow rapid movements made by a person, but it has a sufficient level of artificial intelligence to produce a reflection on the meaning of "similar to an intelligent organism". The spatial technological limitations are not detrimental to the project, moreover, the work does not seek an anthropomorphic physical reproduction, but a visual and intimate contact between systems from the premise of a human-machine interaction.

In this same philosophical line of entities that represent and update the presence of forms similar to those found in Nature, Yamanaka made Ephyra (2007) for the exhibition *Senseware - Tokyo Fiber'07*. The "organism" covered by a flexible and extensive skin, has twelve arms sensitive to contact that move with hydraulic mechanisms, imitating tentacles in continuous movement. At the end of each limb there is a very delicate sensor. When visitors try to touch the creature, it retracts its tentacles and "hides". The robot is programmed to recreate a continuous life process, when nobody touches it, its tentacles expand and contract like an animated being. For Yamanaka, the complexity of robotics must go beyond mere anthropological copy. Each "creature" will assume its own appearance depending on the functions and objectives for which it is intended.

"Robots will develop their own rational forms to suit their technological functions and specific applications. We believe that this project has helped to show that human metaphors don't help us to understand emerging robot technologies. Cyclops is a proposition that we should start a fresh journey in search of an original aesthetic. There is now a unique new class of product - robots - and we are only starting to develop new forms to realise this." [14]

In an interview conducted in 2010 by the director of the Tokyo Gallery, Yukihiro Tabata, with the technological designer Takeshi Ishiguro (<https://takeshiishiguro.blog>) he once again emphasized the non-differentiation between the two areas. He considers art as the first step in conceptualization, experimentation and research that can lead to possible new developments, without denying an exit towards the world of design, with its more commercial aspects. With a classical training as a designer at the Royal College of Art in London, his work leans more towards the artistic sphere, reaching the conclusion that design can be treated as art and art must have a good design. His final degree project *Rice Salt & Pepper Shaker*, a salt and pepper shaker made with artisan techniques, was included in the

permanent collection of the New York Museum of Modern Art.

The interest in working with different materials and technological applications has represented a new challenge in each project, a challenge to find the union between poetry and the delicacy of Asian culture and high tech production. *Balloon* (2007), presented in the *Sonarmatica - International Festival of Advanced Music and Multimedia Art - Sónar* of the same year, is a set of spheres made with reflective material and filled with helium that float in the air. We could not properly define them as robots, but with a very simple programming, a mini fan and a series of sensors a complicated behavior is generated. The flying objects manage to move without ever touching the ground and, at the same time, avoid different obstacles that visitors may find themselves among. The original idea was born from a dream of Ishiguro where he played with an object suspended in space that moved freely and for an unlimited time.

In recent years, parallel to the development of Japanese industrial robotics, there has been an effervescence of artistic production in Asia, especially in South Korea or Taiwan, some close to evolutionary aspects of amorphous and inflatable forms aesthetically similar to recent works. by artist MacMurtrie, as *EX-DD-06* by Shih Chieh Huang; others reproducing conceptual schemes on forms of "slave" work in machines and assembly lines, such as *The self-portrait machine* by Jen hui Liao or, finally, closer to the conception of the body of the living being as a "raw material" capable of being modified and hybridized *Organ-machine Hybrids* by Doo Sung Yoo.

Abstract

The article discusses the use of the proprietary spectrocartography research method to study the interdependencies between history, forms of landscape design, colonization mechanisms, green areas management, processes of ecological degradation, and urban policies. This method involves carrying out research using various data from the fields of sound ecology, biocommunication, botany, ecology, and environmental psychology, as well as methodology from the field of art-based research and art & science. The genesis and hidden ideology contained in the design of the artificial lake Elsensee-Rusałka, which was dug in Poznań by Jewish prisoners of war during World War II, as well as post-war and modern forms of the revitalization of the lake area and adjacent green areas, are analyzed in detail. The ultimate goal of the research project is to create an open experimental digital archive relating to the concept of hybrid space, digiplace, and augmented reality, in which all the data obtained during the research will be collected. These data will be used to create a new form of storytelling, taking into account historical asynchrony, nonhuman actors, and the space itself as a causative entity.

Keywords

spectrocartography, hybrid spaces, digiplace, digital archive, artificial natures, cultural trauma, biochauvinism, totalitarianism, landscape design

Introduction

Since 2011, we have been intensively developing research on the issues of the environment, technology, and societal relations using transdisciplinary teamwork methods and the involvement of various experimental cognitive perspectives – including art-based research and art & science practices. All our activities and projects also involve various forms of design, which are often also perceived from the perspective of critical or speculative design, as well as various ways of using media and technologies – often in an "incorrect" way or in a way inconsistent with their primary purpose.

Based on our practical and scientific experience, we have developed a proprietary methodology for this type of research – spectrocartography. The following article is a short presentation of the application of this method to research conducted in a specific place, which, however, we view as typical and perhaps even representative of many other problematic places on different continents. The genesis and history of this place combine the issues of violence, slavery, exploitation, landscape transformations, controlling biodiversity, designing a place of relaxation for a specific society, as well as recreation policy and ideology. These types of places – as we have studied – are also special lenses in which the interconnection of human history, geological transformations, systemic violence, environmental damage and ecological catastrophe are revealed. The analysis of the functioning of such places reveals the correctness of the ideological influence of the past on the future, unconscious hierarchization and species stigmatization, as well as the existence of dangerous ideologies in landscape projects. The site of our research is Lake Rusałka (called Elsensee during the Nazi occupation of Poland), and the aim of the whole project is to create a digital and hybrid platform – a living archive open to various human and nonhuman forms of storytelling and experiencing this place.

Elsensee

Lake Elsensee is one of the many examples of Nazi Germany's geopolitical modernization project. It was dug out by Jewish prisoners of war. When the work began in the spring of 1941, the Jewish population of Poznań was too small for the task, hence Jews were deported from ghettos from other Polish towns and also from abroad: from Austria, Czechoslovakia, Luxembourg and Germany. In total, approximately 11,000 people, men and women, were resettled to Poznań in this way. They were imprisoned in 29 forced labour camps located within the boundaries of Poznań at that time. Standing waist-deep in the water, Jews had to dig out a basin of the lake. Matzevot (Jewish tombstones) from the

city cemeteries liquidated by Nazis were used to strengthen the bottom and shores of the lake, and other surrounding structures. The conditions prevailing at the sites of slave labour were horrific. Executions were the order of the day. The terrible hygienic conditions, diseases (especially typhus), and the exhausting work, combined with hunger, meant that death was ever present. The forced labour camps in Poznań were liquidated between August and October 1943. Prisoners who survived the horrors of the camps and the slave labour were transported to the Auschwitz-Birkenau concentration camp. [1]

Figure 1: Elsensee, postcard, 1945, Adam Mickiewicz University Library in Poznań.

Designed Nature

The geopolitical and racist expansion of the eastern territories was developed and described by the Nazis in their ‘Generalplan Ost’, which aimed to bring humans, nature, and race into harmony in order to establish a new agrarian way of life for Aryan colonists. In order to achieve this vision, the landscape had to be made anew, first by forcibly removing the Slavic population, by bulldozing away the past, and finally by moving Germans into the newly emptied space. [2]

One of the many examples of this policy was the Lake Elsensee project. It should be emphasized that in the Nazi plans Poznań (Posen) was located in the centre of the so-called Wartheland, an area which was to be an integral part of the Third Reich, inhabited exclusively by Germans. In the Nazi expansion project, Wartheland was to have been a paradise for racist landscape planners, who would have been able to easily implement and experiment with new forms of shaping urban, rural and cultivated areas, based on the ideologies of the German Völk. Elsensee was to have served as a space for implementing the model of the ideal Aryan citizen. The cult of a healthy lifestyle, involving contact with an ideologized and designed nature, was to have contributed to the rapid development of a strong and expansive society. In this regard, planning included not only urban relations between green and built-up areas, but also the ways that citizens were supposed to behave in these new spaces. Nature is in no way free in such a conception: the designed green areas and suburban forests are in effect the same as the gardens of the time, which gave priority to selected biological species over others. [3] The core of these projects was

Figure 2: Lake Rusałka, Google Maps, the description of the lake on Google Maps: “Man-made lake formed in 1943, offering hiking & biking paths, picnic spots & boat rentals.”

ocularcentricism, and the design ideas were subordinated to shaping an attractive landscape.

Transformation Times

In 1943 Lake Elsensee was completed, and in the post-war years all its functions were preserved. In 1974 it was named Rusalka, and from the perspective of Slavic mythology the name ‘Rusalka’ is somewhat peculiar, when the origins of the lake are borne in mind, since a ‘rusalka’ is a nymph who tempts and kills newcomers. This too seems very odd considering that three memorial sites were located by the lake. These sites commemorate the over 2000 people who were shot by the Nazis in 1940 in the area – they were mainly Poles from the first concentration camp in the occupied areas, which was located within 2 kilometres of the future lake.

In the first decades after WWII, the recreational development project for Lake Rusalka was expanded, beaches and sports centre buildings were completed. The 1960s-1980s was a period in which this place was extraordinarily popular. Later, due to a lack of investment, the recreational infrastructure went into decline, and the lake lost its popularity with the inhabitants of Poznań. This state of affairs was particularly pronounced in the 1990s, after the political transformation. In the last 10 years, however, the lake area has been intensively developed, and not only have its recreational functions been restored, but the sports infrastructure has been expanded, and an ecological education programme has been developed.

The trauma and difficult histories hidden in this environment were basically forgotten, though they are sometimes revealed when low water levels in the lake reveal the sunken matzevot. Each reminder and commemoration are associated with reluctance, arousing fear in current users that history may take over this place, which now serves as recreational centre for so many city residents.

Such environments constitute ready-made stories which entangle history and present times, so in the research process it is necessary to focus on finding media that allow the environment to have agency; to design possible forms of generating verbal and – above all – non-verbal spectral storytelling.

Ocularcentric Design vs Urban Noise

The whole Elsensee project (and the later Rusalka continuation) was subordinated to ocularcentric culture, and focused on movement along the perimeter of the water reservoir, but the situation changes considerably if we make hearing the primary cognitive sense. A soundwalk around the perimeter of the lake is generally an unpleasant and irritating experience. Sound artefacts of urban-centred origin dislocate the listener in space, since we are not able to precisely define the source of sound or its propagation in space. The acoustic map of the city of Poznań defines noise levels for

the area of the lake and direct green areas in a general way – without indicating recommendations for this area – due to the fact that it is not subject to acoustic protection by law, and detailed research has only been carried out on a narrow area designated for service and possibly residential activity near the lake. [4] If we were to identify the sources of noise for the lake area, we would first of all have to distinguish traffic noise – railway lines and roads. Interference which exceeds norms is also caused by airplanes on their descents, as they approach the airport landing located about 2 kilometres from the western shore of Lake Rusalka. In addition, the lake is located in a depression, which makes the sounds from very busy roads and railway lines resonate with the water and reflect from the surface. From the perspective of a person visiting the lake – depending on the time of day and year – there is a great deal of anthropogenic sound, the sources of which are service and recreational facilities, as well as the activities of people themselves – cycling, running, sunbathing.

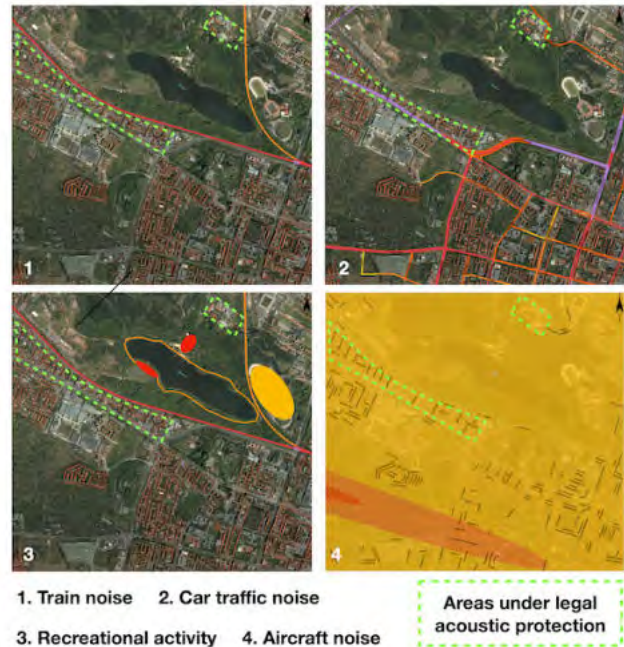

Figure 3: Noise maps of the lake based on Acoustic maps of the city of Poznań 2007-2017.

Mute Actors

The cultural and political perception of plants is that they are mute actors of landscape scenography. This is despite the fact that research conducted by biologists in the field of bioacoustics shows that biocommunication and acoustic activity is one of the basic characteristics of plant behaviours. [5] [6] In the development policy of the Poznań agglomeration, afforestation is treated as a natural acoustic barrier. This theme is also present in the city document examining the impact of spatial development on the environment and

the surrounding area of the lake from 2010 – while plants are mentioned as a positive aspect that reduces noise in the space of the Rusalka Lake, no consideration is given to the problem of protecting plants and animals from anthropogenic noise. [7] However, research on the Rusalka ecosystem from 2016 states that 61 percent of the plant cover is urbanophobic, meaning the plants have problems with adapting to the conditions of anthropopressure. [8]

Visitors to Lake Rusalka are encouraged to “commune with nature”, including engaging in waterfowl observation, which requires silence, but it is difficult to resist the impression that the species gathered in this area are rather subject to concentration, selection, pressure and violence resulting from cultural and acoustic policies.

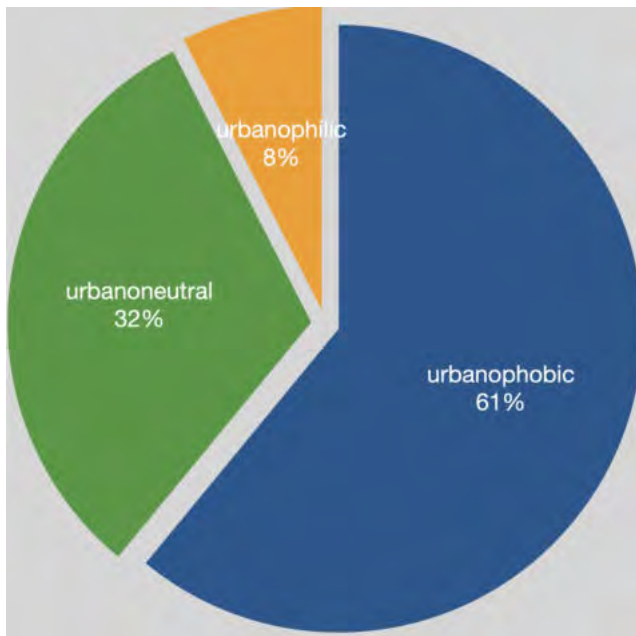

Figure 4: Diagram of plant cover of the areas around the lake according to anthropopressure factors, based on data from: Dyderski, M., Gdula, A. K., Wrońska-Pilarek, D., “Present plant cover of the areas around the Rusalka Lake in Poznan in conditions of human impact”.

Spectrocartography

An important starting point for our research practice is thinking about environments in terms of digital-physical spaces, hybrid spaces, code/space, [9] and the measuring apparatus itself, which is treated as a tool that provides data for analysis, as well as a tool whose cultural functioning should always be subject to critical reflection. The data used for the analysis is always situated. During our work, we use a methodology we called ‘spectrocartography’. Using digital tools and sensors, we are trying to blur oppositions and give voice to different participants of the environments, meaning we

attempt to place nonhuman actants at the centre of the spectral story, not at the borderlines or edges.

The spectrocartographic method is a process of continually and consciously situating both raw and analyzed data in revealed and undisclosed relationships to each other, in a specific geographical and digital reference. We describe the method of obtaining data as sampling. All the obtained samples are then used for spectral analysis. Finally, a spectrocartographic description is created on the basis of sample analysis. Thus, spectrocartography is open, and even calls for further counter-analysis. Spectrocartographic description may also take the form of open diagrams, charts revealing the relationship between the spectres themselves. This method is thus not always geared to obtaining an unambiguous answer, but rather to revealing the interference of spectres from different sources and indicating their possible socio-cultural consequences. Spectrocartographic practices can be used both to produce academic texts and create artefacts at the interface of art&science.

In the case of the Elsensee-Rusalka environment, when creating spectral analysis and spectrograms we took into account:

- the modernist nature landscape design (with the specific Nazi approach to the concept of artificial natures)
- the Nazi concept of ecology
- necropolitics as spectrapolitics
- memory and environmental harm
- urban design and the use of artificial natures in the city centre
- the neo-liberal politics of place as subordinate to recreation and pseudo-ecology

In the sampling process conducted during workshops between 2017 and 2019, while working with our spectrocartographic method, we also introduced data from non-human actants.

For experimental analyses we used, for example:

- official acoustic maps of the city of Poznań which document the sources and paths of noise propagation in the immediate vicinity of Rusalka
- measurement data on pollutants (water, air, soil)
- biological and ecological data (species, living conditions, types of anthropopressure)
- anthropological data (observation of the behavior of human users of the area, interviews, surveys)

We also supplemented the maps with methods of analyzing affective experience – workshop participants filled in questionnaires which assessed their affective state at particular points in space; by marking places of special importance and those associated with certain problems. Additionally, analysis of information on the Rusalka area appearing on social media and in archival materials concerning the creation and development of the lake area from the moment

of its creation, through the post-war years, until today were present throughout the entire process of research.

We compared official acoustic maps with the methods and measuring apparatus used in soundwalks and field recordings; and we also used sound interfaces to listen to the electromagnetic landscape. Field recordings were made with the use of various techniques: from directional recordings to ambisonic recordings.

In the context of biological data, we prepared the speculative taxonomies of beings emerging in space as a critique of the traditional cultural-biological order based on the taxonomy of species/beings; referring to the text of the molecular biologist Andreas Hejnl (Ladders, Trees, Complexity, and Other Metaphors in Evolutionary Thinking). [10]

All these methods of data collecting, and then critically approaching them, open the possibility for infra-active interferences between measurements, apparatuses, data and affects, stories, human and nonhuman actors. [11]

A digital environment for human and nonhuman interaction

In the absence of useful tools capable of presenting the complex structures of our research, we decided to search for new procedures that could create a digital environment: a system of social interaction based on spectrocartographic research and storytelling. (This part of the project is still in the preparation and development phase.)

The digital environment (digiplace) [12] of Elsensee-Rusalka will consist of archives on the creation and post-war history of the lake, its management methods, transformations, etc.; current scientific data on water and air quality, meteorological data, pollution (environmental quality monitoring), and current noise level; and the system will also include data from the natural sciences on species found in the vicinity of the lake.

Access to the Rusalka archive will be possible from two levels:

- 1) Remote access from a computer – i.e. via a web browser – will enable navigation of all the collected materials and data, as a browsable catalogue;
- 2) Direct access from a mobile device – the user will have to be in a certain physical space: the surroundings, using geolocation.

In the direct access mode, the user will have access to many experimental forms of narration and interaction mechanisms. Use will be made of geolocation techniques, augmented reality, and haptic interfaces; part of the narration will be created by artificial intelligence mechanisms. The whole system will not only be a platform for interaction with the complicated and complex history of space and its transformations, as told from the perspective of human and non-human subjects, but it will also serve as a tool for public consultation.

Multi-media, multi-structure, indeterminate storytelling is a socially engaging mechanism; recipients can independently find themselves in multi-layered structures, and independently establish relationships with various subjects of the story. Such methods of using technology, mediatization, and interaction should have an experimental component, and each environmental problem requires separate strategies – “critical design-within-environment”.

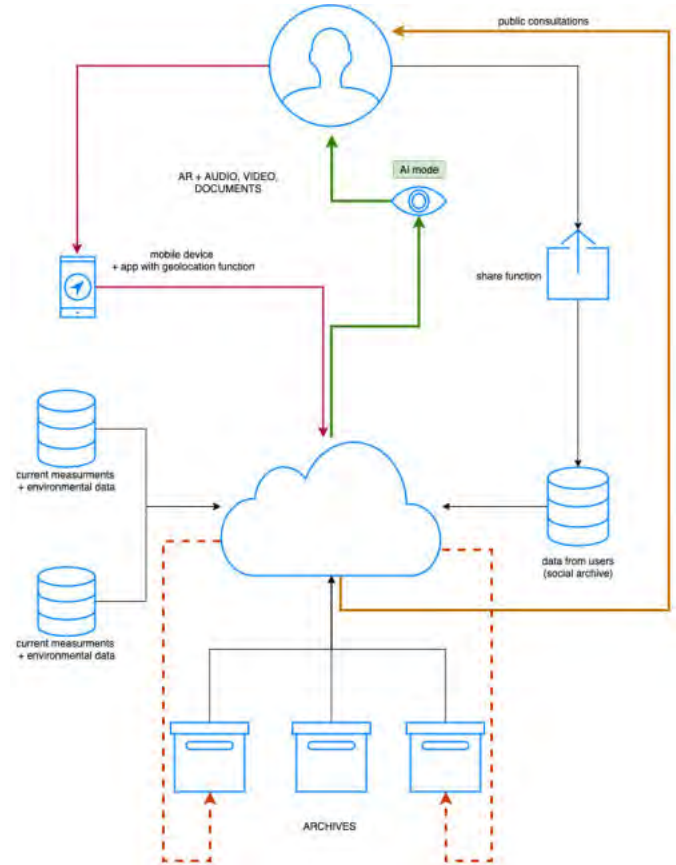

Figure 5: Diagram of the digital environment (digiplace) of Elsensee-Rusalka.

Rebalancing media in environments: analysing flows of action

Rocio von Jungendorf

r.von-jungendorf@kent.ac.uk

Abstract

An exploration into how portable projections can serve to counterbalance the bias towards screen-based media experiences and how these projection devices can contribute to a more texture-based understanding of the relationships between environments and their constitutive actants. The constantly changing relationships between media and things enable the construction of a sense of place which moves and flows. To undertake this exploration, I use a three-fold method to analyse site-specific video walks (*The Surface Inside*, *I-Walk*, and *(wh)ere land*), draw on nascent thoughts derived from a series of workshops about flows, environments materials, and resonance, and engage with critical discussions about space, assemblages and materiality.

Keywords (10 max)

Flows, projections, assemblages, actors, *meshworks*, vessels, post-humanism, new materialism

Introduction

The question of balancing media in environments is strongly tied to the widespread use of screen-based portable devices and mobile technologies which due to their ubiquity have greatly contributed to the connectivity of activities across the globe, but have nonetheless endorsed the isolation of human actants from their immediate surroundings. This isolation is by no means compulsory, but is often chosen and has been associated with a *blasé attitude* that filters information [23], and has been described as having a *cocoon* effect [12].

Screen-based engagement with technology and media content presents a skewed perspective of the intricate relationships between things in the world, pushing aside a relational understanding of environments and the things that compose them. Relationships with environments have become increasingly more abstract and idealized (criticised by Doreen Massey and Tim Ingold among others), and have become more detached especially when considering geographic information system (GIS) technologies and corporate interests [6] which claim to accurately measure the world, but fail to embrace the changing composition of the things that make the world they represent.

Furthermore, 3D technologies also lean towards a fake sense of tangibility as in the case of VR where virtual body parts are visible and controlled (gloves), physical environments are recreated and new environments invented: often idealized or dystopic. These digital and screen-based technologies enable us to find things, places, and each other but also distance us from tangible surroundings and the interconnected material things inhabiting tangible environments.

The technologies that claimed to have found us (as for instance GPS tracking devices) have simultaneously displaced us, as if a claw machine had picked us up, scaled us down and placed us on the screen. Locative devices help us find our way in the world by replacing the physical position of the tracking device with a dot on a screen surface

that is built into the device itself. Curiously, it is as if *place*, which I assign to things which move in environments, had been abstracted, translated into a representation and assigned a set of coordinates in a virtual sphere. When asking ‘where am I?’ [20], an immediate answer could be ‘here, where else could I be?’ while if asking ‘where am I in relation to *x*?’ then the answer could be associated with both virtual and tangible environments: where am I on the screen or in my immediate surroundings, or both?

Constant focus on screen-based portable devices may cause a continuous displacement of things in virtual and tangible environments, triggering an imbalance, as the relationships between humans and non-humans are practised in unstable, hybrid, shifting environments, often tilting slightly towards the virtual. The intangibility of virtual environments does not prevent us from relating to them: in fictional book stories we follow the actions of the characters and things in immaterial worlds. Hybridity is here to stay and plays an active role in the making of our textural and imaginary environments, but would it be feasible to propose hybrid environments which are more balanced, and where tangible things and their material characteristics are given a more prominent place, turning towards the textural qualities of *meshworks* [9] and the *vitality of materials* [1]?

In order to achieve this balance, we may need to bring media content away from screens and into environments and tangible things. This has been in HCI agendas for decades, moving away from graphic interfaces and towards *tangible bits* [13] and regarding materials as interfaces: zones of interaction. Ishi’s *tangible bits* approach has been at the heart of many research projects (too many to list here) but in the meantime *cocooning* devices have gained terrain (e.g. VR and AR headsets, mobiles, tablets).

The key to the balance may be linked with how technology is embedded in everyday life and the time spent attending to these devices but it is more strongly linked with the material ecologies we collectively build around them. If the connectivity and communication that these technologies afford were no longer inside the device, but embedded outside in tangible environments (Figure 1) we may be able to rebalance our connections with the things, especially with the material things around us [1].

Figure 2. From video walk (guided): *The Surface Inside*. Projection on bench surface. Image: Kao.

Verticality is unbalanced

Verticality is a way of hierarchizing things. If we were to observe a vertically structured environment we would easily identify the prominence and power of some things (actants) over others. For instance, in a representation of a geography (e.g. map) some features would have been flattened out in order to highlight others, causing a reductionist line of action which clashes with Bruno Latour's *irreductionist* worldview where *everything* is inter-connected and irreducible to other things unless a serious translation is applied [8]. Needless to say, in such a hierarchically structured environment imbalance is inevitable. The stronger and more powerful components will dominate, while weaker ones fade away without being heard or seen.

On the other hand, in any horizontally arranged environments where attention is given to each element, things are not reduced or faded out, instead the relationships between them are juxtaposed rather than hierarchized. For instance, in the Internet of Things (IoT) where each thing is considered to be instrumental to the network of relations, the hierarchical model of verticality is clearly inefficient and unhelpful, some devices might be more involved in the distribution of information and others in the actioning of the information, yet they are all interdependent. When we talk about things (sometimes not even the tangible ones) without hierarchizing them, we come closer to a horizontal set of relations, where elements are interconnected and things play on more evened grounds [1].

From an IoT perspective, but also from a material connectivity perspective where agency is placed on matter and things, verticality ought to be replaced by this idea of interconnected horizontality which aligns with a post-humanist view of the world [3]: a world in which non-human (sometimes technical, others material or immaterial) and human *things* are on a level playing field; where actants are not stripped of their *potentialities* and capacity to associate in a fluid mesh of relations: *assemblages* [5]. This notion of horizontal levelling up is neither fully achievable nor desirable because environments are multi-dimensional not bi-dimensional. They contain porous and flexible layers of associated ecologies (different forms of habitation or dwelling), so as long as we conceive these environments as

complex layered ecosophical entities (Guattari's *Three Ecologies* [3, 1], based on Bateson's 1972 *Steps to an Ecology of Mind*) or evolving relational meshes where things are housed under common fluid umbrellas, it is impossible to flatten these ecologies or layers out. Figure 2 illustrates that the relationships between things are not flat but spatio-temporal. They change as the video footage plays on the device, the person holding the projector moves or the raindrops on the wooden surface merge, reflect light or slide. Things are housed under different umbrellas and are often associated and can move between them, because their relations are fluid (Deleuze and Guattari's *de-territorialisation*, [5]) and these relations can be explored transversally [1, 3].

Using the video walks, I examine how participating actants (e.g. paths, projectors, people, surfaces, cobbles, trees, benches) collectively construct and are temporarily caught under different umbrellas (assemblages) which are part of an overarching heterogeneous multiplicity of changing assemblages. The study entails looking at their somewhat horizontal relational actions from a three-fold method [14, 15] of analysis: i) a micro, close-up, inside-the-path perspective using Ingold's SPIDER-theory; ii) a macro, detached, map-like point of view using Latour's actor-network-theory (ANT) of isolated instances; and iii) a fluid, evolving, constant heterogeneous assemblage of assemblages using Manuel DeLanda's theory.

Production of environments

Before analysing the video walks and looking at paths, instances, and assemblages of actants, it seems necessary to briefly outline what I mean by the term environment. I part from Ingold's concept of *meshworks* [9] in which environments are textural – Lefebvre's textural spaces [10] – and produced in the action of being, perceiving and participating in a world that is made of an entanglement of paths. Ingold builds upon Jakob von Üxküll who considers environments to be produced by organisms and to be as diverse as the organism themselves [25]: a frog's environment differs from that of a fly, however their environments overlap and are shared to some extent. In addition, environments can also be described as interconnected textures and actants forming what DeLanda,

elaborating on Deleuze and Guattari, refers to as fluid permeable assemblages that are transformed through actions. In my view, environments (*meshworks*) are evolving assemblages of actions but sometimes it is useful to look at them from a static and detached point of observation. If environments are analysed from a frozen point of view, as if they were an instance or a video frame, they can also be described as networks or as Latour prefers to describe them as *worknets* [18]. Although their philosophies are significantly different, there is the unifying concept that traverses Ingold, Latour and DeLanda: co-creation. Things (non-human and human) and the worlds around them affect each other, are collectively, actively produced, not given.

While Massey and Henri Lefebvre posit, using the term *space*, that environments are socially constructed and co-produced [20, 19], from a contemporary stance this co-production is often inverted when undertaken without sensibility towards the other things that constitute the overlapping and co-existing environments outlined by Üxküll. If co-production is inverted co-destruction can be unleashed, going against all those ecological issues we are striving to act upon using our design, creative and scientific know-hows. In this regard, Jane Bennett calls for a renewed appreciation of the vibrant qualities of materials and things (here in relation to environments), and for a revaluation of the actions and relations that things (actants) push onto each other [1]: what does a plastic bag in an urban or non-urban environment activate in us? However, my question is: What does a portable projection activate in us and other things in the environment? Can the relationships between things be strengthened through the projection of moving images of those same things onto the environment?

Figure 3. Video walk (guided): *I-Walk*. Left: projection on paper house. Right: projection on wall. Image: Michelle Aldredge.

I propose that projecting the textures of things and their relationships can positively alter the connections between the things that compose the fluid ever-evolving textural assemblages I call environments (Figure 3). We can never be sure what the things that compose the multitude of environment are, but we can learn about them while establishing connections and recognizing their vitality and their capacity for action and the actions they activate within us. The connection between things is inevitably a translation, an exercise of reckoning and interpreting as Latour proposes in his 1988 appendix *Irreductions* [16, 8]. Each thing assigns a plausible story to another, a story that is not fixed, but is constantly escaping being pinpointed. Surely this way of conceiving the irreducibility of things is useful, but how do non-organismic things in our environments relate to other things [8]? How can they interpret the actions of other things in their environments? In IoT terms this is not an issue since things are technologically sentient, but without the electronic and algorithmic capacity for sensing their relations, how can a wall or plastic bag relate and invent stories about other things around them? If they cannot, then maybe we can tell stories on their behalf, and in doing so build our sensibilities towards these things and their shared ecologies.

Latour's *Irreductions* can only take us so far. Eventually we stumble upon the metaphysical problem of being in flow and in relation to others. Unlike Ingold, DeLanda and others such as Bennett, Lefebvre, and Massey, Latour's original *worknets* are instances and not continuous flows of actions (although this approach changes in Latour's later work). To discuss place, I need to step out of Latour's irreducible networks of actions, and move into an evolving meshwork of flowing actions. At the centre of this meshwork is place: the place that things create and which moves with them as they flow. The notion of place is the last thing I want to unpack before we move on to examine the video walks using the three-fold method of analysis proposed earlier.

Surely, we do not want to reduce anything to anything else [8], but sometimes reducing everything to one single concept can prove useful, as in the action of reducing every 'thing' to the concept of *thing* (pun intended). In this reduction, the agency of things is contained within the things themselves and in their relations of *exteriority* [5]. Building on the work of Tim Cresswell who borrows the idea from Susanne Langer [21], and on Gertrude Stein's notion of geography [24, 4] I propose reducing each thing to the concept of a vessel which contains agency and *potentiality* (dormant actions) [5], and enables navigation and the establishment of relationships with other vessels in the environment. In this analogy of things as vessels, the notion of place lays within the vessel, just as the place of the seafarer is attached to the boat independently of where the vessel happens to be in relation to the shore, sea or horizon.

However, when screen-based portable devices are part of the meshwork of connected vessels, then navigation and place become hybridized: you are both sitting on that bench and inside the screen. Whereas with projections, the place you would occupy in the screen is brought into a textural tangible environment where it has a place that flows and that enables it to resonate with other things, extending its actions into and co-creating the meshwork.

The overarching co-created meshwork is evolving, and made of a multiplicity of individual but interconnected paths. It is a "continuous yet heterogeneous" assemblage [8] of flowing places, of things moving along paths and between assemblages. It is a delicate balancing act: a continuous process of *territorialisation* and *de-territorialisation* [5]. In hybrid textural environments such as those produced by video walks where material and immaterial things coalesce, their actions bring about flows that are "an indivisible continuum of becomings" and their actions are also "that very flow" [1]. Things and actions are intertwined in a continuum which seems to resonate with the notion of vessel: place is attached to the vessel as it moves in the environment in a process of continuous entanglement. To understand the connections between actants, things have to be in a place that is contingent and which changes in relation to the actions of other actants, like an improvised dance where things respond to and resonate with one another.

Site-specific projections

This improvised dance of vessels (things in action) can be found in many scenarios. Here I analyse three video walks where site-specific projections were performed. Portable projectors served to highlight the invisible forces and flows that shape the textures of environments.

These are the three video walks:

- *The Surface Inside* (guided): one projector and multiple headphones,
- *I-Walk* (guided): one projector and origami houses,
- *(where) land* (collectively led): seven projectors.

The video walks had many common features, but one of the aspects that differentiated them and substantially shaped the assemblages of actants as they moved along the meshwork of paths was the possibility of having more than one projector, since this enabled people to handhold and play with the projectors for themselves rather than through a guided experience.

While walking with site-specific projections, intricate assemblages of actants were created: projectors, legs, gloves, pockets, bags, trees, jackets, tarmac, stones, benches, shoes, walls. The list could continue but listing all the actants would be an impossible task, the infinite regression problem that Jorge Luis Borges identifies in his *Library of Babel* [2] and that Graham Harman identifies in Latour's theory [18, 8]. For that reason and for the sake of brevity, I only focus on a handful of actants and analyse them in relation to paths, instances and porous flows.

When the video walks were performed a multiplicity of flowing assemblages were produced too. Just as with the actants, it is not feasible to outline all the existing and potential assemblages, and thus only a few superimposed assemblages will be mentioned. But what I want to stress here is how actants collectively created a hybrid ecology of assemblages that were constantly negotiated as things moved and created the textures of their environments.

Using a three-fold method of analysis has some limitations (a. Each method is best suited to accomplish a specific exploration: following along evolving paths, stepping back to observe from the distance, or moving between different assemblages. The three methods focus on looking at the flows of actions. Even when using Latour's detached instance approach we look at instances of flows. Staying still is not an option, because environments and their actants are constantly reshuffling their relations of exteriority, but in a paper-based analysis like this, pausing the video documentation and using still images becomes necessary.

Going with the flow: paths

Figure 4 shows a sequence of still images from the video documentation. To analyse these images, we need to immerse ourselves in Ingold's meshwork, bringing the viewer into the path that the actants created and shared as they moved along. In this sequence, we can identify some actants: a camera, a projection and a person (or persons).

They, and others, shared the path and produced the hybrid textural environment we can see in the images. To get a better insight into the paths of a meshwork, we are required to adopt Ingold's SPIDER approach [10]. Imagine you are moving within the meshwork, producing a web of connections, perceptions and actions, experiencing and creating the environment as it develops from and around you.

Using this approach, we can better understand the flows of relationships between the things that (on a level playing field) make the environment and how these connections are spun, and actively produced. Video material, at 24 frames per second, would be better suited to show and analyse the flows of actions that connect the things in the SPIDER's path, but a sequence of frames can suffice.

In the sequence, we can identify hybrid digito-tangible textures on the pavement and some of the actants that created these textures as they move along a path. There is a mixed flow of human, material and immaterial things: cobbles, footsteps, portable projector, video camera, moving images, air, parked cars. In this meshwork, the vibrant materialism that Bennett claims needs to be revived is present: the projector activates the projections, the projection activates the cobbles, the cobbles activate the projection, the person holding the projector directs the

projection, the moving images of the projection activate the textures of things in the environment.

All these things (and those that have been omitted) collectively compose the continuous flows that make the texture of the environment, where things are entangled instead of separated from one another. Their associations are horizontal, they need one another and their flows are interdependent. Human actants are not above the meshwork but inside it (post-humanist approach), and are just another part of it, a constituting part of a larger whole. In this way, things can look at each other in the eyes, as when dog owners kneel-down to converse with their animals.

Figure 4. Video walk (guided): *The Surface Inside*. Image: Kao.

Each thing is immersed in their own path: inside a thread of a bigger mesh that they produce together, not in isolation. The actant 'projection' (as part of its path inside the mesh) pushes the action out of the screen, breaking down the screen-based *cocoon* effect and placing the binary video information onto the tangible surfaces of the cobblestones. Although immersed, in this sequence we cannot look around as if we were experiencing a 360° video, but we are aware that the things and textures that participated in these shared environments would have wrapped around all actants, not only in spatial terms but also in duration.

Snapshotting the flow: instances

When taking a snapshot of the flow of actions in any meshwork we stop the actants and their temporal and spatial relations. The fluid mesh of relationships between things and environments freezes, and we are no longer inside a path, but outside. If we turn back to the notion of things as vessels where place resides, the snapshot turns the evolving flow that the video walks are part of into a set of coordinates which defines an instance of this flow, fixing the position of the vessels in a given time and assigning them a place (a pin) in a pincushion [20].

Any event (in this case a video walk) analysed using this approach does not have duration. On the contrary, it is a single frozen instance which, although connected to its contiguous instances, is analysed independently from them, or from the path which they are part of unless a comparison between instances is intended or needed.

With this approach, every *thing* is an event in itself. This is crucial to Latour's discourse of irreducible actors, and is suited for analysing still images or individual frames containing details about actants in their *worknet*. As Harman puts it: "Latour's actors have no choice but to occupy punctiform cinematic frames" [8], and an example of *punctiform cinematic frames* can be seen in Figure 5 where two video frames show the actants and relations in two instances of the same video walk.

In the top image, we can see the actants that have left a trace (no matter how weak) [18]. On the left: two people, a projection, the ground, a hand holding a projector, feet almost stepping onto the projected surface. On the right: projections and people in the distance. The stronger actants are on the left, the weaker ones in the top right corner of the image where they can still be seen, but just barely.

Actants are not different from their relations. In fact, they are their relations, becoming what their connections to other actants give them in exchange for action. For instance, the projector gives the person the possibility of projecting, the projection gives the other person the possibility of looking at and stepping onto the image. Whatever the actions of actants are they have an effect on others, they have the capacity of modifying and being modified by others [1, 17].

Figure 5. Video walk (collectively led): (*wh*)ere land. Top: two groups and projections. Bottom: actants in action. Image: Kao.

In the bottom image (Figure 5), we can analyse this notion of ‘modifying and being modified by’ and how this agentic capacity of producing change enables the co-creation of environments even when these environments – which are actually fluid – have been frozen inside the frame. The image contains three human actants whose actions are connected to a projector, the fabric of a bag, and some distant projections. Each of the elements featured in the frame is unique and irreducible to any other, but when defining them as actants we mediate their differences so we can investigate their alliances [8]. The projection modifies the bag, the bag modifies the projected image, the person holding the bag modifies the bag, the person holding the projector modifies the projector, the actions of the third person modify the actions of the other two, and so on. They are all part of an assemblage of actants which is contingent, and although we can only see an instance it is clear that their alliances and trajectories in the environment are just about to change. Thus, in order to look at these changes we need to move away from Latour’s cinematic instances and move back into flows and trajectories.

Assembles of actions: porous flows

In order to investigate the video walks as “continuous yet heterogeneous” assemblages, the previous methods have enabled us to study them from within (SPIDER) and from outside (ANT). Assemblages can be studied as *worknets*; as collections of events, but they are more closely related to

meshworks (collections of paths of becoming), which Bennett calls trajectories (and Ingold calls lines).

Although both meshworks and *worknets* are concerned with actions, in assemblage theory instances cannot be considered in isolation because there is no escape from flows of actions. More importantly, we have to deal with the potentialities of our actants and their capacity to participate in different assemblages simultaneously or to change between them at any time. Actants are their relations, but they are more than that because they can exercise their potentialities and create new relations of exteriority at any point, and by doing so create and become part of new assemblages.

For instance in Figure 6, we can see a series of stills which show a different set of relations than those shown in Figure 5. The images feature the ground and the projections, occasionally the portable projector or the hands of people operating the devices. Just because we cannot see a particular actant all the time we cannot ignore them as when dealing with instances, where if they do not leave a trace (action or activation) they are no actants.

Before the video walk started, a projector was given to groups of 3-5 members and these groups started to walk at intervals. Being aware of this, gives us a different insight into the assemblages shown in these images. For instance, in order for the super-imposition of projections to happen, a series of changes along the path had to take place: different actants had to activate the potentialities in others, so as to resonate with them; groups had to come physically closer, acting and modifying their collective actions.

The superimposition of the projections was possible because of the distributed agency of actants, and their ability to collectively practice their *becomings* while experiencing and participating in the textures of multi-dimensional fluid assemblages. Projections, people, floor and other actants functioned as flowing matter [10, 11].

Every group in the video walk participated in an overarching assemblage; each group was an assemblage in itself too, and each person was another assemblage made of bones, hair, clothes, gadgets, biota, and other things. Different aspects in the actants needed to be activated so they could participate of different assemblages.

The capacity of being part of several assemblages simultaneously is possible because the boundaries defining the assemblages are permeable, porous [1]. And depending on which characteristics are activated in the actants, different assemblages will emerge, some may dissolve while new territories may open up [5].

Figure 6. Video walk (collectively led): (*wh*)ere land. Series of images featuring combined projections. Image: Kao.

Striving to rebalance

It seems that the balancing of the relationships between technology, environments and people is dependent on our ability to apply post-human and vibrant materiality discourses, object-oriented philosophies, assemblage theories and meshwork approaches to our everyday lives and our creative and technical endeavours.

An avenue that has not been explored in this paper, but which has great potential for contributing to the building of a collective ecological sensibility towards things in our environments is Hartmut Rosa's notion of *Resonanz* [22]. He proposes slowing down and bringing actions, things and materials together, leaving aside desires for instant gratification and making an effort to finding time to explore the relationships between things around us in depth, and in particular their resonance.

As discussed in this paper, each thing is irreducible and has a unique set of relations and potentialities which need to be activated and enacted. Things *are* in relation to one another and do not have a fixed place in the world because they are like vessels constantly negotiating their relations of exteriority while participating in complex yet delicate assemblages of constant *re-territorialisation* [7].

Not only in everyday life but also in our artistic practices we need to reconsider our associations and relationships with materials, environments and the things within them. Since we *are* in relation and make our environments through action, and things (us included) are made of relations and potentialities, it would be fruitless to distinguish between humans who actively construct environments and other things in those environments (i.e. non-human) because they and we are enmeshed: we are a multiplicity, "*an array of bodies*" [1], some are made of flesh while others are made of materials or are simply immaterial. What is clear is that we, as much as the video walks, are part of fluid evolving assemblages where actants and actions modify each other. Therefore, we need to attempt to discern the resonating qualities of the materials and things that are both external and internal to us so that we can be on a level playing field and exercise our relations of exteriority horizontally with things.

Conclusions

The portable projectors used to co-produce the video walks offer opportunities for things to mingle, relate to and modify each other. Although human actants operate the projecting devices, the assemblages and hybrid digitotangible environments created through these projections are made of fluid and constantly negotiated relationships between material and immaterial things.

The projections bring the content out of the screens of portable devices and the *cocoons* they offer, and embed the content into the changing textural qualities of fluid environments where they can be shared, explored and co-created (Figure 6). The counterargument may be that portable projections somewhat litter the environments in which they are presented. Dark urban parks where other bodies and things go about their everyday existence may be affected by minor and temporary light pollution caused by the projection device.

Projections cannot counteract the primacy of screen-based communication, but can bring people closer to the textuality of their environments, to slow people down and highlight the subtle and changing characteristics of the things and the world around them. Projections can support the creative exploration of horizontal relationships between actants and reconnect actants with the flows of environments as they walk and create their place in them.

The question remains: what is it that artists, researchers, and educators can do to rebalance media in environments. How can we use our expertise to inspire the coming generations to side with materials and things as partners in environments, instead of viewing them as external and disposable? If our practices do not resonate with materials and things we are lost, but if as Massey's sheep we highlight that we are "not lost" and that we know exactly where we are: "right here" [20], then with our presence and the actions we perform in relation to other actants we might be able to move towards a rebalance.

Author Biography

Rocio von Jungenfeld is a German / Spanish creative practitioner and media researcher based at University of Kent (UK), working in embodied perception and how media art and technology alter human-non-human interactions in environments. Her creative practice involves collaborative, interdisciplinary, and participatory media production; hybrid / immersive installations; outdoor-mobile projections; interaction design; and art in public space.

In collaboration with Dave Murray-Rust, she won the British Computer Society A.I. Award (Lumen Prize 2019). She is part of two large research projects: Playing A/Part & SOCORRO. She obtained her PhD and MSc at University of Edinburgh (UK), and her BFA at University of Barcelona (Spain).

She has presented her artistic, collaborative and research work in venues such as ZKM, IBM, Scottish National Gallery, EISF, NTAA, MAN-Singapore, EIF, National Museum of Scotland, Talbot Rice Gallery, Margate Festival, I-Park (US), ACM CHI and C&C, EvoMusArt, Leonardo, ISEA, AMPS, and NECS.

Acknowledgements

A series of workshops about flows, materials and environments organised with Vincent Van Uffelen and David Strang have contributed to the arguments developed in this paper (see Figure 7), and so has the on-going research collaboration with Dave Murray-Rust where we have been grappling with ideas about designing participatory interactive environments and designing for and with the things themselves, rather than simply for people.

Queer Communication: Human-Nonhuman Encounters

Natacha Lamounier

nlamounier@gmail.com

Abstract

In the times of Anthropocene, with global pandemic and climate change, it is necessary to investigate narratives that show respect and accountability for all forms of life. In this scenario, the research for interspecies communication reveals other ways to promote human-nonhuman encounters that overcomes a past of human mastery over nonhumans. This research analyzes how interspecies communication can be conceived beyond language. Moreover, it also analyzes how those communications can be understood as queer. The source of investigation is the series of artworks *Wombs* (2018-2019), by Margherita Pevere. The artist searched for bonds between her body on hormones, from taking birth control pills, and two different species, bacteria (asexual) and slug (hermaphrodite). The queer communication in *Wombs* talks about disrupting the opposition nature/culture and man/woman in interspecies encounters while articulates more equalitarian narratives that are accountable for human actions.

Keywords

Interspecies communication; queer; nonhumans; humans; bio-art; contraceptive pills; sexuality; nature.

Introduction

The format of human bodies, bipods with small teeth and large brains, differentiates biologically *Homo sapiens* from other species. The political differentiation between what is human and what can be considered nonhuman, though, might raise some doubts. The philosopher Isabelle Stengers comments on the problems of defining nonhumans. The particle “non” can give the idea of negation as if nonhumans are the negative of humans. [1] It indicates that nonhumans are all that humans are not. For Stengers, the definition of nonhumans is attached to the definition of humans. Some authors might base on culture, history, arts, and language, to delineate the boundaries of what is human and what is not. [2] What determines humans is the very idea of being able to define ourselves as humans. [1]

However, serious researchers show that being human encompasses, most of the time, the subjugation and exploitation of nonhumans by human mastery. [3] For instance, animals are also largely incorporated in biotechnological research for the development of drugs, cosmetics, agriculture, and biomaterials. In some cases,

nonhuman lives are disregarded in face of human lives. [3] Therefore, the dimension of what is human goes beyond the idea of segregation from the rest and should also represent the consequences humans bring to all forms of life. An encounter between a human and a nonhuman should not be about praising for their differences, but the search for equality.

When it comes to communication, the encounter between humans and nonhumans can also reassure the human mastery over nonhumans. This research aims to investigate new ways to communicate with nonhumans beings besides verbal and written language. From the identification of the parts that compose a communication system, to the analysis of nonhumans beings as capable to communicate, and the identification of differences that unities humans and nonhumans, it is researched interspecies communication that is queer. The study cases are the artworks *Wombs* (2018-19) by the artist Margherita Pevere. The first artwork, named W.01, is a culture of bacteria in a growth medium made with hormones subproducts and residues extracted from the artist’s urine (fig. 1). On the second one, named W.02, the artist cultivated on the same growth medium her vaginal epithelial cells and slug eggs (fig 2). The last artwork, named W.03, is a series of photographs registering a slug sliding through the artist’s skin (fig 3).

These artworks were chosen since the artist promoted encounters between her body, or its subproducts, and nonhuman beings, while she was administrating contraceptive hormones daily. The artist is changing her body from the inside, but the contraceptive pills also introduce in the discussion biological, sexual, social, political, and economic issues. Moreover, the pills are analyzed as a medium source that facilitates interspecies communication in *Wombs*.

Sexual hormones are the bridge to connect the research with queer studies, however, it is also investigated other queer aspects in *Wombs*. The research proposes new connections between different fields such as communication, animals studies, media art, contraceptive hormones, and queer theory. It expands queer beyond sexuality and gender issues by including nonhumans in the discussion. According to Birke, Bryld & Lykke, feminist

studies lack connection with studies of human/animal relationships. [4] Thus, the relevance of the research is based on the construction of new knowledge that emerges from the intersection of feminism, communication, and animal studies. The definition of queer communication and its integration with different academic fields will strengthen the discussion about the multiple possible speeches and acts among humans and nonhumans.

Methodology

The methodology used in the research encompasses discourse analysis combined with semiology. A discourse analysis tries to unveil new relations between objects and subjects. It does not consider preexisting relations and understands that those relations can be built in the discourse. [5] The semiotic analysis, in its turn, evaluates the aspects of an image, in which the meanings of that image are produced. [5] The semiotic analysis, thus, was used to withdraw meanings from the visual aspects of the artworks that would add to the argumentation for new discourses.

The analysis used as a primary source of information the description of the artworks *Wombs* on the artist's website, the presented photos of the artworks, and an interview with the artist. The research, therefore, investigated the artworks W.01, W.02, and W.03 as queer communication. The theories used range from communication, media theory, feminism, and queer studies, to post-humanist animal studies.

The investigation begins with the analysis of the bio-artworks *Wombs* as communication between humans and nonhumans. The communicational aspect of this series of artworks was analyzed from the mathematical theory of communication, media studies, and animal studies. While the mathematical theory offers a direct understanding of communication, the media art theory addresses a bio-art investigation. At the same time, the artworks involve nonhumans animals, and microorganisms, the reason why the communication was also analyzed within the frame of animal studies.

In the analysis, it was researched how the hormones mediate the communication in *Wombs* and how they introduce queer theory. Moreover, it also mapped the queer concept beyond gender and sexuality issues while applying it to the artworks. Therefore, it investigates queer as the main feature of interspecies communication in *Wombs*.

Interspecies Communication

The mathematical theory of communication defines that information must travel from the source to the destination. [6] This theory helps us understand that communication is the transmission of a message from one end to another. ¹ To understand the artworks of *Wombs* as communication, it is necessary to analyze which role can be designated to each part according to the mathematical point of view: source, destination, transmitter, channel, or receiver. Therefore, it can be interpreted that the parts performing communication in *Wombs* are: a woman, the artist, and two different nonhumans, a slug and bacteria. In each artwork, there is an encounter between the artist, or the subproducts of her body, and nonhuman life. The analysis of the parts communicating comes from that encounter.

In artwork W.01, there is no direct encounter between the artist and the bacteria. The visual aspects of that semi/living sculpture also do not reveal the presence of the artist. The encounter between the artist and the bacteria happens inside of the sculpture, once the bacteria live in a growth medium made from the artist's urine. Therefore, in this case, the artist is represented by her urine. The bacteria and the artists are the two endings of the communication in W.01, source, and destination.

On the artwork W.02, as in the case of the artwork W.01, it might not be easy to visually identify the parts communicating. The artwork W.02 also encompasses a semi/living sculpture that is composed of a microscopic encounter between human cells and slug eggs. The artist stated that she intended to create in W.02 a strange womb, made by human cells, for the slug eggs. [7] The artwork W.02, therefore, is an encounter between a human and a slug represented by their cellular material.

In the artwork W.03, by what is depicted in the photographs, it can be assumed that the communication happens between the artist's skin and the slug's skin. It is an encounter between the artist and the slug in their natural body and shape, therefore, they are the source and destination of the communication. However, the interspecies communication in *Wombs* does not account for a transmitter or a receiver. It is proposed as a simplified version of the communication, in which there are just sources, destinations, and the channel, or medium. This is because those artworks are an encounter between human and nonhuman life, and, to assume that some parts code and decode the message would mean that it is known which types of signals they are transmitting. It is not possible to access signals that nonhumans beings transmit, and any trial of that would mean anthropomorphizing more-than-human lives. Moreover, I cannot account for the signs the artist

transmitted. It is considered, then, that between the human and the nonhuman there is only one medium to transmit the message. However, before analyzing the medium, it is necessary to investigate if communication between human and nonhuman life is possible.

Macroscopic Communication

Cary Wolfe studying language, representation, and species, correctly states that, for a long time in human history, philosophers have wrongly connected intelligence as exclusively human. [2] Since the Enlightenment animals are defined as inferior beings to humans based on presumptions such as the lack of a universal system of communication and lack of reason and logic. [3] Most of the human superiority ideology over nonhumans comes from the Cartesian concept that only language is capable to represent mental ideas. [2] However, as Wolfe correctly argues, language cannot exactly mimic our thoughts or express what we are thinking. [2] Meanings of words and sentences can change according to the context of the conversation, the interpretation, and so on.

The analysis of nonhuman beings, such as slugs and bacteria, as intelligent entities that lack language, comes with the disruption of the association of language with a capacity for thinking, which means that they are capable to communicate in other forms besides language.

On the other hand, communication with other species is not about teaching them human language. [8] It is also not about giving them agency to respond to humans nor addressing anthropomorphized features to them. [9] The philosopher MacCormack states that some animals can learn how to enunciate words, and even how to communicate with some meaning, but it is done by mimicking the humans' masters or by choosing words that we can understand and make sense of. [9] Humans often give voices to animals or speak on their behalf. [9] In this sense, they take the agency out of the animal and pretend to be them. [9]

MacCormack is critical of human encounters with nonhumans and advocates that we should step away and let the animals be themselves. [9] However, it is not always possible to avoid human mastery over nature, especially in the analysis of bio-artworks that deal with life. Humans must stay always conscious of the bioethical dimensions when dealing with other forms of life. Therefore, it is important to deconstruct some notions of interspecies communication to avoid speaking on the animals' behalf or reinsuring human mastery over animals due to our social and linguistic abilities. It is necessary to explore more ways to communicate with nonhumans animals than verbal signs. It is necessary to expand how the act of thinking can be imagined, to possibly understand that animals can respond,

¹The mathematical theory considers communication a physical system that produces discrete signals. It is used to analyze written languages, such as English, and electronic transmitters, such as television signals. [6] The artworks of *Wombs*, however,

encompass encounters of organic life, and not electronic components nor written languages. Therefore, the mathematical theory of communication was approached only for the identification of the parts that compose a communication system.

they just have other ways to do so, or, other ways to communicate besides language. [2]

Communication can be understood as a transmission of messages that goes beyond the words of humans. It can be an encounter with others in which humans and nonhumans are closely embedded, showing each other's vulnerability. It is about purposely approximating the human to the nonhuman to unpack their relations and communicate with them equally.

Considering hearing or touching forms of communication can be useful to propose the de-hierarchization of language as a representation of communication. [2] The ability of animals to communicate can be related to their ability to respond to sounds or touch. Intelligence can be correlated with the ability to apprehend with the senses the information on the surroundings. [8] In this way, intelligence to communicate is more than being able to speak words.

Touch, for instance, can be understood as a way for animals to get information from their surroundings because it is an encounter between two different surfaces. [10] Humans' and nonhumans' skin has sensory terminals that allow haptic feelings. Touch is a non-hierarchical way of arguing for interspecies communication because, contrary to language that is understood as exclusively human, touch is the sense located throughout the body of all animals.

The communication in the artwork W.03, thus, happens in the encounter between the artist's skin and the slug's skin. The slug is intelligent enough to communicate by the simple fact that it can slide through the artist's back. The fact that the artist stayed in silence while the slug slid on her back, is an interesting point to understand the lack of words as communication. Nothing was said between her and the slug, nonetheless, they spoke the same language: touch, an encounter without words, and at the same time loaded with meaning.

However, I cannot address any intention in the slug's movement nor state what the slug wanted to say because I speak from the position of a human. At the same time, this is not a biological study to analyze how slugs feel the touch or the difference in surfaces when moving. The analysis of the slug sliding through the artist's back as communication by touch is based on the fact that the slug and the artist are capable of touching each other. It is not possible to state what is being exchanged without anthropomorphizing. However, the silent communication by touch is a homogeneous process that happens in the same way with both artist and the slug. They touch each other, they feel each other in a macroscopic communication.

Microscopic Communication

Donna Haraway investigates the transformative power of touch as capable to provide information in an interspecies encounter. Haraway argues that one cannot know much about a species before an encounter, once both humans and nonhumans are shaped by the encounter. [11] The philosopher states that the nonhumans, and humans as well,

become who they are "in the dance of relating". [11] This dance defines an embodied communication that goes beyond words, "which takes place in entwined, semiotic, over-lapping, somatic patterning over time, not as discrete, denotative signals emitted by individuals". [11] Therefore, the embodied dance made by touch is an interspecies communication, in which signals are transmitted through the flesh.

The philosopher states that touch regards the others inside of us, especially because our DNA contains the same genome found in bacteria, fungi, protists, and animals. [11] According to Haraway, we inherit in our flesh the other whom we touch. [11] This concept is very useful in the analysis of artwork W.02, once it encompasses human cells and slug cells in close contact. From Donna Haraway's approach, the encounters of those different cells communicate on their most intrinsic level: the touch of their materiality. They do not constitute flesh, however, they are in the previous state of the tissue. Like flesh, the tissue has the same basic structures that encompass all living cells. The signals they emit are basic life signals. Their communication, therefore, is on the biochemical level of sharing nutrients. They communicate with each other to survive on the same growth medium.

In the artwork W.01, the artist dealt with bacteria, which are not animals nor tissue. Besides that, there is no direct touch between the artist and the bacteria. Nonetheless, W.01 can be understood as communication from Haraway's concept of embodied dance if we consider not touch, but nutrition as the entwined signals between the bacteria and the artist. That approach is also explored by Haraway, whom unite species "at the table". [12] According to Haraway, those encounters can have different aspects: "... parting bites that might nourish mortal companion species who cannot and must not assimilate one another but who must learn to eat well, or at least well enough that care, respect, and the difference can flourish in the open". [12] In the case of W.01, the encounter between the artist and the bacteria can be understood as the assimilation of the artist's excrements by the bacteria, in which the artist cares for the bacteria to flourish. They embody a dance that starts with the artist taking the pills, the pills being digested, its subproducts excreted, then refined, and serving as "food" to the bacteria.

The encounter of the bacteria with the artist is not at the table, but it is connected with parting bites of the same element: hormones. The bacteria are in a symbiotic relationship with the artist by eating the same molecules that were once ingested by the artist. Her excretions are part of the bacteria formation. By using the artist's excretion to survive, the bacteria are performing a very close embodied dance with the human. The rests of one are the continuum of the other. Their touch is made indirectly, not in the flesh nor the tissues, but among unitary entities. The artworks W.01 and W.02, therefore, represent a microscopic communication.

Hormones as media

The same element that the artist and bacteria share the nutrition, is the medium in which they communicate with each other. In the case of W.01, it is easier to argue that the media in the communication between the artist and the bacteria are the hormones because their subproducts constitute the growth medium. When describing the artwork W.01, the artist states "Its culture medium is infused with hormones metabolites and residues extracted from my urine by re-staging scientific methods". [13]

In the case of the artworks W.02 and W.03, though, it is necessary to deeper into the analysis of a biological medium. The agency of a biological medium is different from the agency of traditional communication media. In life sciences studies, according to Hauser, the medium is understood as "milieu and ambiance". [14] The biological media, therefore, encompasses a biological structure that has a direct impact on life. It can also be defined as "existential media that surround a body or enable its internal functions". [14] The biological medium allows the artist to create semi-living structures in a different milieu as they are seen in nature. [14] Hauser argues that this is exactly the characteristic that artists working with bio-art want to emphasize. [14] In the project *Disembodied Cuisine* (2004), for instance, the artists Oron Catts and Ionat Zurr manipulated the biological medium to grow tissue-engineered steaks from frogs. [15] They worked with the biological medium to create new semi/living structures.

In the case of *Wombs*, the contraceptive hormones control internal processes inside of the artist's body. They trigger biochemical changes inside the cells in the artist's body. The hormones are dissolved in her body, they are part of her body. They are present on her excretions, be it urine or sweat. The focus on the artist's body lies in the fact that she performed with it in artwork W.03 and collected her vaginal cells for artwork W.02 while making daily use of them. Therefore, the hormones can be understood as biological media as defined by Hauser because those substances alter the artist's body and its functions.

However, when the artist takes her daily hormone and creates a series of artworks to interact with nonhumans, she is not only preventing pregnancy or changing her body from the inside but also bringing to the stage sensitive topics related to birth control pills. Contraceptive hormones carry strong messages about sexuality, heterosexual dominance, reproduction, responsibility, power, and justice. [16] The biological and social issues introduced by the hormones are part of the analysis to understand the interspecies communication in *Wombs* as queer.

The hormones as a medium introduce queer aspects to this interspecies communication. Sexual hormones have the potential to disrupt the sexuality in humans and nonhumans' bodies. [16] The toxicity that sexual hormones introduce into the environment is one of the problems of the Anthropocene. As subproducts of pesticides, plastics, or

even due to the large world production of synthetic hormones, they are accumulated on the soil, the water, and on the body of animals and plants we eat. [16] Biochemically speaking, hormones are "endocrine disruptive compounds" (EDCs), or, chemical components capable to induce morphological and sexual changes. [16] An excess of sex hormones can cause cancer, and sexual consequences such as infertility, low sperm count, feminization of boys, and so on. [17] Di Chiro presents study cases in which excess hormones in the environment led to problems in wildlife development and reproduction. [17] Those researches demonstrated that an excess of estrogen can transform some animals into intersex, infertile, or hermaphrodites. Therefore, other sexualities, besides heterosexuals and homosexuals, come into play. These consequences were observed in frogs, fishes, and salamanders. [16] Malin Ah-King and Eva Hayward commented that studies on the effects of birth control pills on sea snails showed that they became intersex, with both male and female sexual organs. [16]

The modified bodies from hormones' disruption can be considered queer bodies because they deviate from what is assumed as normal. The hormones are capable to transform "normal" bodies into queer bodies. [16] According to Di Chiro, queer bodies are considered abnormal bodies. [17] To call a body abnormal is to give voice to heterosexual fears. The fears brought to society concerning hormones are the ones that harm heterosexual values. The sex division between male-female and the transmission of genes to the offspring is considered endangered. The diverse sexual orientations we see flourish nowadays are seen as a threat to heteronormativity.

Therefore, the narrative to call this series a queer communication lies in the fact that hormones can produce bodies that deviated from the norm. Those bodies inspire fear of the heteronormative values concerning sexual disruptions. To name transsexuals or feminized men as a queer product of hormones disruption is to apply a social discourse that categorizes those bodies as abnormal. Therefore, the queer discourse in *Wombs* is also present in the parts that communicate. The bacteria living on a glass full of hormones subproducts, the slug by its hermaphrodite nature, and the artist administrating sexual hormones can be considered queer subjects.

Queer Communication in Nature

The term queer has different definitions according to the context and the era [18]. According to Marchyshyna and Skrypyk, queer can be understood as a language sign, as a social construct, and also as a philosophical phenomenon. [18] Moreover, the authors also comment that queer theory comes from sexual and feminist studies, but its concept was expanded to other areas of social studies and even to scientific research. [18]

The scholar Karen Barad expands queer beyond sexualities and ontologies and applies it to nature. For Barad, nature is queer by itself, but not only because many animals can express homosexual behaviors. [19] According to Barad, it is simple to define queer concerning sexual and gender expressions, between heterosexuals or homosexuals, but it is necessary to think queer as a natural expression of different subjects, objects, phenomena, causalities, agency, and rationalities. [19] All of these differentiations are entangled in the web of nature. [19] Nature is queer by itself because it encompasses all of the different forms of life and expressions possible. [19]

Barad correctly affirms that the entanglement of one entity with another is more than an interconnectedness, but a specific material relation of obligation with that another, for those relations bounds one and the another. [19] That entanglement shows the differentiation among entities in the world. The differentiation for Barad is essential to hold things together. [19] The author comments that such separability does not work to build hierarchy or domination. [19] Queer in nature can be understood as this differentiation, which the scholar also calls discontinuity. [19] It is a discontinuity because of the infinite possibilities of expressions and entanglements. Nature is queer because all of its entities are different from one another, and that differentiation is what constitutes the entangled web. Queer is in all places. [19]

Based on Barad's approach to nature as queer, the encounters between the artist and the nonhumans in *Wombs* can be understood as queer communication because in such encounters both parts open their flesh to each other. Those flesh relations in queer communication do not make separations but open both bodies to the infinite possibilities of entanglement. They cut things together because, at the same time that they reveal the distinctions between humans and nonhumans, it is at the moment of touch, flesh encounter, and nutrition that the connections between them are made.

Barad gives a very good example to illustrate how nature is a queer discontinuity, concerning how the lightning phenomenon works. The lightning does not appear in the sky and runs upwards, as we conceive in common sense, or as our vision shows us. [19] In the lightning, the light travels both upwards and downwards at the same time, with no pre-information from the location where the lightning will happen. [19] Lightning, therefore, is an example of a queer phenomenon, one that is uncertain, and discontinuous. She compares this electric act to a conversation, one that gets ahead of itself and happens at the same time that it ends in a place that is only visible once it happens. [19]

Barad's example of queer performance on nature is another way to analyze queer in the interspecies

communication in *Wombs*. The comparison Barad makes between the lighting and a communication process gives us more insights to define queer communication beyond the sexual and gender aspects. As in the case of lightning, in which the particles come from under and above, the message in the queer communication comes from both endings and reaches each other. Both parts, artist and slug or artist and bacteria, become destinations and sources, but not in a feedback system, in a simultaneous system.

In the artwork W.03, the artist placed the slug on her back while she was laying down facing the ground. They did not interfere with each other's process to communicate. Moreover, the artist stayed in silence during the performance with the slug. Therefore, it is possible to compare this artwork to a queer communication as conceived by Barad.

In artwork W.02, there is no information that the human cells took over the slug eggs in the growth medium, or vice-versa. In that sense, it is possible to state that neither the human cells nor the slug eggs interfere with each others' messages. Moreover, in W.02 the cells are considered a source of the information in the communication process. The presence of hormones in the human cells, and the fact that they can alter the milieu, open to vulnerabilities in humans and nonhuman bodies. In that encounter, the artist's cells and the slug eggs are exposed to each other. Both send their biochemical signals to live and to die.

The hormones as a medium in those communications, therefore, also play a role in unfolding human and nonhuman bodies to their vulnerabilities. This can be better approached in the case of artwork W.01, in which the communication in W.01 happens at the level of nutrition. The bacterial agency lies in the capacity to survive or not in the growth medium. The bacteria need to digest the medium to communicate back to the artist. Bacteria dying or flourishing is their way of communicating back to the artist. Therefore, even though the communication in W.01 does not happen with simultaneous transmission of a message from the bacteria and the artist², both parts are intrinsically depend on the hormones.

This analysis introduces another dimension to the understanding of queer communication in *Wombs*, combining the encounter between human-nonhuman in touch, flesh encounter, and nutrition mediated by the sexual hormones. Compared to the case of the lightning, which represents a discontinuity in the way the light travels, the discontinuity in the communication in *Wombs* happens because, in the encounter between the human and the nonhuman, both parts send messages in uncertain and distinctive ways. The hormones as a medium open the human and nonhuman bodies to different vulnerabilities, but their message encounters a mist of survival, co-sharing, caring, and simply being themselves. No matter how

² In the case of the artwork W.01 the communication between the artist and the bacteria can be understood as a monologue of human domination, and that is not because the artist cultivated

bacteria but because she cultivated them on her excretion. Nevertheless, the bacteria still have the agency to reply, which is by living or dying.

different humans and nonhumans are, queer communication uses those differences to argue for equalitarian encounters while showing that different entities can share the same susceptibility to a common substance. In the end, more things unite us to nonhuman than set us apart.

Conclusions

The use of distinct theories in the analysis showed the complexity of the research question. The research connected interspecies communication with mediation by hormones and queer theory. However, *Wombs* encompass a series of artworks that afforded links among different areas of study. Based on the analysis of the artworks from *Wombs*, a human-nonhuman encounter can be understood as queer communication that addresses not only sexual and gender issues but also conceives nature as queer. Sexual hormones have the potential to disrupt sexuality in many species. The artist's queer body and the hermaphrodite slug defy the heteronormative society, which is also part of the queer rhetoric.

The analysis of the encounters between human-nonhuman as interspecies communication that materialized on touch, flesh encounter, and nutrition, was essential to build the discourse of *Wombs* as queer communication. It was also important to comprehend that the hormones can be understood as media because they are biological components that change the milieu in which the artworks take place. The analysis of the hormonal mediation of this communication was also essential to connect the human and nonhuman in more than verbal signs, in queer ways.

The queer communication as proposed communicates the disruption of bodies and theories. The queer communication in *Wombs* goes beyond the lack of language in nonhumans and the sexual divisions in society and nature. It accounts for all forms of life and critically evaluates human interactions with nonhumans. Nonhumans might lack the language or written history. However, an analysis of human-nonhuman encounters made by human theories (mathematical theory of communication, media art theory, queer theory) shows that their differences can generate equality, especially when both humans and nonhumans share the same vulnerabilities to sexual hormones. Queer communication is about transmitting equalitarian narratives in human-nonhuman encounters.

Abstract

This paper discusses the potential of computational media and museum collections to enable encounters with the technological present that complicate narratives of progress, modernity and individual (male) genius that often frame the conceptualization of technology in the museum space. It provides an account of an exhibition and associated time-based objects to help anchor a wider discussion of the potential of posthumanist modes of thinking in the museum space.

Keywords

Museum collections, computational media, data visualization, posthumanism, science analysis and communication.

Introduction

As N. Katherine Hayles notes in a recent discussion of the ethics and politics of human and machine interaction, there are “alarmingly few ethical frameworks” with which to approach the increasing role highly complex technological systems play in our lives and in the societies and material realities they help shape.[1] In view of the broad problematic Hayles’ words begin to bring into sight, this paper discusses the unique possibilities major museum collections can provide to facilitate encounters with complexity that can generate fresh ways of thinking, fresh exhibitionary and pedagogical practices, and ways of relating to technological mediation that complicate the utopian and dystopian imaginaries that dominate the way the future is envisioned in (Western, anglophone) media-scapes.

The perspective we open here emerges from an on-going collaboration between a museum practitioner employed at a major public science, technology and applied arts museum in Sydney and an academic in media and the theoretical humanities at a large anglophone university in a settler colonial context in Australia. Since early 2019, we have been engaged in an experiment in teaching and research that seeks to bring a practice broadly inspired by posthumanist modes of thinking to the highly stratified institutional spaces we work in. These routinely replicate a set of human centric, progress-oriented narratives of achievement and excellence that privilege certain modes of investigation and ways of knowing over others.

By bringing posthumanist practices to the museum and university, we seek to face the reality that “the human”, or rather, the image of the human as a self-aware, thinking and feeling “I” handed down from the European Enlightenment, provides a lens that is ill equipped to confront the complex, entangled and deeply historical challenges that words such as climate change, decolonialization, technological automation and mass extinction point towards. And against this backdrop, museum (technology) collections, and computational media especially, provide unique access-points to inspire nuanced debate about the intrinsically connected but also highly conditional and stratified “we” the word “human” projects.

Rather than aiming to provide answers or offering some sort of guide to this complex terrain, our paper will seek to pinpoint some of the questions that are materializing and isolate points of complexity and discussion that are evolving in the course of our collaboration and the wider museum practices they intersect with.

Computational Media and Museum Collections Some co-ordinates of a complex problematic

“Computational media”, as Hayles contextualizes the rapid proliferation of computer-based technologies over the last fifty years in her book *Unthought*, “have a distinct advantage over every other technology invented.”[2] Although they are by no means the most important for sustaining human life (Hayles points to water treatment plants and sanitation technologies here) and although they are historically not the most impactful and transformative, (transportation technologies “from dirt road to jet aircraft” are Hayles’s suggestion here), computational media have one distinguishing characteristic that sets them apart from all other technologies: they have cognitive capabilities that invest them with “stronger evolutionary potential than any other technology, [capabilities, which] among other functionalities enable them to simulate any other system.”[3] To say the same thing another way: computational media comprise of hardware and software and have the capacity to translate inputs into data that can be stored and computed. As a pragmatic consequence of this, Petrina Foti notes, “two examples of the same computer-based technology might look identical, but have entirely different software [and we might add: memory], making them two distinctly different objects.”[4]

Museums, as we discuss in detail elsewhere, have traditionally navigated the complex assemblages technology collections represent by reverting to the exhibition of ‘firsts’ or iconic designs, and integrated them into chronologically linear, human-centric narratives of progress, modernity and individual (i.e. often male) genius. [5]

In one of the few articles on the display of computational media, Tilly Blyth, keeper of technologies and engineering at the Science Museum in London, further notes that “traditional museum galleries and exhibitions” have tended to legitimize “ideas of technological progress and [have] fed into the dominant global capitalist narrative, promoting the idea that new information and communication technologies enable us to be more productive and more efficient.”[6] Blyth offers this assessment in her account of the curatorial process that resulted in the *Information Age* gallery at the Science Museum, a gallery that actively sought to counter, reinscribe and counter these narratives with alternatives.

As Blyth elaborates, in a present shaped by hidden material infrastructures, massive server farms that are removed from maps for security reasons, proprietary and highly secretive corporate (and military) research and innovation, “representing the materiality of our information in a museum is particularly important”. [7] Put otherwise, and to frame the inference in our own words: public museums provide one of the few spaces that can spark informed public debate about the constellations of power and technological processes that shape modern societies.

In response to the possibilities museum space opens, it is the aim of our collaboration to develop conceptual frameworks that can help activate the complexity of collections to complicate and reframe human-centric narratives that often still shape the space of the museum.

Significantly, and as discussed in the context of the exhibition and specific objects contained within, this conceptual reframing is taking place in an environment in which the very possibilities computational media, digitization, augmented reality and distributed computing provide, are also fundamentally transforming museum practice. These not only offer new possibilities to encounter computational media by utilizing the very possibilities they provide, but they also promise to facilitate new encounters with the limits of human perception and cognition that thinkers such as N. Katherine Hayles are gesturing toward, with their critiques of the “human”-centered, or rather (patriarchal, colonial and Euro-centric and universalist) modes of thought that center on the individual, thinking and feeling “I” the word human is often associated with.

They do so, precisely by enabling encounters with a shared, deeply historical technological infrastructure that continually creates an at once connected, but radically stratified and atomized “we”, a “we” that is comprised of individuals and users with radically different affordances, levels of access and agency.

But how, and in accordance with what guiding principles and concepts should such encounters be facilitated?

What are the hidden realities and processes that ought to be revealed?

What new methods or practice-based frameworks would be helpful to these kinds of questions?

Through asking such questions we produce situated knowledge dealing with the changing dynamic and intricate flows at play within museum practice.

From a curatorial practice perspective, a cross-section of needs, relationships, research, artefacts, trajectories of thinking, engagements, experiences and/or technologies, and their associated materials, partners and communities, helps us to position public engagements. Through the ongoing interplay and actions of curation and experience multiple

readings emerge. In other words, we concurrently accept unpredictable forces are at play.

In a first step, this paper will provide an account that will show how computational media are being activated in the context of a specific exhibition which was assembled by lead curator Deborah Lawler-Dormer alongside lead scientist Dr Joseph Bevitt from the Australian Science and Technology Organisation (ANSTO) and lead engineer Tomasz Bednarz who at the time of the exhibition was Director of the Expanded Perception and Interaction Centre at University of New South Wales (EPICentre) and Powerhouse Research Fellow. This exhibition (*Invisible Revealed*) will provide a sense of how the museum and scientific actors are activating these practices in a variety of settings including curatorial practice, collection analysis, exhibition frameworks, complex research engagements and creative practice outcomes. In a second step, the paper turns to a conversation between Deborah Lawler-Dormer, the lead curator of *Invisible Revealed* and Chris Müller, who comes to the exhibition as a viewer and museum research fellow who was not involved in its inception, to discuss the wider role of technology. The conversation will also turn to the potential of specific time-based objects in the collection, and this exhibition, by focusing on how a collection item becomes activated conceptually adding an alternative framework to the experience. This exhibition provides a sense of how these practices are set in action in the context of the museum and the wider question of human centrality and marginality.

Revealing the Invisible. How is the Powerhouse Museum activating the possibilities of computational media.

Museum collections, as this is put in a classic theorization of the museal space of exhibition, enable an exchange between the visible and invisible, and as such they provide “access to a realm of significance which cannot itself be seen”. [7] Before we return to this question in the context of our conversation and the collection, we will provide a detailed account of how computational media are providing possibilities that are having transformative effects not only on what kind of realities might be revealed, but also on the collaborative practices museum collections can facilitate.

These possibilities are also transforming a vision of museum practice that “privileges the agency of curators, education officers, architects, and the public”, over that of the object, for computational media provide new ways to position collection items at the heart of a generative process that can give rise to exhibitions and new forms of knowledge, collaboration and science communication. [9]

As Deborah Lawler-Dormer elaborates further below, for all collaborators on the *Invisible Revealed* exhibition at the Powerhouse Museum (26 November 2021- September 4 2022) new methodologies, techniques and findings have emerged, both for internal and external practitioners. The development process from which *Invisible Revealed* [<https://www.maas.museum/event/the-invisible-revealed/>] emerged was intimately bound to the scientific and technical processes and consequently the research and development entailed phases of testing, feedback and analysis. The exhibition and development processes became a site for both innovation and investigation. At its heart, the exhibition begins with the Powerhouse Museum’s collection of more than half a million objects and the many stories as well as the many questions that reside within. Working with ANSTO the Museum has been given time under a partnership agreement to examine objects within the collection to learn further information about the materials, the manufacturing and construction methods, dating, working mechanisms and

their engineering and, in some cases, to look for evidence of contextual or cultural stories that surround the object.

The Museum has been able to examine selected collection objects at an atomic, chemical and molecular level through sourcing beamtime at ANSTO's neutron beam and synchrotron x-ray facilities alongside sophisticated processes relating to specific methods of testing to help reveal answers to long-standing research questions or mysteries that accompanied the collection objects. The resultant data and imaging were combined with digital data visualization techniques to create an engaging and aesthetically striking show. The exhibition narrative profiles how through these non-destructive methods of analysis the museum was able to investigate how objects were constructed, how time pieces were engineered, what historical damage and corrosion had occurred throughout the object's history and proof that such items as a Lydian coin were found to be authentic rather than fake.

As Deborah Lawler-Dormer elaborates in more detail below, *The Invisible Revealed* proved to be a project where experimentation and speculation was embedded into the process. The exhibition was developed in a nine-month period during Covid-19 lockdowns and due to the restrictions caused a level of innovation brought about by necessity. Specific objects within the museum's collection were investigated by ANSTO using their facilities at Lucas Heights in Sydney and the Synchrotron in Melbourne.

This science and technology research and exhibition development journey actively engaged and highlighted interplays between data, the digital and the physical object and temporary exhibition environment. As Geismar notes, the definition of a digital object slips between digital files that themselves serve as their own kind of 'objects' and the technologies (screens, phones, kiosks) that deliver them. She argues that "we need to think about the digital not only as material, rather than immaterial, but also in terms of a trajectory of materiality that links our commonplace understandings of the digital to the analogue, information to material, systems to structures, knowledge to form." [10]

This nexus of states and purposes resides in these newly created digital objects for this exhibition. The digital models remediate our relationship to the physical object by presenting the scientific data embedded in a digital simulation or twin. In so doing the digital object is replicating a knowledge construction specifically of scientific analysis overlaid onto the edifice of knowledge construction held within the museum and its collection. Geismar asks: "As collections themselves shift across platforms, what counts as a real object, worthy of preservation and care, subject to property regimes and the call of sovereignty, is also drawn into question." [11]

Viewed through the framework of this paper, *The Invisible Revealed* is an example of what in Hayes' terminology, would be called a cognitive assemblage. In cognitive assemblages, Hayes explains, "technical components typically filter and interpret data prior to human intervention, thereby deeply affecting what humans see and how they see it; they communicate with other technical devices and initiate cascading effects; they include sensors and actuators as well as databases and networking capabilities; and they make consequential decisions across a wide range of scales and sites that determine not only what will happen but also what are perceived (by humans) as possible courses of action.." [12] As the short introduction of *The Invisible Revealed* has sought to foreground, computational media are not merely being deployed as a tool in the control of a masterly human subject, they are in fact actively involved in a deeply collaborative, curatorial/creative/scientific process that is itself shaped by the material properties of collection items. As

such, this process generates outcomes that cannot fully be anticipated. And the generative limits to knowledge that come into sight here, provide a useful platform for a brief discussion of one particular aspect of the conceptual framework for museum technology collections that is gradually beginning to take shape. Rather than focusing on an exhibition, our second case study will focus on several specific collection items, and the ways they help decenter the human as primary, logical and 'masterly' to the human as "always already evolving with, constituted by and constituent of multiple forms of life and machines." [13]

A conversation: Encountering the Unseeable and the limits of the human perspective.

This paper takes the form of a mutual conversation, which reflects how we work on posthumanist concepts together.

Chris M: I'm a cultural theorist and, as such, I'm often trying to inquire into technologies that are very obvious. In my thinking, technology is conceptualized not so much as a tool, but more as a space of possibility, where the boundaries between our own abilities and abilities that are somehow borrowed or enhanced become blurred.

Just to contextualize for people who are reading this, I was not involved in the exhibition *Invisible Revealed*. I was witnessing its development from a distance as a research fellow at the museum working on posthumanist perspectives on the technology collection. In a really concrete way this exhibition uses these amazing imaging technologies, in a sense, almost as tools, but I also get the sense that it was a journey into the unknown for you all and that it was trying to explore what these technologies could be. Is there a line between this idea that technology is this tool that we kind of control and apply to very specific questions to produce new knowledge and, a perhaps more difficult to define encounter, where the way the technology works is actually shaping the way you collaborate?

Deborah L-D: I would say that this is an interesting project for the kind of speculative space that got set up between levels of expertise and this museum collection. On the one hand we had the museum staff with people like curators, conservators, researchers, technicians and photographers and on the other hand we have the scientific community that was grouped around ANSTO who had expertise around the instruments, processes and facilities.

Image caption: Brooke Randall, Powerhouse conservator, Dr Deborah Lawler-Dormer, Powerhouse curator, Dr Tomasz Bednarz, Powerhouse research fellow at the DINGO facility at Australian Nuclear Science Technology Organisation. Photograph courtesy of Joseph Bevitt 2021 409

We also had an additional collaborator in the team at the Expanded Perception and Interaction Center who were working on data visualisation, photogrammetry, augmented reality and artificial intelligence systems. And it was in the meeting of it all that a sort of evolution of new techniques began to happen in order to get this project on the floor of the museum.

So, in that sense technology was kind of like both a way of developing new knowledge, and a mechanism for us to show that new knowledge to our audiences. This then evolved into a shared performative space that was highly unpredictable due to the level of experimentation in techniques. We were also working remotely and working through teams and zoom meetings and shared digital platforms to evolve the work.

Chris M: We said right at the outset of our paper that traditionally the museum collection has been used as an access point to something invisible such as the cultural context or a certain intangible story or narrative or context. My very open question - is what other kind of wider significance attached to this process, what are some of the meanings and conversations you wanted to make possible with this exhibition?

Deborah L-D: The *Invisible Revealed* grew out of a partnership agreement between the museum and ANSTO, which is an important, although kind of pedantic, place to start. At the core of the exhibition is an investigation into the museum's collection and really looking at objects that we had outstanding research questions around such as what materials the objects are made of, how are they manufactured, what date they were made, what region they might have been made amongst others. For several years we have been using ANSTO's non-destructive analytical techniques so that there's no harm done to those objects whilst trying to answer these questions. The exhibition is moving across the collection, and across many different disciplines, really looking at those mystery objects as objects that we have some quite big questions around. Through the ANSTO imaging and analysis using methods like neutron tomography and carbon dating we are able to get some clues towards those bigger questions. It's kind of like being a detective as you journey with each one of these objects searching for clues.

To answer to your original question, every object in the exhibition had a set of questions that we didn't know the answer to so that was the starting point. We wanted to show our publics how we go about trying to find answers to those questions and show the diagnostics as a form of science communication whilst also being engaging and inspiring curiosity. These objects are so unique and the stories they were telling, and the questions, meant they almost became characters forming a dramatic journey along the way. In fact when we went to build the exhibition, we chose to work with a theatre designer as designer to highlight this notion of a performative space. Then, we had the challenge that we were imaging in various ways the collection through a set of very disparate digital artifacts acquired out of the investigations. Then this kind of very intense collaboration began between Joseph Bevitt who is the lead scientist and myself to bring all of that data together and work on it to animate it and to enliven that required new forms of visualization to be developed. In a way we had to kind

of look at that imaging almost like a choreographer trying to design the movement that we would take through that data that conceptualized the journey, without it being too overwhelming or driving too hard, and too deep into the science.

In doing that everybody developed new techniques so there's a technology innovation discussion overlaid over the whole project. We believe that there are techniques that have never been done before. And so there were moments of excitement during the angst in trying to do this. [laughs] The exhibition was developed in a nine-month period which is a very fast development period for such a technical science investigation.

Chris M: What you just said captures really my excitement of coming into a museum space as someone who's more at home in academic treatments of technology. You know the exhibition in a sense, is showcasing to the public a behind the scenes working and revealing a certain process of knowledge creation and making. The technology and the data visualizations act as visible agents in the exhibition. All the categories that are usually easy to separate in a written text or in academic reflections here become incredibly hard to separate from these vital processes, because when we go back, we create separations, imposing knowledge and uncertain unitary perspectives on them in writing. You are highlighting, if I understand correctly, how collaborative those processes have been and how much the technology itself becomes the space of collaboration. Were there moments where you felt kind of productively stuck, where there were limitations or where you were aware of a certain technological kind of imposition?

Deborah L-D: The data arrived in various forms such as clustered points of data, graphs of chemical composition or single black and white images that were quite pixelated. The first thing we did was take these single slices that travelled all the way through the object and animated them into one sequence. The quality of resolution was still not that great although highly readable and sufficient from a scientific perspective. But as a curator, that imaging is not that understandable to the public. I was asking how can we make this so there's some insight into the facilities, instruments and the various techniques that were being applied to the objects. It was kind of like peeling back the processes of investigation, almost placing the viewer or the participant in the position of explorer and empowering them to discover themselves by giving them a few tools.

We created stations in the exhibition where you could break apart and see what was synchrotron imaging what was neutron tomography imaging and you could see the benefits of what each imaging was supplying. For instance synchrotron was useful for looking at the surface of an object such as glazing or the textures or the warp and weave of a textile. For the neutron tomography it is really penetrating objects and you could see details such as breaks, and glues that had been applied, you could see the bubbles in the clay that were formed at the time of creation. The imaging was digitally refined became quite visceral and aesthetic forming registers of this journey these objects had traversed over centuries.

What was revealed was an interesting way that technology then instigated a sort of dialogue around time, around the past, present and the future that was embedded in these new digital artifacts.

Chris M: So, one of the core points of our ongoing conversations over the last few years has I think been this idea, this question of progress and how technology changes so quickly and makes it possible to do things which would have been unimaginable in the past. It can create this automatic story of progress, I guess, in museums as places where often development is shown, or when something super high tech is matched with something less high-tech creating a sense of advance. I think your story has just unpacked something that to me is equally interesting because it shows a kind of strange continuity. What is revealed through this imaging technology is the absolute complexity of an object that if you just encountered in its everyday, object form would look like the creation of, say, a single person or would look kind of self-enclosed.

An object is a thing often experienced to have very clear boundaries, both in time and space. In a sense, you're revealing the ongoing work on that object over centuries and the way it has been the kind of catalyst for new kinds of production of meaning. Today, in your exhibition, the object is shown as active and productive.

Deborah L-D: The horse figure from the T'ang period is a great example because on the outside that horse looks kind of perfect. It looks like it survived the centuries intact.

But when we image the horse in the form of a radiograph what we end up with is a technical vision that's almost entirely opposite to what we are perceiving with human vision. Through neutron imaging what we then see is a horse that has been broken many times and has been patched together over the centuries by different conservators and crafts people. To view it as whole, strong and beautiful but it's actually revealed to be incredibly fragile. We have to build a scaffold around that horse in order to move it because it's structurally so fragile that we can't just handle

and lift. This imaging, for instance, now gives us the information that we know where to build the scaffold to support it. In a way, it's interesting when you look at it from a post humanist perspective. It has its own agency its own life its own kind of energetic experience that is ongoing and is engaged today in active encounters – such as in a neutron imaging instrument, when its sitting on a table having a scaffold built around it with new materials, the way it is then parcelled up being trucked from one site to another, how it moves into a studio to be photographed. I mean it's changing, evolving, encountering all the time.

To recall an earlier part of your conversation there is a practice-based discussion to be had as well. I work in the research part of the museum and we often have academics, who can analyse and tell us a lot about objects in our collection, but one of the things that's often missing from a conversation with an academic is that practice of working with objects on site every day and working in that sort of matrix. Like choreographing a journey through a data set or how you would photograph that object and how you would even photograph its relationship between the physical object and the data set.

Chris M: That's the fascinating thing for me when I think back through your exhibition and the imagery created is that it reveals this complexity, which is actually incredibly hard to represent, you can kind of only become alerted to it. So if we had to kind of narrate the story like you know to think of the person who probably broke off the horses' leg who years ago was probably desperately upset or annoyed by this. Yet centuries later that becomes an important productive component of connection to past centuries that then reveals a kind of limited human story that has been preserved in very interesting ways through the remaining traces.

Deborah L-D: When you were talking about the limitations of technology and how that had been thought about and the process of putting together the show, I was thinking we actually exhibited objects that were part way through their investigation, so we revealed them as partially investigated and we also showed objects that had failed in their investigation.

Additionally, in a museum display you would see this exterior of an object and you can't display the engineering or the mechanism or the way that that object actually works. We created a section of the exhibition which exposes complex mechanisms so that you can start to see the beautiful engineering that's usually inside. It's very difficult to unpack that knowledge. For instance, we have a fob watch that used to play a tune on the hour and if you look at the imaging you can see this very precise engineering that generated sound. The imaging is so precise that if at some point, because of say corrosion or damage we were unable to use the watch, we now hold this incredibly precise imaging, so precise that we could re-manufacture that sound. I would say at this point, this is a speculative experiment, but it would be an interesting one to resound the mechanism using what we can see in the imaging.

Chris M: As you were talking, I started to think of digital technology which allows to somehow edit out the marks of repairation. You could have easily edited these marks out. One of the images is a carpet mended with the help of Artificial Intelligence. I am interested in this generative space between this idea that the digital somehow gives us means

to perfect and also the means to undo. It makes available a different kind of mastery. Do you see this as an extension for the work you are doing with modelling or is it something fundamentally different?

Deborah L-D: I would say that working with digital artifacts is certainly generative. I think this notion of the digital somehow presenting a more perfect vision is not correct. I think at that point there is a decision about what one wishes to show and showing digital imperfection is just as important. In both digital and physical worlds imperfections are in themselves very interesting and engaging.

Tomasz Bednarz is an expert in artificial intelligence and data visualization and by combining these two techniques, we were able to recreate the Uşak carpet from Western Turkey that was really in fragments and be able to get a sense of what it may have looked like in the past. With this new digital data set you can go to any sizing because it's resolution is very high, and consequently you can go way outside the boundaries of the original physical object. When that AI extension was built it moves over a sequence of time and in that sequence of time one could see almost like the stitching of a whole as it moves back and forth between processual states whilst being very sympathetic to the materiality of the physical object, and to the materiality of the digital information driven platform. Tomasz also built an augmented reality experience revisioning half a dozen objects in the exhibition. Photogrammetry models of objects were placed into an augmented reality program which can be accessed through a QR code and online. These augmented reality digital objects are available to people in their homes, and we have got a series of photographs that document these engagements that show the digital artefact having a life in its own performative right. The object has broken out of its case. It is a different kind of engagement that's happening with the object.

Chris M: Yeah it's a wonderful expansion of a space of significance.

Deborah L-D: I would like to ask you a question. So you came to an Open Late which is a themed live night that is run as part of the exhibition program. We had a variety of programs happening including contemporary dancers responding to the exhibition, we had lectures, we had photogrammetry workshops and a large-scale projection in the turbine hall. We sort of took the show and expanded it and it began to populate across the museum.

I was very interested in hearing about your experience of that night and how, when you think about the ways that we have been talking about the exhibition, how you would see this aspect of the project. Going back to the title of the paper which concerns museum practices and post humanist assemblages, how did you see that evening from a post humanist perspective and how the event kind of began to break out of its existing exhibition assemblages into something else?

Chris Muller: I mean, for me it was fantastic to experience the multiple forms of knowledge that run through these objects. It needed that additional aspect like the dancers who were adding aesthetic elements that offered something very tangible and a kind of an emotional transfer between the images that were projected and something very immediately humanizing that added to just looking at or interacting with the digital imaging. I found that

emotional transfer very interesting. The talks from an Indigenous perspective help me really understand and experience an additional complexity that runs through the objects. There was four different people speaking to some of the objects, with four different perspectives including the engineering, the scientific, the curatorial and the Indigenous. All of them came together as an inspiring experience simply from the perspective of a museum visitor. I was thinking how much I would love that this could become a very established genre and format, in which we have these conversations much more frequently. I was very grateful that it also revealed to me some pragmatic tensions and I guess some of the ways that my work thinks about. Like the possibilities that technology makes available and what we can do with it.

I enjoyed the listening more than anything, I enjoyed the learning and the kind of slowing down of that complexity. How does an interdisciplinary practice kind of translate back into an everyday practice because, as an academic I know we have similar kind of events and then you know, sometimes it will kind of pass through our everyday life and not much will happen, but sometimes it really transforms the way in which we teach and deliver our content. It was a very interesting way to encounter an exhibition.

Deborah L-D: I think the experience of having those sort of breakout moments is incredibly influential and necessary to one's practice as a curator and as a researcher and will undoubtedly inform other projects, including with the same partners. Its important to think about what is contemporary museum practice (or any practice) and enable a way to engage in that space where the unexpected can occur.

When you look with these objects, we are moving down to the atomic structures, right up to the external skin dislocated in a Perspex case to protect the object with a screen with the digital artefacts above it.

We have often had discussions about technology and time and technology and emotion. In the exhibition there were objects such as time keeping, time capturing and measuring devices such as an alarm clock, a spy camera and a curta calculator that was developed in a concentration camp. These sorts of objects hold an active kind of historical record keeping in a way, but with this overlay of a previous time, previous tensions or heightened emotional stories. I was wondering about the way we present objects in museums today and how this changes the way you are thinking about technology around time, memory and emotion.

Chris M: There's something incredibly fascinating, unsettling and complicated going on when we have these sequences of technology. It's for me always quite uncanny in the sense that looking back we have this incredible narrative imposing structures onto a temporal experience. How technology is restructuring, our experience of time, not simply through measurement but also through marking this passage of time, whilst also addressing in these past structures in these past ways of thinking.

You know, it would be almost impossible for us, I guess, to imagine a world without clock time yet for the vast majority of human life on Earth it's not these mechanical measuring devices that coordinate whole societies.

What becomes interesting when the digital is added is precisely to think so what is being projected towards the future, when we use these kinds of technologies and when we showcase that potential. So, for me this is something that I think the museum is just uniquely able to activate as an experience, because I think there are very few places where we can go to see technology kind of folded back on itself, or one technology used to expose another in a way that isn't trying to sell you a better technology or a different technology.

The place where I find great inspiration in the museum, and in other interfaces that shape our vision, is for me this very paradoxical thing. On the one hand, they give you this enhanced sense of control, insight, and power, on the other hand they normalize and kind of make it very hard for us to see the work that the technology is itself doing on our perception, how it's shaping our body experience and kind of positioning us.

So it's those kind of things I thought about quite intensively. I was especially interested in one exhibition item the tree with the kind of radiation curve that shows a very potent visualization of one of the start points of the Anthropocene as this new age in which you know we're supposedly leaving an inscribed mark on the globe for the kind of radioactive testing. This work shows the complexity of these registers of time. On the one hand, there is the linear time that we try to kind of master. On the other hand, our own acts are continuously continuing to act and are complicating those linear progressions. [14]

I think it is so important that we bear that in mind, and that we experience, those two different registers of time in a dialogue or in a way that it doesn't lead to simple resolution.

I do think there is a wonderful potential that is demonstrated in this collection to say, well, what is this digital moment? The clock you can put in your pocket, and you can kind of own it, which is not true for the technologies that are being used to create this amazing insight into the clock's inner workings. Now, it is processional, it's not a thing that you can pinpoint and say 'Oh, this is the thing

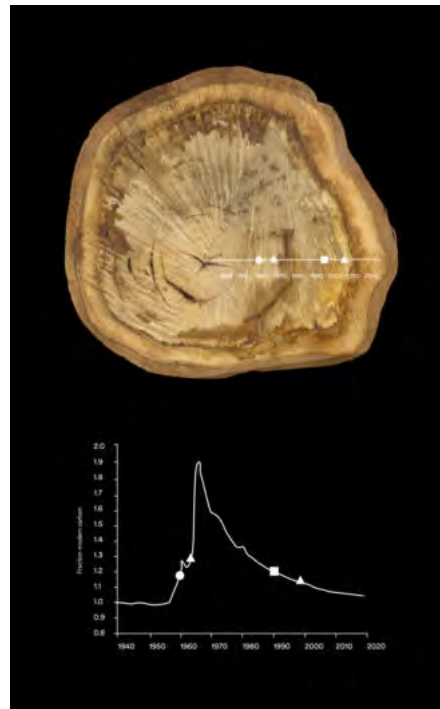

Image caption: Tree sample and animation from Eucalyptus Plantation, Museum Discovery Centre, Castle Hill, New South Wales, Australia, 2021. Powerhouse collection. Photographer Enzo Amato.

that makes it all work.' It is now a very distributed technology that is controlled to various degrees. It has a very different model of sociality that comes with a very different society so that's kind of, I think, for me the exciting potential of this kind of experience. It shows there's incredible continuity, but there is also something happening that is hard to understand or intuit. Change has all this amazing potential, but it also brings about new kinds of blind spots we are finding quite hard to expose, think and talk about.

What I enjoyed about this exhibition is that there is no hiding of that process which is usually so invisible.

The challenge is we are always only shown the end product and we never get to see how it is created, what kind of conversations happen, who the stakeholders are in that. Mainly because its proprietary technology. An amazing illustration of different voices coming together in a dialogue that was to me very productive and uncovering the complexity of these kind of processes and that the people who are involved in that process also matter. Being in that evening event, where it is exactly the qualitative difference between knowing something and experiencing it that becomes very clear. Like experiencing the kind of processional nature of technology and the difficulty to pin it down that precisely.

I think that for me, what I take from your exhibition and I'd like to come back to, is what the space of significance (technology) revealed. For me, it was precisely that complexity becoming more visible. I think, or at least this is my sense that you are letting people experience that complexity, rather than telling them about it. The museum was revealed as a space for encounter rather than displaying a representation.

An ending and outlook of sorts

By bringing posthumanist frameworks of thinking into the museum space, therefore, the encounter with the museal space of significance remains open and evolving rather than leading back to the old vision of social control that gave rise to the museum in the 19th Century. Museums provide unique spaces in which to confront and experience the paradoxes by which human beings are created out of the very technologies that they appear to create.

A Case for Play: Immersive Storytelling of Rohingya Refugee Experience

RAY LC and Fabeha Monir

City University of Hong Kong
Hong Kong, SAR and Dhaka, Bangladesh

LC@raylc.org

Abstract

The displacement of refugees from their natural homes have caused violence and estrangement all over the world, to the detriment of victims who live in unbearable conditions outside their homelands. There's misunderstanding amongst hosts and Western media that see refugees as destructive hoarders of resource. Educating two sides of a refugee-host divide have applied immersive filmmaking following the cinematic 2D approach, portraying static scenes with narratively voiced works that try to put us inside refugee camps to elicit empathy. Instead of this approach, we embarked on a refugee-centered journey-based approach to show the daily lives of Rohingya refugees in Balukhali, Bangladesh using dynamic movements in VR space, spatial audio that surprise, and collaborative filmmaking that involves the participants empowering themselves using 360 camera and phone as tools for exploration. Instead of investigating the hardships of refugees from a Western perspective, we enabled a boy and his family in the refugee camp to create a visual experience that represent their lives. The interactive VR film is an empowerment tool to enable self-expression in a corner of the world that have become used to being the observed as opposed to the observer, taking advantage of VR as a medium for immersion and capability to surprise.

Keywords

virtual reality, 360 film, refugee camp, social empathy.

Introduction

Documenting the truth requires telling stories that faithfully represent the subjects in the way they are affected emotionally, not merely the reality. Thus, showing only the physical destructions of an event would not get at the truth of the way people were affected, both the perpetrators and the victims. However, subjective stories that get at the truth emotionally can be laden with bias. How do you tell subjective stories objectively without agenda? How to represent your subjects in their subjective states?

The medium of Virtual Reality (VR) is a way for journalists to show the assumed natural state of its subjects, by placing a 360 camera where events occur. VR films like Chris Milk's "Clouds Over Sidra" put audiences in a static scene

in the middle of the refugee camp to evoke empathy for the plight of its subjects [15]. But VR fundamentally changes the responsibilities of the journalist filmmaker, as the producer and its sponsor quickly learn to produce material that evokes emotional responses for their own sake, making the viewer emotionally vulnerable due to the high level of fidelity [13]. Because the director steps away from a completely immersive but static scene, we forget that the entire experience is orchestrated to evoke a certain type of reaction under the impression of duplicating reality. Unlike traditional filmmaking in 2D, the entire set is part of the VR experience, so that all arrangements with subjects have to be done well before hand, with mutual understanding.

How do we overcome the propensity to use VR to make agendas? In order to tell subjective stories in a transparent way, we used VR in three ways that remind us of the limitations and ethics of the medium. 1. We aim not to hide the director filmmaker, but to make her a part of the truth-telling, for in making the documentary, we inserted ourselves into the sociology of the environment, so why should we disingenuously hide ourselves? 2. We invite the subjects to make the film, empower themselves to express what they would like, giving them direct access to the audience and allowing them to have agency about being the portrayer and not just the portrayed. 3. We use dynamic movements and spatial audio from surprising sources to explore the VR medium, reminding audiences that VR is telling us a story by the way an actor with agency moves her journey in time, not a static representation of reality.

Together, these methods show viewer experiences that coalesce into stories framed collaboratively by the creator and her subjects, illustrating VR as process of expressive filmmaking rather than description of reality, opening up opportunity for the filmmaker and subject to play together, to involve both parties in the documentary process.

Background

Historical Context To investigate the 360-VR medium as collaborative play, we visited the Rohingya refugee camps in Southern Bangladesh to document a refugee community. The Rohingya is a Muslim group previously living in the Buddhist Rakhine state in Myanmar, with a history of violence that cuts deep into its culture [2]. During WWII, the Rohingya Muslims were aligned with the British while the

Rakhine Buddhists supported the Japanese. After the war, the Rohingya were denied citizenship, after the Myanmar government launched operations to clear the area of the Rohingya. In reaction, attacks were led by the Arakan Rohingya Salvation Army in 2016, leading the Myanmar government to systematically uprooting hundreds of thousands of Rohingyas away from their homes using violence and humiliation. Over 750,000 refugees fled to neighboring Bangladesh, whose government is dealing with massive populations, and wants to prevent further explosion [16].

Photographic images from both sides have appeared that seem to support different agendas. Myanmar officials claim one image supporting ARSA attacking its own village, but later investigation led to identification of Hindu arsonists. Thus there's a need for objective, immersive documentation of the refugees' plight. Refugees themselves do not have means of making films or documenting their lives, making misperception on the Bangladeshi side common place. The public perception in Bangladesh as perpetrated by government-sponsored media is that Rohingya militants are breeding in refugee camps [17], aligning with the reluctance of Bangladesh to absorb the 1.3 million Rohingya amidst the stalemate between the UN and Myanmar. The Bangladeshi authorities have portrayed the Rohingya as militant and self-serving outsiders who seek to benefit from Bangladeshi resources.

Virtual Reality as Medium Humans are uniquely able to empathize not only with other humans, but animals and fictional situations. VR transports humans to a story environment to see the same situation and interact at high fidelity. This generates participatory empathy, which comes from our own experience of the subject, as opposed to affective empathy that comes as an emotional reaction to a someone's plight [20]. Study shows VR results in greater engagement and empathy compared to 2D displays when viewers saw a girl living in a refugee camp [18]. Further studies found greater empathic response to color blindness after a VR experience, facilitating perspective taking [1].

VR allows immersion in other perspectives, but does VR change behaviors enough to drive activism? In study of charitable giving to local aid organizations, VR experiences of a destroyed Middle Eastern city, and not flat monitor 360 video, led to greater number of givers and greater amount of donation per giver [8]. Perspective taking in VR led to a significant increase of post-exposure-experience petition signing at 82% compared to 61% for the 2D screen equivalent [9]. Others have found that dissemination of VR material led to both positive and negative emotion increases that call for behavioral and political change, highlighting the role of VR outside purely immersion [6].

The interaction of human emotion with VR experience is not as simple as one-directional influence, however. Personality traits are correlated with immersion in VR, suggesting that humans have purposeful intention over control of VR experiences [19]. This bidirectional influence ushers in a VR landscape in which storytelling is implicit and based on

a perspective where the environment is set up and configured for self-exploration that leads to its own stories being told, as in interactive games. Future immersive film practices will create spaces and social connections that form empathetic relations without overt, direct narratives [12]. We leveraged this opportunity with VR to create collaboratively empowering work that allows subjects to create their own stories to tell without deliberate narratives.

Virtual Reality as Journalism In the use of VR as a medium for journalistic narratives promulgating peace, viewers are allowed to roam in a virtual world created from 360 photos or videos. UN's VR documentary "Clouds Over Sidra" tells the story of a Syrian girl refugee living in Jordan [15]. Seeing the world from her perspective increases self-reported empathy and emotional response, and facilitates behaviors like willingness to support humanitarian work [6]. A VR film about an Ebola survivor in Liberia [3] led to a 16% rise in donations for Amnesty International.

Immersive journalism provides local populations with technology to narrate their lives, like the works of Fran Edmonds and Grady Walker. In the Shootback Project, journalists gave Kenyan youths \$30 plastic cameras to document their lives for 3 years, empowering storytelling for those without such means [21]. Such work was also done in Tanzania with the Baraza Television initiative. We were inspired to take participatory video-making projects to a more immersive and accessible level with 360 video.

Immersive work with refugees are not limited to 360 video. This includes Al Jazeera's ContrastVR project [14], and *I Am Rohingya*, a play that documents 14 Rohingya youths discussing onstage their lives during the escape from Myanmar [22]. Theatre may be the most immersive form of experience of all since it duplicates the experience with subjects every time the play is performed. Another example of telling the story rather than reality is Khaled Hosseini's immersive animation about the death of a 3-year-old refugee boy who drowned attempting to escape the camp [10]. Drawn in 360, it gives the feeling of the events surrounding the boy as told by his parents.

While these previous efforts utilize VR as an immersive medium, they rely on static shots reminiscent of screen-based filmmaking. Sound is non-spatial, and the camera is stationary. This makes for a static set where the filmmaker is absent from the theme, so that whatever is presented is imaged to be reality. This fails to recognize that behind the scene, the filmmakers have given directions to their subjects, who may be told instructions prior to the shot to maintain the theme, which are unknown to the VR viewer. These experiences tend to be slow and show sad, depressing scenes that evoke sympathy, not empathy. We don't feel like it's the way life is in the camp, but rather the dreary life that we should believe exists there based on what the filmmakers have wrapped up and presented to us. These films use dubbed voices and westernized music, and tend to have beautiful renderings of nature that contrasts with the camp, emphasizing their decrepit state. Point of view of the camera

seldom shifts, in fear of dizziness in VR, and even the equipment that the 360 camera sits on is painstakingly smudged out in post-production, emphasizing the lack of perturbing into the scene by the filmmakers.

However, the filmmakers did perturb the camp, by the existence of the crew and the directions given, for making the 360 film was an agenda that blurred out the true state of the camp the way it was lived in. Instead of this packaged process, can we create a participatory method which involves both subjects and filmmakers, so that the result is an organic representation of what the journey was: that of outsider journalists exploring homes of people they are curious about? Can we get refugees to play collaboratively with us, telling us a version of their own story?

Figure 1: (Top) Rohingya refugee camps in Balukhali, Bangladesh, a 4.5 hour drive away from nearest town Cox's Bazar. (source: maps.google.com). (Bottom) Block B56 of Balukhali. The football field is surrounded by shanty in all four directions.

Methods

We stayed in Cox's Bazar in the month of Ramadan in late May, and visited the Balukhali Rohingya camps by a 5 hour drive every morning, because we are not allowed to stay close to the camps (Fig. 1). We had no power, and must leave before 3pm each day during Ramadan due to camp closure, so only refugees themselves can take videos in the evening. Upon arriving at the area, we climbed up the hills in block B56 to meet the Maji (leader) Salim. Working with the Program for Helpless and Lagged Societies (PHALS), Salim took us to Camp 8E, where we visited two families before deciding to work with the family of Ameena Khatun, who had 10 children--5 sons, 5 daughters. Like most Burmese, the family does not have last names, so we refer to each of them by their unique first names.

Ameena and her husband Ehsan's family came from Pattiya Para, Myanmar during the forced extradition (Fig. 2).

They walked through hills and forests for 16+ days in the heat of the burning sun and in the rain. The children became sick and they had to beg for rice from others on the way. The Myanmar military already burnt their houses down so there was no choice but to go forward. People were seen jumping into rivers and falling from hills, fleeing from the military. They cooked only once every four days, and must rely on these provisions during that time.

One daughter of the family, Shamima, died on the way to Bangladesh. She was vomiting and having diarrhea, with very little to eat, but cause of death is unknown. Because there were so many family members, they had to leave her in the jungle and move on. No one has any mementos, souvenirs, photos, or clothing of hers, because they took no belongings from home. The only remnant of Shamima that Ameena Khatun has is in her memory. Ameena can neither draw nor write, so Shamima's memory will be hard to pass on. The only thing she had wanted was her children's safety, so Ameena has difficulty dealing with this pain to this day. Currently they also lack provisions and clean water, but in Bangladesh at least they do not fear having the light on during Ramadan or fear practicing their religion.

Figure 2: (Top) Select members of the family of Ameena Khatun, including father Ehsan (left), and son Mofizur Rahman (front left), who narrated the VR experience. (Bottom) Children of the refugee camp in the 360 VR production interacting with the short footage they themselves took after using the 360 camera to record some movement associated with navigation using the camera.

To tell the story of the Rohingya refugee experience of the family of Ameena Khatun, we needed to describe their lives from different perspectives, so that audiences can be immersed in the many dimensions of the narratives. Thus we took a multi-disciplinary approach of 1. A narrative film about how Ameena and the family deals with the death of

Shamima, as a way to serve as the lasting memory that otherwise would be lost to posterity; 2. A documentary about empowering refugees to express themselves by teaching them video-making using a phone during evenings at Ramadan when we don't have access to them; 3. A VR experience that takes the audience inside camp life, narrated and guided by Mofizur Rahman, with camera work and playful initiative by Mofizur and friends. For the rest of the paper we will concentrate on the VR experience.

The VR film was shot using a Ricoh Theta V 360 camera attached to a TA-1 3D spatial audio microphone, and stitched and converted offline. Refugee-handled camera work was hand-held, while tracking scenes following Mofizur during his journey were done by lifting a fully extended tripod above the head of the cinematographer. Mofizur and his companions were instructed only on how to hold the camera without obstruction, and allowed to roam freely around the house and to pass off the camera to others. Before recording the main interactions, subjects were given the camera to take a short footage. That footage is converted from two-fisheye view into 360 video format on the computer and shown to the subjects, who could interact with the 360 nature using the computer trackpad (Fig. 2). We then loaded the 360 video into a Unity scene with a single sphere and inverted normal for display on the inside of the sphere. The result is exported to a Google Pixel XL phone for immediate viewing by the subjects as a prototype in VR. They were allowed to iterate as many times as desired before taking the main footage.

Outcomes

Unleashing the Auteur Previous VR films in the refugee camp space exhibit static scenes, passively viewed subjects in narration, and hidden evidence of directorship and cinematography. Our work with the Rohingya attempt to address these issues to produce a more active experience that shows collaboration between subject and director.

Both "Clouds Over Sidra" and "Waves of Grace" contained long, static shots with the camera smudged out so that audiences cannot see the mechanisms of the filmmaking. This technique is especially pronounced in "My Mother's Wing," a VR film about a mother's loss of her children in Gaza [4], which narrates the experience like a traditional 2D film, with long voice-overs. In one moment, a car seat is emptied in order to accommodate the invisible but present audience. The voice-overs are in English and the music is orchestral. Not shown are the filmmakers' involvement and the behind-the-scenes production that led to the naturalistic behaviors shown. Instead of showing the refugee experience in isolation, we recognized that any observational process is inherently transformative of the subject being studied [7]. The moment we arrive at the refugee camp, we are dealing with subject preconceptions of what should be shown and not shown to us. For example, do these filmmakers wanting to make a sad story? Should we show them our sad side? What do they expect refugees to be like? Shall I show them what they want to see? These preconceptions necessarily influence the documentary, so that the supposedly objective

film with an invisible narrator is already impossible upon first arranging such a visit.

Instead, we wanted to show the collaborative nature of such a visit. We are not the only ones observing; the refugees are observing us as well. We should not be the only ones expressing ideas; the refugees have things they want to show as well. The first order of action was to show us not hidden from view but as part of the collaborative process. Instead of objective cameras planted on the ground, we held up the 360 camera with our hands and holding on to our tripods. We played in the football games they play, not hiding from it (Fig. 3). We followed along during the tour, and participated in passing the camera to each other. In turn our camera exists in the scene, not apart from it. The story that emerges is not an impossible attempt to hide our presence, but rather to document how visiting refugee camps occur, and how we learn from each other.

Figure 3: Involvement of the creators in 360. (Top) A scene where journalists are working with documentation of the family while Mofizur Rahman enters with the camera. (Bottom) A scene where the director plays football together with Rohingya children.

Subject Empowerment Current VR experiences reply on filmmakers to provide the context, both in terms of where the film takes place and who we can meet in it. In "The Displaced," a VR film about three children from refugee camps, we get to meet the protagonists but never follow them [11]. We are ferried on a boat we cannot step away from and asked to read subtitles as the protagonists read their lines. When we really want to see the protagonists face-to-face, we are confronted instead with desolate landscapes. What if instead of being a passive subject, we let protagonists take the camera where they wish to take us, and let them dictate the terms of the journey?

To empower the refugee subjects, we took four approaches to making the VR film experience: 1. We gave the family a Samsung phone capable only of taking video and

photo, and asked them to document evening activities when we were not there, and used their content in our documentary and exhibition. 2. We showed them how VR filmmaking works from taking footage to importing to stitching to viewing the binocular result on a phone, then asked them to take the camera around the house and beyond to give us a tour as they pleased (Fig. 4). 3. We followed the subject around as they move about town, so that we with the camera mounted high above us on a tripod, is the follower to the initiative of the subject. 4. We let the children learn about VR filmmaking via demos and then let them pass the camera between themselves, allowing them to see what their presence looks like on the stitched video on the computer. This allows them to play with passing the perspective amongst themselves, and with the audiences' view using their own creative movements (Fig. 5).

Figure 4: Empowering refugee subjects in creating their own voice. (Top) Providing a phone and instructions on use to a family member so that they can be free to document their evenings during Ramadan. (Bottom) Mofizur Rahman giving a tour of his home using a 360 camera as perspective.

The result of this initiative-based filmmaking is an increase in the way the refugees promote their own stories. After learning initially about how their movements in space in the camera translated to a 360 view that evolves in time on the computer and in binocular form in the phone, they began taking the camera to places we did not envision. Mofizur Rahman put the camera high on the cabinet when the family began making Semai cakes, to give us a better view. The children took turns playing with the camera, giving it to each other without choreography. At the football field, following the person pursuing the ball led everyone to follow the camera, and to play with it as if it was part of the game they are orchestrating. When we showed the children the footage they helped to make, they flocked to the computer and marveled at the technology.

Dynamic Video and Audio The static nature of video and audio in VR productions makes it seem as if it's part of the limitation of the genre. Refugee VR films are reluctant to tire the audience, or push the boundaries of camera movements. In "Meet the Soldier" [5] and "Refugees," VR films from Scopio, soldiers running to refugees arriving on harbor is portrayed without a jolt of movement of the 360 view. While dynamic events like shooting and pushing occur all around, the audience is fixed to the ground without a trace of movement. This is used by major VR refugee releases, along with Westernized music that often don't fit. It caters to the eye that is used to cinema: subtitles, fixed camera, sad music. To document the refugee experience as opposed to a sad vision of them (who are happy and playful), we play with perspectives and surprises, to fit the medium to the view of the subject as opposed to our own.

Figure 5: Empowering refugee subjects in expressing their own voice. (Top) Following the trek laid out by Mofizur Rahman as he takes his friends and us around the camp, showing us his favorite places. (Bottom) The children passing the 360 camera around amongst themselves, playing with perspective.

To show dynamic interactions reminiscent of play, we traveled with the 360 camera either on a tripod that we move, or by hand hold. We also enabled static scenes where families are eating or making food, only to have Mofizur Rahman take the camera during the recording and go outside. There are movements in vessels like the vehicle that took us to camp, in refugees taking the camera to places like football fields and kitchens, and in the cinematographer following the subjects while carrying the instrument (Fig. 6). Interactions are unpredictable, such as when children interrupt us from behind, taking advantage of the VR medium to truly use all 360 degrees.

Audio of our VR experience is also dynamically enabled

to surprise and play in 3D. Family members frequently interrupt our movement in following Mofizur Rahman with voices that occur behind us as we move forward, causing audiences to turn around, a feat that is unique to VR compared to 2D, and which is not taken advantage of by static-scene VR refugee films. We also used only original voices of the refugees with subtitles placed at the location of their speaking to heighten the immersion with spatial audio (Fig. 6). We used music improvised by Rohingya musician Takir, recorded by the group Music in Exile, to give a genuine voice to Rohingya musical creative roots, as opposed to Western traditions. The resulting production is filled with Rohingya initiative, collaboration, and influence.

Figure 6: Audio and spatial dynamism. (Top) Following a player with 360 camera during play while he chases the ball, as if audience is also chasing the ball. (Bottom) Subtitle coupled to place in the environment where voice should emanate or point towards.

Story Experience

The audience arrives in Balukhali on a jeep and realizes that it's a dynamic immersive experience, because she is in a moving vehicle throughout. At the family hut, Mofizur Rahman introduces himself, poking his head in from the window, and gives her a tour. The footage is shot by Mofizur holding the 360 camera. The tour begins outside the window overlooking the landscape and brings the audience into the shack. The music of Rohingya by Takir plays in the background, as recorded by Music in Exile. Mofizur dictates the terms of viewing, going fast at times and slow at others, making the experience spontaneous for the viewer, who feels as if her hands are led by the boy. The tour ends in the living room, where the family gathers. The scene changes from a 360 video to a 3D scene where the viewer can move around and interact. When the viewer gets close to a family member she triggers conversations. Each family member

Figure 7: Storyboard of VR experience (part two). All scenes are 360 video, but scenes 1,2,3,5 have dynamic camera moves.

has a recorded voice in Rohingya language from the interview, with English subtitles. The words give her clues about family life far from their native homes. When you approach Ehsan, he says “during Ramadan whenever I sit to pray, I pray for my daughter, for her soul; I couldn’t give her water when she died.”

After talking to 3 family members, the scene moves to the kitchen, where Ameena is making preparations. Here, when items are collided with, Ameena narrates what the item means to her and Shamima. When you touch the pot, Ameena says in Rohingya “when we left Myanmar we could only bring our pot with us, it’s ancestral memory; inside is Shamima’s favorite food Semai that we made together.” After interacting with at 3 items, the scene shifts to Mofizur Rahman, who takes the viewer out of the house to show you around the village (Fig. 7). As we look from above, Mofizur talks during his tour about how each location you see is like his home in Patiya Para, Myanmar. When we reach the football field, Mofizur is reminded of how they would tease Shamima by passing the ball around. Triggered by this memory, the scene becomes a dynamic scene, where the friends play chasing the ball. The audience runs after the child chasing the ball as others pass the ball around. We realize that Mofizur is emulating his sister chasing after the ball, because he would pant her name.

After playing, Mofizur takes us back home by a different way across a bridge. As we walk beside the children, we can talk to them by triggering. They each know Shamima in their own way, and talks about what she did back home, and what home means. When back in the hut children pass the camera around as the viewer gets a closeup of each family member exchanging hugs and kisses with the viewpoint that shows their affection (Fig. 8). The audience realizes she is now representing Shamima to the family because they are all hugging the audience with salutations reminiscent of what they said to Shamima. The audience has gathered what’s known about Shamima in this journey, and has come to represent her to the family. The scene is shot collaboratively so that children can move the camera in the direction they deem personal to them. After the hugs, Mofizur gets the last kiss. He takes the camera that is the audience and, once the room clears, puts the camera away, as if he is putting Shamima away as well. The camera (and thus the audience) is put inside the blankets and the VR scene closes like a curtain to black, just as the Rohingya music finishes. SHAMIMA as a memory has been kept in this VR experience and it’s now time to let her go back.

Figure 8: Storyboard of VR experience (part three). Conclusion of VR experience consists of camera passing amongst the children.

Abstract

Adverse childhood experiences (ACEs) are an underestimated public health threat. It impairs children's brain development, immune system, and hormonal systems. These impairments predispose children to various chronic mental and physical diseases. However, its negative impacts are not widely known by the general public. Chang Liu created a mixed reality (MR) installation based on her personal experience with ACEs and ACEs related Post-traumatic stress disorder (PTSD), which aims to provoke the audience's reflection on ACEs and the influence of their upbringings on their mental and physical development. We conducted semi-structured interviews with 12 audiences, and their response to this MR installation was analyzed using the thematic analysis method. The analysis proved that this MR installation is capable of eliciting the audience's reflection on ACEs and their upbringing. In addition, The VR experience enabled participants to emotionally and somatically experience several symptoms of PTSD, and 75% of the participants demonstrated a high level of emotional self-awareness during the VR experience. Lastly, the analysis revealed that participants who had never encountered ACEs are more likely

to sympathize with both the victim and abuser in a fictional narrative about ACEs than those who had undergone ACEs.

Keywords

Mixed Reality Installation, Adverse Childhood Experiences, Augmented Reality Installation, Interactive Virtual Reality Narrative, Spatial Montage, Emotional Self-awareness, Post-traumatic Stress Disorder.

Introduction

ACEs are an underestimated public health concern that has garnered increased attention from academic researchers but is still poorly understood by the general public. ACEs refer to family-related traumas that individuals experienced during their childhood, such as 1)being psychologically, physically, and sexually abused, or 2)being raised by parents who have mental illnesses, substance use disorders, and criminal records, or 3)being forced to witness domestic violence and experience parental separation [2]. ACEs damage children's emotional, somatic, drug abuse, memory, sexual, and

aggression-related brain areas, as well as their immune and hormonal systems. These impairments predispose them to liver diseases, ischemic heart diseases, cancer, pulmonary diseases, and chronic mental disorders such as depression, anxiety disorder, PTSD, and borderline personality disorder [2, 12, 15]. Moreover, sufferers of ACEs tend to adopt health risk behaviors such as smoking, drinking alcohol, drug abuse, overeating, and sexual activity as the coping mechanism for their distress, which significantly reduces their life span [12].

ACEs are shockingly prevalent. The World Health Organization's survey of eight European countries found that more than half of respondents had encountered at least one type of ACEs [5]. According to a meta-analysis of 47 research articles on the prevalence of physical abuse among Chinese citizens under the age of 18, 36.6% of children in China are subjected to physical abuse [17]. A survey across 34 states of the United States reports that 57.8% of respondents had experienced at least one type of ACEs, and 21.5% of the respondents had experienced more than three types of ACEs [13]. According to a survey performed among young adults in South Africa, 45% of participants reported the experience of at least one type of ACEs [20].

It is crucial to inform the wider public about ACEs so that new parents or expectant parents can be aware of the constituents and consequences of ACEs and may therefore deliberately prevent child maltreatment. Additionally, people suffering from sequelae of ACEs can discover that ACEs are the root of their persistent mental and physical diseases, allowing them to seek more effective treatments for their diseases. Chang Liu is an example of a patient who realized at age 24 that her chronic depression, anxiety, and suicidal ideation were closely related to her ACEs. She used to rely on depressants for temporary relief until she met a therapist who identified the abnormality of her childhood experience and guided her to disclose all of her ACEs. Chang Liu was diagnosed with childhood PTSD, and her therapist started treating her depression and anxiety disorders by releasing negative beliefs, emotions, and somatic sensations linked with her traumas. After two years of treatment, Chang Liu's mental condition improved significantly; she had fewer nightmares, panic attacks, and intrusive memories and emotions.

To encourage audiences to reflect deeply upon ACEs and their upbringings, Chang Liu created an MR installation that depicts several aspects of ACEs using various media and narrative strategies (see Figure 1). This MR installation is highly interactive and immersive, but it also contains elements to motivate the audience to reflect while they are actively involved in the narratives. This MR installation features three immersive yet thought-provoking experiences:

- An interactive augmented reality (AR) installation that juxtaposes a holographic animation, a sculpture, and viewers' reflections on the holographic screen. This installation aims to encourage audiences to think about the duality of kinship: nourish/shield vs. erode/fetter (see Figure 2).
- A collage film to inform the audiences of signs of domestic abuse and to provoke reflection on the phenomenon that domestic abuse is often passed down through generations.
- An interactive virtual reality (VR) narrative that immerses

viewers in the inner world of Chang Liu, a patient with childhood PTSD. This work aims to stimulate audience reflection on the consequences of ACEs.

Artists and researchers have been utilizing virtual reality (VR) as a means to reveal the subjective experience of people with mental illnesses such as Autism [27], Bipolar disorder [6], Narcolepsy [4], Dementia [24], and Chronic fatigue syndrome [23]. To our best knowledge, *Nevermind* is the only VR artwork that attempts to raise public awareness about PTSD. However, it only depicted the amnesia experienced by PTSD patients and did not mention any other PTSD symptoms [25]. We presented an interactive VR narrative that enables viewers to gain an insight into PTSD by emotionally and somatically experiencing several PTSD symptoms: emotional numbness, hypervigilance, and intrusive memories. Additionally, this VR film motivates audiences to be consciously aware of their emotional arousal to facilitate their interpretation of the spatial montage within this work.

Narrative Design

Interactive Augmented Reality Installation

The AR installation consists of three parts: a sculpture, a holographic screen projected with animation, and audience participation. When the viewer approaches the holographic screen, his/her body movement will be captured by a depth camera, and the captured image will be projected onto the holographic screen in real-time, which blends with the abstract animation. This arrangement aims to make the audience feel that he/she is no longer the spectator but the protagonist of this animation.

The animation is inspired by Nicole M. O'Neil's poem "A family is like a circle" [22]. The audio of Chang Liu reading this poem accompanies the holographic animation, describing the positive aspect of kinship: the bond between family members is unbreakable; family is always there to watch over and support us; parents educate and enlighten us through their words and behaviors. In contrast, the animation depicts the negative aspect of kinship: the indestructible blood ties could also be lifelong torture from which one cannot escape; the excessive attention from family members may evolve into ceaseless blaming and abuse; Parents will stifle children's autonomy by imposing values on them. The juxtaposition of the poem and the animation emphasizes the duality of consanguinity: nourish/shield vs. erode/fetter.

The sculpture is a metaphorical representation of children growing up in an abusive family, who are like the seedlings rooted in noxious soil. The vines twined around the sculpture symbolize blood ties that fetter and erode the children; the mutated lower part of the sculpture indicates the emotional numbness and impaired physical health of abused children (see Figure 2). The juxtaposition of the sculpture, the animation, and the audience's reflection on the holographic screen will prompt the audience to associate the holographic animation with the sculpture and to associate the entire installation with his/her personal experiences; thus, the audience will be guided to reflect on kinship by recalling his/her upbringing.

Figure 2: The AR installation consists of a sculpture, a holographic animation, and audience participation. ©Chang Liu

Collage Film

Domestic emotional abuse is often overlooked by the public and victims because its effects take time to manifest. Long-term emotional abuse leads to severe damage to a child's "intelligence, memory, recognition, perception, attention, language, and moral development" and causes various mental and behavioral disorders such as anxiety, depression, self-abasement, social withdrawal, and emotional dysregulation [32]. Chang Liu created a collage film to promote public awareness of emotional abuse. The film depicts various forms of emotional abuse that may occur in a family, such as isolation, acting superior, emotional blackmail, invalidation, having unrealistic expectations, nitpicking, and over-control [10].

Research suggests that people will have more empathic responses to the narrative when it is claimed to be a real incident or adapted from a real incident [9]. In order to suppress the audience's emotional engagement and foster their reflective thinking, Chang Liu developed the collage film using footage from several fictional films portraying domestic violence. These fictional films are listed at the end of this collage film. The first half of this collage video depicts various ways in which parents mistreat their children, while the second half of this video reveals the abusive parents' ACEs. This film structure highlights the concept that domestic violence is like a curse that is passed down through generations.

The Hemingway curse is an example of the vicious circle of domestic abuse. The traumatic childhood was the key factor that led to the mental and behavioral issues of Ernest Miller Hemingway, which were exacerbated by his physical impairments and ultimately culminated in his suicide in 1961. Ernest's father committed suicide in the same manner in 1928. After Ernest's death, Ernest's youngest brother also performed suicide with a gun. The granddaughter of Ernest, Mariel Hemingway, claimed publicly that her parents struggled with alcoholism and depression. As a result of their father's physical and emotional abuse, she and her sisters suffered from a variety of mental illnesses [21, 14].

Interactive Virtual Reality Narrative

Emotional numbness is a common psychological dysfunction among sufferers of childhood PTSD. Stressful events result in endorphin hypersecretion, which immediately alleviates an individual's fear and pain associated with the stressful circumstance; nevertheless, endorphin hypersecretion also weakens the individual's awareness of all types of emotions [11, 1, 26]. Through repeated activation of endorphin hypersecretion, an individual's fear and pain responses to stressful situations get weaker and weaker, while his/her numbness to stressful situations becomes stronger and stronger. Thus, for people who have endured years of mental and physical torture, emotional numbness will become their primary response to domestic abuse-related stimuli [29].

As a consequence of their diminished perception of any feelings, individuals who experience emotional numbness are afflicted by a sense of being disconnected from others, and they may feel as if they are affectless characters living in a simulation game. This mentality leads to the patient's deep feeling of unreality and unfamiliarity with the real world. Chang Liu disassembled and rearranged the 3D scans of Hong Kong's landscapes to make audiences feel unfamiliar with their everyday lives, which is expected to elicit the audience's feeling of unreality for the real world (see Figure 3). Furthermore, audiences could move freely in the VR world using the controller, but their existence in the world remains ghost-like due to the lack of a controllable body in the VR scene. This interaction modality is expected to make the audience feel detached from their physical being and the external world.

Whenever people with PTSD encounter sensory stimuli associated with their traumatic experience, they will simultaneously experience hypervigilance and intrusive symptoms. Their suppressed memory fragments of being traumatized and the somatic and affective sensations accompanying those memories will be evoked; Their sensory perception will be heightened, and they will suffer from great anxiety. To provide audiences with an emotional and somatic experience of this hypervigilant mental state in VR, Chang Liu designed a mechanism that can transfer viewers from open and bright city scenes consisting of realistic 3d scans to enclosed and dusky spaces made up of 2d videos and 3d animations (see Figure 3).

This abrupt change in space and visual aesthetic is intended to make the audience feel alert. The experience of being trapped within an enclosed and dark area is expected to heighten the audience's sensitivity to sensory inputs. Following that, viewers will watch a fragment of Chang Liu's traumatic memories inside this enclosed space, after which they will be transferred to a world that represents Chang Liu's hypervigilant mental state. In this world, the audience can see how the arousal of traumatic memories affected Chang Liu's perception of reality, and hear her internal monologue describing her physical and psychological abnormalities. Portals are provided for audiences to return to this film's initial city scenes that represent Chang Liu's habitual mental state. In this VR experience, there are four enclosed spaces to reveal the traumatic memories of the Chang Liu, which can only be accessed through the four portals distributed over the initial

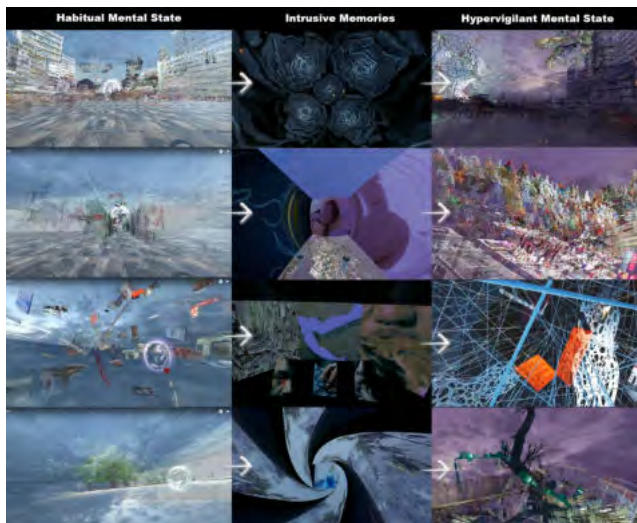

Figure 3: The VR simulation of PTSD patients' psychological shift after exposure to intrusive memories. ©Chang Liu

city scenes. This arrangement aims to provide audiences with an in-depth understanding of PTSD sufferers' psychological shifts by transitioning four times from the city scene to the memory space and finally to the chaotic world (see Figure 3).

Chang Liu's hopelessness and fear of being chased down a street by his abusive father are shown in the first memory space. Images and sounds in the second memory space portray the Chang Liu's emotional numbness following her mother's neglect. Chang Liu's mental state while being fostered and emotionally abused by her parents' siblings is represented in the third memory zone. Chang Liu's longing for maternal love is shown in the fourth memory space.

The memory spaces in VR are constructed based on the theory of embodied spacial montage (ESM), which aims to let the audiences subjectively experience the inner feelings of PTSD patients when intrusive memories overwhelm them. ESM is a theory presented by Sojung Bahng, who expanded the montage theories of Eisenstein and Manovich to emphasize the special role of VR in facilitating the audience's interpretation of montage. Bahng's ESM theory built upon the idea of Eisenstein that montage is an intersubjective collaboration between audiences and the film in which the subjective interpretation of the audience is indispensable. Additionally, this theory was formed based on the spatial montage theory devised by Manovich, which emphasizes the systematic juxtaposition of heterogeneous elements such as photography, audio, and computer-generated graphics within a 2d or 3d space as an alternative to the traditional sequential model of montage. Bahng pointed out that the bodily and emotional sensations elicited through the embodiment in VR can facilitate the audience's interpretation of the spatial montage [3].

Inspired by ESM theory, the four enclosed spaces in VR that represent Chang Liu's traumatic memories are composed of heterogeneous elements such as 2D videos and abstract animations, as well as 3D objects and animations. However, a random juxtaposition of various elements cannot be

called spatial montage. Manovich believes that spatial montage must adhere to two criteria:

"Juxtapositions of elements should follow a particular system, and these juxtapositions should play a key role in how the work establishes its meaning and its emotional and aesthetic effects [19]."

In concordance with Manovich's criteria of spatial montage, the placement, visual style, and order of appearance of the components of these four spatial montage areas were deliberately designed to implicitly reveal Chang Liu's traumatic childhood experience and her emotional and psychological response to these experience. For example, within one of the memory regions, the moving image that faces the audience depicts a girl sleeping on a bed. On the audience's left side, a video clip of a lady leaving with a suitcase is shown. The video on the right side of the audience portrays a bunny fairy approaching the sleeping girl. These two moving images, which are contradictory in content and visual style, imply that the mother neglected the child, who can only imagine an alternative mother to fill the void in her heart. An animation replaces the ceiling of this enclosed space, which conveys the girl's dream. In her dream, she throws off the shackles of physical beings and roams around uncharted legendary places. The floor of this space is transparent, allowing audiences to float in mid-air, and the 3d scans of the graveyard underneath them symbolize the cruel real world. When the girl wakes up, the audience will drop to the scene beneath them. The contrast between the images of the ceiling and floor indicates that the little girl fantasizes to escape from her ACEs and the cruel reality (see Figure 4).

Figure 4: The spatial montage within the second memory zone of this VR film. ©Chang Liu

We hypothesize that immediately upon entering the confined spatial montage spaces, participants will experience emotional arousal. This hypothesis is based on David Bordwell's constructivist theory of perception. David Bordwell states that the perception of a narrative could happen in two ways.

"In top-down processing, the organization of sensory input is predetermined by the audiences' expectations, background knowledge, presupposition, and other cognitive operations. In bottom-up processing, the organization of sensory inputs happens involuntarily [7]."

Participants will be engulfed by various audio and visual stimuli scattered across the 360-degree environment when they enter the spatial montage areas. The absence of explicit connections between dispersed montage components will inhibit the audience's top-down processing of sensory inputs; thus, audiences will be forced to process these clues in a bottom-up way. Consequently, spectators may experience indefinable emotional arousal evoked by the involuntary gathering of sensory clues before grasping the meaning of the spatial montage. The desire to interpret the spatial montage will motivate the participants to make connections between seemingly unrelated visual and auditory information based on their evoked emotional and bodily reactions, as well as their experience and knowledge.

The overall process, which begins with the audience being exposed to a space filled with fragmented images and sounds, continues with the emergence of indefinable emotional and bodily feelings, and concludes with the audience's attempts to connect and interpret the visual and auditory information, is similar to how people with PTSD experience intrusive symptoms. When Chang Liu encountered trauma-related sensory stimuli in her daily life, she was engulfed by fragmented memories of her childhood traumas, as well as the emotional and bodily sensations linked with these memories. She must piece together those fragmented messages in order to create a coherent narrative that can assist in the treatment of her negative cognition about those memories.

Audience Study

Methodology

We invited 12 audiences (5 males and 7 females) to participate in this audience study, with the participants' ages ranging from 22 to 29 years old ($m = 25$). This audience study was approved by the School of Creative Media at the City University of Hong Kong. All participants signed a consent form confirming their voluntary participation. Participants were interviewed after experiencing all three parts of this MR installation. The interview was semi-structured and began with three predetermined questions:

- Does the VR narrative/ AR installation/collage film evoke any memories or feelings in you?

Based on the participant's responses to these three questions, further questions were improvised. The interview with the 12 audiences was audio-recorded and then transcribed into English text. In concordance with the criteria of thematic analysis, the data were analyzed in six steps [8]. After reading the transcription several times, Chang Liu organized and summarized the interview data to form initial codes. For example, "I feel completely numb already; even the sight of my father strangling my sister will not elicit any of my emotional reaction." was coded into "feel emotional numbness towards domestic violence." All the initial codes were then sorted to form overarching themes. Some of the themes were merged into one, and some of the themes were discarded due to the lack of supporting evidence. In the next section, I will articulate the main findings drawn from the finalized main themes.

Findings

Participants who had never encountered ACEs are more likely to sympathize with both the victim and the abuser in a fictional narrative about ACEs than those who had undergone ACEs. The analysis of the audiences' response toward the college film revealed that the intensity of ACEs experienced by participants affected their attitude toward the victim and abuser in the film. According to the personal experiences that the participants described during the interview and the definition of ACEs given in [1], P8, P6, and P11 had never encountered ACEs; P1, P3, P4, P9, and P10 suffered from emotional abuse; P12 experienced both physical and emotional abuse. P2, P5, and P7's experiences with ACEs are unknown as they did not reveal any personal experience throughout the interview. P8, P6, P11, who had no prior experience with ACEs, said they could sympathize with both the children being abused and the abusive parents in the film, who also experienced ACEs in their childhood. Participants who had encountered ACEs projected a more complicated emotion onto the abusive parents in the film. Although P3 agreed with the abusive parents' good intention to educate their children and understood their burdens, he felt angry for the parents who mistreated their children. P1 expressed resentment against the abusive parents in the film. P12 reacted to the film indifferently despite being severely abused by her family. P3, P4, P9, and P10 said they could empathize with the victims in the film. P1 showed no empathy for the victims, and P12 stated she understood the victims' situation in the film, but she could not share their emotions.

Based on the thematic analysis of the audiences' response towards the collage film, we identified a phenomenon that audiences who had never suffered from ACEs could sympathize with the victims and the abusive parents in the film more easily than those who had undergone a certain degree of ACEs. After probing into literature regarding ACEs, the mechanism of empathy, and emotional numbness, we found possible explanations for this response pattern: The second half of the collage film revealed the fragility and distress of the abusive parents who had also undergone severe domestic abuse in their childhood. According to the mechanism of empathy, when the viewers perceive the painfulness of the abuser, the mirror neuron system in their brain will be automatically activated to create an inner representation of the emotional state of the abuser, which triggers the audiences' autonomic and somatic responses to that emotion [16]. Through this process, audiences can understand the intention and emotions of the abusive parents and thus could empathize with them. However, for audiences who had experienced ACEs, empathy will not be the only feeling that appears when watching this film. The images of various children being abused in diverse forms and contexts will remind the audiences of their traumatic experiences. Recalling those memories is likely to elicit the audiences' anger and resentment toward their abusive family members. Audiences tend to project their emotions towards their abusive family members onto the abusive parents in the film; therefore, if the ACEs that they encountered were severe, audiences' rage for the abusive parents in the film might outweigh their empathy for them.

P1, who had undergone relatively severe emotional abuse,

was outraged while watching the collage film. Being aggressive is a common strategy employed by people with emotion dysregulation to terminate emotions that they are unable to cope with, such as a sense of emotional vulnerability [28]. This theory could explain P1's lack of compassion for himself and the victims in the film. P12 had no emotional reaction to the film despite having been cruelly mistreated. This non-responsiveness might be attributed to P12's emotional numbness caused by her traumatic experience. P12 said that she used to experience domestic violence frequently. According to the previously described process of developing emotional numbness, recurrent domestic abuse frequently stimulated P12's endorphin secretion. The repeated hypersecretion of endorphins progressively eliminated her fear, pain, and any other feelings and therefore caused numbness to become her primary response to domestic abuse-related stimuli [11, 1, 26, 29].

Audiences experienced PTSD symptoms emotionally and somatically in the interactive VR narrative. P1, P4, P5, P6, P8, and P9 said that they recognized various landscapes of Hong Kong in the VR film. However, the point cloud texture and the unusual rearrangement and animation of the 3D scans made the landscapes unfamiliar and unreal for them. Audiences' feeling of unreality and unfamiliarity with the surrounding environment in the VR world is analogous to how PTSD sufferers feel in the real world. P6 said that immobile pedestrians in the VR film made her feel detached from others and the rest of the world. P1 stated that the absence of a controllable body inside the VR world and hearing the protagonist's inner monologue induced an illusion that he became the protagonist in this story. He said he felt the protagonist's helplessness, loss, and panic of being isolated.

Analysis revealed that the abrupt shift of space and visual aesthetic in VR made participants feel alert (7/12 participants), insecure (5/12 participants), and nervous (7/12 participants). Furthermore, some participants reported increased sensitivity in perception inside the confined spatial montage zones. P8 said eating is stressful to her, but watching others eating in real life does not make her anxious. However, she felt very stressed when seeing people eating in front of her in the VR spatial montage spaces. P7 said that he suffers from mild social anxiety and is afraid of encountering situations in which individuals sitting near him refuse to communicate. Even though P7 was aware that the visuals of individuals eating in the VR experience were just a prerecorded film, P7 was anxious about not being able to speak with the people in the video.

In the narrative design section, we made two hypotheses based on the ESM theory and the constructivist theory of perception, which are:

- VR spatial montage may activate the bottom-up process of narrative perception, eliciting emotional arousal in spectators.
- The bodily and emotional sensations evoked by VR spatial montage may assist the viewer in comprehending the spatial montage.

Analysis of audiences' responses to the spatial montage ar-

reas in VR verified both of these hypotheses. P8 said that she instantly felt alert, scared and nervous upon entering the first memory zone. The elicited emotions and the perceived visual and auditory cues reminded her of the experience of walking home late at night. Thus, P8 concluded that this montage is intended to convey the protagonist's insecurity and fear while being chased by someone at night. P4 described feeling alert, insecure, anxious, fearful, and caged after entering the first memory region. P5 also felt alert, trapped, insecure, scared, and nervous inside the first VR montage zone. She then recalled being locked up at home, and she tried to understand the protagonist's feelings by projecting her memories and feelings onto the protagonist. Following entry into the first memory zone, P6 felt alert, impotent and upset. She said that the visuals and the elicited emotions made her feel as if she had stumbled into the protagonist's nightmare. She imagined that the protagonist felt nervous, scared, and helpless as a result of being trapped in the nightmare about her traumas. And she felt impotent and upset for her inability to help the protagonist. P2 felt alert, scared, and insecure, and P10 felt alert, impotent, and nervous upon entering the first memory space.

In the third memory zone in VR, P8 felt very stressed seeing three males eat in front of her, but she could not explain why. She speculated that this scene shows how uncomfortable the protagonist felt staying with these people. P1 was vigilant, slightly nervous, and insecure while inside this space. By associating his emotions with the image of several males eating and drinking rudely, he thought that the protagonist must feel uneasy, powerless, and suffocated when staying with these males. P3 expressed disgust, insecurity, and stress about this space. The visual clues and the elicited emotions made him worry that the protagonist was compelled to witness things she dislikes. P4 reported feeling trapped, nervous, and uncomfortable when within this place. P7 experienced feelings of unease, fear, and being trapped upon entering this area. To interpret the spatial montage, he attempted to link the visual and auditory clues that intrigued him in this emotional state. Moreover, P5 felt alert within the second spatial montage space, and P6 reported feeling comfortable and relieved in the fourth memory zone.

The spatial montage in VR elicited a high level of emotional self-awareness in the audience. The theory of levels of emotional awareness divides a person's capacity to realize his/her emotion into five levels. Individuals at level 1 are unaware of or unable to comprehend their emotional arousal and can only detect bodily arousal such as "My heart is pounding rapidly." Individuals at Level 2 have a vague awareness of their emotional arousal and can only identify it as positive or negative. Individuals at Level 3 will describe their emotional arousal with a single word (e.g., nervous). Individuals at Level 4 can identify that their emotional state is a composite of distinct emotions and can articulate each component of this composite. Individuals at Level 5 are capable of identifying not just their own mix of emotions but also the blend of emotions of others. People in Levels 1-2 are defined as having an implicit emotional awareness, and people in Levels 3-5 are defined as having an explicit emotional awareness [18]. This theory provides a standard for assessing the effectiveness of

a virtual reality narrative in eliciting viewers' awareness of their emotional arousal throughout the experience.

12 participants' emotional reactions to the four spatial montage regions were classified into five groups based on the theory of five levels of emotional awareness (see Table 1). Audiences' responses to the four VR montage spaces varied. Table 1 shows the maximum degree of emotional self-awareness obtained by the 12 participants throughout their experience of the four spatial montage zones.

	Level1 Bodily arousal	Level2 Vaguely aware of the emotional arousal	Level3 Identify single emotion	Level4 Identify the blend of emotions	Level5 Identify the blend of emotions of self and other
P1					Self: Alert, Nervous, Insecure Protagonist: Lincasy, powerless, suffocated
P2				Alert, Scared, Insecure	
P3				Disgusted, Stressed, Insecure	
P4				Alert, Nervous, Scared, Insecure, Trapped	
P5				Alert, Insecure, Nervous, Scared, Trapped	
P6					Self: Alert, Upset, Impotent Protagonist: Nervous, Scared, Helpless
P7				Nervous, Scared, Trapped	
P8					Self: Alert, Scared, Nervous Protagonist: Insecure, Scared
P9			Nervous		
P10				Alert, Impotent, Nervous	
P11	Dizzy				
P12	Heart is pounding rapidly				

Table 1:12 participants' level of emotional self-awareness in the spatial montage areas.©Chang Liu

Two conclusions could be drawn from Table 1. Firstly, the VR experience allowed viewers to emotionally and somatically experience several PTSD symptoms while retaining self-awareness that enabled them to differentiate their own feelings from the protagonist's. One possible explanation for this separation of feelings is that participants tended to associate their emotions elicited in the montage zones with perceived auditory and visual stimuli to interpret the spatial montage, which is likely to trigger participants' memories of personal experiences. The recalling of personal experiences will let the participants realize that they are the observer, not the protagonist, of this VR film. Therefore, they will be able to disentangle their recalled memories from the protagonist's story and disentangle the emotions associated with their own experiences from the protagonist's feelings.

Secondly, nine out of twelve participants reached a high level of emotional self-awareness (level 4-5) during the VR experience. This result could be particularly interesting for the research of improving people's emotional self-awareness through VR narrative. People with implicit emotional awareness are susceptible to mental illnesses. Research has proved that people with implicit emotional awareness tend to suppress their affective arousal, which, in the long run, leads to depression and anxiety disorders [31, 33]. Implicit emotional awareness can be attributed to innate deficiencies in emotion perception or acquired diseases. Psychotherapy can transform one's implicit emotional awareness into explicit emotional awareness regardless of the causes [30].

None of the participants requested to terminate the test, indicating that the emotions elicited by this VR experience were bearable and had no adverse effect on the audience. However, it is unclear that which part of the emotions experienced by participants in the spatial montage spaces was elicited by the

rapid shift of visual style and space and which part was provoked by the auditory and visual stimuli inside the enclosed areas.

This MR installation prompted spectators to reflect on ACEs and their upbringings. When watching the collage film, audiences who had no direct involvement with ACEs reflected on the signs and influence of emotional abuse by recalling the experiences of people they knew who had encountered domestic abuse. Audiences who had direct experience with ACEs reflected on emotional abuse by associating the film with their personal experiences. P1, P3, P4, and P6 reflected on the standard of good upbringing, the nature of kinship, and the influence of upbringing on adulthood when experiencing the holographical installation. Furthermore, after seeing the VR film, P1, P3, P4, P5, P6, and P8 expressed affective empathy toward the people with PTSD.

Some participants reflected on how their upbringing influenced their personality, outlook, and mental health when experiencing the holographic installation. P1 said he inherited all his parents' shortcomings. P6 said she was fettered by the values imposed by her parents. P12 developed various mental disorders under the stress of domestic abuse. P4 suffered from an everlasting feeling of insecurity and loneliness due to her father's neglect.

P12 recalled the similar feelings of being unable to control her body and concentrate when she heard Chang Liu talk about her dissociation from reality and her own body in the VR film. This abnormal mental state, as stated by P12, was attributed to the persistent fighting and arguing in her family. P1's attitude towards his parents changed after experiencing the AR installation. The collage film reminded him of his own childhood and roused his rage against his parents. The holographic installation, on the other hand, had a soothing effect and prompted him to reconsider his upbringing.

"The sentence "A family is like a circle." struck a chord with me. I realized that when I resist my parents' impact on me, my parents are fighting their own upbringing. By considering this, I understood my parents."

Conclusion

This article introduced a novel MR installation framework for provoking reflexivity on ACEs and addressed a research void by presenting the first VR artwork that can make audiences emotionally and somatically experience several symptoms of PTSD: emotional numbness, hypervigilance, and intrusive memories. Additionally, the audience study proved that the VR narrative framework presented in this article is capable of eliciting a high degree of emotional self-awareness, which is informative for future research on treating patients with implicit emotional self-awareness using VR narrative.

Pulcher Aureus Filum. Biological Substrate Computers and the Ecological Paradigm Shift

Jaime Alonso Lobato Cardoso

Research Seminar in Music, Mathematics and Computer Studies. Research Institute in Applied Mathematics and Systems. National Autonomous University of Mexico.
Mexico City, Mexico.
jaimelobatocardoso@gmail.com

Abstract

With the imminent decay of Moore's law and the difficulties in solving NP problems in computing, researchers around the world have been given the task of finding new ways to manage, process and store information. These new paradigms are known as unconventional computing and among them, biological substrate computers have been developed. These coupled logic gates do not work by directing an electrical current through circuits made of conductive materials, but with collectivities of living organisms and the interaction of their emergent patterns with specific geometries. In this article we will address the implementation of a genetic chip (bacterial computer) in the creation of an artistic work, as well as the paradigm shift from the individualistic artist to the ecology of affections.

Keywords

Human/non-human, unconventional computing, biological substrate computers, sound art, postdigital, genetics, complexity, participative art, biohacking, bioart, human ecology.

Introduction

In the last decades, a group of theories and methodological approaches known as the complexity sciences, strongly supported by systems theory and computation, have been developed, they study how and why phenomena in reality oscillate between chaos and regularity, they have been in charge of working on three main axes: the mathematical theory of computability –more properly known as the set of P-NP problems–, the relationships between the microscopic universe and the macroscopic universe, and the theory of dynamic systems. (Maldonado & Gómez, 2010)

In particular the P-NP problem informally asks which ones can be quickly verified by a Turing machine. And since there were no significant advances by the end of the 20th century, several scientists began to look for different ways to solve this problem when observing the imminent decay of Moore's law, no matter how many computers there were, the computational goal was not being reached, would it be possible to design new computational models capable of surpassing the barrier of Turing machines? (Claude, 2016)

The computers we use in our day to day are electronic computers with the Von Neuman or Princeton architecture, described by John Von Neuman in 1945 in his “First Draft of a Report on the EDVAC” (Neuman, 1945), but these are not the only computers that humans have used, calculators (*computare* in Latin means to calculate) have not always been automated and much less electronic, two great examples of ancient computers are the Mesopotamian abacus or the Inca quipu. Likewise, there are modern computers that do not work through electricity, but through water, light, colliding objects, slime molds, bacteria, DNA, chemical reactions, etc. (Adamatzky et al., 2017). And in 1994, Christian S. Claude and John Casti coined the term unconventional computations to group all these attempts to alternatively manage and process information (Claude, 2016). Thus, in 1998 they organized the first international conference on unconventional computing models organized by the Auckland Center for Discrete Mathematics and Theoretical Informatics in New Zealand and the Santa Fe Institute in New Mexico. (Claude, Casti & Dinneen, 1998)

When talking about biological substrate computations, many doubts and confusion arise about the relevance of the term. In particular with bioinformatics, which is a field of computational science that carries out the analysis of sequences of biological molecules (Austin, 2020). For this purpose, electronic computers are used and software is developed, especially statistical, as a tool to study biological phenomena. Unlike bioinformatics or bioinspired computing, biological computers do not have silicon chips, nor circuits of conductive materials through which an electric current is channeled, but excitable systems, living organisms, fluids or chemical reactions interacting with a particular geometry. Some of the biological substrate computer implementations work on the basis of Physarum Polycephalum (Schumann & Pancers, 2016), microfluidics (Gravesen, Branebjerg & Jensen, 1993), plant leaves (Adamatzky, 2019), bacterial cultures (Daniel, Woo, Turicchia, et al., 2011), DNA (Daniel, Woo, Sarpeshkar, et al., 2013), neurons (Scelfo, Politi, Reniero, et al., 2012), non-linear chemical reactions (Adamatzky, 2004), etc. And in some of these paradigms it has been possible to flatten the exponential growth of time to solve a problem (Zhu, Kim, Hara, et al., 2018) or implement non-deterministic universal

Turing machines in a successful way (Currin, Korovin, Ababi, et al., 2017).

The work presented in this article is based on the computer model of bacteria that appears in the article “A synchronized quorum of genetic clocks” (Danino, Mondragón, Tsimring & Hasty, 2010). These *Escherichia Coli* bacteria have inserted a plasmid that functions as a genetic oscillator, known as the Elowitz represilator (Elowitz & Leibler, 2000), and in order to see the phase of this oscillator it also has the luxI operon of the *Vibrio Fisheri* bacterium. In this way, *E. Coli* is made to glow artificially and intermittently (an effect similar to fireflies), making it possible to visualize the processes of bacterial communication, known as quorum sensing. The system allows bacteria to produce acyl-homoserine lactone (AHL) which is the molecule with which they can communicate and the geometry of the chips where the culture is placed allows it to spread in different ways, this causes the bacteria can synchronize in various ways and bring out different spatio-temporal patterns. The paper shows two possibilities, the first is a circular space where over time all bacteria synchronize because the wavefront can diffuse in a regular and symmetrical way. The second option is a very elongated rectangular space in which the bacteria culture presents an asymmetric emergent pattern, like doing the Mexican wave. So, the geometry of the chip affects the distribution of the inducer molecule (AHL) thus this relationship controls a community of coupled oscillators that allow activating the computational mechanisms of this computer.

Pulcher Aureus Filum

Pulcher Aureus Filum (from Latin: A Beautiful Golden Thread) is a processual work of art. Inspired by the genetic chip work cited above, this work attempts to produce all the tools necessary to create a computational work of art and not just a computer-assisted audiovisual work of art. The shapes of a computer as the basic element for the creation of a work, the computer as an aesthetic object and all the human aspects that surround this cultural artifact, not only what can be produced with it. The creation of a spatial-sound work that represents the forms that human cognition generates when encountering a specific problem.

Let's take an example within a more familiar paradigm, the world of oil painting. In analogy let's say that for this work we would like to build all the tools and materials necessary to paint an oil painting. Learn carpentry to make the brush handle, godet, frame and easel; learn the chemical bases for making linseed oil and natural pigments; learn textiles to make a canvas. And then make an oil painting as a synthesis of this ecology of knowledge.

In the specific case of the work in question, the central technological development was a bacterial computer, so first the tools were developed to be able to insert a plasmid into the bacteria that would make up the genetic chips. An openPCR, an electrophoresis machine, a transilluminator, incubators were built, some machines such as a microscope, micropipettes, as well as glassware were purchased. (Fig. 1)

Fig. 1. Detail of the Pulcher Aureus Filum installation, showing the molecular biology tools that were developed for the project.

At the same time that the instruments were built, the design of the chips began with the help of digital manufacturing techniques (3D modeling, 3D printing and CNC router). The limits of these tools were tested to be able to design and generate the chips, what materials could work and how much could the experiment be scaled? (Fig. 2)

Fig. 2. First prototypes of genetic chips. With 3D printing with PLA (polylactic acid) filament and roughing with a CNC machine on solid polycarbonate.

Implementation of a genetic chip for transmedia art creation.

The chips were designed with 3D modeling software called Rhinoceros and manufactured with a CNC machine on the material known as solid polycarbonate. This material was chosen for its characteristics: at least 200 times more resistant than glass, it is lighter than glass, high transparency and up to 90% light transmission, protection against UV or IR rays, it can be modeled with thermoforming, formed cold and CNC, electrical, acoustic and thermal insulation, corrosion resistant. This allows to contain culture media for bacteria and supports the autoclave protocol.

This computing paradigm is not based on the implementation of software on specific hardware, that is, the world and its properties are not digitalized in a binary formal representation, but matter and its emergent properties are directly computed, therefore the shapes in which the hardware is designed to manage the information is also the software, the geometries of the chips are in some way a geometric programming language and the kernel of this computer can be conceptualized as the emerging patterns that are produced by the interaction of the quorum sensing and the way in which the chips allow the diffusion of the inducer molecule (AHL). This programming language can be considered an object-oriented programming language with a prototype-based approach also called classless or instance-based approach. The notion of object is based on stationary nodes of a Bayesian network with attractive capabilities that can be placed differently to obtain different topologies.

The proposal is based on the creation of small geometric units that we will call primitives. These were designed thinking in the easiness of information flow through their geometries in mind. (Fig. 3)

Fig. 3. Primitives and first combinations.

Here are 4 of the 12 chips designed based on these primitives, extending the first 4 combinations. (Fig. 4)

Fig. 4. Variations on the chips.

The logic that chip designs follow responds to two important factors, the first is different types of width in the communication channel between the circuits, the second is the connectivity between each of the nodes and the third is the number of obstacles. It finds the expansion front of the wave and the critical size it has to have to interrupt its continuous formation. This first group of chips can be placed between abstract machines for parallel programming and abstract machines for specific purposes: group theory and boolean algebra.

Once the programming language and the first designed chips were finished we began to create a culture medium with the biohacker protocol and to plant the bacteria in them, the bacteria used were genetically modified *Escherichia Coli* (Figure 5) and *Vibrio Fischeri* (Figure 6). The behaviors of these bacteria were analyzed through computerized vision algorithms to collect data on the space-time rhythms that emerged. This data was analyzed with algorithms in Python, then used as a database to control the video mapping of the final piece.

Fig. 5. Escherichia Coli cultures and chips.

Fig. 6. Aliivibrio Fischeri cultures and chips.

At this point in the development of this work, several of the considerations of the original publication had been put to the test in terms of the possibilities and restrictions of working with bacteria and its relationship with the physicality of the culture medium, as well as the technical challenges to scale these chips. Creating artificial spaces to make bacteria inhabit allows us to understand why they appear in nature in one way or another and not in another.

Another consideration of this experiment was directly aimed to bacteria as living beings, not only as parts of a biotechnological device that allows solving boolean, arithmetic or geometric operations. The fact that the bacteria are glowing means that we are stressing them to limit levels and the colonies at some point begin to compete for food. All the studies on quorum sensing allow us to conceptualize bacteria as collective, perhaps social, entities, which is why it was necessary to generate a level of empathy and affection for bacteria. In contrast to electronic art works where sensors and even biometric sensors are used, this work proposes being participatory, changing the place of tools for accomplices. But how to achieve this post-anthropocentric approach without falling into the simplistic and humanized

idea of the pain of another species? The answer was proposed as a sound action.

K'usi avo'onton (Maya Tzotzil for “How is your heart?”). Collaborative sound piece

Scaling this synchronization phenomenon on a human level represented an almost unattainable theoretical and energetic challenge for an artistic project. But if bacteria could give this work their light, humans could give it their voice. The sound part of this work was an active meditation. This meditation consists in that the assistants can sing anything, in any volume, with or without lyrics, with any technique that is within their reach. As part of the work, a choir is also included that is presented in the action in an unknown way, the public does not know that there will be a part of the work where professional singers will sing with a score written by the author. The parts of the action are divided into three:

- 1.- Introduction: everyone begins to breathe deeply and listen carefully to their surroundings to enter a state of meditation. They are all with their eyes closed.
- 2.- Prelude: Everyone begins to emit voice, softly and warmly.
- 3.- Theme: Everyone begins to sing freely increasing the intensity little by little.
- 4.- Autoinductor: The choir begins to sing the part written for them.
- 5.- Cadenza: The author makes a voice solo with harmonic singing and a loop station, spatialized in a quadraphonic system.
- 6.- Coda: The chorus returns with the meditation mechanics and everyone begins a decline to total silence.

This action was recorded with 8 independent channels in different places in the space in order to be able to analyze them later and determine the areas and ways in which the public was synchronized and desynchronized at the frequency level. The analysis made it totally conclusive that the deterministic written part made the whole group of people synchronize in a very tight way, and when finishing little by little they were changing notes and harmonies, but they did not completely desynchronize. The traditional mechanism of the score where a composer in a deterministic way organizes a group of people served as the AHL, having a minimum percentage of people with a common agreement, the rest were added to the agreement and the notes of the score functioned as the geometries applied in the genetic chips designed for this piece. (Fig. 7)

Fig. 7. Details from the audiovisual register of K'usi avo'onton.

When analyzing the data from the two experiments it became clear that each of the spatial scales has its own characteristics and laws. Even so, all these scales coexist in the same space simultaneously, that is why physics continues to search for that theory of everything that allows us to encompass our reality regardless of the spatial or temporal scale to which we refer. But, within these changes of nature in the spaces there is an element that transversely crosses these limitations indifferently, and that is the information. Absolute of physicality, information, as well as matter, is neither created nor destroyed and we could add that it does not transform either depending on its environment. The different scales are like the beads of a universal necklace, and these are linked by a beautiful informational thread, a beautiful golden thread.

The transmedia installation that synthesizes all this process consists of two parts. The first is a totemic sculpture inspired by the shapes of the chips, a work that aesthetically exposes a computational code that, although functional, appears encrypted to the public in the presentation, in the manner of the obfuscated code tradition. On this piece a generative video mapping is projected whose seed of behavior is the

data collected from the genetic chips. On the other hand, the sound is composed of the 8 recordings of the active meditation spatialized in a quadraphonic surround sound system, in the same way, the behaviors of the spatialization are fed by the data of the spectral analysis carried out. A spatialization technique developed by the author known as spectral granular synthesis is used. But the work overflows the exhibition space, it is not only made up of material objects, but also of interpersonal relationships and an ecology of knowledge that simply cannot remain in a museum on display. (Fig. 8)

Fig. 8. Detail from the installation-lab "Pulcher Aureus Filum".

Discussion

One of the most important challenges of this project was to be able to transcend the barrier of technological development to impact aesthetics, to be able to propose a new artistic form, instead of only producing transmedial art in the same way, but with computers with a biological substrate. This intention was achieved in the participatory performance that sonified the project, so we will focus on this participatory performance in the discussion.

A work of art is hardly exhausted in itself. As a cultural artifact it is inevitably associated with its context, so the relationship of its meaning with its signifier does not exhaust its communicative possibilities. It is also deeply related to the audiences to which it is addressed and with the way in which the message is distributed, or how it is presented to the public. This trifecta can be considered as the scheme of relationships that allows us to analyze a work of art as a complex system.

The invention of the score in the West marks a foundational milestone in music because it changes the way in which the figure of the performer, the composer and the audience begins to separate. In the oral tradition there is no defined

composer who tries to send a message to a specific audience, rather there is a custom that is transmitted from generation to generation and that is enriched with the passage of time, each of the interpreters recreates the work. But with the invention of the score, a process of change began, a composer leaves expressed in a graphic text indications for an interpreter to activate the text in front of a listener. And with the standardization of symbols, music can travel faster through different contexts, languages and cultures, with the promise of breaking the barrier of time and lasting, the most ephemeral art of all managed to petrify itself to become an object.

For several centuries the score served as a tool that facilitated communication between the parts of the world of music and was quite open, there were many opportunities for the interpreter to improvise and to be part of the recreation process of the work, delivering a more collective message to the listener. But with the rise of the bourgeoisie and the industrial revolution, the composer emancipated himself from his role as a craftsman and servant of some court or abbey to become a solitary genius who gave his art to the world. The opportunities for the interpreter to improvise decrease, the passage of time is regulated by the metronome, the spatial component is flattened by the uniqueness of the "Italian theater", the consolidation of musical groups like the orchestra leaves little room for timbral variation and the indications of the score begin to mutate, from suggestions to reactivate a sound text into orders for a performer to move his body and activate a musical instrument. From the listener-interpreter-composer that existed in the oral tradition, the communication scheme separates these figures and distances them from each other. The composer as the epitome of individuality delves into himself to produce an increasingly accurate score, the interpreter has to do a research exercise to decipher the meaning of the work that he is going to activate and the listener becomes a passive agent that receives this complex semiotic process as a black box.

The next phase in this process is radicalized in the twentieth century, the individuality and the composers own voice becomes so important that they even stop using the conventional score and begin to create their own symbol systems, which instead of representing the sound they want to hear, indicate the way in which the performer's body should move, music has not only been stripped of its cultural but also organic dimension, two of the post-war composition currents represent this agenda: integral serialism and the new complexity. Some reactions to this aesthetic fashion are the open/graphic scores and free improvisation that try to reduce the communication gap between composers and performers by merging them, but the public continues to be

left out of the creation processes, the concert halls represent that agenda and begin to be emptied. There are even composers who wonder what does it matter if you listen? (Babbitt, 1958) They not only get rid of the interpreters with the use of electronic and automated instruments, but also the listeners to whom the doors of any dialectic exchange have been closed in the generation of this art.

In the work *Pulcher Aureus Filum* there is a post-anthropocentric intention in relation to the relation with bacteria in such a way that instead of projecting human cognition onto bacteria, it is proposed to replicate the experiment on a human scale in order to imagine how could be the process of information exchange between them. On the other hand, the experience acquired in the design of the chips was transferred to the strategy to generate a sound work, in this paradigm the components that traditionally find in an electronic computer are unified: the circuit, the kernel and the software are one and the same. They activate through a collectivity of coupled oscillators. In the case of this participatory performance, the communicative scheme is articulated as follows:

Addressing the listener

The public is invited to take part in an active meditation. They are invited to participate actively in the creation of the work and in a way in which you must turn off your mind to reach the desired state, it is important for the work that there are no intellectual exercises to relate the parts of the work and thus understand the "form", but rather an intuitive flow in collectivity.

Space of the presentation

The space where the play takes place is not a concert hall with an Italian theater layout, but a garden near an ecological reserve where the experience will be totally immersive. As part of this performance of vocal synchronization, there is a mixed choir that at some point in the work sings a written part and is located randomly, in such a way that the audience is completely spatially mixed with the performers.

The relation between the meaning with its signifier

Inspired by non-linear systems of equations, the strategy of using active meditation as a structuring method of a sensible experience allows the components of a concert to be unified, as happens with genetic chips. The public becomes a performer and a composer. The interpreter becomes a public, due to the indeterministic component of the work and a composer. And the composer becomes an audience and a performer. Although human beings cannot shine, they can sing, so the method to analyze their synchronization is through the Fast Fourier transform, the louder the content, the less synchronization and the fewer beats appear, the

more synchronized. Intuition and active listening of each of the participants works like the AHL. And the score that the chorus sings works like the geometries of the chips that channel the information towards certain synchronization vectors.

In his composition treatise, Arnold Schönberg describes musical form as the sequential organization of the parts of a work, as well as the relationships between them, like those of a living organism, but deployed in time; logic, coherence and kinship as qualities of a composition to make it intelligible. On the other hand, an active meditation is an amorphous mass of unconnected events from which a structure emerges thanks to the resonance by empathy of the participants, it is not a structure imposed by an abstract and distant agent, but a timbre relationship to which all the participants arrive. Participants by connecting with others. The feeling of well-being and self-awareness as an abstract machine model, a social computer with a cohesive swarming kernel by active listening, intuition and empathy.

Author Biography

Multimedia artist, composer, curator and independent researcher. He made his studies at the Faculty of Music in the National Autonomous University of Mexico (UNAM). He has had three solo exhibitions, at the Sound Experimentation Space in the University Museum of Contemporary Art, at the Laboratorio Arte Alameda, and his retrospective at the Contemporary Art Gallery in Xalapa, México. His work is part of public and private collections. As a multimedia artist he has participated in several collective exhibitions in Mexico, Berlin, New York, Madrid, Montevideo, Hamilton, Saõ Paulo, Bergen, Tallinn, etc. He is founder of SEMIMUTICAS Research Seminar in Music, Mathematics and Computer Studies and Independencia BioLab a biohacker space based in Mexico City. He has several international publications in conference proceedings, journals and books, in editorials such as Cambridge Scholars, Springer-Verlag, Taylor & Francis, the Institute of Electrical and Electronics Engineers, Siglo XXI and the Mexican Mathematical Society.

Towards a Theory of Machine Learning and the Cinematic Image

Owen Lyons

Ryerson (X) University
Toronto
owen.lyons@ryerson.ca

Abstract

This paper addresses the state-of-the art and prehistory of machine learning technologies as they pertain to the moving image. It discusses the challenges and potential hazards of these technologies, before showing how artists and image-makers are using these techniques to create a new relationship to the space of the cinematic in the age of big data. This paper strives to interrogate and overcome technologically deterministic accounts of this new technology. Accordingly, it situates examples within the discursive fields from which they emerge and favors diachrony over synchrony in outlining four clusters of media-archaeological inquiry that intersect in the application of machine learning techniques to the moving image. In so doing, it seeks to acknowledge the ideological problems inherent in the hegemonic adoption of machine learning tools while attempting to theorize the potential of machine learning in its application to the moving image and cinematic production.

Keywords

Machine Learning, Artificial Intelligence, Cinema, Cultural Analytics, Surrealism

Introduction

Within the last decade, and due to key technological breakthroughs, interest in the application of artificial intelligence to the production of imagery has reached fevered proportions. A focus on the imminent arrival of artificial *general* intelligence – i.e. the full simulation of human cognition – has overshadowed a potentially more interesting reality. For decades, discourse on AI was heavily influenced by Raymond Kurzweil’s notion of the “singularity” – i.e. the application of the simple geometric sequence that informs “Moore’s Law” to the highly complex problem of the simulation of human intelligence. Kurzweil was, and still is, a major theoretical touchstone for both the Californian ideology and popular culture, and his work speaks to a broader expectation that these technologies are clearly progressing towards the end goal of mimicking human intellect. However, the development and application of machine learning algorithms to imagery has proceeded through unexpected mutations that create unanticipated results. In terms of media production, what has emerged are a wide range of specialized tools that prompt us to question the ontology of the digital image in new ways, while also reviving older modalities of image creation. Before moving to my critical analysis of these technologies and techniques,

I will outline some of the ways that they are already being used within the creative industries.

Applications of Machine Learning in Cinema

Within the film industry machine learning algorithms are being used in the service of what Lev Manovich has called “cultural analytics” – i.e., the “computational analysis of cultural data”. [1] For example, the service scriptbook.io, which is presented with the tagline “hard science, better content”, promises to analyze film scripts and produce a report of metrics including genre, target audience, demographics, and hundreds of other data points. It also claims to predict box office performance, return on investment and suitability, of the content in various markets. A similar service is offered by cinelytic.com, which signed a major deal with Warner in 2020. [2] These services extend the logic of “formulaic” script writing to its inevitable conclusion. As such, they are in line with the business models of major studios that base their blockbuster production schedules on market research into heavily engaged fan cultures or, what Henry Jenkins has labelled “participatory culture”. The creators of scriptbook.io go one step further, introducing a service called DeepStory that generates new scripts in the style of existing ones. While the prospect of developing more sophisticated tools for determining the return on investment for a motion picture is tantalizing to venture capital, these tools clearly rely on identifying patterns of consumption within of previous commercial films and projecting those patterns into the future – a form of knowledge making that machine learning systems are particularly well suited to, and also well suited to abusing through the amplification of inherent biases. One question that arises is: will cultural analytics and machine learning algorithms merely accelerate the homogenization of cinema and further enshrine the dominance of the Marvel Cinematic Universe school of filmmaking, or are there other potentialities that it might unlock?

As a first step towards theorizing machine learning and the cinematic image, it should be stated that what we are seeing in these commercial applications of cultural analytics is a revival of an older idea of film as a language itself. The technologies behind script services are essentially classifying cinematic content at the level of the script according to the internal logic of an algorithm. What emerges is not unlike early

theorizations of cinema as a language or language system of images. We should recall that prior to the invention of sound cinema Rudolf Arnheim, Béla Balázs and Sergei Eisenstein were deeply engaged with the problem of developing and thinking of film as a “universal language”. Christian Metz also asked whether film could be considered a “language” or “language system” and attempted to identify and account for a semiotics of the cinema “to analyze film texts in order to discover either textual systems, cinematic codes or sub-codes”. [3] Though Metz eventually abandoned this ambitious project, it is clear today that an applied semiotics of the still and moving image is already being put into practice. This is occurring not only at the level of the script, but also through the use of image classifiers and the application of machine learning techniques: such as the combination of tools like VQGAN + CLIP, OpenAI’s Dall-E, or StyleGAN2 and Artbreeder. Huan Ling et al.’s recent demonstration of “high-precision semantic image editing” in its EditGAN software continues to refine what is possible with these techniques. [4]

Machine learning techniques are already being used in a variety of ways in the production of imagery. They are also now a standard tool in the realm of photography, including in the “neural filters” that have recently appeared in the Adobe software suite, as well as in the hardware architecture behind the cameras in smartphones. Deep learning techniques are being used to automate the tedious and time-consuming process of rotoscoping, in a variety of special effect applications such as automatic colorization of black and white footage, for color analysis and automated color correction, [5] in the generation of procedural textures for CGI in the cinema and games industries, and more recently in full-fledged web-based editing systems such as Runway, or corporate presentation tools such as Synthesia or Synthesis.io.

While forms of machine learning have been used since the mid-20th century by generative artists – and the notion of “algorithmic” images can be traced back to antiquity – the application of modern machine-learning techniques to the moving image first began to appear in films such as Guy Maddin’s *Seances* (2016), Kristin Stewart’s *Come Swim* (2017), the artificial intelligence, “Benjamin’s” *Zone Out* (2018), EYE Museum’s *Janbot* (2018), and in the editing of the trailer for Luke Scott’s *Morgan* (2016). Today, the use of machine learning for the generation of moving imagery has become far more common – appearing primarily in short video works and demos on social media and created with off-the-shelf tools and apps that require no knowledge of coding. With the rapid development of these techniques, particularly in connection with game engines and virtual production tools such as Unreal Engine or NVIDIA’s Omniverse,

it seems clear that their adoption will radically change the crafts of editing, visual effects, and set design within virtual production.

While these applications can be seen as the inevitable creep of new software techniques into the realm of cultural production, we should be critical of their adoption and ask what the potential consequences of their use might be. Furthermore, this survey of specific applications only begins to provide us with a larger picture of what I believe is the paradigm shift in image-making and analysis that these technologies could represent. In order to theorize this new paradigm, I will outline what I believe to be the set of discursive and historical clusters that constitute machine learning in its current application to cinema.

First Cluster: Cybernetics, Automata, Generative Art

One of the most important recent developments in machine learning for image synthesis and analysis is the deep neural network. Accordingly, the examples that I will be discussing here today are mostly based on various forms of outputs from neural networks and, in particular, of Generative Adversarial Networks (or GANs). Invented in 2014 by Ian Goodfellow, GANs are one variety of machine learning algorithm that pits two neural networks against one another in a contest of reinforcement learning. Within this arrangement, a discriminative neural network reads and “judges” the output of a generative network. These networks “compete” to create novel arrangements from a vast trove of training data. It is through this process of feedback that the legacy of cybernetics can be seen at work in these systems. Though the term was popularized by Norbert Wiener in the 1940s, the idea of a cybernetic feedback loop was already operative in simple mechanical machines before this time – such as James Watt’s centrifugal governor of 1787. This elegant physical machine – which effectively and automatically regulates the output of a steam engine – describes the fundamental concept of the feedback loop that lies at the heart of even today’s most advanced forms of machine learning. [6] The machine reads its own output and reacts to it thus “learning” and adapting. Though a drastic simplification, GANs and other machine learning techniques act in a similar manner except that, when applied to a database of imagery, their intended purpose is not to reach a steady state of equilibrium, but rather, to produce novel and convincing interpretations of the underlying data set.

The impulse toward generative *imagery* was also anticipated long before Wiener’s time, first in the automatic writings and paintings of Hilma af Klint, and then by the Surrealists in the 1920s. On his explorations into the psychological processes of the

human mind through techniques like automatic writing, André Breton defined Surrealism itself as: “Psychic automatism in its pure state, by which one proposes to express—verbally, by means of the written word, or in any other manner—the actual functioning of thought.” [7] And it is the second part of his definition that I think is particularly apt to the discussion here. Breton writes that Surrealism is: “Dictated by thought in the absence of any control exerted by reason, exempt from any aesthetic or moral concern.”

As we shall see, this definition remains particularly apt for the description of neural networks, which attempt to mimic “the functioning of thought”, but whose inner workings proceed in ways that are not yet clearly understood. The Surrealist fascination with automata also anticipated Norbert Wiener’s own recognition of cybernetics’ place in a long lineage of the changing definition of what an automaton is. According to Wiener, automata through the ages have “always been expressed in the living techniques of the age. In the days of magic, we have the bizarre and sinister concept of the Golem [...] In the time of Newton, the automaton becomes the clockwork music box [...] In the 19th century, the automaton is a glorified heat engine [...] Finally, the present automaton opens doors by means of photocells or points guns to the place at which radar beams picks up an airplane, or computes the solution of a differential equation.” [8] It should be noted that, historically, many of these automata, in practice, were elaborate illusions and often hid the workings of human agents behind the scenes. Today, we should add to this list of automata by acknowledging the so-called “human-in-the-loop” nature of many of the systems that we refer to as “artificial intelligence.” These would be the self-driving cars that are trained on our frustrated mouse clicks identifying traffic lights in captchas, or more alarmingly, through the actual off-shoring and disavowal of exploitative labor through services like Amazon’s “Mechanical Turk” – a labor rights disaster masquerading as a “crowdsourcing marketplace.”

Cybernetics has of course informed the practice of generative and conceptual artists like Roy Ascott, Sol Lewitt’s *Wall Drawings*, and as Harold Cohen (and his robotic partner AARON), who turned to automated processes and computer art to approach their own ideas and practice in a fresh light. This legacy of cybernetics and automatism continues today in the work of artists like Sougwen Chung, whose painting practice incorporates neural-network-controlled robots that are trained on her own work and paint in collaboration with her gestural style. Or, in Kyle McDonald’s work that incorporates human choreography with recursive neural networks to create systems of interdependency between human and

machine. Notably, these artists and others discussed here are keenly aware of the ethics of the creation of their own data and training sets. The central problems concerning the role of the artist, and of the nature of creativity, that artists like LeWitt and Les Levine grappled with in the 1960s, with the first expression of the concept of art as the “software” and its expression as secondary or “hardware”, are being rehashed today in the discourse surrounding generative artists minting editions of NFTs on various blockchains. The shadow of cybernetics still looms large on the contemporary image.

Within the realm of the moving image, the seemingly rapid adoption of machine learning to large image databases has produced arresting and surreal results that initially emerged on a wide scale with Google’s DeepDream. This imagery, which appeared for the first time when it was “leaked” by its creator, Google engineer Alexander Mordvintsev, was significant as a viral sensation and because it introduced the wider public to the ongoing research into the classification of large image databases at Google. Part of its allure and perhaps a major factor in its virality was that it was so evocative of a highly human characteristic – the idea of dreaming itself, with its deep association with human creativity. However, the motive for the generation of imagery from DeepDream was that the workings of the inner layers of the neural network were something of mystery to its designers as they functioned as a form of cybernetic feedback loop, meaning that once the algorithm was set in motion, its processes were obscured through the levels of complexity of its convolutions. This black box effect is a common feature of neural networks in practice, where the complexity of the statistical models they are based on obscures their inner workings and decision-making structure.

When the image classification function of DeepDream was used to *generate* imagery, its output both revealed something of its nature while also appearing to amplify to psychedelic extremes the human psychological phenomenon known as *pareidolia*. This is the tendency in the human sensorium to search for and reveal familiar objects when presented with unfamiliar visual stimuli – for example imagining a human “face” in the knotted trunk of a tree. The imagery emerging in the recognizable style that has been referred to as “GANism” may owe a debt to surrealism in not only its formal characteristics, but in its ethos of revealing the inner-workings of (artificial) thought unfiltered by the arbiter that is (artificial) consciousness. However, as Rob Horning has pointed out, instead of plumbing the unconscious, machine learning may become a “search engine of the collective consciousness, liberated from any of the contextual social relations

that would discipline what it produces.” Further, Horning argues that, in a mediated world that has become increasingly surreal, “Surrealism’s dreamscapes no longer posit an escape from the bourgeois life of convention but form a commonplace experience of it”, and further, “recuperated as AI, Surrealism provides the basis not for liberation but for further entrapment in existing cultural patterns reshuffled in novel ways, but not fundamentally changed.” [9] It seems clear that we must both interrogate the legacy of Surrealism within AI further as well as address promise of the creation of novel imagery that is in fact a reorganization of well-worn paths.

Second Cluster: Photography, Surveillance, Bias in the Dataset

Later iterations of this type of neural network (StyleGAN 2) have been used to generate new and convincing human faces when trained on a database of existing ones. This practice has already raised ethical issues in the application known as “Deep Fakes” or AI-generated video footage of existing people, but also has clear potential for the creation of characters in games and cinema. For image making and the image arts in general, this technology is potentially groundbreaking, but it also poses several ethical problems that are increasingly familiar to us. Initiated by Fei Fei Li, ImageNet has for the last decade been one of the largest and most widely used image databases for the training of neural networks. It is a searchable database of over 100,000 “synonym sets” – i.e., meaningful concepts that can be described by more than one word, such as “tree” and “plant”. The majority of these “synsets” (80,000+) are nouns, and within each there are usually about 1,000 images that correspond to the description and from which the neural network draws its comparative inferences. ImageNet has been used to train neural networks for facial recognition software, commercial photographic applications, surveillance and countless other implementations. However, in recent years, the importance of the criteria of categorization and classification of these image sets have become the focus of criticism. Since they are trained on an existing set of human-compiled data, neural networks inherit the biases of the systems of classification that were used to tag, sort and arrange them. In practice, these systems become hyper-efficient amplifiers of any inherent bias. Accordingly, within the community of artists and image-makers of the demo scene surrounding these technologies, the curation and creation of these databases has become an object of vigorous debate.

It is to this database and its construction that artists and researchers like Kate Crawford and Trevor Paglen have turned. Through exploring its underlying structure and understanding how the logic of the machine has shaped and formed it, they have identified a concerning legacy of biopower relations within their implementation. As Susan Sontag suggested, photography emerged from the 19th century as a “fledgling form of information culture”, making possible new modes of surveillance and methods of quantifying and fixing identity such as the mugshot (Bertillon system). The initiation of panoptic disciplinary society was of course heavily reliant on this new technology of representation. Similarly, and as Crawford and Paglen have shown, these training datasets (and specifically ImageNet) have inherited the troubling legacy of racist and pseudo-scientific systems such as eugenics. [10] Their work also recalls that of Cathy O’Neil, in her book *Weapons of Math Destruction*, in its uncovering of the troubling legacy of visual classification of categories of race in the machine learning algorithms that are used in popular forms of phot-retouching software. As Moira Weigel has noted, these algorithms “take the histories of oppression embedded in training data and project them into the future”. Through her analysis of the intellectual formation of key figures in the tech sector who have staked their claim on the side of authoritarianism – namely Alex Karp and Peter Thiel of Palantir – Weigel further suggests that this is perhaps not a bug but rather a feature. She writes that “big data analytics could be said to constitute an authenticity jargon in this sense: although they treat the data set under analysis as having something like an unconscious, they eliminate the temporal gaps and spaces of ambiguity that drive psychoanalytic interpretation.” [11]

In a similar sense, the complexity and obscurity of these specialized systems foster what computer scientist Joseph Wesienbaum in 1976 called a “fetishization” of the instrumentalized reason of code itself – a code that was only legible to the “magicians” who were “initiated” into its language. Wendy Chun has referred to this process as “sourcery” (a play on source code) as taking on the trappings of religious rites or mysticism – an obfuscation that covers over what Safiya Umoja Noble identifies in *Algorithms of Oppression* as real instances of discrimination and racism.

Further, in *Making Kin with the Machines*, Jason Lewis et al. argue that the “Singularitarians” (like Kurzweil), who proselytize for the current dominant ideology of AI, exhibit “striking parallels to the biases of those who enacted the colonization of North America and the Pacific, as well as the enslavement of millions of black people.” [12] Kurzweil’s own

seminal fantasies of interstellar travel and “infusing the universe with computronium” in a hunt for more resources to fuel an augmented and expanded human intelligence drive this point home. [13] As a potential corrective, institutions like the Indigenous Protocol and Artificial Intelligence Working Group are currently exploring if systems can be built with Indigenous languages and epistemologies at their core in order to explore the potential of decolonized forms of artificial intelligence. This brings us to a third discursive cluster – the rise in importance of the database itself.

Third Cluster: Data as Symbolic Form

As Sontag already anticipated in 1973, one central consequence of the invention of photography has been the creation of the flood of images that surround us today. In *On Photography*, she writes that the camera has already made reality “atomic, manageable, and opaque”, sampling reality, organizing it and abstracting. Today, it is clear how this collecting impulse manifests itself in the grids of imagery that we consume regularly. Photography’s most popular form today, Instagram, is clearly an aestheticization of the database form itself – an attempt to create an experience of the familiar and beautiful out of the fundamentally awe-inspiring informational sublime that resides in the massive data centers behind the screen.

Lev Manovich has demonstrated the importance of the “database” in media as an organizing framework. Beyond this, Manovich recognized an epochal shift at work that was equivalent in its magnitude to Erwin Panofsky’s description of the primacy of perspective as the symbolic form of the modern age. Accordingly, Manovich asked how we could develop “a poetics, aesthetics and ethics of this database.” While this new form or structuring logic has been widely discussed in relation to the emergence of distributed database effects such as “transmedia storytelling”, it is in the very recent work of artists working with deep learning and generative techniques that we may be seeing the outline of an aesthetics, poetics, and even ethics, emerge. For it is the technique of machine learning that accesses the database and use it as raw material while also reconfiguring the space of the figural – in a similar sense that the techniques of perspective transformed the figural rendering of space in the Renaissance. I would like to propose that what we are seeing are new tools for coming to terms with the database as symbolic form.

In response to the emergence of the importance of the actual construction of the database for these images, artists like Anna Ridler have taken on the task of creating their own databases – in her case, vast quantities of images of tulips that are fed into a GAN

which then produces (imagines) entirely new tulips whose generation is tied to fluctuations of the Ethereum cryptocurrency – recalling the tulip mania of the first speculative financial bubble. Ridler’s work acknowledges the importance of the database while also engaging with the time-consuming human labour that often stands behind these ostensibly “automated” systems, while also acknowledging the new forms of financial exchange of our time.

Fourth Cluster: Cinematic Time, Cyberspace, Image Synthesis

I will briefly touch on a fourth cluster that reveals the importance of the emergence of machine learning techniques to how we conceive of space in the production of the moving image. This discursive network is characterized by the interaction of data science, generative art and 3D rendering technologies. The production of cinematic space has increasingly relied on the adoption of tools and techniques from the realm of architecture and computer aided design – a situation that has opened possibilities for the representation of space that transcend traditional lens-based media. These technologies have, to this point, been largely pressed into the service of the creation of photo-realistic 3-dimensional environments. But the radical potential of how computers represent space has not yet been fully explored. As Wolfgang Ernst writes, “in digital operations, space is nothing but a metaphor” – meaning that the dimensionality of Cartesian space is merely a question of nested arrays of data and the representation of n-dimensional space (beyond three dimensions) is relatively trivial. He writes that “cyberspace is fundamentally spaceless. It is purely relational, thus not representing anything in terms of mapping.” [14]

I raise this point here to draw attention to the fundamental difference between how these new machine learning technologies represent and work with space in comparison to existing CAD-based 3D design tools. I believe that what we are seeing here is a fundamental change in the way in which space – now configured as data – can be represented, and further, that this can be thought of along the lines of previous paradigm shifts in the history of the moving image. Similar to Mary Ann Doane’s claim that the birth of cinema was an attempt to “make tolerable an incessant rationalization” of time that was the result of “industrialism and the expansion of capitalism” by the concurrent “structuring of contingency and temporality” that is the hallmark of the moving image in the late-19th century, the reconfiguration of space as data in the works of artists and image makers can today be read as a similar “coming to terms” with data as symbolic form and also of the uncertainty of the

stochastic model of reality. Doane claims that thermodynamics is a central metaphor of the 19th-century emergence of cinematic time. She writes that “images of entropy and exhaustion, of the heat death of the universe” corresponded with the “irreversibility of time” of Newtonian mechanics and a “pure record of time” of “contingency”. [15] But what we are seeing here is something new; as Norbert Wiener noted, the cybernetic model emerges out of the transition from “Newtonian to Bergsonian time”. This corresponds with the 20th-century shift from Newtonian physics to statistical mechanics. As an illustration, Wiener suggests the difference between “Newtonian astronomy” vs. “meteorology.” [16] The first is a system of certitude that is compatible with the notion of the harmony of the spheres, while the second is an attempt to model the chaos of complex natural systems using probability with no notion of the absolute.

I see potential here in the work of artists who have begun to work within this new space of the image. The frenzied machine visions of GANs are produced from the “latent space” of neural networks and artists like Mario Klingemann have begun to traverse this space in the role of photographer, or “neurographer,” as he terms it, composing, selecting and framing images from within it. When set loose on a dataset of imagery, the visual output of these GANs has ignited the interest of artists such as Memo Akten, Helena Sarin and Robbie Barat, whose own explorations of the latent space circulate largely in the computer art world and across platforms of open-source code. [17] Until very recently, and partly because accessing hardware to do so has until recently been prohibitive, this work has largely been done using still imagery and not video. However, recent advancements have begun to make similar techniques realistic for the moving image. Works such as Memo Akten’s *Gloomy Sunday* (2018) revealed the potential in real-time generative animation and cinematic imagery. Here we see the technique of “real-time style transfer” at work – a process that maps the latent space data of one set of imagery onto an entirely new one.

This was a very computationally intensive task in 2018, but it has already become a fairly trivial effect – one that can be assimilated into a toolbox of filters that. Another recent experiment by Arun Mallya et al., reveals the potential of similar methods to synthesize images of space using only rudimentary semantic inputs. [18] These recent experiments reveal the speed at which the technology of neural-net video synthesis is moving, showing how a basic two-dimensional image that is tagged based on the color of objects can be used as an input for a neural network that generates photo-*surrealistic* moving imagery of a streetscape based on an internal semantic logic or, in Metz’s terms, a language system for the cinematic image. This is

undoubtedly impressive as a technical feat, but it also illustrates how the space of the image has been effectively reconfigured as information – not as pixels, as in previous understandings of the digital image – but as a synthesis of newly imagined space that is nonetheless derived from a database of existing imagery.

Conclusion

To conclude, I will briefly summarize this attempt at theorizing the application of machine learning to the cinematic image.

1. It has inherited the discourse of generative art as well as the conceptual lineage of Surrealism. There is potential here for machine learning tools to function in a manner reminiscent of automatic writing – as an extension or augmentation of creativity that can bypass rote methods and patterns.
2. At the same time, machine learning inherits the legacy of the stochastic methods that drive it. When applied as a system of sorting and generating imagery, it has been correctly criticized as amplifying internal bias within its operative data set. Further, AI image generation may gloss over (or perhaps amplify?) the potential of its Surrealist legacy by replacing psychoanalytic interpretation with the fetishization of instrumental reason.
3. That said, machine learning may stand as the most clearly articulated technique of image production that has emerged as a reaction to the flood of imagery and big data analytics that are an unavoidable feature of contemporary media. If the database is the new symbolic form of our time, cinematic production techniques will clearly be altered through the adoption of AI-driven applications and specialized software solutions in the form of editing and visual effects suites. The question then remains then, to what end?
4. The work of artists including and beyond the few mentioned here points to potential for new forms of imagery and a reimagining of the ontology of the digital image in the era of big data – of a movement away from the or the frame as fundamental units of the image and towards the emergence of the stochastic image. These systems also promise to realize a persistent dream of cinema – that cinematic imagery can be analyzed and understood as fundamentally a semiotic system or a rule-based language.

In this brief outline I believe we see an at times tantalizing, at times troubling contour of the present

state of machine learning as it is being applied to the moving image. That these tools might unlock a new language of analysis and generation of imagery is fascinating and full of potential. However, the rules for decoding this language of imagery are already being written and research into the application of machine learning to the moving image is rapidly progressing with the blessing of major industry figures such as NVIDIA and Google. These are nascent and exciting technologies but there is a danger in their uncritical roll-out of falling prey to the allure of what Robert Oppenheimer referred to as the “technically sweet”. The application of machine learning to the moving image is in its infancy but it is being largely led by leading industrial players within computer graphics big data. To realize the potential of this new technology, and to avoid the many pitfalls that have already been identified, we, as imagemakers, audiences, artists, critics and cinephiles, should strive to understand the potential of these technologies beyond the narrow bounds of these industry applications and within a larger history of the cinematic image.

Artistic residencies in digital companies

Sylvain Martet

Centre de recherche Art et engagement social ARTENSO

Montréal, Canada

sylvainmartet@artenso.ca

Abstract

This paper aims to enrich the knowledge of artists' residencies in digital companies, both to understand their particularities and to help develop methods to evaluate the processes and effects of these initiatives. The popularity of artists' residencies has increased since the 1990s. This can be seen in the funding organizations that develop support programs but also in the diversity of the host institutions, community organizations and private companies that want to welcome artists and develop links with the art worlds. What explains this growth? What are the different parties involved looking for? What are the effects of these residencies on artistic careers? This research brings a particular attention to artists' residencies in digital companies. Acting as a precursor in Quebec, the Conseil québécois des arts médiatiques (CQAM) set up its first residency in 2016 at the interactive media company Turbulent, followed the next year by another at the audiovisual entertainment company VYV and in 2018 by Milieux, an Institute of Arts and Technologies. Our research explores the ten residencies that have taken place to date, based on interviews with artists and company employees. A literature search was also conducted to better understand this growing phenomenon. Our work allows us to better understand what artists' residencies in companies are, do and allow. The host companies seem to seek, in the presence of the artist, a force of reflection and change for the practices and rhythms of work. For artists, the main interest of residencies is the possibility to devote time and resources to a project. However, the link between these two worlds is not automatic and requires a strong commitment, which in turn requires the involvement of intermediary organizations.

Keywords

Artistic residencies, artist, art, creative, digital companies, digital art

Understanding artistic residencies

Since 2019, the research center ARTENSO has begun a process of documentation, research and knowledge production on the subject of artistic residencies in order to, among other things, accompany project leaders on their modalities and results. In our approach, we consider the support of creation through artistic residencies as a potential space for cultural mediation to increase interactions between artists and the community. Two pieces of research have been produced: on artist residencies in municipal cultural spaces and on artist residencies in college settings. This research

brings a particular attention to artist residencies in companies and particularly in digital companies. Our study intends to promote the understanding of these mechanisms, and the reflection to contribute to their development. In Quebec, artist-in-residence programs are relatively rare and there is no academic research specifically devoted to them, both in their deployment and in their impacts, both for the host company and for the resident artist.

Today, artists' residencies are very present in the arts and culture sector, both for institutions and for artistic careers, but in their current form they are relatively recent. It is important to underline the common and conscious use of the plural for the expression "artist residencies". The research shows that what characterizes this mode of support for creation is its diversity. This diversity is present as much in the artistic disciplines concerned (dance, visual arts, literature, etc.) as in the host structures (artist-run centers, museum institutions, living environments, businesses, etc.). The existing formats are also varied. There are short and long stays, residencies with or without accommodation, residencies focused on creation and dissemination, others on research, online residencies, residencies dedicated to a specific territory, etc. Finally, the great fluidity of the modalities that link the artist to the host structure and to the different interlocutors that they may have (public, neighbors, workers, artists, etc.) contributes to drawing this very diversified portrait. In all cases, however, artists' residencies are based on two fundamental dimensions: the artist is, in one way or another, immersed in an environment other than his or her usual practice space; what is produced during the residency is not an artistic commission and the artist is not an employee of the host structure. This is as true for a writing retreat in a monastery as it is for a virtual creation residency in a self-managed digital arts center. Thus, apart from this succinct definition, residential arrangements, understood as the forms, structures and organizations of artistic residencies, are characterized by their diversity.

In Quebec, artist-in-residence programs for private companies are relatively rare and there is no academic research specifically devoted to them. Acting as a precursor, the Conseil québécois des arts médiatiques (CQAM) set up in 2016 their first residency in the premises of the interactive media company Turbulent, started with the participation of artist Thomas Ouellet Fredericks. Several other editions have followed since: Elise Trinh (2017), François Quévillon (2018) and Peter VanHaafden (2019) and Lucas Laroche (2021). This residency is now included in the support programs of the Conseil des arts de Montréal. Starting

in 2017 the CQAM program was enriched with a residency at VYV, a company specializing in technological entertainment, which hosted artists Lucas Paris (2017) and Matthew Biederman (2018). In 2019-2020, VYV worked in collaboration with the Society for Arts and Technology (SAT) to disseminate the work of artists in residence Charline Dally and Gabrielle Harnois-Blouin. The most recent addition to this program of support for artistic residencies in digital companies is Milieux, Concordia University's Institute for Arts, Culture and Technology, which has hosted Christopher Willes (2018) and Amélie Brindamour (2019), for a total of two experiences so far. This ensemble appeared to us as an ideal research ground to pursue our reflections on the objectives and effects of artistic residencies in digital companies. By studying these different residencies, this research will therefore pursue three complementary objectives:

- To document the processes, the modalities of implementation and development of the residencies.
- To better understand how the worlds of business and professional art meet in the residencies.
- To develop an evaluation framework for artist residencies in companies.

The CQAM was involved as a research partner, which allowed us to access documents related to the implementation and development of the residency program, while guaranteeing a role of accompaniment and follow-up of the research to the CQAM representatives.

Methodology

In addition to a rich review of the literature in English and French on artistic residencies, artistic residencies in companies and cultural entrepreneurship, our research is based on mixed data:

- Interviews with 4 artists and 3 representatives of host companies;
- Results of a survey conducted by our partner CQAM with 4 artists and 4 representatives of host companies;
- Meetings with three project leaders of artist residencies in digital companies;
- Follow-up and working meetings with our partner.

The rest of this paper is organized according to three explanatory poles of the implementation of artistic residencies found in our literature review: philanthropy, management and creative entrepreneurship. For each, we will review the literature on the subject and compare it to the data collected in the context of the program studied. Far from seeking exhaustive answers, we aim here to highlight the diversity of the cases, both in the residential forms and in the professional paths of the artists who participate.

Artists in companies

Our definition allowed us to integrate in our readings and reflections a part of the field of artistic intervention in companies. In fact, in Europe in particular, there are several initiatives that come close to what the CQAM program proposes, but which are described with terms other than residency: "workarts", "arts-based initiatives", "arts-based learning programs", "artful learning alliances", "artsbased interventions" or, most commonly, "artistic interventions". For Joost Heinsius and Kai Lehtikoinen (2013), artistic interventions are understood as artist-led processes that are adapted to address organizational challenges through artistic inquiry. As such, many art interventions unfold over time, with recurring or ongoing presences in the workspace. The interventions are often conceived over time. In Quebec, the organization Culture Pour Tous initiated in 2007 a pilot program entitled Art at Work. This program has allowed about thirty projects to be born, in a variety of sectors (industrial, manufacturing, daycare, municipal...) and in different cities of Quebec. For this research, we have therefore taken into account all the projects involving artists and companies that fall within our two definitional criteria (which excludes the commissioning of works or the use of artist-coaches, for example). The grey literature (reports, guides) as well as scientific literature allows us to identify 4 challenges:

A first challenge for the full development of these devices is that of the interest of leaders in artistic intervention (Quintas 2012; Berthoin Antal et al, 2018). Companies are hierarchical structures for which the allocation of resources in time or personnel is framed. A lack of interest is thus going to have fairly direct repercussions on the resources and attention that the artist will receive.

Secondly, it is often necessary to set up training or integration programs dedicated to artists beforehand in order to help them integrate into a social space and a work rhythm other than their own. This step, if done appropriately, helps artists better utilize their artistic visions and skills in non-artistic contexts (Heinsius & Lehtikoinen, 2013). However, not all residencies incorporate this step, which can complicate the relationship between the artist and the host organization.

Third, although the artist's presence is intended to have an impact on the daily life of the employees, this does not happen automatically. The tasks of the host organization's staff, their work rhythms and organizational particularities may conflict with the artist's presence. The positive dynamic intended by the artist's arrival can turn into disappointment (Berthoin Antal and Strauss, 2013).

Finally, it seems common that corporate residencies aim both to integrate artistic processes but also to see the final production of a work or body of work. This is related in particular to the very nature of the company. However, not all artists' residencies necessarily have a final production imperative. Therefore, there is a challenge in the organization to clearly define the expectations of the different parties (Taylor and Ladkin, 2009).

Creative management

Artistic residencies are generally understood from the companies' perspective as artist-led processes that are tailored to address particular organizational challenges with artistic research (Heinsius and Lehtikoinen 2013). It is thus a practice that brings artists into collaboration with different stakeholders such as employees, management, customers, and the community (Heinsius and Lehtikoinen 2013; Schiuma 2009). The stated goal of the actions designed and implemented at the heart of these arts residencies is to support or trigger the development of organizations in the 21st century business landscape, based on the use of artistic practices and/or resulting works (Grzelec and Prata, 2013). In Quebec, a pilot program was initiated in 2007 by the organization *Culture pour tous*. Entitled Art at Work, this program has allowed about thirty projects to start, in a variety of sectors (industrial, manufacturing, daycare, municipal...) and in different cities in the province of Quebec. The results show that the motivations for companies are rooted in the integration of artistic processes as tools for managerial innovation, which is confirmed by other work done in Europe (Berthoin Antal 2018; Heinsius and Lehtikoinen, 2013).

To understand this openness to artistic processes in business, it is essential to make a detour through the notion of creativity. Appearing initially as a specialized term in the field of psychology, the notion of creativity gained popularity as its meaning opened up to designate the ability to imagine the creation of something new. Initially referring to individual capacities of imagination, it will be applied to larger ensembles: creative cities (Yencken, 1988), creative economies (Howkins, 2002) or creative classes (Florida, 2002). The arts and culture are mobilized in these conceptual thoughts not as the sole domain of creativity, but rather as an expression of the new modes of production and relationship to work generated by the most recent mutations of capitalism (Boltanski and Chiapello, 1999). Project work, flexibility, continuous innovation and the importance of passion in one's career are inspiring management. The cultural industries are gradually becoming the creative industries, and artists' work processes are becoming a source of inspiration for the organization of work in companies, particularly in creative and digital companies. From a critical point of view (Tremblay, 2008), there is a real injunction to creativity that takes the form not only of a moral imperative, but also of a commercial must (Schiuma and Carlucci 2018). In the interventions accompanied by *Culture pour tous* in Montreal, the argument stated that "creativity, knowledge, diversity and beauty are indispensable foundations for human development" (Quintas, 2012 : 49). These are values that we seek to insert into the world of work and the managerial culture through the intervention of artists. How are these intentions translated into the experiences of those involved? The notion of creativity was mentioned when the different participants were discussing their motivations. The motivations for companies seems rooted in a desire to integrate artistic processes

as tools for managerial innovation (Berthoin Antal 2018; Heinsius and Lehtikoinen, 2013). In one of the few works that includes a coherent research field on the motivations of host companies, Anna Grzelec and Tiago Prata (2013) argue more specifically that it is the development of new methods or processes, creativity, change management and motivation that constitute what host organizations expect from artists. It is therefore expected that through their presence, their practice, the artist will share with the company their sense of innovation, even disruption, and that they will lead to the development of the organization's creativity. However, this must be organized, and it is therefore necessary to set up contexts for meetings and exchanges, without which there is no possibility of evaluating the effect of the artist's presence.

Objectives and expectations

There is little research on artist residencies in companies, and none directly on artist residencies in digital companies. Some of the sources consulted present themselves as research or evaluation of residencies, however, we note that the methodologies used actually limit the conclusions of these works. Indeed, evaluation practices are not generalized, and the indicators used when this is done vary enormously. This difficulty also stems from the fact that participants observe different outcomes depending on their roles, but also because they confer multiple/changing roles on the intervention throughout its duration (Berthoin Antal, 2012). Thus, it seems "impossible to establish clear mono-causal links between an artistic intervention and organizational outputs" (Berthoin Antal and Strauss 2013 : 8). The residency cannot be judged by conventional management indicators to assess the impacts of the initiative in the organization such as reduced absenteeism and increased productivity (Berthoin Antal et al, 2018 :17).

Several criteria appear in the literature to gauge the effects that should be sought for the people involved in the development of artistic residencies. Within a company, the implementation of an artistic residency seems to be mainly justified by the managerial contribution it allows. Schiuma (2009) sees impacts on human resources as well as on the functioning of the economic model. Nissley (2010) discusses the transfer of applied artistic skills in organizational contexts. He believes that the goal of artistic intervention should be to encourage artistic creation for employees, both as a mode of expression and as a technique for reflection. The report commissioned by Tilt Europe (2011) on the subject lists several indicators along these lines: encouraging disruptive thinking and challenging management routines to improve organizational effectiveness; engaging organizations in innovation; generating new perspectives; and helping organizations define their identity through creativity. Berthoin Antal et al. (2018) propose three indicators that signal a successful residency: allows individuals to express and develop themselves in ways they consider meaningful; contributes to enriched relationships at work

and service to others; expands the organization's potential to contribute meaningfully to society. Those approaches emphasize the benefits to the company, but not to the artists. However, these benefits are accompanied by duties, especially for the entire organizational chain. Indeed, the literature indicates that it is the responsibility of project/team leaders as well as company managers to closely monitor artistic interventions in order to ensure that the investment is not wasted and that people are not confused and frustrated (Berthoin Antal and Strauss, 2013).

This dimension is central to the literature on the topic. Yet, in the program studied, management through creativity does not seem to be a primary motivation for host companies, which put forward more of a corporate or personal (management) interest in the arts. Artists are thus coupled with technicians to meet production needs, rather than with management, which limits their effect on the structure and rhythm of the company. For granting organizations as the CQAM, it is the inclusion of art and artists in other environments that motivates the support of artistic residencies. Finally, on the artists' side, it is the working conditions and the development of artistic projects made possible by the system that seem to predominate in explaining the commitment. From then on, a major challenge appears: the need to coordinate the different motivations and needs of the parties involved.

The challenges of integration

The work rhythms are not the same for artists and host companies. It is not only the working hours that need to be considered, but also the alternation of rush periods and quieter periods, the rhythm of meetings, the rhythm of development of projects. Our research shows that it is essential to take into consideration the differences in project development and management between artistic practice and the creative industries. The mode of project development is fundamentally different, yet the residency is overseen as a project (project manager, dedicated staff), which in itself is normal in a structure of this type, but it tends to limit the possibility of being destabilized by the artist's presence. The time of the dedicated employees must obviously be managed in the best interests of the company, which is why in the different residencies considered, there were several changes in the person providing assistance according to the priority needs of other projects. Time and resources are therefore limited and changeable, which does not necessarily bother the artists, since the development of an artistic project does not have to end at the end of the residency. However, this is less common in the management of a corporate project. These differences in relationships and work rhythms explain in part the difficulty of meetings and sharing practices. The integration of the artists is not similar according to the possibilities of the employees of the structure to grant time to it.

For a good integration, it is also necessary to pay attention to the expected uses of the technological tools. All the

artists do not necessarily have the same level of mastery, knowledge or curiosity for the technological tools. We also see a difference between those who seek an application and those who opt for experimentation. For example, two artists underlined a "gap between practices" that could not be bridged, due to the lack of time for exchanges. The importance of sharing the artistic process is clear, and it is done well especially with the dedicated employees who, in order to help the artist, spend time together, and understand each other.

Thus, the decision about which employees will participate is going to be discussed: either on a voluntary basis or selected by management based on the relevance of the program issue (Berthoin Antal et al, 2018). Determining goals and strategies beforehand is a key factor in the success of an arts intervention (Schiuma, 2009). It is also upstream that the objectives must be defined and validated by all parties in the organizational structures (Grzelec & Prata, 2013). The duration of the residency is another important issue. First of all, because participation in projects is added to the normal workload of employees. And also because of the importance of having a good schedule done beforehand, in order to organize the work, measure the results and create a sense of urgency to promote the activities at specific times (Berthoin Antal et al, 2011). In this structure, what place does the artist take? How can we understand his commitment? What are his motivations for participation?

Cultural entrepreneurship

The figure of the cultural entrepreneur has been developing for several years, particularly in institutional contexts through training or dedicated funding. The development of creative entrepreneurship is also related to the employment status of artists. In Quebec, a higher proportion of artists are self-employed (53%) than other cultural workers (24%). In the overall experienced labor force, the percentage of self-employed is 12% (Danvoye, 2020). This situation can be understood through the prism of the evolution of the forms of institutional support for cultural production (Martet, Lussier and Bélanger, 2018) but also as a necessity in the face of the precariousness of artistic creation (Menger, 2003). The labor market in the cultural sector is classified as difficult, "atypical, characterized by oversupply and the need for flexibility" (Hausmann 2010, 17). In a deteriorated labor market, Borja and Sofio denounce the demand for versatility and realism imposed on artists, in a context where cultural funding is becoming increasingly scarce (Borja and Sofio 2009), so that members of the arts and culture sector are more likely to create their own jobs and work on a project basis. Yet researchers speak of an increasing entrepreneurialization of work (Hausmann 2010; De Heusch et al. 2011; Gandini et al. 2017; Borja and Sofio 2009). Finally, artists seem to suffer from a public image devaluing their work which forces them to con-

stantly negotiate the value of their practices and their productions (Novak-Leonard 2017). The entrepreneurial approach to artistic careers seems to be promoted in part to counter these pitfalls and challenges. For Borja and Sofio (2009), the entrepreneurial regime appears as a new way to justify the heteronomous tendencies of the art field. Greffe (2014), shows that cultural entrepreneurship is linked to the forms that the relationships between the artist and other artistic professions take. He describes the artist as often being considered as a producer of concepts brought to subcontract certain tasks and mobilize other skills than his own. Thus, the artist becomes an entrepreneur "when he or she must insert himself or herself into the lives of other enterprises and assume debates as equals" (Greffe 2014 : 50). Rooted in this notion is an approach that presents the artist-entrepreneur as a very small business (De Heusch et al., 2011; Wyszomirski and Chang 2012; Bonin-Rodriguez 2012; Courvoisier et al., 2015; Enhuber 2014; Claden 2016; Novak-Leonard and Robinson 2021). In these approaches, the artist seems destined to incorporate entrepreneurial practices into his or her creation, production, and dissemination processes in order to be able to pursue a career. Therefore, artistic residencies in companies should produce effects on the entrepreneurial capacities of artists, and eventually constitute reasons for artists to get involved. However, our fieldwork nuances this hypothesis. We expected the notion of entrepreneurship to appear more clearly in the artists' motivations, as a value sought for career development or with the idea of an artistic exploration of the entrepreneurial milieu. This was not really the case. In the end, the artists' commitment seems rather pragmatic: they need funding, space and specific tools to develop their projects, their practice. On the side of the companies, the support to the artists also appears to be the main way of understanding their commitment. However, this form of support differs from patronage in that, as we propose in our definition, it aims to allow an artist to be immersed in another environment, with time and resources to create, without compensation. It seems, however, that adjustments could be made to encourage meetings and exchanges between the artist and the host environment to improve these residential arrangements

Career and working conditions

If it is clear that artists benefit from their career progression from residency initiatives, it is not so much because of the content of the residency but rather because of its material conditions. An artist residency requires funding and in-kind contributions (access to space, tools, remuneration, creative expenses, etc.). Programs are funded from a variety of sources, including external funding in the form of grants or support from regional, national, local, or foundation sources, which in most cases use a dedicated budget for cultural action. There are also programs in which funding is supported by the company. These funds are regularly combined.

From the point of view of the artists, the residency is an opportunity to develop research or a body of work under advantageous conditions. The residency is an opportunity to have time and a dedicated space for artistic research and/or the creation of a body of work. Since most artists are in precarious situations, the residency appears to be an ideal context for working. As such, the residency, whether in a digital company or elsewhere, is firstly access to time and space for creation. Secondly, access to industrial, technological or organizational processes is also a strong incentive, as it allows new ideas and techniques to be tested. Thus, most of the artists we met were able to benefit from work on computer engines and the support of programmers to develop projects that would have been difficult to create with their personal equipment. Finally, participation in residencies, particularly residencies organized with institutional structures of the cultural milieu, is important in the CV of artists and the pursuit of their career. Indeed, the selection to the residencies passing by a stage involving a jury of peers, the process constitutes a form of professional validation of the artistic project, and this type of consideration of the peers is a major criterion for the granting of other forms of institutional financing. In sum, participation in the residency is fully integrated into the artistic career and contributes to the improvement of the working conditions of artists.

Conclusion

Our work has allowed us to highlight the complexity of the definition of artist residencies due to the variety of their forms, their objectives and the actors they bring together. However, we have highlighted several essential elements of definition: a space outside the artists' usual practice environment, the artists are not employees of the company and do not produce a commission. We have been able to identify the historical sources of the current forms of these modes of cultural action and to underline their current unavoidable character.

The dominant approach on these questions is based on the promotion of the integration of artists in order to feed managerial innovation. The sources we have mobilized are often institutional reports. It seems important to develop critical research on the subject. Our work has enabled us to identify the modes of structuring and organization existing in companies that welcome artists. The portrait that we draw underlines the diversity of the motivations and needs of the different parties involved, which encourages a flexibility of the forms of artistic residences.

The term of artist residency in companies is not necessarily used in projects based on the presence of artists in companies. If certain authors favor the term of artistic interventions, we affirm the relevance of the use of the term of residence to underline the potential integration in a long temporality. This seems important in certain contexts

to allow the development of strong links between the parties involved. There is indeed a need to integrate the artist more into the daily life of the company, to weave links with the employees of the host structures. The integration of cultural mediation practices by the artists, or by mediation professionals, seems to be a relevant way to improve artistic residency programs in digital companies.

Impact evaluation is often documented in very specific documents that focus on a particular initiative. We argue for the importance of developing a more comprehensive or easily mobilized approach to impact evaluation for artists, companies and intermediaries.

Our research field shows us that the main motivation for developing artistic residencies in digital companies seems to be philanthropic practices. Secondly, it is the effects of the presence of an artist for the management that are evoked, even if our research shows that these are limited, notably by the little interaction of the artists with the employees. Finally, artistic residency programs seem to be essential for the development of artistic careers and the improvement of artists' working conditions. Our research shows that there is a concordance between the wills of the business community, cultural support organizations and artistic communities to develop artistic residencies.

Based on this work, we identify 8 recommendations for artistic residencies in companies.

1. Integrate presentation times to encourage meetings with the company and different groups of employees.
2. Think about the duration of residencies in the medium term and encourage flexibility in the artist's work rhythm, depending on the project.
3. Work with a support organization that is close to the artistic community (e.g. CQAM).
4. Plan and manage work schedules in accordance with the artists and the dedicated employees.
5. Introduce the artist to the tools, resources and culture of the company prior to their arrival.
6. Identify expectations in terms of technology use and ensure the selection of artists in accordance.
7. Encourage artist residencies within and outside of technology departments (management, HR, etc.).
8. Implement evolutionary evaluation methods.

Abstract

Online new media art archives exist throughout the world as repositories documenting theory and practice of electronic art. For a researcher, instructor, or student using these resources for scholarly work or inspiration, the process often involves visiting multiple websites with different interfaces and information. Without knowledge of the wide variety of archives that catalog new media art, the sought-after material may be missed. In 2018, the seeds of an initiative were sown at a roundtable discussion at ISEA2018 (South Africa) and during ISEA2019 (South Korea), the real work began to investigate and initiate the process of connecting new media art archives from around the world. Beginning with a core group including representatives from the ISEA, SIGGRAPH, FILE, Ars Electronica, and the Archive of Digital Art (ADA) archives, group discussions, implementation meetings, summits (Summit on New Media Archiving @ ISEA2020, mini-conferences (FILEALIVE 2020) and presentations at various conferences occurred. This paper outlines the details of the project along with the implementation procedures and challenges.

Keywords

archive, new media art, ISEA, SIGGRAPH, ADA, FILE, Ars Electronica, online repository, electronic art, digital art

Introduction

Over the past 50 years the number of events that could be labelled 'electronic art' has grown exponentially and so have the number of online archives of these events. Also, a number of museums around the world have begun collecting electronic art and archiving documentation of this work via an online archive. The vast collection of archives vary in scope and intention, and online archives of electronic art have different structures, use different taxonomies, and contain different types of materials. There are also a number of similarities in the archives in that they often contain information about artists and/or academics. All online new media art archives typically document events, works, accomplishments, publications, innovations and other historically-relevant materials, and disseminate this information to the public through the web.

Access to information via the web is fast, convenient, and accessible to those who have an internet connection, but searches often do not return comprehensive and complete results. Therefore, it seemed logical to initiate a project to connect new media art archives so that researchers, artists, educators, students, and the general public could broaden their awareness of the information available. Establishing connections among new media art archives is a complex task due to the technical and logistical obstacles. Through the dedication and expertise of the parties involved, this initiative is currently underway. Significant planning has been accomplished and we are now working on the logistics. The technical specifications are currently being developed and implementation will begin in the next year.

History of the Initiative

Electronic Art Archive Meeting in Durban

In 2018, the ISEA archivists organised a roundtable discussion at the ISEA symposium in Durban, South Africa. [1] The original idea behind the founding of ISEA was to create a central hub to connect electronic art initiatives, institutes, and organisations. Therefore, it seemed logical for ISEA to spearhead a discussion related to connecting online new media art archives. The meeting had three aims:

1. To discuss how to connect to each other's new media art archive on-line.
2. To investigate the possibility of a common platform that would be able to search all connected archives.
3. To collaborate and learn from each other and to avoid duplicate efforts.

Approximately ten representatives of different archives from around the world participated in the roundtable. During the meeting they talked about their archive and discussed concerns as well as important topics to be researched, challenges to be met, and steps to move forward.

Electronic Art Archiving Meeting in Gwangju

The ISEA2018 roundtable on Electronic Art Archiving led to a follow-up roundtable discussion organised during the ISEA2019 symposium in Gwangju, South Korea by Wim van der Plas and co-chaired by Oliver Grau of the ADA archive. [2] A flyer announcing the meeting was distributed to all symposium participants via the conference bags. The room reserved for the discussion was designed to hold approximately 25 people but because of the wide appeal of the topic, the room was packed with at least 50 people. It was therefore impossible to have a roundtable discussion where all participants contribute equally. Instead, participants introduced themselves and their archive and made comments on their challenges and successes. The meeting was fruitful in the sense that:

1. There is a lot of interest in archiving new media art.
2. Participants experience similar challenges.

During the meeting, a list of participants was compiled, and participants agreed to take the initiative a step further.

Online New Media Art Archive Summit

During ISEA2020, a day-long Summit on New Media Art Archiving was organised by four cooperating parties: the ISEA archives, Archive of Digital Art (ADA), the Ars Electronica archive, and the SIGGRAPH Art Show archive. [3] The 2020 ISEA symposium, hosted from Montreal, Canada, was held entirely online. Twelve papers from nine different countries were presented and were accompanied by short presentations by the four organising archive representatives along with a keynote address by Oliver Grau. The proceedings of the Summit are included in the Proceedings of the 26th International Symposium on Electronic Art. [4]

The second part of the Summit consisted of three parallel break-out sessions: “Connecting New Media Art Archives”, “Creating Ties to Museums”, and “Funding for New Media Art Archives”. A plenary, concluding session was called ‘Creating a Roadmap Towards the Goals of the Liverpool Declaration’. The Liverpool Declaration [5] makes a case for the need to establish international and sustainable funding structures. This includes the development of a cooperative process of knowledge transfer between artists, institutions, and researchers internationally. Through the supported alliance of art organisations, media art archives, and individuals, a system of sharing data, resources, and expertise should be established. This declaration was published several years ago and was signed by close to 500 leading experts and institutions in the field of new media and electronic art.

The summit triggered interest from new parties, including the European University at St. Petersburg (Russia), the Electronic Language International Festival (FILE) from Brasil, and many others.

We felt it was necessary to form a core group of archives to initiate the process so we could hold focused and structured discussions that led to action (see figure 1). The

SIGGRAPH, ISEA, FILE, Ars Electronica and ADA archives appeared to be logical choices because of the similarity in the data they contained. We held meetings and focused on the task at hand by outlining priorities and establishing goals.

Figure 1. A vision of the initial international archives network.

New Media Art Archives in the Core Group

ISEA

The International Symposium on Electronic Art (ISEA), consists of an academic conference, accompanied by art events and supported by workshops. Beginning in 1988, the presentations, workshops and artworks were documented in printed proceedings and catalogues. The ISEA archive initiative began in 2006 with financial support provided by the Mondriaan Foundation. Because of the nomadic character of the ISEA symposium, without a funded central office, the first version of the archive (2008-2012) was constructed long after the symposium series started and had to be built on the basis of retrospective research.

In 2012, a completely new version of the archive, now referred to as the classic archive, was developed to rescue the archive’s data from a soon-to-be decommissioned server (see figure 2). [6] To facilitate bi-directional relationships between the data along with data visualisation and rich media, a third version of the archive was established in 2017 and moved to the SIGGRAPH server in 2019 (see figure 3). [7] The two archives act in tandem with text information researched, formatted, and added to the classic archive and then moved to the new archive. Both archives are continually being updated to accommodate new information, restructure existing information, and enhance the text with added visuals and videos.

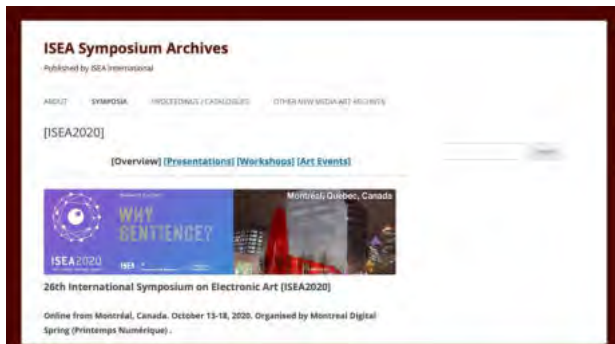

Figure 2. Classic Online ISEA Symposium Archive.

Both the classic and new archives use WordPress but the new archive is custom-coded using PODs, PHP, HTML, CSS, and Javascript. Both archives contain information about symposia, presentations, workshops, and art events and includes metadata that allows data to be accessed in a multitude of ways. The new archive also includes information on venues and a gallery of images from each event. Another major difference between the archives is that the new archive is able to handle thousands of images, videos, and other rich media. The archive team has started a Youtube channel and is embedding videos into the pages in the archives. [8] Both the classic and new ISEA archives have been developed by a team of international volunteers, student interns, and ISEA representatives with very little funding.

Figure 3. New ISEA Symposium Online Archives.

SIGGRAPH

The Association for Computing Machinery (ACM) is the world's first and largest educational and scientific computing society with Special Interest Groups (SIGs) forming communities within the computing field. [9] ACM SIGGRAPH, established in 1974, is a Special Interest Group of the ACM on Computer Graphics and Interactive Techniques and hosts annual conferences [10]. Beginning in 1981, the SIGGRAPH conference included an annual art show showcasing some of the world's most innovative and creative digital artworks.

In 2015, an archive of digital artworks exhibited at the conference was started under the ACM SIGGRAPH

Digital Art Committee (DAC). The archive was expanded to include writings and presentations (art papers, panels, roundtables, essays, and so on) as well. Developed with a team of students, this new archive contains interconnected resources from SIGGRAPH, SIGGRAPH Asia, and the Digital Arts Community Online Exhibitions (see figure 4).

[11] The ACM SIGGRAPH Digital Art Archive encapsulates the development of computer/digital art as it evolved from algorithmic approaches in the 1980s to contemporary interactive forms of expression. The archive includes information about the artists, presenters, chairs, juries, and other individuals who contributed to the art shows over the years.

Figure 4. ACM SIGGRAPH Art Show Online Archives

In 2020, the digital art archive was expanded into a broader archive containing a wider array of SIGGRAPH materials (see figure 5). [12] The ACM SIGGRAPH History archive contains information and artifacts organised into the following categories: Experiences (e.g. Art Shows, Computer Animations and Electronic Theater, Emerging Technologies, and Extended Reality), Contributors, Learning (e.g. Courses, Posters), Publications, Awards, and so on.

Figure 5. ACM SIGGRAPH History Online Archives.

Festival of Electronic Language (FILE)

FILE, the Electronic Language International Festival, founded in 2000, is a non-profit cultural organisation based in Sao Paulo, Brasil. FILE's mission is to promote wider access to technological forms of expression (languages) to the general public. Their goal is to demonstrate how the

advances of new and digital media help shape the contemporary world. FILE promotes creative and innovative electronic language across Brasil and South America through events and publications. The main categories of the festival are:

- Electronic Sonority: soundscapes, performances, installations, art, poetry, and robotics, etc.
- Interactive Art: installations, performances, internet projects, virtual & augmented reality, etc.
- Digital Language: games, animation, theatre, video, architecture, fashion, poetry, dance, etc.

File has a physical archive that contains an exclusive collection of more than 8,000 works selected from 15,000 submissions from more than 48 countries. FILE also maintains an online archive documenting the works shown at the festival as well as publications and other events they hosted (see figure 6). [13] A new online archive is under construction that will allow cross-connections between internal data and enable it to be connected to other new media art archives. They reconsidered the migration of digital data to a headless system but opted to organise the online database using the Tainacan technology, compatible with the WordPress environment in which the festival's data is already hosted. Tainacan is a Brazilian technological solution for the creation of digital collections on the Internet and contributes to the preservation and communication of cultural production on the Internet, through the management and sharing of collections.

Initially, a diagnosis was made of the organisation scheme and cataloging of FILE's digital data content, then the informational architecture was designed through a survey of informational typologies, collections characteristics and institutional informational modeling needs, while considering the interconnection strategies with the ISEA/SIGGRAPH archives. The festival online database is under construction with the data input of the last five years of the festival's digital content.

Figure 6. Festival of Electronic Language (FILE) Archive.

In March 2020, FILE hosted the FILEALIVE meetings (an online mini-conference) which focused on digital memory, preservation of cultural heritage, challenges of archiving media art, conservation strategies for collections, mapping, and metadata interconnection between archives.

Ars Electronica

Ars Electronica, based in Linz, Austria, and founded in 1979, holds one of the world's largest archives of digital media art. Ars Electronica is a stage for media art, a competition, a festival for art, technology, and society, and a showcase for creativity and innovation. They host a laboratory for research and development, a school of the future, and a museum open to the public year-round.

The Ars Electronica archive's mission is to preserve the ideas and the diversity of Ars Electronica, and to make as much of it as possible freely available to users (see figure 7). [14] Highlights include the collection and presentation of the winning projects of Prix Ars Electronica (a yearly competition), and video documentation of the early festival years and center exhibitions. This was possible through the involvement of the ORF – Austrian Broadcasting Company's Upper Austria Regional Studio.

The structure of the archive consists of three parts: a custom-built internal database as the heart of the archive designed for internal use and special research requests; an online archive, with content easily accessible and open to the public; and air-conditioned premises for the collected data carriers, print materials, and a few special items.

The digital part of the archive is a database that stores multimedia data (texts, images, videos, etc.) in common formats in the form of archival documents. The metadata information belonging to the archival items is stored by the archive in a relational database. Access to the archive is browser-based for both the collection and research.

Figure 7. Ars Electronica Archive.

Archive of Digital Art (ADA)

As a pioneer in the field of Media Arts research, the Archive of Digital Art (ADA) has documented the rapidly evolving field of digital art since 1999 (see figure 8). [15] This research-oriented overview of works at the intersection of art, science, and technology has been developed in cooperation with international media artists,

researchers and institutions as a collective project. Artists are free to upload images, text, and other rich media and maintain a collection of their work on the site. Each month an artist/scholar is featured.

Figure 8. Archive of Digital Art (ADA).

Connecting New Media Art Archives

Goals and Challenges

Connecting new media art archives is a complex endeavor and must be approached strategically. First, we needed to generate a list of new media art archives. This was accomplished by information provided during the ISEA2019 roundtable and ISEA2020 Summit, as well as conducting independent research on the internet. An extensive list of international online new media art archives was posted on the ISEA classic archive. [16]

Second, a deeper understanding of the variety of new media art archives was necessary. During the roundtable discussions at ISEA and also at the FILEALIVE meeting, participants presented their archive projects along with their goals and challenges.

Differences and Similarities

We started with the core group and held meetings to discuss the technologies used to develop their archives. SIGGRAPH and the new ISEA archive use the same customisable frameworks technology called PODs and both archives are located on the same server. The FILE representatives were in the process of developing a new archive and planned to use the WordPress plugin Tainacan. Ars Electronica’s archive documents the works presented at the festival. The site had been recently hacked and was no longer online and they were in the process of repairing the damage. The ADA archive differed significantly in that the contents did not document events but instead was subscriber-driven and focused on the works of individual contributors to the website. ADA’s archive was running

using an older content management system and they were looking for solutions to upgrade. All of the archives use SQL databases to hold and manage the information. They all focus on showcasing the scholarly and creative works of people in the new media art field.

The meetings proved to be useful in identifying the issues related to connecting the archives. It was thought that we might need similar variable names or data structures. In addition, we wondered whether differently designed interfaces, and the use of various languages in the archives (e.g. English, German, Portuguese) would pose a problem. All archives resided on different servers except the new ISEA and SIGGRAPH archives. Would this factor into our ability to connect the archives?

Taxonomies and Metadata

There are major challenges to address before connecting archives. First, there would be a massive amount of data from each archive; many archives have accumulated materials over many decades. Second, each archive categorises the information in a different manner.

It was clear that the metadata and taxonomies of each archive would be important, therefore we started by outlining the ISEA and SIGGRAPH archive’s contributor, presentation, workshop, and art event types. Through the generation of lists, the differences were apparent. The metadata for artworks varied between archives. For instance, ISEA contains art events that are tagged with types such as Art Exhibition, Screenings, Performances, etc. and subtypes such as Bio Art, Installation Art, VR, AR, Robotics (see figure 9). Each art event entry also contained information such as medium, size, year produced and exhibited, etc. The SIGGRAPH archive also contained the same basic information but was not organised by the same type and subtype structure. The ISEA archive contains a wide variety of presentation types (keynotes, papers, artist talks, summits, meetings, posters, etc.) whereas the SIGGRAPH archive only had four types (papers, essays, talks, and panels). There were similar, although not exactly the same, categories for the art events between the two archives. The SIGGRAPH archive does not contain workshops or tutorials.

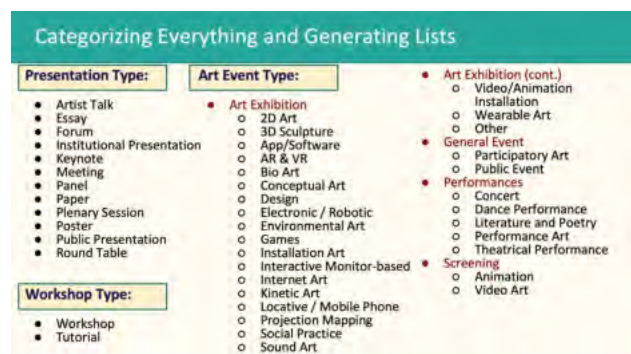

Figure 9. List of presentation, workshop, and art events types in the ISEA archives.

When focusing on the types of contributors included in the archives, similarities and differences were again apparent. The important metadata, including the person's name, affiliation, and location, appeared to be similar in all the archives. The SIGGRAPH Art Show archive's people types ranged from administrative to artists to presenter (see figure 10). The people types in the ISEA archive included roles such as presenter, workshop coordinator, artist, International Program Committee member, and more. The FILE festival archives used these lists to create a complementary data structure that addressed the needs of their archive while mirroring the basic structure of the SIGGRAPH and ISEA archives' taxonomies. ADA uses a variety of types within top level categories (genre, subject and technology for art events). All the archives use keywords as well as types to enable advanced query capabilities.

Although generating lists of types and categories was a useful exercise in understanding each archive, the similarities and differences appear to not be as important as initially thought.

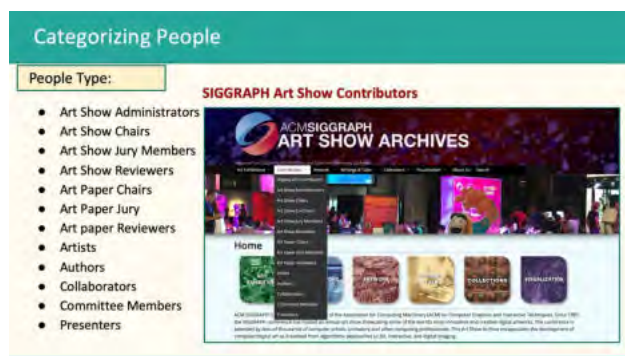

Figure 10. People types in the SIGGRAPH Art Show Archives.

Challenges

Funding, Personnel, and Technical Expertise

The group discussed the potential of co-authoring grant proposals but so far, multinational grant opportunities have been elusive. Individual archives receive limited funding from various sources but only a very small fraction of that funding has been devoted to connecting the archives. Each archive employs volunteers, students and/or staff to program, populate, and proof the contents of their archive.

The challenge of creating a technical solution to connect new media art archives was solved when a faculty member working with FILE proposed a viable solution including the development of an API (Application Programming Interface), which is a software intermediary that allows two applications to communicate. In order to expedite the process, funding is needed to enable him to dedicate more of his time on the project. Therefore, as important as this initiative is for educators, researchers and artists, the lack

of funding is inhibiting progress. Co-authoring grant applications remains a priority.

Standards and Name Authority Control

The group discussed the need to establish standards that would permit cross-communication between archives. The most apparent problem was the verification of the name of the artwork or person in each artwork. It is not uncommon for an artist to have multiple versions of a work or different titles for the same artwork and occasionally artworks share the same title, e.g. *Untitled*. In terms of handling names for a person, common problems include different names for the same person, surname changes through marriage, missing middle names, reversals of last and first names, deviation in spelling from non-English language translations, the use of aliases, artist collective names, etc. How will this issue be resolved when trying to connect to other archives?

To solve the name authority problem, a variety of solutions was considered, and Wikidata was selected as the best one. Since SIGGRAPH, ISEA, and FILE's technological back-end were so closely related we discussed the potential of uploading the contributor information to Wikidata and retrieving the unique identifier to use in verifying identity. Dalton Lopes Martins, who is one of the developers of Tainacan, is taking the lead on creating the technology to connect all the archives.

Approaches to connecting archives

Centralised System

During the FILEALIVE meeting in 2020, a variety of methods of establishing a connection between the archives were presented. A central hub containing all the data from all the archives was proposed (see figure 11). This solution would enable archives to connect to the site to retrieve data from each of the archives when a user looked at information in any of the archives. This "motherhip" would manage the connections between all the archives. This requires resources including server space, management personnel, technical expertise, and funding. This method would handle challenging issues related to copyright, permission, and ownership of data. A centralised system puts the burden and authority in the hands of one party. Another problem with a centralised system was the dependency issue—all archives would have to retrieve their information from the "motherhip" and if the server went down, all parties would be affected. Another approach is to use a trusted centralised storage repository to search for unique identifier data and return information. We need to find and examine existing systems that could be used by archives around the world. This method of using a system to search for unique identifiers has potential but more research is warranted.

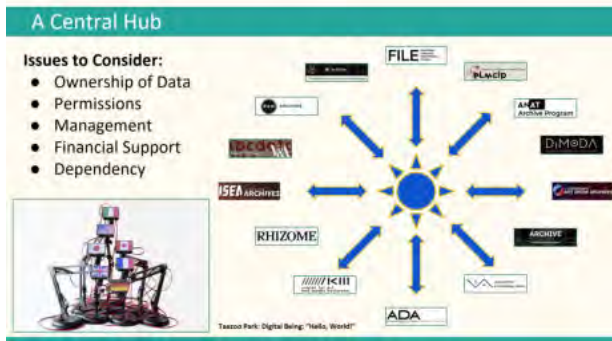

Figure 11. Centralised System.

Decentralised System

Another solution would be to construct a decentralised system. We considered two possibilities: the Absorption method (each archive’s data is exported and then imported into the other archives) and the Index File method (each archive has an accessible XML file searchable by other archives). The Absorption method was not optimal because the archives are being updated regularly and the technical logistics placed a burden on all archives involved. In addition, this method posed permissions and copyright issues. The Index File method would involve inserting a link into the original archive if a query returned a positive result. Each archive would be responsible for maintaining its own index file. This approach has potential and further research is needed.

Starting Points and Interface

After carefully investigating the different archives, our analysis suggested there are two common types of information in most online media art archives—People and Artworks. Therefore, it made sense to start by creating a connection to people and artworks located in other archives. A proposed interface for the People pages would be to display the person’s information in the originating archive and also display icons of other archives that contain information about that same person (see figure 12).

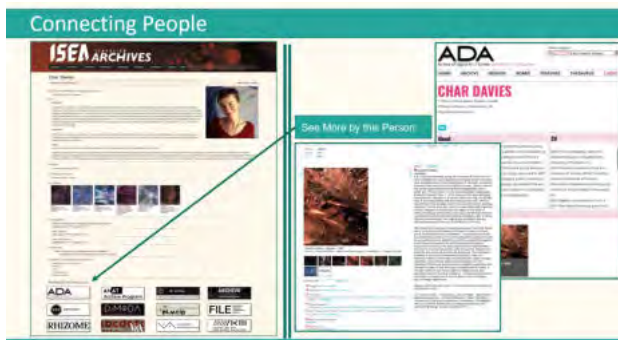

Figure 12. Connecting people.

This same method could be used for artworks and other art events. If an artwork is found in other archives, the page would state: “This [artwork] is also available in the [name] archive” and provide a link to the entry in the other archive (see figure 13).

Figure 13. Connecting artworks.

This method will require modifications to templates and webpage coding in all the archives as well as implementing the procedure outlined in the next section.

Procedure to Connect Archives

Using Wikidata as a Standard

For the formation of this interoperable network of digital archives, each participating repository must meet some technical requirements. The first is to have an API for collecting and recording data, allowing data to be exported and updated computationally. The second requirement is to use a standardised entity identifier. We propose to use Wikidata QIDs, the unique identifier used by Wikidata. The purpose of the QID is to verify that a person listed in one archive is in fact the same person listed in the other archives. For this to work satisfactorily, all repositories need to reconcile the names of people on Wikidata, recording that artist’s QID in their own database, when it exists, and creating a new QID for that artist when it doesn’t already exist. You must assume the creation of a web service to perform this type of operation for each archive. The repository reconciliation service can be created, for example, using Python scripts that collect data from each repository through its API and use a reconciliation API with Wikidata, such as the Wikidata Reconciliation Service for OpenRefine. OpenRefine is a free tool that can be used to clean tabular data and connect it with knowledge bases, including Wikidata. [17] One of the main functions in OpenRefine is the reconciliation service that matches items in a local data source against the same items in an external data source. [18]

Making the Connection

A user will initiate the process by going to a person's profile in one of the archives. This will automatically trigger the API. The API will search Wikidata to find the person using the QID and filter through the identifiers to extract the links to other archives for the person, if any. If found, the resulting URL that leads to the person's profile page in another archive will be added to the page in the original archive. The original archive will display the icons, as selectable buttons, of each of the other archives that person is found in.

If a user clicks on one of the buttons, a new browser window will be opened using the URL associated with that button. This will then display the person's profile page in the other archive. A very similar procedure can be used for artworks as well.

Conclusion

Our goal is to establish a system that will minimise the need for support, with each party responsible for their own archive's connection to Wikidata. The prototype will be developed by Dalton Lopes Martin in Brasil and modified to be used by each archive. Interface modifications to accommodate the connections will be the responsibility of the individual parties. Although the technology to connect archives is still in the planning stages, we now have a road map to achieve our goal. Through the dedication and expertise of the parties involved, there will be a day when researchers, educators, students, artists, and other community members will be able to access the rich history of new media art with minimal effort.

Acknowledgments

We would like to thank the archive representatives from the core group of archives: Paula Perissinotto, Fabiana Krepel and Dalton Lopes Martin (FILE); Oliver Grau, Wendy Coons (ADA), Christina Radner, Veronika Liebl (Ars Electronica). Special thanks are due to Dalton Lopes Martin for his innovative vision, technical expertise, and contributions to this project.

Abstract

The existence of a new hybrid spatial ontology (material/virtual, offline/online) has triggered some unique territorialization processes closely linked to the technopolitical and technoeconomic domain. These processes involve a new symbolic-cultural output that questions the validity of locative art's theoretical framework, initially associated with situationist psychogeography and with the informational context associated with GPS metadata. By contrast, postlocative art deploys strategies that critically accept the important role that non-humans play in public representation as well as in delegating the production of meaning to AI, thus moving beyond the locative framework and closely associating itself with the postphenomenology of complex systems.

Keywords

Locative art; postlocative art; inforg; onlife; artificial intelligence; geosemantics postanthropocentric; non-anthropocentrism.

Introduction

In May 2003, during the Art + Communication Festival at the RIXC (the Center for New Media Culture in the Latvian capital of Riga), media artist and activist Karlis Kalnins coined the term locative media. He proposed this novel term as a category within new media artistic practices to denote the products and processes aimed at researching the uses and applications of geolocation-based ICT services designed especially for smartphones. The purpose of locative media was to give context to the information in hybrid space, as understood from its physical and "datified" dimension, which facilitates the mixed (offline and online) or *onlife* experience, to borrow a term from Luciano Floridi [1]. However, this contextual link of geocoded cultural production, available at the user level and first integrated by the GPS service, was subsequently expanded (from Web 1.0 and 2.0 to Web 3.0) to other geosemantic relationships and encodings of the locations of networked data, objects, subjects and discourse. This would gradually modify and move beyond the term locative media toward postlocative media, introduced by Marc Tuters. So, while the functional

link of the information in locative media was initially established with geographic location, the locus, or the fixed position in the physical space of the locative object or medium that emits its GPS signal (or of the subject that conveys the locative object or medium), geosemantics began to orchestrate other positions relative to the information within a heterogeneous network of interactions with other data, objects and subjects. In light of the ubiquity of networked information, this concept went beyond the initial locative meaning of information to emphasize other filters and contextual links. Following the thinking of Timothy Morton, this question brings us closer to the idea of a technocultural production inscribed on a symbiotic mesh [2] in a state of constant evolution and dialogue, in which the interconnections, the relationships and overlaps would be formed almost organically in a fragile political and socio-technological contingency. And, following Bruno Latour, in his Actor-Network Theory (ANT) [3], we are able to identify the connection nodes and the *actants* in interactions, perhaps the most active and dominant of the aforementioned mesh, by mapping networked controversies or, in following Frederic Jameson, by creating cognitive maps [4] that give shape in a contingent and knowable form to the complexity of hybrid space production.

The Promise of Locative Art

Since 2003, we have definitely left the desktop computing phase behind, and, of course, we have moved past the initial fascination with the synchronous networking capabilities associated with Web 1.0. We have helped popularize many WebGIS applications and services (with the launch of its most popular versions Google Earth and Google Maps) and accelerate media integration and portability, which gradually made ubiquitous computing possible thanks to the technological devices of geocoded cultural production integrated into the civil realm within the Web 3.0 framework. In fact, when this acceleration began in 2006, artist, designer and academic researcher Drew Hemment gave rise to the term locative art, which was confirmation at the time that the use of locative media had moved beyond poetics focusing on the phenomenology of the Internet itself, and therefore beyond the artistic practices of *net art* [5]. The

defining characteristic of locative art was to emphasize the relationship between information and place through techno-artistic mediation, proposing new poetics of mobility and the globalization and relocation of network communication and interaction. In this regard, given the many approaches to locative art, Marc Tuters and Kazys Varnelis proposed a classification system in 2006 based on two general strategies [6]: First, annotated locative art,¹ with works that would allow users/participants to make virtual contributions with their own geocoded informational content. And second, phenomenological locative art,² with works that trace the phenomenology of the data/subjects/objects in the hybrid space.

It should be noted that the initial experimental projects with locative media were, for the most part, product demonstrations and tests of the incipient technological possibilities, and were in large part absorbed by the technology industry itself for its own benefit. We must bear in mind that, prior to 2005, locative media were still evolving and continuously being defined, and they were still in a situation of emerging territorialization. We should also consider that media portability during this period had not been fully developed nor popularized (it was not until 2007 that smartphones became popular due to the successful marketing of the iPhone), and geolocated data mapping required expensive and heavy technological devices – like the GPS backpack – with very little battery life. This was a major factor in its public and private funding, which facilitated the costs of technological development to a great extent. It also led to a certain skepticism about the ability of locative art to critically and effectively appropriate geolocation-based technologies.

However, some of the first locative art projects and works did take a critical stance using their own medium, generally associated with cultural production fields of neo-mapping seminars, new media art workshops and festivals.³ The successive technological advances, often resulting from the artistic research itself, have been gradually integrated from these fields. In this revitalization emanating from the arts, authors such as Hemment and Ben Russell saw an optimistic “promise of transformation” [7][8], which involves the medium questioning itself, adding to the echo of the euphoria (and skepticism) of the defenders and detractors of the gradual empowerment of locative media in the civil realm.

Nevertheless, as Lauren Cornell and Kazys Varnelis announced in 2011 in their famous article ‘Down The Line’

[9], the term locative media, along with its use and commercial potential, spread rapidly to the private and public sectors. And it was there that it took shape strategically and economically, shutting down the transformational promise of locative media, which was reflected in the work of authors such as Russell and Hemment, and even William Gibson's science fiction [10]. Indeed, the authors underscored the fact that the evident shift from cultural (and artistic) production toward a greater role for private business and public institutions in the commercial use of locative media meant that the promise of a liberating transformation of locative media users was lost, making it clear that it was just that: a promise.

Psychogeography as the First Descriptive Framework of Locative Art

According to artist and locative media researcher Simon Pope, the psychogeographic influence associated with locative media became, right from the start, “something of an orthodoxy, with the requisite dissenters and historical revisionists” [11]. In fact, authors such as Tuters and Varnelis discuss this polarization existing in locative media texts, and add that “there’s something peculiar, even comical, in how the movement is ‘the Next Big Thing’ to some and a capitalist apocalypse to others” [12], thereby confirming that it was established as a field in dispute, with the power to attempt to define, represent and control the cultural production of hybrid space.

Evidence suggests that the psychogeographic practices were adopted as a concept to describe locative media uses, as asserted by authors such as Andrea Zeffiro [13]. Its early adoption can be determined in the numerous references in the early texts on locative media festivals, as evidenced by the tribute to the SI movement, with a version of the famous 1960 photograph, by the participants in the cartographic conference that took place in London between May and June of 2003 [14]. In his famous 1999 text, “Headmap Manifesto”, Russell also devoted a complete section to psychogeographic situations, suggesting that locative media are an opportunity for collective criticism and dissent against the surveillance and power of social control of location-aware devices. Hemment argued that the critical area in which they began to operate was the same one in which they emerged: that of military, state and commercial monitoring and surveillance. This circumstance set them up as accomplices but also as a medium through which to

¹ It is worth noting some of the early annotated locative projects here: “[murmur]” (2003) by Shawn Micallef, Gabe Roussel & James Sawhney; “Urban Tapestries” (2002-2008) of the group Proboscis; “Yellow Arrow” (2004-2006) by Brian House, Christopher Allen and Jesse Shapins; and the paradigmatic “Bio Mapping / Emotion Mapping” (2004 to present) by the artist Christian Nold.

² The paradigmatic projects of early phenomenological locative art are: “Listening Post” (2001) by Mark Hansen and Ben Rubin; “The Choreography of Everyday Movement” (2001) by Teri Rueb; or the works of the artist Jeremy Wood, as “GPS Drawing from Berlin to London” (2000); or the renowned project “Amsterdam RealTime (2002) by Esther Polak and Waag Society.

³ In this regard, the role of RIXC, the Center for New Media Culture (Riga, Latvia) is very important.

articulate the challenge of such means of social control. In this situation, Hemment differentiated between what he called the “dystopia of total control” and a “locative utopia” characterized by an optimism that “provides an antidote to our fears about ever encroaching forms of surveillance, and an important answer to the politics of fear” [15]. Like Russell, Hemment was optimistic about the rhetoric of situationist empowerment, and identified a certain transformational promise in the contingent reappropriation of the territorialization of hybrid space with locative media, using psychogeographical techniques.

Pope noted that, in a way, it would be odd not to find references to the situationist approach and to psychogeographical comparisons in location media practices, since both share methodologies such as drift or diversion, and implied walks and encounters in urban spaces, and the use of maps to examine the nature of the spaces they represented, as well as cartographic representation itself. However, he also notes that the similarities and correlations are not complete, nor – as we assert in this article – can they withstand analysis and interpretation under the current epistemic conditions [16].

End of the Locative Promise and Moving Beyond Psychogeography

Beyond the initial fascination due to the novelty of locative art and optimism, as Daniel James Frodsham notes, art with locative media was still a highly anticipated topic of interest at the famous ISEA symposiums specializing in electronic art and new media of 2004 and 2006. However, for the year 2011, many specialists were already talking about the “end of locative media” [17]. What end did they mean? What artistic idea with locative media had reached its end?

In the 2011 ISEA panel discussion, “Beyond Locative: Media Arts after the Spatial Turn”, Marc Tuters urged a rethinking of the city network, i.e., hybrid space, beyond locative media, pointing to Latour’s ANT and its descriptive alternative as the theoretical framework to follow. Science and technology researcher Tristan Thielmann stated outright that locative media had failed as social media disguised as indispensable, new and modern mobile devices [18], while artist, architect and researcher Mark Shepard was even more blunt, suggesting that it might be time to forget locative media, because the creative, theoretical and aesthetic possibilities of location as context filter had been exhausted [19], and he noted the need to move beyond and expand on the contextual anchoring of information exclusively associated with its geographic coordinates.

In his famous 2004 article, “Drifting Through the Grid: Psychogeography and Imperial Infrastructure”, Brian Holmes wrote that, within the uses of locative media, “the aesthetic form of the *dérive* is everywhere. But so is the hyper-rationalist grid of Imperial infrastructure” [20]. Holmes accepted the psychogeographical potential to understand the production of space from the perspective of

aesthetics, but he did not miss the fact that ICTs have a decisive impact on subjectivation processes, as well as territorialization processes, and play a role in shaping the imperial infrastructure from its political/military foundation (ultimately responding to hidden political interests). In this respect, the researchers Paraskevopoulou, Charitos and Rizopoulos point out that Holmes opposes the careless use of technology to generate an aesthetic with political intentions that are merely decorative [21]. According to Zeffiro, uncritical defenders of locative media might want to be invested in a “new kind of locational humanism” tailored to the world leader [22]. In fact, Holmes’ critique addresses the ambiguities of certain cultural productions and artistic projects that, in alliance with technological developments, would tacitly allow the computer tracking and registration of the actions and intentions of the subject, always recorded and monitored with footprints of their individual differences in hybrid space. In Holmes’ judgement, these footprints should be critically integrated into the artistic project itself and constitute the basis of its political intentions, as well as in its own questioning as a medium, at least if it wants to be under the hypothetical protection of the radical project of Situationist International (SI).

Since 2011, and continuously with the criticism of locative art, there has been a growing desire to move beyond the initial promises and associations with situationist practices (bluntly described as a failure to be overcome). This impulse toward self-criticism is in response to a broader turn in cultural theory that began with the spatial turn, followed by the informational turn and the object turn in the poststructuralist cultural theories of Speculative Realism (SR) and Object-Oriented Ontology (OOO) closer to the new episteme of the current “Hyperhistory.” [23].

The end of locative media mentioned on the ISEA 2011 panel discussion called, on the one hand, for moving past the descriptive model identifying with the rhetoric of contingent reappropriation of psychogeographical techniques from the SI and their promises of critical empowerment, which were unable to address the contextual problems of the geocoded hybrid space. And, on the other hand, for moving beyond the idea of localization as the only calculation associated with physical position (and therefore also associated with its historical origins of tracking data/subjects/objects with the GPS system). Thus, the exclusive relationship between the contextualization of spatial information, and the concept of mapping and representing a homogeneous territory characteristic of modernity, was broken.

In his 2012 article, “From Mannerist Situationism to Situated Media”, Tuters, who was especially involved with the criticism of locative media, explicitly stated that locative art projects should go beyond what he called “mannerist situationism”. Which is to say they should pay more attention to and stress the concept of localization and network location as opposed to physical location, as the only and exhausted contextual filter of informational

geosemantics (in line with what Shepard already mentioned). This would require reconsidering and replacing the idea of space and location, in accordance with a relational dimension of a physical/virtual nature: “Replace the concept of geographic location as the core concept of locativity, with the more relational notion of proximity, not only in relation to place but also in relation to matters-of-concern” [24].

This necessary change of approach advocated by Tuters made it possible to address the relationships and phenomena that were not necessarily anchored to physical location, and also established the trend – very contemporary and accepted now – of conceiving physical space as something completely instrumentalized beneath the geocoded space that coproduces it. A space in which floating information appears on our screens in accordance with action and interoperability protocols controlled by artificial agents to bring order to the informational chaos of the network system according to protocols that – mostly – serve technoeconomic, business and supranational interests. In this scenario, according to Tuters, the maps will increasingly become “cognitive maps” (as defined by Jameson), and less geographic or political. Which is to say that the special, geosemantic and relational orientation, takes into account the inter-relational dynamics that the actants establish in the network system, reformulating the artistic practice of locative media toward approaches that are close to Latour’s OOO and, specifically, ANT.

Postlocative Media in the Context of Ubiquitous Computing

It was Tuters himself who introduced the term postlocative media during his conference “Forget Psychogeography: The Object-Turn in Locative Media”, presented in May 2011 at the Massachusetts Institute of Technology. In particular, he spoke of a postlocative practice specifically referring to those that had gone beyond (and definitely forgotten) the legacy of situationism and of modernity’s orientation of homogeneous space. Practices that would consider mappable not just those events produced by humans but also those produced by non-humans. Practices that, in terms of orientation, would be considered the actions and positions of a user in relation to the spatial framework described by subjects and by objects, or information produced and interacting in hybrid space. In Tuters’ own words, postlocative would therefore be a practice inscribed in a theoretical framework capable of accommodating:

[...] its traditional geographic concerns (the physical location of one’s body will always be relevant), but also, crucially, praxis ranging from experiments with the Internet of Things, to information visualizations functionally bound to objects. [25]

Pursuing the inertia of the terminology proposed by Tuters, we deem it necessary to first define what postlocative media are so we can subsequently define postlocative media. Once

this is done, we can discuss what is new and different in our proposed definition of postlocative art in relation to moving beyond locative art. This will also allow us to clarify and specify what we consider to be most important with respect to the contributions already made in this regard by other authors.

Postlocative media would be those everyday technological devices that succeed locative media in geocoded cultural production. Considering their historical context, they are therefore devices that are already immersed in a widespread media and computer ecosystem (ubiquitous computing) with geocoding of the information that is scalable to many diverse objects (Internet of Things) and, above all, with geosemantics that are mostly managed by multi-agent systems (artificial intelligences distributed in a network). Therefore, the informational context they manage does not depend so much on the metadata of the geographic location, but on the relational contingencies that occur in a network with multiple interactions, social dynamics and personalized browsing histories for each user. Within these contingencies, georeferencing is just one more piece of metadata that affects geosemantics, but not the only or main one (as it is, by contrast, in locative media). Now, it is algorithmic filters that prioritize the relationships of proximity between data/subjects/objects in the network, orienting and determining our experience and perception of the hybrid space. Postlocative media have gradually liberated themselves from the materiality of old computers, smartphones or tablets with GPS, merging into corporal and environmental computing that is widely accepted by users in their *onlife* experiential state, where everything constantly interacts with everything, in both very public and social as well as very private and intimate surroundings.

Toward Postlocative Art

If we consider that the artistic practice of locative media, locative art, has been overtaken by another arising from the artistic practice of postlocative media, it is logical to speak here of postlocative art. We are defending the relevance of the term, based on the terminology proposed by Tuters, but we have nevertheless observed that it is used in a very vague way by a minority in the thinking and practice of contemporary new media art. In fact, in the academic papers published to date, this artistic practice is only mentioned as *post-locative art* in the dissertation “The Social Production of Hybrid Space” (2018) by researcher Robin van den Akker. However, he only introduces the term merely to adjectivize the phrase *post-locative media art* in the context of the “second wave of locative media art” [26]. In addition, we have also found only one online exhibition project presented as a delocalized gallery of post-digital & post-locative art, as in the case of the LIMb0 Gallery (which currently seems to have suspended its activity temporarily) [27]. We assume that the term postlocative art is still a proposal closely associated with moving beyond the initial

theoretical framework of locative art, and therefore very confined to the specialized field of critiquing locative media. Despite this situation, we do consider it a proposal that deserves to be expanded into the broader realm of contemporary art with new media, precisely because it clearly marks a change of period in the practice and geocoded artistic production in hybrid space. And, likewise, because it provides a framework for the consequent reflections and debates currently arising around such practice.

Hence, postlocative art would be the artistic practice arising from the creative, critical and experimental use of postlocative media that goes beyond contextualizing information solely due to its geographical location, thus placing the individual in a geocoded hybrid space defined as a network of multiple interactions between ubiquitous and hyperconnected data, subjects and objects. It is therefore an art that produces a particular arrangement around the geosemantic context of – in the current context, hyper-historical – information that influences the events that coproduce the human experience and – at the same time – coproduce the same hybrid space. Consequently, its artistic reflection is situated around the taking of positions and aesthetic-political representations of the *infor*, as this term was used by Floridi [28]. That is to say, an informationally embodied organism in a network resulting from the computerization of the category of subject and of agency. An organism that, according to Floridian thought, constitutes the “infosphere” by means of its interactions and relationships, as an entity that is information and operates informationally in a symbiotic manner with its environment. Thus, our *infor* state blurs the distinction between human and non-human, and between real and virtual, within the complex geosemantic network’s permanent capacity for connection. A network that offers new relational characteristics both *of* and *between* persons and *of* and *between* things, as well as *of* and *between* persons and things. With this approach, postlocative art attempts to give rise to a much more cybernetic and relational notion of the proximity between networked data/subjects/objects, with the aim of participating in the *infor* subjectivation processes inscribed in current technocultural productions.

The important thing about the term postlocative is that it gives us an idea about geocoding and the apparently dematerialized geosemantics, which nevertheless demands biopolitical performativity from us in our state of *infor*. That is, it demands the renewed political will of the subject which, as Tuters points out, consists of the active participation in and infiltration of the cybernetic dynamics of the chain of references in the cultural production network of this systemic arrangement:

Through the careful work of representation every object could carry with it its own unique chains of reference, thereby revealing the substance of ‘the local’ to be composed of an endless variation of scales. [29]

The definition of postlocative art that we extrapolate and expand upon here emerges – as we mentioned earlier – from the approach proposed by Tuters, but also echoes the approach put forward by Benjamin H. Bratton in his book “Suspicious Images, Latent Interfaces + Community Wireless Networks as Situated Advocacy (Situated Technologies Pamphlets, 3),” published in 2008. As Tuters does with Latour, Bratton points to the thinking of Rancière on the “distribution of the sensible,” as a more fruitful starting point for conceptualizing art after the locative phenomenon. An art that observes that an opportunity exists for a more heterogeneous process of representation using technology as a means to facilitate this process [30]. In return, however, such technology should be continuously examined, shared and decentralized by public audit, and certainly also be of an artistic nature. It is therefore an art that echoes a thought that puts new practices into play that take into account its ability to help radically transform the conditions of collective life in hybrid space. For Rancière, this new “aesthetic art regime” [31] is at the core of political action at the present time, but is not exclusively the result of a self-referential practice. What’s more, the new aesthetics it offers, understood in this way, determine what is presented and appears, what is visible from the invisible, intervening in the delimitation of space and time, and interfering contingently in the definition and production of the ordinary. Rancière therefore connects with the aesthetic opportunity that Jameson also claims for cognitive mapping as he imagines and calls for the creation of a new public space in which to express dissent and map conflicts and aspirations. This involves a technopolitical contingency with a community function, consisting of “building a specific space, an unprecedented way of sharing the ordinary world” [32].

In our understanding, what is interesting about the aesthetic notion noted by both Tuters and Bratton, relying on the thinking of Latour and Rancière, is the utopian and transformative potential of postlocative art due to the liberating relationship it establishes between the aesthetic and the technopolitical. A relationship that does not consist of aestheticizing politics, nor of the familiar practices of so-called political art or compromised art, but of disrupting the standardized coordinates of the sensory and cognitive experience. Hence, it is a relationship that would not be established by messages about the established order, or by representing the existing structures of society, but precisely by keeping distances without following any predetermined model, which is to say, “by the kind of time and space it establishes, by the way in which it divides that time and populates the space” [33].

We argue that the redistribution of the sensible among *actants* arises from a more profound change in the very nature of hybrid space (which is broader than a momentary redistribution of the sensible in the urban space in which situationism functions). Not surprisingly, both locative art, and later postlocative art, gradually point to a structural

transformation of the public space, and to a new aesthetic regime that is already fully inscribed in the ontology of hybrid space. This is the true experimental and speculative territory of postlocative artistic practices, a territory in which non-humans acquire the ability to comment on their own environment, gaining agency skills and influencing the chains of events that affect the human experience, and therefore the very idea of subjectivity.
