**HAL** is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

**Key Words:** Liquid metal batteries, Magnetohydrodynamics, Numerical simulations

Liquid Metal Batteries (LMB) are composed of three layers of fluids (liquid metal electrode–electrolyte–liquid metal electrode) of different densities lying over each other and stabilized by gravity. The composition of the positive/bottom electrode of an LMB may become very inhomogeneous over charge/discharge cycles, which limits the battery efficiency. Yet rotational flows in electrically conducting fluids can be generated by the Electro-Vortex-Flow (EVF) phenomenon, i.e. the interaction of a non-uniform current with the magnetic field it generates [1]. Using axisymmetric and fully three-dimensional numerical simulations with the multiphase magnetohydrodynamic code SFEMaNS [2], we investigate whether the mixing induced by the EVF mechanism can help homogenize the positive electrode against buoyancy during charge/discharge cycles.

**Figure 1:** Molar fraction of Li atoms in the positive/bottom electrode during the charge of a Li||Pb liquid metal battery after a discharge.
