HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers. L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

Introduction

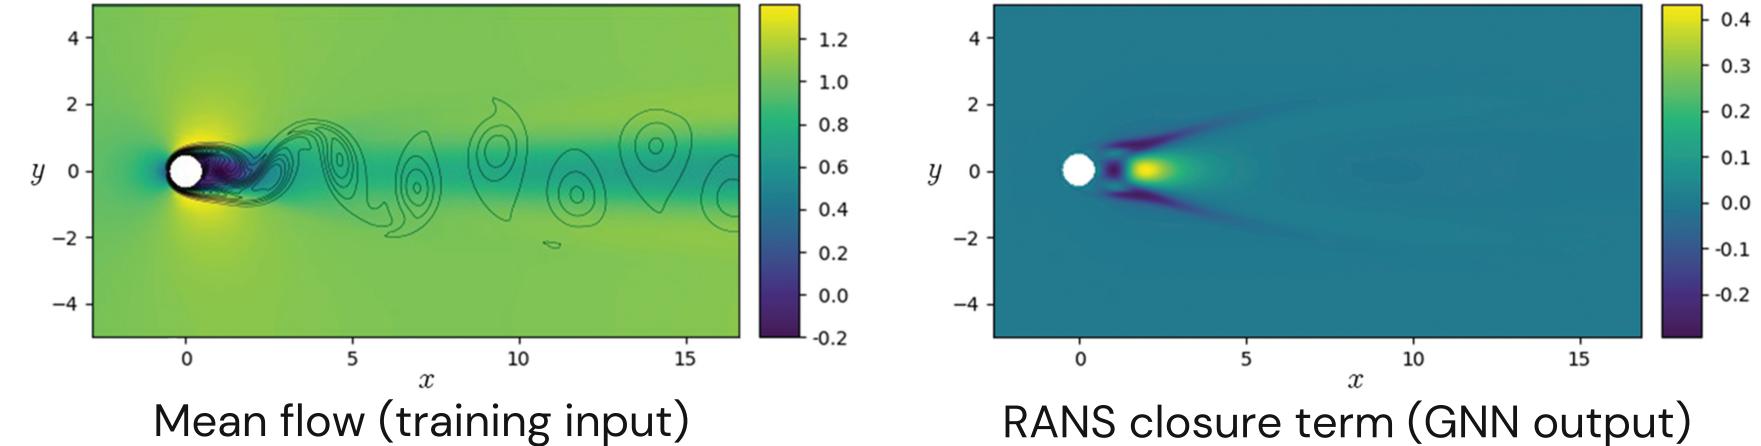

for Reynolds-averaged Closure modeling Navier-Stokes (RANS) equations is an active area of research. Finding an effective closure term may require significant modeling effort; sometimes a suitable closure model may not even exist. Here, we combine the use of Graph Neural Networks (GNN) [2] and finite-elements (FEM) solvers, in order to approximate a general, mesh-free **closure model** for RANS equations by solely leveraging the available data.

Dataset & training

Training dataset: Centered cylinder at different Reynolds numbers [Re=50 to Re=150, ΔRe=10] [Re=110 is excluded for validation]

Methodology

We exploit geometrical information from the mesh as a relevant part of the process of operator learning, using GNN, in order to reproduce the convective/diffusive dynamics of the underlying system. Points and connections of the mesh are one-to-one coupled with nodes and edges of the GNN architecture, creating a direct interface etween FEM and GNN algorithm.

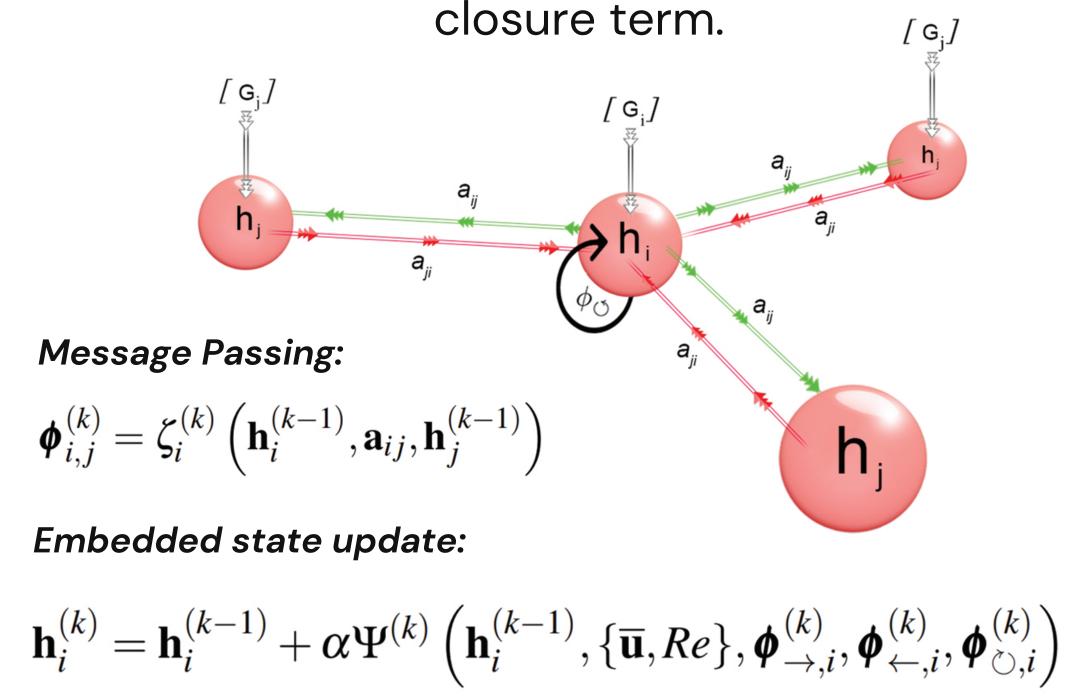

The training process has been performed on 3 differently refined meshes, depending on the Reynolds numbers, to ensure the mesh independence of the NN model. The loss function to be minimized during the training process is as follow:

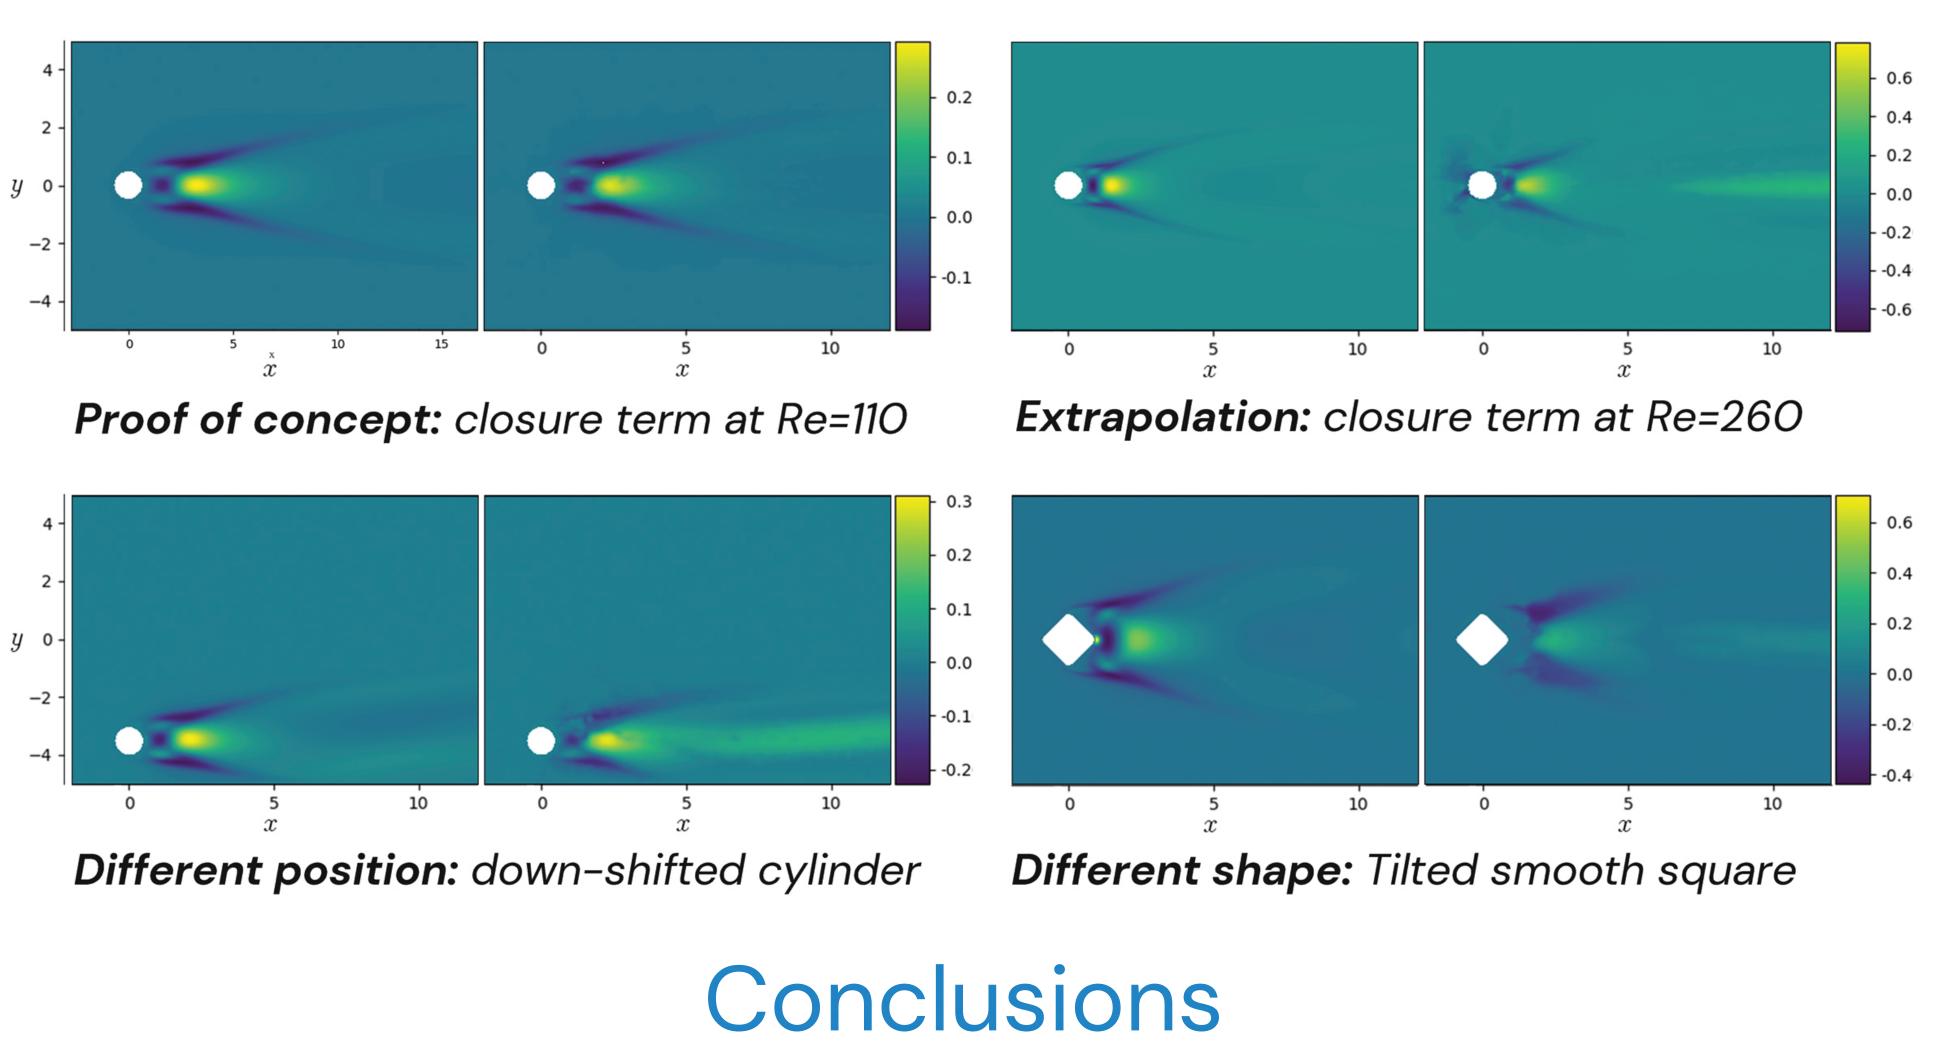

$\varepsilon = \sum_{k=1}^{\bar{k}} \gamma^{\bar{k}-k} \left[\frac{1}{N} \right]$	$\sum_{i=1}^{N} (x_i - y_i)^2 \bigg]$
--	---------------------------------------

in which N is the number of nodes, **x** is a vector containing the GNN's prediction for each node, **y** is a vector of the same dimensions representing the ground truth, k is the number of GNN layers and γ a process parameter

Then, the message passing technique allows to collect the information stored in each node of the node-wise reconstruct, via net and a encoding-decoding process, meaningful а

In this work we show the use of GNN in combination with FEM simulations for RANS modeling. Despite the relatively small amount of data required for the training (10

In the previous, **h** is the embedded state, defined on each node; k indicates the progression of updates over **h**; **a** stands for the directed connection; ϕ indicates the messages shared across the net, Ψ and ζ are two functions approximated by Multi-Layer Perceptrons (MLP), and α is a hyper-parameter of the net. G indicates the inputs: the velocity $\overline{\mathbf{u}}$, and the Reynolds numbers (Re).

snapshots), this architecture can show remarkable results in prediction terms. Future and ongoing work focuses on enforcing physical constraints deriving from the mathematical RANS equations to provide physical information to the GNN structure [1].
