Safety, Optimization & Learning

Cyber-physical systems (CPS) are physical systems enhanced with computation and communication capabilities: *smart vehicle, smart grid, smart building...*

CPS characteristics:

- Evolve in uncertain and highly dynamic environment
- Are subject to critical safety requirements
- Achieve complex tasks with a high degree of autonomy

Formal methods for CPS

- Computational approaches for verification or synthesis of systems, based on mathematical formalization and rigorous reasoning, they require
 - Specifications whose semantics is precisely defined mathematically
 - Mathematical models of systems (possibly based on data)
- Suitable for the design of safety critical systems (correctness guarantees)
- Personal reflection fed by several projects CODECSYS (2016-2019) / PROCSYS (2017-2023) / Chair RTE-CentraleSupélec (2017-2027)

The symbolic control approach

Symbolic control is a formal method for controller synthesis:

- based on symbolic (i.e. finite state) abstractions of systems
- applies to nonlinear systems with input/state constraints and bounded uncertainties
- mathematical correctness of synthesized controllers

Fundamentals of symbolic control:

- Discrete controller synthesis Safety, reachability, attractivity and recurrence
- Symbolic control of nonlinear systems System abstraction, controller concretization, robustness issues
- Recent advances in symbolic control:
 - Symbolically-guided model predictive control High performance controllers with safety guarantees
 - Data-driven symbolic control *Towards safe learning approaches for nonlinear systems*

Fundamentals of symbolic control:

Transition systems

Definition

A transition system is a tuple S = (Q, P, F) where

- Q is a set of states
- P is a set of inputs
- $F: Q \times P \rightrightarrows Q$ is a (set-valued) transition map

S is said to be finite or symbolic if Q and P are finite.

• The set of enabled inputs at state $q \in Q$ is

$$\mathsf{enab}_F(q) = \{ p \in P | F(q, p) \neq \emptyset \}$$

• The set of non-blocking states is

$$\mathsf{nbs}_{F} = \{q \in Q | \mathsf{enab}_{F}(q) \neq \emptyset\}$$

• The transition system is deterministic, if

 $\forall q \in \mathsf{nbs}_F, \ \forall p \in \mathsf{enab}_F(q), \ \mathsf{card}(F(q,p)) = 1$

Definition

A trajectory of S is a couple of state and input sequences $(\{q_t\}_{t=0}^{t=T}, \{p_t\}_{t=0}^{t=T-1})$, where $T \in \mathbb{N} \cup \{+\infty\}$ and

 $p_t \in enab_F(q_t)$ and $q_{t+1} \in F(q_t, p_t), \forall t = 0, \dots, T-1.$

- A trajectory is maximal, if $T = +\infty$ or else if $q_T \notin nbs_F$
- A trajectory is complete, if $T = +\infty$
- The set of maximal trajectories of S is called the behavior of S, denoted B_{max}(S)

Symbolic system - example

($enab_F(1)$	=	$\{a\}$
	$enab_F(2)$	=	Ø
	$enab_F(3)$	=	$\{a, b\}$
	$enab_F(4)$	=	{ <i>b</i> }

- $\mathsf{nbs}_{\textit{F}} = \{1,3,4\}$
- S is deterministic

- (日)

æ

→ ∢ ∃ →

Symbolic system - example

- $\begin{cases} \operatorname{enab}_{F}(1) = \{a\}\\ \operatorname{enab}_{F}(2) = \emptyset\\ \operatorname{enab}_{F}(3) = \{a, b\}\\ \operatorname{enab}_{F}(4) = \{b\}\\ \operatorname{nbs}_{F} = \{1, 3, 4\} \end{cases}$
- $\mathsf{card}(F(1,a))=\mathsf{card}(F(4,b))=2$

 \implies *S* is non-deterministic

Symbolic system - example

Definition

A (static state-feedback) controller for transition system S = (Q, P, F) is a set-valued map $C : Q \rightrightarrows P$ such that for all $q \in Q$, $C(q) \subseteq \text{enab}_F(q)$.

The domain of the controller is dom(C) = { $q \in Q | C(q) \neq \emptyset$ }.

The controlled dynamics is described by transition system $S_C = (Q, P, F_C)$ where $q^+ \in F_C(q, p) \iff$ $p \in C(q)$ and $q^+ \in F(q, p)$ Safety: keep the system state in a set $Q_s \subseteq Q$ forever.

Definition

 $C: Q \Longrightarrow P$ is a safety controller if for any initial state $q_0 \in \text{dom}(C)$, all maximal trajectories of $S_C(\{q_t\}_{t=0}^{t=T}, \{p_t\}_{t=0}^{t=T-1})$ are complete and satisfy:

$$\forall t \in \mathbb{N}, q_t \in Q_s$$

Definition

A state q is safety controllable if there exists a safety controller C such that $q \in \text{dom}(C)$.

The set of safety controllable states is denoted s-cont(S, Q_s).

Termination by finiteness of Q.

Theorem

Termination by finiteness of Q.

Theorem

Termination by finiteness of Q.

Theorem

Reachability: bring the system state in $Q_s \subseteq Q$.

Definition

 $C: Q \Rightarrow P$ is a reachability controller if for any initial state $q_0 \in \text{dom}(C)$, all maximal trajectories of $S_C(\{q_t\}_{t=0}^{t=T}, \{p_t\}_{t=0}^{t=T-1})$ satisfy:

$$\exists t \in \mathbb{N}, q_t \in Q_s.$$

Definition

A state q is reachability controllable if there exists a reachability controller C such that $q \in \text{dom}(C)$.

The set of reachability controllable states is denoted r-cont(S, Q_s).

Reachability synthesis $R_0 = Q_s$ loop $| R_{k+1} = Q_s \cup \operatorname{Pre}(R_k)$ until $R_{k+1} = R_k$ return $R^* = R_k$ Termination by finiteness of Q.Theorem

Reachability synthesis $R_0 = Q_s$ loop $| R_{k+1} = Q_s \cup Pre(R_k)$ until $R_{k+1} = R_k$ return $R^* = R_k$

Termination by finiteness of Q.

Theorem

Reachability synthesis $R_0 = Q_s$ loop $| R_{k+1} = Q_s \cup Pre(R_k)$ until $R_{k+1} = R_k$ return $R^* = R_k$

Termination by finiteness of Q.

Theorem

Reachability synthesis $R_0 = Q_s$ loop $| R_{k+1} = Q_s \cup Pre(R_k)$ until $R_{k+1} = R_k$ return $R^* = R_k$

Termination by finiteness of Q.

Theorem

Reachability synthesis $R_0 = Q_s$ loop $| R_{k+1} = Q_s \cup Pre(R_k)$ until $R_{k+1} = R_k$ return $R^* = R_k$

Termination by finiteness of Q.

Theorem

Uniform reachability controllers

Definition

 $C: Q \Rightarrow P$ is a uniform reachability controller if for any initial state $q_0 \in \text{dom}(C)$, there exists $K \in \mathbb{N}$, such that all maximal trajectories of $S_C (\{q_t\}_{t=0}^{t=T}, \{p_t\}_{t=0}^{t=T-1})$ satisfy:

$$\exists t \leq K, x_t \in Q_s.$$

Proposition

For symbolic systems, reachability and uniform reachability are equivalent.

Counter-example for infinite systems:

Attractivity: bring the system state in Q_s and then keep it in Q_s forever.

Definition

 $C: Q \Rightarrow P$ is an attractivity controller if for any initial state $q_0 \in \text{dom}(C)$, all maximal trajectories of $S_C(\{q_t\}_{t=0}^{t=T}, \{p_t\}_{t=0}^{t=T-1})$ are complete and satisfy:

$$\exists K \in \mathbb{N}, \ \forall t \geq K, \ q_t \in Q_s.$$

Definition

 $C: Q \Rightarrow P$ is an uniform attractivity controller if for any initial state $q_0 \in \text{dom}(C)$, there exists $K \in \mathbb{N}$ such that all maximal trajectories of S_C $(\{q_t\}_{t=0}^{t=T}, \{p_t\}_{t=0}^{t=T-1})$ are complete and satisfy:

$$\forall t \geq K, \ q_t \in Q_s.$$

Definition

A state q is (uniformly) attractivity controllable if there exists an (uniform) attractivity controller C such that $q \in \text{dom}(C)$.

The sets of attractivity controllable states and of uniform attractivity controllable states are denoted a-cont(S, Q_s) and ua-cont(S, Q_s), respectively.

Even for symbolic systems, attractivity and uniform attractivity are not equivalent:

Synthesis through nested fixed point computation:

Attractivity synthesis $R_0 = \text{r-cont}(S, \text{s-cont}(S, Q_s))$ loop $| R_{k+1} = \text{r-cont}(S, \text{s-cont}(S, Q_s \cup R_k))$ until $R_{k+1} = R_k$ return $R^* = R_k$

Termination by finiteness of Q.

Theorem

- $R_0 = ua\text{-cont}(S, Q_s),$
- $R^* = a\text{-cont}(S, Q_s)$.

$$R_1 = R^* = \operatorname{a-cont}(S, Q_s)$$

Recurrence: bring the system state in Q_s infinitely often.

Definition

 $C: Q \Rightarrow P$ is a recurrence controller if for any initial state $q_0 \in \text{dom}(C)$, all maximal trajectories of $S_C(\{q_t\}_{t=0}^{t=T}, \{p_t\}_{t=0}^{t=T-1})$ are complete and satisfy:

$$\forall K \in \mathbb{N}, \exists t \geq K, q_t \in Q_s.$$

Definition

A state q is recurrence controllable if there exists a recurrence controller C such that $q \in \text{dom}(C)$.

The set of recurrence controllable states is denoted rec-cont(S, Q_s).

Synthesis through nested fixed point computation:

Recurrence synthesis

 $R_0 = \operatorname{r-cont}(T, Q_s)$ loop | $R_{k+1} = \operatorname{r-cont}(S, Q_s \cap Pre(R_k))$ until $R_{k+1} = R_k$ return $R^* = R_k$

Termination by finiteness of Q.

Theorem

$$R^* = rec\text{-cont}(S, Q_s).$$

$$R_0 = r \text{-cont}(S, Q_s)$$

$$R_1 = R^* = \operatorname{rec-cont}(S, Q_s)$$

Example 1: go to Q_1 , then go to Q_2

- Compute the product of system and specification automaton
- Solve a reachability problem in the product space: *Reach the green state.*

Example 2: go to Q_1 , then go to Q_2 ; repeat this task infinitely often

- Compute the product of system and specification automaton
- Solve a recurrence problem in the product space: *Visit the green state infinitely often.*

Wide range of possible specifications \rightarrow Linear Temporal Logic

Example 2: go to Q_1 , then go to Q_2 ; repeat this task infinitely often

A control problem with safety constraints

We consider a nonlinear system subject to state/input constraints and bounded disturbances:

$$x_{t+1} = f(x_t, u_t, w_t), x_t \in \mathbb{X}, u_t \in \mathbb{U}, w_t \in \mathbb{W}$$

where $\mathbb{X} \subseteq \mathbb{R}^{n_{x}}$, $\mathbb{U} \subseteq \mathbb{R}^{n_{u}}$, $\mathbb{W} \subseteq \mathbb{R}^{n_{w}}$.

Objective: compute a symbolic model that can be used to synthesize controllers with formal guarantees.

A. Girard (CNRS, L2S)

Abstraction: from continuous to discrete

Let us consider:

• A finite "partition" $(\mathbb{X}_q)_{q\in Q}$ of $\mathbb{R}^{n_{\chi}}$ such that

$$Q = Q_{\mathbb{X}} \cup \{q_{\mathsf{out}}\} ext{ and } igcup_{q \in Q_{\mathbb{X}}} \mathbb{X}_q \subseteq \mathbb{X};$$

• A finite sample $(u_p)_{p \in P}$ of \mathbb{U} .

We consider a symbolic transition system S = (Q, P, F):

$$q_{t+1}\in F(q_t,p_t),\ q_t\in Q,\ p_t\in P$$

where

- Q and P are the finite sets of symbolic states and inputs;
- $F: Q \times P \rightrightarrows Q$ is the transition map defined by

$$F(q,p) = \left\{ q^+ \in Q \mid \mathbb{X}_{q^+} \cap \mathbb{Y}_{q,p}
eq \emptyset
ight\}$$

where $\mathbb{Y}_{q,p} \subseteq \mathbb{R}^{n_{\chi}}$ is an over-approximation of the reachable set:

$$f(\mathbb{X}_q, u_p, \mathbb{W}) \subseteq \mathbb{Y}_{q,p}, \ \forall q \in Q, \ p \in P.$$

Abstraction: from continuous to discrete

2

Reachability analysis

Assume
$$\mathbb{X}_q = [\underline{x}_q, \overline{x}_q]$$
, $\mathbb{W} = [\underline{w}, \overline{w}]$ and let

$$x_q^c = \frac{\underline{x}_q + \overline{x}_q}{2}, \ \delta x_q = \frac{\overline{x}_q - \underline{x}_q}{2}, \ w^c = \frac{\underline{w} + \overline{w}}{2}, \ \delta w = \frac{\overline{w} - \underline{w}}{2}.$$

• If f is Lipschitz with respect to x and w:

$$\mathbb{Y}_{q,p} = \mathcal{B}\left(f(x_q^c, u_p, w^c), L_x \|\delta x_q\| + L_w \|\delta w\|\right)$$

• If f has uniformly bounded derivatives: $|\frac{\partial f}{\partial x}| \leq D_x$, $|\frac{\partial f}{\partial w}| \leq D_w$

$$\mathbb{Y}_{q,p} = \left[f(x_q^c, u_p, w^c) - \delta y_q, f(x_q^c, u_p, w^c) + \delta y_q\right]$$

where $\delta y_q = D_x \delta x_q + D_w \delta w$.

Reachability analysis

Assume
$$\mathbb{X}_q = [\underline{x}_q, \overline{x}_q], \ \mathbb{W} = [\underline{w}, \overline{w}].$$

• If f is monotone: $\frac{\partial f}{\partial x} \ge 0, \ \frac{\partial f}{\partial w} \ge 0$

$$\mathbb{Y}_{q,p} = \left[f(\underline{x}_q, u_p, \underline{w}), f(\overline{x}_q, u_p, \overline{w})\right]$$

Theorem

Given a symbolic controller $C : Q \rightrightarrows P$, and the quantizer ^a $\theta : \mathbb{R}^n \rightrightarrows Q$, consider the closed-loop system

$$\begin{cases} x_{t+1} = f(x_t, u_{p_t}, w_t) \\ q_t \in \theta(x_t) \\ p_t \in C(q_t) \end{cases}$$

Then, $(\{q_t\}_{t=0}^{t=T}, \{p_t\}_{t=0}^{t=T-1})$ is a trajectory of S_C .

 $a q \in \theta(x)$ iff $x \in \mathbb{X}_q$

- Closed loop trajectories of the continuous system are included in those of the symbolic model.
- Extends to more general class of controllers (dynamic, with memory).

Controller concretization: from discrete to continuous

 \implies We can use the symbolic model to synthesize a controller that provides formal guarantees for the original system.

A. Girard (CNRS, L2S)

э

< 口 > < 同 > < 回 > < 回 > .

What are good partitions $(X_q)_{q \in Q}$ and samples $(u_p)_{p \in P}$?

• If chosen too coarse, these may produce stuttering transitions, i.e. artefactual transitions from a symbolic state to itself that do not correspond to any physical behavior.

• Stuttering transitions may result in uncontrollable symbolic models, e.g. for reachability specifications.

Let
$$x_q^c \in \mathbb{R}^{n_x}$$
, $w^c \in \mathbb{R}^{n_w}$, $\eta_x > 0$, $\eta_u > 0$ and $r_w \ge 0$ such that
 $\mathbb{X}_q \subseteq \mathcal{B}(x_q^c, \eta_x), q \in Q \setminus \{q_{out}\}; \ \mathbb{U} \subseteq \bigcup_{p \in P} \mathcal{B}(u_p, \eta_u); \ \mathbb{W} \subseteq \mathcal{B}(w^c, r_w)$

Proposition

Let us assume that f is Lipschitz with respect to x, u and w and that there exists $b > L_w r_w$ such that

$$\forall x \in \mathbb{X}, \exists u \in \mathbb{U}, \text{ such that } \|f(x, u, w^{c}) - x\| \geq b$$

Let $(X_q)_{q \in Q}$ and $(u_p)_{p \in P}$ be such that $L_u \eta_u + (1 + L_x) \eta_x \leq b - L_w r_w$. Then,

$$\forall q \in Q \setminus \{q_{out}\}, \ \exists p \in P, \ such \ that \ q \notin F(q,p).$$

• Symbolic control makes it possible to deal with bounded disturbance

э

→ ∢ ∃ →

• Symbolic control makes it possible to deal with bounded disturbance

• We get additional robustness for free !

A. Girard (CNRS, L2S)

Theorem

Let us assume that \mathbb{X}_q is a closed set, for all $q \in Q$ and let us consider the symbolic model S computed for

$$\mathbf{x}_{t+1} = f(\mathbf{x}_t, \mathbf{u}_t, \mathbf{w}_t), \, \mathbf{x}_t \in \mathbb{X}, \, \, \mathbf{u}_t \in \mathbb{U}, \, \, \mathbf{w}_t \in \mathbb{W}$$

Then, there exists $\varepsilon > 0$ such that all previous results hold for the perturbed system

$$x_{t+1} = f(x_t, u_t, w_t) + w'_t$$

where $w'_t \in \mathcal{B}(0, \varepsilon)$.

Note that the precise value of ε can be effectively computed.

Safety, Optimization & Learning

3

Consider a mobile robot modeled as a unicycle:

$$\begin{cases} x_1(t+1) &= x_1(t) + u_1(t)\cos(x_3(t)) \\ x_2(t+1) &= x_2(t) + u_1(t)\sin(x_3(t)) \\ x_3(t+1) &= x_3(t) + u_2(t) \end{cases}$$

and subject to state and input constraints:

$$\mathbb{X} = \left\{ x \in \mathbb{R}^3 \ \middle| \ \begin{array}{c} x_1^2 - x_2^2 \leq 4 \\ 4x_2^2 - x_1^2 \leq 16 \end{array}
ight\}, \ \mathbb{U} = [0.2, 2] imes [-1, 1].$$

Let us remark that for all $t \in \mathbb{N}$, $u_1(t) \ge 0.2 \implies$ the robot cannot stop.

Safety controllable set

Working environment:

$$\mathbb{X} = \left\{ x \in \mathbb{R}^3 \left| \begin{array}{c} x_1^2 - x_2^2 \le 4 \\ 4x_2^2 - x_1^2 \le 16 \end{array} \right\} \right.$$

Non-convex, sharp corners.

Safety controllable set computed using symbolic control techniques:

- 109200 symbolic states
- 40 symbolic inputs
- $\bullet~$ CPU time: \sim 2 minutes

Example: safe navigation in complex environments

- Performance criteria: tracking a constant reference position $p_r \in \mathbb{R}^2$.
- Time horizon: N = 20.

Fundamentals of symbolic control:

- Discrete controller synthesis Safety, reachability, attractivity and recurrence
- Symbolic control of nonlinear systems System abstraction, controller concretization, robustness issues
- Recent advances in symbolic control:
 - Symbolically-guided model predictive control High performance controllers with safety guarantees
 - Data-driven symbolic control *Towards safe learning approaches for nonlinear systems*

Consider a nonlinear system subject to state and input constraints:

$$x_{t+1} = f(x_t, u_t), x_t \in \mathbb{X}, u_t \in \mathbb{U}$$

We want to use a model predictive control scheme to enforce contraints while optimizing some performance criteria, i.e. $u_t = u_{0|t}$ with:

$$\begin{split} \min_{u_{0|t},...,u_{N-1|t}} & \sum_{k=0}^{N-1} \ell(x_{k|t}, u_{k|t}) + L(x_{N|t}) \\ \text{subject to} & \begin{cases} x_{0|t} = x_t, \\ x_{k+1|t} = f(x_{k|t}, u_{k|t}), & k = 0, ..., N-1 \\ x_{k|t} \in \mathbb{X}, & u_{k|t} \in \mathbb{U}, & k = 0, ..., N \end{cases} \end{split}$$

A. Girard (CNRS, L2S)

Recursive feasibility

- For safety critical systems, one needs to guarantee that the optimization problem is feasible at all time.
- One classical solution is to append terminal constraints to the optimization problem:

$$\min_{u_{0|t},...,u_{N-1|t}} \sum_{k=0}^{N-1} \ell(x_{k|t}, u_{k|t}) + L(x_{N|t})$$

subject to
$$\begin{cases} x_{0|t} = x_t, \\ x_{k+1|t} = f(x_{k|t}, u_{k|t}), & k = 0, ..., N-1 \\ x_{k|t} \in \mathbb{X}, & u_{k|t} \in \mathbb{U}, & k = 0, ..., N \\ x_{N|t} \in \mathbb{X}_{I} \end{cases}$$

where $X_I \subseteq X$ is a (maximal) controlled invariant set.

- (Maximal) controlled invariant sets for nonlinear systems subject to non-convex contraints:
 - can be hard to compute,
 - may not admit simple representations.
- Controlled invariant sets computed using symbolic control are typically unions of many intervals

$$\mathbb{X}_I = igcup_{q \in Q_I} \mathbb{X}_q, ext{ where } Q_I = ext{s-cont}(S, Q_s)$$

 \implies Not suitable for real-time optimization.

Let us consider the following MPC scheme:

$$\begin{split} \min_{u_{t}, u_{0|t}, \dots, u_{N-1|t}} & \sum_{k=0}^{N-1} \ell(x_{k|t}, u_{k|t}) + L(x_{N|t}) \\ \text{subject to} & \begin{cases} x_{0|t} = x_{t}, u_{t} = u_{0|t} \\ x_{k+1|t} = f(x_{k|t}, u_{k|t}), & k = 0, \dots, N-1 \\ x_{k|t} \in \mathbb{X}, & u_{k|t} \in \mathbb{U}, & k = 0, \dots, N \\ x_{N|t} \in \mathbb{X}_{t} \end{cases} \end{split}$$

where $X_t \subseteq X$ is a (simple) time-varying terminal constraint.

Objective: propose a design mechanism for time-varying terminal constraints guaranteeing recursive feasibility of the optimization problem.

Symbolically-guided mode predictive control

Let us consider:

- a controlled invariant set $\mathbb{X}_I \subseteq \mathbb{X}$
- an invariance controller κ , i.e. $\forall x \in \mathbb{X}_I$, $f(x, \kappa(x)) \in \mathbb{X}_I$
- an interval-valued map T such that for all $x \in \mathbb{X}_I$

$$f(x,\kappa(x))\in T(x)\subseteq \mathbb{X}_{I}$$

Theorem

Consider the following sequence of terminal constraints given by

$$\mathbb{X}_{t+1} = T(x_{N|t}), \text{ for all } t \in \mathbb{N}$$

Then, the MPC optimization problem is recursively feasible.

Symbolically-guided mode predictive control

- X_I , κ and T can be computed using symbolic control:
 - $X_I = \bigcup_{q \in Q_I} X_q$, where $Q_I = \text{s-cont}(S, Q_s)$
 - $\kappa(x) = u_p$, where $p \in C(\theta(x))$
 - $T(x) = \theta^{-1}(F(\theta(x), p))$

- Reference position inside the environment: $p_r = (0.5, 0.5)$.
- Prediction horizon: 20.

model predictive control

Case 1: focus on SgMPC

Case 2: comparisons

- Reference position in the corner: $p_r = (\sqrt{32/3}, \sqrt{20/3}).$
- Prediction horizon: 20.

MPC stopped at t = 13 because optimization problem becomes infeasible.

Case 2: focus on SgMPC

Fundamentals of symbolic control:

- Discrete controller synthesis Safety, reachability, attractivity and recurrence
- Symbolic control of nonlinear systems System abstraction, controller concretization, robustness issues
- Recent advances in symbolic control:
 - Symbolically-guided model predictive control High performance controllers with safety guarantees
 - Data-driven symbolic control Towards safe learning approaches for nonlinear systems

We consider an unknown nonlinear system subject to state and input constraints:

$$x_{t+1} = f(x_t, u_t), x_t \in \mathbb{X}, u_t \in \mathbb{U}.$$

We are given a finite data set

$$\mathcal{D} = \left\{ (x_k, u_k, x_k^+) \, | \, k \in \mathbb{K} \right\}, \text{ where } x_k^+ = f(x_k, u_k).$$

Objective: compute directly from \mathcal{D} a symbolic model providing formal guarantees.

We use a similar approach as before based on a finite "partition" $(\mathbb{X}_q)_{q \in Q}$ of \mathbb{R}^{n_x} and a finite sample $(u_p)_{p \in P}$ of \mathbb{U} .

We consider a symbolic transition system S = (Q, P, F) where

- Q and P are the finite sets of symbolic states and inputs;
- $F: Q \times P \rightrightarrows Q$ is the transition map defined by

$$F(q,p) = \left\{ q^+ \in Q \mid \mathbb{X}_{q^+} \cap \mathbb{Y}_{q,p} \neq \emptyset \right\}$$

where $\mathbb{Y}_{q,p} \subseteq \mathbb{R}^{n_{\chi}}$ is an over-approximation of the reachable set:

$$f(\mathbb{X}_q, u_p) \subseteq \mathbb{Y}_{q,p}, \ \forall q \in Q, \ p \in P.$$

 \implies Can we compute $\mathbb{Y}_{q,p}$ from the data \mathcal{D} ?
The case of monotone systems

$$x_1 \preceq x_2, u \preceq u' \Rightarrow x_1' \preceq x_2'$$

• Characterization:

$$rac{\partial f_i}{\partial x_j} \geq 0, \; rac{\partial f_i}{\partial u_k} \geq 0, \; \forall i, j, k$$

• Applications: vehicles, energy, biology...

The case of monotone systems

• Characterization:

$$\frac{\partial f_i}{\partial x_j} \geq 0, \ \frac{\partial f_i}{\partial u_k} \geq 0, \ \forall i, j, k$$

• Applications: vehicles, energy, biology...

$$x_1 \preceq x_2, u \preceq u' \Rightarrow x_1' \preceq x_2'$$

Then, assuming $\mathbb{X}_q = [\underline{x}_q, \overline{x}_q]$, it holds

$$f(\mathbb{X}_q, u_p) \subseteq [f(\underline{x}_q, u_p), f(\overline{x}_q, u_p)].$$

Theorem

Consider the following set of indices:

$$\mathbb{K}^{+}(\overline{x}_{q}, u_{p}) = \{k \in \mathbb{K} \mid \overline{x}_{q} \leq x_{k} \text{ and } u_{p} \leq u_{k}\}$$
$$\mathbb{K}^{-}(\underline{x}_{q}, u_{p}) = \{k \in \mathbb{K} \mid x_{k} \leq \underline{x}_{q} \text{ and } u_{k} \leq u_{p}\}$$

Then, $f(\mathbb{X}_q, u_p) \subseteq \mathbb{Y}_{q,p}$ where

$$\mathbb{Y}_{q,p} = \left(\bigcap_{k \in \mathbb{K}^+(\overline{x}_q, u_p)} \left\{ x^+ \mid x^+ \preceq x_k^+ \right\} \right)$$
$$\cap \left(\bigcap_{k \in \mathbb{K}^-(\underline{x}_q, u_p)} \left\{ x^+ \mid x_k^+ \preceq x^+ \right\} \right)$$

Image: Image:

Assume that we know lower bounds on the partial derivatives of the unknown function f:

$$\frac{\partial f_i}{\partial x_j} \ge a_{ij}, \ \frac{\partial f_i}{\partial u_k} \ge b_{ik}, \ \forall i, j, k.$$

Consider the matrix A^- and B^- be given by

$$a_{ij}^- = \min(a_{ij}, 0), \ b_{ij}^- = \min(b_{ij}, 0).$$

Then,

$$f(x,u) = A^{-}x + B^{-}u + g(x,u)$$

where $g(x, u) = f(x, u) - A^{-}x - B^{-}u$ is a monotone function.

- 4 個 ト 4 三 ト 4 三 ト

Theorem

We have that $f(\mathbb{X}_q, u_p) \subseteq \mathbb{Y}_{q,p}$ with

$$\mathbb{Y}_{q,p} = \left[A^{-}\overline{x}_{q} + B^{-}u_{p}, A^{-}\underline{x}_{q} + B^{-}u_{p}\right] + \mathbb{Y}_{q,p}^{g}$$

where the over-approximation $\mathbb{Y}_{q,p}^{g}$ of the monotone function g can be computed from the data set \mathcal{D} .

- Using an efficient implementation, a symbolic model can be computed from data in O (|D| × log(|Q| × |P|) + |Q| × |P|).
- If we collect new data, the symbolic model can be updated without restarting from scratch.
- The approach can be also extended to systems with bounded disturbances and/or with partially known dynamics.

Example: adaptive cruise control

Consider two vehicles (leader and follower):

- Relative distance d;
- Follower velocity v₁;
- Leader velocity v₂;
- Unknown monotone dynamics

Data-driven symbolic model computed from 10^6 data points:

- 125000 symbolic states
- 50 symbolic inputs
- CPU time: < 1s

- Symbolic control is a powerful computational technique for safety-critical control of nonlinear systems with state and input constraints, and robustness guarantees.
- Performances of symbolic controllers are limited but can be drastically improved by combining with MPC, while retaining safety guarantees.
 ⇒ Symbolically-guided Model Predictive Control (SgMPC).
- Symbolic models can be computed from data, opening the way to safe learning-based control of nonlinear systems.
- Current and future work:
 - SgMPC for complex navigation problems (e.g. temporal logics, etc.).
 - Combine SgMPC and data-driven abstraction to design safe learning-based MPC for nonlinear systems.
