Submitted on 30 Jan 2024

HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

  abstract  = {In this paper we present Scylla, a methodology for  
domain adaptation of Neural Machine Translation (NMT) systems that  
make use of a multilingual FrameNet enriched with qualia relations  
as an external knowledge base. Domain adaptation techniques used in  
NMT usually require fine-tuning and in-domain training data, which  
may pose difficulties for those working with lesser-resourced  
languages and may also lead to performance decay of the NMT system  
for out-of-domain sentences. Scylla does not require fine-tuning of  
the NMT model, avoiding the risk of model over-fitting and  
consequent decrease in performance for out-of-domain translations.  
Two versions of Scylla are presented: one using the source sentence  
as input, and another one using the target sentence. We evaluate  
Scylla in comparison to a state-of-the-art commercial NMT system in  
an experiment in which 50 sentences from the Sports domain are  
translated from Brazilian Portuguese to English. The two versions of  
Scylla significantly outperform the baseline commercial system in  
HTER.},

abstract    = {Universal Conceptual Cognitive Annotation (UCCA)
(Abend and Rappoport, 2013a) is a cross-lingual semantic annotation
framework that provides an easy annotation without any requirement
for linguistic background. UCCA-annotated datasets have been already
released in English, French, and German. In this paper, we introduce
the first UCCA-annotated Turkish dataset that currently involves 50
sentences obtained from the METU-Sabancı Turkish Treebank (Atalay et
al., 2003; Oflazeret al., 2003). We followed a semi-automatic
annotation approach, where an external semantic parser is utilised
for an initial annotation of the dataset, which is partially
accurate and requires refinement. We manually revised the
annotations obtained from the semantic parser that are not in line
with the UCCA rules that we defined for Turkish. We used the same
external semantic parser for evaluation purposes and conducted
experiments with both zero-shot and few-shot learning. While the
parser cannot predict remote edges in zero-shot setting, using even
a small subset of training data in few-shot setting increased the
overall F-1 score including the remote edges. This is the initial
version of the annotated dataset and we are currently extending the
dataset. We will release the current Turkish UCCA annotation
guideline along with the annotated dataset.},

abstract  = {Recent studies in cross-lingual learning using
multilingual models have cast doubt on the previous hypothesis that
shared vocabulary and joint pre-training are the keys to cross-
lingual generalization. We introduce a method for transferring
monolingual models to other languages through continuous pre-
training and study the effects of such transfer from four different
languages to English. Our experimental results on GLUE show that the
transferred models outperform an English model trained from scratch,
independently of the source language. After probing the model
representations, we find that model knowledge from the source
language enhances the learning of syntactic and semantic knowledge
in English.},

abstract  = {We present a dataset containing source code solutions
to algorithmic programming exercises solved by hundreds of Bachelor-
level students at the University of Hamburg. These solutions were
collected during the winter semesters 2019/2020, 2020/2021 and
2021/2022. The dataset contains a set of solutions to a total of 21
tasks written in Java as well as Python and a total of over 1500
individual solutions. All solutions were submitted through Moodle
and the Coderunner plugin and passed a number of test cases
(including randomized tests), such that they can be considered as
working correctly. All students whose solutions are included in the
dataset gave their consent into publishing their solutions. The
solutions are pseudonymized with a random solution ID. Included in
this paper is a short analysis of the dataset containing statistical
data and highlighting a few anomalies (e.g. the number of solutions
per task decreases for the last few tasks due to grading rules). We
plan to extend the dataset with tasks and solutions from upcoming
courses.},

  year      = {2022},  
  address   = {Marseille, France},  
  publisher = {European Language Resources Association},  
  pages     = {976--986},  
  abstract  = {Frame shift is a cross-linguistic phenomenon in  
translation which results in corresponding pairs of linguistic  
material evoking different frames. The ability to predict frame  
shifts would enable (semi-)automatic creation of multilingual frame  
annotations and thus speeding up FrameNet creation through  
annotation projection. Here, we first characterize how frame shifts  
result from other linguistic divergences such as translational  
divergences and construal differences. Our analysis also shows that  
many pairs of frames in frame shifts are multi-hop away from each  
other in Berkeley FrameNet's net-like configuration. Then, we  
propose the Frame Shift Prediction task and demonstrate that our  
graph attention networks, combined with auxiliary training, can  
learn cross-linguistic frame-to-frame correspondence and predict  
frame shifts.},

pages      = {1003--1008},
abstract   = {The Norwegian Parliamentary Speech Corpus (NPSC) is a
speech dataset with recordings of meetings from Stortinget, the
Norwegian parliament. It is the first, publicly available dataset
containing unscripted, Norwegian speech designed for training of
automatic speech recognition (ASR) systems. The recordings are
manually transcribed and annotated with language codes and speakers,
and there are detailed metadata about the speakers. The
transcriptions exist in both normalized and non-normalized form, and
non-standardized words are explicitly marked and annotated with
standardized equivalents. To test the usefulness of this dataset, we
have compared an ASR system trained on the NPSC with a baseline
system trained on only manuscript-read speech. These systems were
tested on an independent dataset containing spontaneous, dialectal
speech. The NPSC-trained system performed significantly better, with
a 22.9\% relative improvement in word error rate (WER). Moreover,
training on the NPSC is shown to have a "democratizing" effects in
terms of dialects, as improvements are generally larger for dialects
with higher WER from the baseline system.},

year        = {2022},
address     = {Marseille, France},
publisher   = {European Language Resources Association},
pages       = {1009--1015},
abstract    = {We developed a bilingual Frisian/Dutch speech
recognizer for council meetings in Fryslân (the Netherlands). During
these meetings both Frisian and Dutch are spoken, and code switching
between both languages shows up frequently. The new speech
recognizer is based on an existing speech recognizer for Frisian and
Dutch named FAME!, which was trained and tested on historical radio
broadcasts. Adapting a speech recognizer for the council meeting
domain is challenging because of acoustic background noise, speaker
overlap and the jargon typically used in council meetings. To train
the new recognizer, we used the radio broadcast materials utilized
for the development of the FAME! recognizer and added newly created
manually transcribed audio recordings of council meetings from
eleven Frisian municipalities, the Frisian provincial council and
the Frisian water board. The council meeting recordings consist of
49 hours of speech, with 26 hours of Frisian speech and 23 hours of
Dutch speech. Furthermore, from the same sources, we obtained texts
in the domain of council meetings containing 11 million words; 1.1
million Frisian words and 9.9 million Dutch words. We describe the
methods used to train the new recognizer, report the observed word
```

  address   = {Marseille, France},  
  publisher = {European Language Resources Association},  
  pages     = {1016--1022},  
  abstract  = {There is a need for a simple method of detecting  
early signs of dementia which is not burdensome to patients, since  
early diagnosis and treatment can often slow the advance of the  
disease. Several studies have explored using only the acoustic and  
linguistic information of conversational speech as diagnostic  
material, with some success. To accelerate this research, we  
recorded natural conversations between 128 elderly people living in  
four different regions of Japan and interviewers, who also  
administered the Hasegawa's Dementia Scale-Revised (HDS-R), a  
cognitive impairment test. Using our elderly speech corpus and  
dementia test results, we propose an SVM-based screening method  
which can detect dementia using the acoustic features of  
conversational speech even when regional dialects are present. We  
accomplish this by omitting some acoustic features, to limit the  
negative effect of differences between dialects. When using our  
proposed method, a dementia detection accuracy rate of about 91%  
was achieved for speakers from two regions. When speech from four  
regions was used in a second experiment, the discrimination rate  
fell to 76.6%, but this may have been due to using only sentence-  
level acoustic features in the second experiment, instead of  
sentence and phoneme-level features as in the previous experiment.  
This is an on-going research project, and additional investigation  
is needed to understand differences in the acoustic characteristics  
of phoneme units in the conversational speech collected from these  
four regions, to determine whether the removal of formants and other  
features can improve the dementia detection rate.},

  abstract   = {Spoken medical dialogue systems are increasingly
attracting interest to enhance access to healthcare services and
improve quality and traceability of patient care. In this paper, we
focus on medical drug prescriptions acquired on smartphones through
spoken dialogue. Such systems would facilitate the traceability of
care and would free the clinicians' time. However, there is a lack
of speech corpora to develop such systems since most of the related
corpora are in text form and in English. To facilitate the research
and development of spoken medical dialogue systems, we present, to
the best of our knowledge, the first spoken medical drug
prescriptions corpus, named PxNLU. It contains 4 hours of
transcribed and annotated dialogues of drug prescriptions in French
acquired through an experiment with 55 participants experts and non-
experts in prescriptions. We also present some experiments that
demonstrate the interest of this corpus for the evaluation and
development of medical dialogue systems.},

address = {Marseille, France},
publisher = {European Language Resources Association},
pages = {1032--1039},
abstract = {The current largest open-source generic automatic speech recognition (ASR) system for Dutch, Kaldi_NL, does not include a domain-specific healthcare jargon in the lexicon. Commercial alternatives (e.g., Google ASR system) are also not suitable for this purpose, not only because of the lexicon issue, but they do not safeguard privacy of sensitive data sufficiently and reliably. These reasons motivate that just a small amount of medical staff employs speech technology in the Netherlands. This paper proposes an innovative ASR training method developed within the Homo Medicinalis (HoMed) project. On the semantic level it specifically targets automatic transcription of doctor-patient consultation recordings with a focus on the use of medicines. In the first stage of HoMed, the Kaldi_NL language model (LM) is fine-tuned with lists of Dutch medical terms and transcriptions of Dutch online healthcare news bulletins. Despite the acoustic challenges and linguistic complexity of the domain, we reduced the word error rate (WER) by 5.2%. The proposed method could be employed for ASR domain adaptation to other domains with sensitive and special category data. These promising results allow us to apply this methodology on highly sensitive audiovisual recordings of patient consultations at the Netherlands Institute for Health Services Research (Nivel).},

booktitle = {Proceedings of the Language Resources and Evaluation Conference},
month = {June},
year = {2022},
address = {Marseille, France},
publisher = {European Language Resources Association},

```
pages      = {1040--1046},
abstract   = {Machine learning methodologies can be adopted in
cultural applications and propose new ways to distribute or even
present the cultural content to the public. For instance, speech
analytics can be adopted to automatically generate subtitles in
theatrical plays, in order to (among other purposes) help people
with hearing loss. Apart from a typical speech-to-text transcription
with Automatic Speech Recognition (ASR), Speech Emotion Recognition
(SER) can be used to automatically predict the underlying emotional
content of speech dialogues in theatrical plays, and thus to provide
a deeper understanding how the actors utter their lines. However,
real-world datasets from theatrical plays are not available in the
literature. In this work we present GreThE, the Greek Theatrical
Emotion dataset, a new publicly available data collection for speech
emotion recognition in Greek theatrical plays. The dataset contains
utterances from various actors and plays, along with respective
valence and arousal annotations. Towards this end, multiple
annotators have been asked to provide their input for each speech
recording and inter-annotator agreement is taken into account in the
final ground truth generation. In addition, we discuss the results
of some indicative experiments that have been conducted with machine
and deep learning frameworks, using the dataset, along with some
widely used databases in the field of speech emotion recognition.},

the question as to which type of training data yields the most
suitable speaking style for such applications. This study compares
voices trained on three corpora of equal size recorded by the same
speaker: an audiobook character speech (dialogue) corpus, an
audiobook narrator speech corpus, and a neutral-style sentence-based
corpus. The voices were trained with three text-to-speech
synthesisers: two hidden Markov model-based synthesisers and a
neural synthesiser. An evaluation study tested the suitability of
their speaking style for use in customer service voice chatbots.
Independently of the synthesiser used, the voices trained on the
character speech corpus received the lowest, and those trained on
the neutral-style corpus the highest scores. However, the evaluation
```

results may have been confounded by the greater acoustic variability, less balanced sentence length distribution, and poorer phonemic coverage of the character speech corpus, especially compared to the neutral-style corpus. Therefore, the next step will be the creation of a more uniform, balanced, and representative audiobook dialogue corpus, and the evaluation of its suitability for further conversational-style applications besides customer service chatbots.},

  abstract    = {Speech characteristics vary from speaker to speaker.
While some variation phenomena are due to the overall communication
setting, others are due to diastatic factors such as gender,
provenance, age, and social background. The analysis of these
factors, although relevant for both linguistic and speech technology
communities, is hampered by the need to annotate existing corpora or
to recruit, categorise, and record volunteers as a function of
targeted profiles. This paper presents a methodology that uses a
knowledge base to provide speaker-specific information. This can
facilitate the enrichment of existing corpora with new annotations
extracted from the knowledge base. The method also helps the large
scale analysis by automatically extracting instances of speech
variation to correlate with diastatic features. We apply our method
to an over 120-hour corpus of broadcast speech in French and
investigate variation patterns linked to reduction phenomena and/or
specific to connected speech such as disfluencies. We find
significant differences in speech rate, the use of filler words, and
the rate of non-canonical realisations of frequent segments as a
function of different professional categories and age groups.},

abstract     = {Identifying phone inventories is a crucial component
in language documentation and the preservation of endangered
languages. However, even the largest collection of phone inventory
only covers about 2000 languages, which is only 1/4 of the total
number of languages in the world. A majority of the remaining
languages are endangered. In this work, we attempt to solve this
problem by estimating the phone inventory for any language listed in
Glottolog, which contains phylogenetic information regarding 8000
languages. In particular, we propose one probabilistic model and one
non-probabilistic model, both using phylogenetic trees ('`language
family trees'') to measure the distance between languages. We show
that our best model outperforms baseline models by 6.5 F1.
Furthermore, we demonstrate that, with the proposed inventories, the
phone recognition model can be customized for every language in the
set, which improved the PER (phone error rate) in phone recognition
by 25\%.},

abstract    = {This paper develops the first question answering
dataset (DrugEHRQA) containing question-answer pairs from both
structured tables and unstructured notes from a publicly available
Electronic Health Record (EHR). EHRs contain patient records, stored
in structured tables and unstructured clinical notes. The
information in structured and unstructured EHRs is not strictly
disjoint: information may be duplicated, contradictory, or provide
additional context between these sources. Our dataset has
medication-related queries, containing over 70,000 question-answer
pairs. To provide a baseline model and help analyze the dataset, we
have used a simple model (MultimodalEHRQA) which uses the
predictions of a modality selection network to choose between EHR
tables and clinical notes to answer the questions. This is used to
direct the questions to the table-based or text-based state-of-the-
art QA model. In order to address the problem arising from complex,
nested queries, this is the first time Relation-Aware Schema
```

Encoding and Linking for Text-to-SQL Parsers (RAT-SQL) has been used to test the structure of query templates in EHR data. Our goal is to provide a benchmark dataset for multi-modal QA systems, and to open up new avenues of research in improving question answering over EHR structured data by using context from unstructured clinical data.},

pages = {1098--1103},
abstract = {Neural Network (NN) architectures are used more and more to model large amounts of data, such as text data available online. Transformer-based NN architectures have shown to be very useful for language modelling. Although many researchers study how such Language Models (LMs) work, not much attention has been paid to the privacy risks of training LMs on large amounts of data and publishing them online. This paper presents a new method for anonymizing a language model by presenting the way in which MedRoBERTa.nl, a Dutch language model for hospital notes, was anonymized. The two-step method involves i) automatic anonymization of the training data and ii) semi-automatic anonymization of the LM's vocabulary. Adopting the fill-mask task where the model predicts what tokens are most probable in a certain context, it was tested how often the model will predict a name in a context where a name should be. It was shown that it predicts a name-like token 0.2\% of the time. Any name-like token that was predicted was never the name originally present in the training data. By explaining how a LM trained on highly private real-world medical data can be published, we hope that more language resources will be published openly and responsibly so the scientific community can profit from them.},

abstract      = {The successes of contextual word embeddings learned
by training large-scale language models, while remarkable, have
mostly occurred for languages where significant amounts of raw texts
are available and where annotated data in downstream tasks have a
relatively regular spelling. Conversely, it is not yet completely
clear if these models are also well suited for lesser-resourced and
more irregular languages. We study the case of Old French, which is
in the interesting position of having relatively limited amount of
available raw text, but enough annotated resources to assess the
relevance of contextual word embedding models for downstream NLP
tasks. In particular, we use POS-tagging and dependency parsing to
evaluate the quality of such models in a large array of
configurations, including models trained from scratch from small
amounts of raw text and models pre-trained on other languages but
fine-tuned on Medieval French data.},

  abstract    = {Social media has provided a platform for many
individuals to easily express themselves naturally and publicly, and
researchers have had the opportunity to utilize large quantities of
this data to improve author trait analysis techniques and to improve
author trait profiling systems. The majority of the work in this
area, however, has been narrowly spent on English and other Western
European languages, and generally focuses on a single social network
at a time, despite the large quantity of data now available across
languages and differences that have been found across platforms.
This paper introduces RU-ADEPT, a dataset of Russian authors'
personality trait scores--Big Five and Dark Triad, demographic
information (e.g. age, gender), with associated corpus of the
authors' cross-contributions to (up to) four different social media
platforms--VKontakte (VK), LiveJournal, Blogger, and Moi Mir. We
believe this to be the first publicly-available dataset associating
demographic and personality trait data with Russian-language social
media content, the first paper to describe the collection of Dark
Triad scores with texts across multiple Russian-language social
media platforms, and to a limited extent, the first publicly-
available dataset of personality traits to author content across
several different social media sites.},

  pages     = {1114--1124},  
  abstract  = {The prevailing practice in the academia is to  
evaluate the model performance on in-domain evaluation data  
typically set aside from the training corpus. However, in many real  
world applications the data on which the model is applied may very  
substantially differ from the characteristics of the training data.  
In this paper, we focus on Finnish out-of-domain parsing by  
introducing a novel UD Finnish-00D out-of-domain treebank including  
five very distinct data sources (web documents, clinical, online  
discussions, tweets, and poetry), and a total of 19,382 syntactic  
words in 2,122 sentences released under the Universal Dependencies  
framework. Together with the new treebank, we present extensive out-  
of-domain parsing evaluation utilizing the available section-level  
information from three different Finnish UD treebanks (TDT, PUD,  
00D). Compared to the previously existing treebanks, the new  
Finnish-00D is shown include sections more challenging for the  
general parser, creating an interesting evaluation setting and  
yielding valuable information for those applying the parser outside  
of its training domain.},

  year      = {2022},  
  address   = {Marseille, France},  
  publisher = {European Language Resources Association},  
  pages     = {1159--1166},  
  abstract  = {Word embeddings (Mikolov et al., 2013; Pennington et  
al., 2014) have been used to bolster the performance of natural  
language processing systems in a wide variety of tasks, including  
information retrieval (Roy et al., 2018) and machine translation (Qi  
et al., 2018). However, approaches to learning word embeddings  
typically require large corpora of running text to learn high  
quality representations. For many languages, such resources are  
unavailable. This is the case for Wolastoqey, also known as  
Passamaquoddy-Maliseet, an endangered low-resource Indigenous  
language. As there exist no large corpora of running text for  
Wolastoqey, in this paper, we leverage a bilingual dictionary to  
learn Wolastoqey word embeddings by encoding their corresponding  
English definitions into vector representations using pretrained  
English word and sequence representation models. Specifically, we  
consider representations based on pretrained word2vec (Mikolov et  
al., 2013), RoBERTa (Liu et al., 2019) and sentence-BERT (Reimers  
and Gurevych, 2019) models. We evaluate these embeddings in word  
prediction tasks focused on part-of-speech, animacy, and  
transitivity; semantic clustering; and reverse dictionary search. In  
all evaluations we demonstrate that approaches using these  
embeddings outperform task-specific baselines, without requiring any  
language-specific training or fine-tuning.},

abstract = {Machine learning (ML) approaches have dominated NLP during the last two decades. From machine translation and speech technology, ML tools are now also in use for spellchecking and grammar checking, with a blurry distinction between the two. We unmask the myth of effortless big data by illuminating the efforts and time that lay behind building a multi-purpose corpus with regard to collecting, mark-up and building from scratch. We also discuss what kind of language technology minority languages actually need, and to what extent the dominating paradigm has been able to deliver these tools. In this context we present our alternative to corpus-based language technology, which is knowledge-based language technology, and we show how this approach can provide language technology solutions for languages being outside the reach of machine learning procedures. We present a stable and mature infrastructure (GiellaLT) containing more than hundred languages and building a number of language technology tools that are useful for language communities.},

abstract = {Questions asked by humans during a conversation often
contain contextual dependencies, i.e., explicit or implicit
references to previous dialogue turns. These dependencies take the
form of coreferences (e.g., via pronoun use) or ellipses, and can
make the understanding difficult for automated systems. One way to
facilitate the understanding and subsequent treatments of a question
is to rewrite it into an out-of-context form, i.e., a form that can
be understood without the conversational context. We propose CoQAR,
a corpus containing 4.5K conversations from the Conversational
Question-Answering dataset CoQA, for a total of 53K follow-up
question-answer pairs. Each original question was manually annotated
with at least 2 at most 3 out-of-context rewritings. CoQA originally
contains 8k conversations, which sum up to 127k question-answer
pairs. CoQAR can be used in the supervised learning of three tasks:
question paraphrasing, question rewriting and conversational
question answering. In order to assess the quality of CoQAR's
rewritings, we conduct several experiments consisting in training
and evaluating models for these three tasks. Our results support the
idea that question rewriting can be used as a preprocessing step for

```

abstract  = {In this paper, we present the FABRA: readability
toolkit based on the aggregation of a large number of readability
predictor variables. The toolkit is implemented as a service-
oriented architecture, which obviates the need for installation, and
simplifies its integration into other projects. We also perform a
set of experiments to show which features are most predictive on two
different corpora, and how the use of aggregators improves
performance over standard feature-based readability prediction. Our
experiments show that, for the explored corpora, the most important
predictors for native texts are measures of lexical diversity,
dependency counts and text coherence, while the most important
predictors for foreign texts are syntactic variables illustrating
language development, as well as features linked to lexical
sophistication. FABRA: have the potential to support new research on
readability assessment for French.},

publisher = {European Language Resources Association},
pages = {1249--1255},
abstract = {Often both an utterance and its context must be read to understand its intent in a dialog. Herein we propose a task,

Self-Contained Utterance Description (SCUD), to describe the intent of an utterance in a dialog with multiple simple natural sentences without the context. If a task can be performed concurrently with high accuracy as the conversation continues such as in an accommodation search dialog, the operator can easily suggest candidates to the customer by inputting SCUDs of the customer's utterances to the accommodation search system. SCUDs can also describe the transition of customer requests from the dialog log. We construct a Japanese corpus to train and evaluate automatic SCUD generation. The corpus consists of 210 dialogs containing 10,814 sentences. We conduct an experiment to verify that SCUDs can be automatically generated. Additionally, we investigate the influence of the amount of training data on the automatic generation performance using 8,200 additional examples.},

abstract = {Dialog system developers need high-quality data to train, fine-tune and assess their systems. They often use crowdsourcing for this since it provides large quantities of data from many workers. However, the data may not be of sufficiently good quality. This can be due to the way that the requester presents a task and how they interact with the workers. This paper introduces DialCrowd 2.0 to help requesters obtain higher quality data by, for example, presenting tasks more clearly and facilitating effective communication with workers. DialCrowd 2.0 guides developers in creating improved Human Intelligence Tasks (HITs) and is directly applicable to the workflows used currently by developers and researchers.},

abstract    = {In human-human conversations, Context Tracking deals
with identifying important entities and keeping track of their
properties and relationships. This is a challenging problem that
encompasses several subtasks such as slot tagging, coreference
resolution, resolving plural mentions and entity linking. We
approach this problem as an end-to-end modeling task where the
conversational context is represented by an entity repository
containing the entity references mentioned so far, their properties
and the relationships between them. The repository is updated turn-
by-turn, thus making training and inference computationally
efficient even for long conversations. This paper lays the
groundwork for an investigation of this framework in two ways.
First, we release Contrack, a large scale human-human conversation
corpus for context tracking with people and location annotations. It
contains over 7000 conversations with an average of 11.8 turns, 5.8
entities and 15.2 references per conversation. Second, we open-
source a neural network architecture for context tracking. Finally
we compare this network to state-of-the-art approaches for the
subtasks it subsumes and report results on the involved tradeoffs.},

abstract     = {Every model is only as strong as the data that it is
trained on. In this paper, we present a new dataset, obtained by
merging four publicly available annotated corpora for task-oriented
dialogues in several domains (MultiWOZ 2.2, CamRest676, DSTC2 and
Schema-Guided Dialogue Dataset). This way, we assess the feasibility
of providing a unified ontology and annotation schema covering
several domains with a relatively limited effort. We analyze the
characteristics of the resulting dataset along three main
dimensions: language, information content and performance. We focus
on aspects likely to be pertinent for improving dialogue success,
e.g. dialogue consistency. Furthermore, to assess the usability of
this new corpus, we thoroughly evaluate dialogue generation
performance under various conditions with the help of two prominent
recent end-to-end dialogue models: MarCo and GPT-2. These models
were selected as popular open implementations representative of the
two main dimensions of dialogue modelling. While we did not observe
a significant gain for dialogue state tracking performance, we show
that using more training data from different sources can improve
language modelling capabilities and positively impact dialogue flow
(consistency). In addition, we provide the community with one of the
largest open dataset for machine learning experiments.},

  pages     = {127--136},
  abstract  = {Most systems helping to provide structured
information and support opinion building, discuss with users without
considering their individual interest. The scarce existing research
on user interest in dialogue systems depends on explicit user
feedback. Such systems require user responses that are not content-
related and thus, tend to disturb the dialogue flow. In this paper,
we present a novel model for implicitly estimating user interest
during argumentative dialogues based on semantically clustered data.
Therefore, an online user study was conducted to acquire training
data which was used to train a binary neural network classifier in
order to predict whether or not users are still interested in the
```

content of the ongoing dialogue. We achieved a classification accuracy of 74.9\% and furthermore investigated with different Artificial Neural Networks (ANN) which new argument would fit the user interest best.},

abstract = {We present a machine-readable structured data version  
of Wiktionary. Unlike previous Wiktionary extractions, the new  
extractor, Wiktextextract, fully interprets and expands templates and  
Lua modules in Wiktionary. This enables it to perform a more  
complete, robust, and maintainable extraction. The extracted data is  
multilingual and includes lemmas, inflected forms, translations,  
etymology, usage examples, pronunciations (including URLs of sound  
files), lexical and semantic relations, and various morphological,  
syntactic, semantic, topical, and dialectal annotations. We extract  
all data from the English Wiktionary. Comparing against previous  
extractions from language-specific dictionaries, we find that its  
coverage for non-English languages often matches or exceeds the  
coverage in the language-specific editions, with the added benefit  
that all glosses are in English. The data is freely available and  
regularly updated, enabling anyone to add more data and correct  
errors by editing Wiktionary. The extracted data is in JSON format  
and designed to be easy to use by researchers, downstream resources,  
and application developers.},

```
pages      = {1344--1352},
abstract   = {We present NomVallex, a manually annotated valency
lexicon of Czech nouns and adjectives. The lexicon is created in the
theoretical framework of the Functional Generative Description and
based on corpus data. In total, NomVallex 2.0 is comprised of 1027
lexical units contained in 570 lexemes, covering the following part-
of-speech and derivational categories: deverbal and deadjectival
nouns, and deverbal, denominal, deadjectival and primary adjectives.
Valency properties of a lexical unit are captured in a valency frame
which is modeled as a sequence of valency slots, supplemented with a
list of morphemic forms. In order to make it possible to study the
relationship between valency behavior of base words and their
derivatives, lexical units of nouns and adjectives in NomVallex are
linked to their respective base words, contained either in NomVallex
itself or, in case of verbs, in a valency lexicon of Czech verbs
called VALLEX. NomVallex enables a comparison of valency properties
of a significant number of Czech nominals with their base words,
both manually and in an automatic way; as such, we can address the
theoretical question of argument inheritance, concentrating on
systemic and non-systemic valency behavior.},

  publisher = {European Language Resources Association},  
  pages     = {1365--1375},  
  abstract  = {Emotion classification is often formulated as the  
task to categorize texts into a predefined set of emotion classes.  
So far, this task has been the recognition of the emotion of writers  
and readers, as well as that of entities mentioned in the text. We  
argue that a classification setup for emotion analysis should be  
performed in an integrated manner, including the different semantic  
roles that participate in an emotion episode. Based on appraisal  
theories in psychology, which treat emotions as reactions to events,  
we compile an English corpus of written event descriptions. The  
descriptions depict emotion-eliciting circumstances, and they  
contain mentions of people who responded emotionally. We annotate  
all experiencers, including the original author, with the emotions  
they likely felt. In addition, we link them to the event they found  
salient (which can be different for different experiencers in a  
text) by annotating event properties, or appraisals (e.g., the  
perceived event undesirability, the uncertainty of its outcome). Our  
analysis reveals patterns in the co-occurrence of people's emotions  
in interaction. Hence, this richly-annotated resource provides  
useful data to study emotions and event evaluations from the  
perspective of different roles, and it enables the development of  
experiencer-specific emotion and appraisal classification systems.},

  abstract  = {In this paper, we introduce a new Czech subjectivity
dataset of 10k manually annotated subjective and objective sentences
from movie reviews and descriptions. Our prime motivation is to
provide a reliable dataset that can be used with the existing
English dataset as a benchmark to test the ability of pre-trained
multilingual models to transfer knowledge between Czech and English
and vice versa. Two annotators annotated the dataset reaching 0.83
of the Cohen's K inter-annotator agreement. To the best of our
knowledge, this is the first subjectivity dataset for the Czech
language. We also created an additional dataset that consists of
200k automatically labeled sentences. Both datasets are freely
available for research purposes. Furthermore, we fine-tune five pre-
trained BERT-like models to set a monolingual baseline for the new
dataset and we achieve 93.56\% of accuracy. We fine-tune models on
the existing English dataset for which we obtained results that are
on par with the current state-of-the-art results. Finally, we
perform zero-shot cross-lingual subjectivity classification between
Czech and English to verify the usability of our dataset as the
```

cross-lingual benchmark. We compare and discuss the cross-lingual and monolingual results and the ability of multilingual models to transfer knowledge between languages.},

abstract = {RED (Romanian Emotion Dataset) is a machine learning-based resource developed for the automatic detection of emotions in Romanian texts, containing single-label annotated tweets with one of the following emotions: joy, fear, sadness, anger and neutral. In this work, we propose REDv2, an open-source extension of RED by adding two more emotions, trust and surprise, and by widening the annotation schema so that the resulted novel dataset is multi-label. We show the overall reliability of our dataset by computing inter-annotator agreements per tweet using a formula suitable for our annotation setup and we aggregate all annotators' opinions into two variants of ground truth, one suitable for multi-label classification and the other suitable for text regression. We propose strong baselines with two transformer models, the Romanian BERT and the multilingual XLM-Roberta model, in both categorical and regression settings.},

  pages     = {1400--1407},  
  abstract  = {The traditional evaluation of labeled spans with  
precision, recall, and F1-score has undesirable effects due to  
double penalties. Annotations with incorrect label or boundaries  
count as two errors instead of one, despite being closer to the  
target annotation than false positives or false negatives. In this  
paper, new error types are introduced, which more accurately reflect  
true annotation quality and ensure that every annotation counts only  
once. An algorithm for error identification in flat and multi-level  
annotations is presented and complemented with a proposal on how to  
calculate meaningful precision, recall, and F1-scores based on the  
more fine-grained error types. The exemplary application to three  
different annotation tasks (NER, chunking, parsing) shows that the  
suggested procedure not only prevents double penalties but also  
allows for a more detailed error analysis, thereby providing more  
insight into the actual weaknesses of a system.},

abstract = {Multiple works have proposed to probe language models (LMs) for generalization in named entity (NE) typing (NET) and recognition (NER). However, little has been done in this direction for auto-regressive models despite their popularity and potential to express a wide variety of NLP tasks in the same unified format. We propose a new methodology to probe auto-regressive LMs for NET and NER generalization, which draws inspiration from human linguistic behavior, by resorting to meta-learning. We study NERs of various types individually by designing a zero-shot transfer strategy for NET. Then, we probe the model for NER by providing a few examples at inference. We introduce a novel procedure to assess the model's memorization of NERs and report the memorization's impact on the results. Our findings show that: 1) GPT2, a common pre-trained auto-regressive LM, without any fine-tuning for NET or NER, performs the tasks fairly well; 2) name irregularity when common for a NER type could be an effective exploitable cue; 3) the model seems to rely more on NER than contextual cues in few-shot NER; 4) NERs with words absent during LM pre-training are very challenging for both NET and NER.},

booktitle = {Proceedings of the Language Resources and Evaluation Conference},

month = {June},

year = {2022},

address = {Marseille, France},

publisher = {European Language Resources Association},

pages = {1418--1427},

abstract = {As input representation for each sub-word, the original BERT architecture proposes the sum of the sub-word embedding, position embedding and a segment embedding. Sub-word and position embeddings are well-known and studied, and encode lexical information and word position, respectively. In contrast, segment embeddings are less known and have so far received no attention, despite being ubiquitous in large pre-trained language models. The key idea of segment embeddings is to encode to which of the two sentences (segments) a word belongs to – the intuition is to inform the model about the separation of sentences for the next sentence prediction pre-training task. However, little is known on whether the choice of segment impacts performance. In this work, we try to fill this gap and empirically study the impact of the segment embedding during inference time for a variety of pre-trained embeddings and target tasks. We hypothesize that for single-sentence prediction tasks performance is not affected – neither in mono- nor multilingual setups – while it matters when swapping segment IDs in paired-sentence tasks. To our surprise, this is not the case. Although for classification tasks and monolingual BERT models no large differences are observed, particularly word-level multilingual

prediction tasks are heavily impacted. For low-resource syntactic tasks, we observe impacts of segment embedding and multilingual BERT choice. We find that the default setting for the most used multilingual BERT model underperforms heavily, and a simple swap of the segment embeddings yields an average improvement of 2.5 points absolute LAS score for dependency parsing over 9 different treebanks.},

  abstract    = {This paper addresses the semi-automatic annotation of
  subjects, also called policy areas, in the Danish Parliament Corpus
  (2009–2017) v.2. Recently, the corpus has been made available
  through the CLARIN-DK repository, the Danish node of the European
  CLARIN infrastructure. The paper also contains an analysis of the
  subjects in the corpus, and a description of multi-label
  classification experiments act to verify the consistency of the
  subject annotation and the utility of the corpus for training
  classifiers on this type of data. The analysis of the corpus
  comprises an investigation of how often the parliament members
  addressed each subject and the relation between subjects and gender
  of the speaker. The classification experiments show that classifiers
  can determine the two co-occurring subjects of the speeches from the
  agenda titles with a performance similar to that of human
  annotators. Moreover, a multilayer perceptron achieved an F1-score
  of 0.68 on the same task when trained on bag of words vectors
  obtained from the speeches' lemmas. This is an improvement of more
  than 0.6 with respect to the baseline, a majority classifier that
  accounts for the frequency of the classes. The result is promising
  given the high number of subject combinations (186) and the skewness
  of the data.},

abstract    = {A significant challenge in developing translation
systems for the world's ~7,000 languages is that very few have
sufficient data for state-of-the-art techniques. Transfer learning
is a promising direction for low-resource neural machine translation
(NMT), but introduces many new variables which are often selected
through ablation studies, costly trial-and-error, or niche
expertise. When pre-training an NMT system for low-resource
translation, the pre-training task is often chosen based on data
abundance and similarity to the main task. Factors such as dataset
sizes and similarity have typically been analysed independently in
previous studies, due to the computational cost associated with
systematic studies. However, these factors are not independent. We
conducted a three-factor experiment to examine how language
similarity, pre-training dataset size and main dataset size
interacted in their effect on performance in pre-trained
transformer-based low-resource NMT. We replicated the common finding
that more data was beneficial in bilingual systems, but also found a
statistically significant interaction between the three factors,
which reduced the effectiveness of large pre-training datasets for
some main task dataset sizes (p-value < 0.0018). The surprising
trends identified in these interactions indicate that systematic
studies of interactions may be a promising long-term direction for
guiding research in low-resource neural methods.},

pages      = {1444--1453},
abstract   = {TimeML is a scheme for representing temporal
information (times, events, \& temporal relations) in texts.
Although automatic TimeML annotation is challenging, there has been
notable progress, with F1s of 0.8--0.9 for events and time detection
subtasks, and F1s of 0.5--0.7 for relation extraction. Individually,
these subtask results are reasonable, even good, but when combined
to generate a full TimeML graph, is overall performance still
acceptable? We present a novel suite of eight metrics, combined with
a new graph-transformation experimental design, for holistic
evaluation of TimeML graphs. We apply these metrics to four
automatic TimeML annotation systems (CAEVO, TARSQI, CATENA, and
ClearTK). We show that on average 1/3 of the TimeML graphs produced
using these systems are inconsistent, and there is on average 1/5
more temporal indeterminacy than the gold-standard. We also show
```

that the automatically generated graphs are on average 109 edits from the gold-standard, which is 1/3 toward complete replacement. Finally, we show that the relationship individual subtask performance and graph quality is non-linear: small errors in TimeML subtasks result in rapid degradation of final graph quality. These results suggest current automatic TimeML annotators are far from optimal and significant further improvement would be useful.},

address = {Marseille, France},
publisher = {European Language Resources Association},
pages = {1454--1461},
abstract = {From both human translators (HT) and machine translation (MT) researchers' point of view, translation quality evaluation (TQE) is an essential task. Translation service providers (TSPs) have to deliver large volumes of translations which meet customer specifications with harsh constraints of required quality level in tight time-frames and costs. MT researchers strive to make their models better, which also requires reliable quality evaluation. While automatic machine translation evaluation (MTE) metrics and quality estimation (QE) tools are widely available and easy to access, existing automated tools are not good enough, and human assessment from professional translators (HAP) are often chosen as the golden standard \cite{han-et-al-2021-TQA}. Human evaluations, however, are often accused of having low reliability and agreement. Is this caused by subjectivity or statistics is at play? How to avoid the entire text to be checked and be more efficient with TQE from cost and efficiency perspectives, and what is the optimal sample size of the translated text, so as to reliably estimate the translation quality of the entire material? This work carries out such a motivated research to correctly estimate the confidence intervals \cite{Brown_etal2001Interval} depending on the sample size of translated text, e.g. the amount of words or sentences, that needs to be processed on TQE workflow step for confident and reliable evaluation of overall translation quality. The methodology we applied for this work is from Bernoulli Statistical Distribution Modelling (BSDM) and Monte Carlo Sampling Analysis (MCSA).},

 abstract = {Visual Question Answering (VQA) is a challenge
 problem that can advance AI by integrating several important sub-
 disciplines including natural language understanding and computer
 vision. Large VQA datasets that are publicly available for training
 and evaluation have driven the growth of VQA models that have
 obtained increasingly larger accuracy scores. However, it is also
 important to understand how much a model understands the details
 that are provided in a question. For example, studies in psychology
 have shown that syntactic complexity places a larger cognitive load
 on humans. Analogously, we want to understand if models have the
 perceptual capability to handle modifications to questions.
 Therefore, we develop a new dataset using Amazon Mechanical Turk
 where we asked workers to add modifiers to questions based on object
 properties and spatial relationships. We evaluate this data on
 LXMERT which is a state-of-the-art model in VQA that focuses more
 extensively on language processing. Our conclusions indicate that
 there is a significant negative impact on the performance of the
 model when the questions are modified to include more detailed

  abstract  = {In this study, we thrive on finding out how code-  
switching and code-mixing (CS/CM) as a linguistic phenomenon could  
be a sign of tension in Holocaust survivors' interviews. We first  
created an interview corpus (a total of 39 interviews) that contains  
manually annotated CS/CM codes (a total of 802 quotations). We then  
compared our annotations with the tension places in the corpus. The  
tensions are identified by a computational tool. We found that most  
of our annotations were captured in the tension places, and it  
showed a relatively outstanding performance. The finding implies  
that CS/CM can be appropriate cues for detecting tension in this  
communication context. Our CS/CM annotated interview corpus is  
openly accessible. Aside from annotating and examining CS/CM  
occurrences, we annotated silence situations in this open corpus.  
Silence is shown to be an indicator of tension in interpersonal  
communications. Making this corpus openly accessible, we call for  
more research endeavors on tension detection.},

booktitle = {Proceedings of the Language Resources and Evaluation Conference},

month = {June},

year = {2022},

address = {Marseille, France},

publisher = {European Language Resources Association},

pages = {1509--1518},

abstract = {One of the processing tasks for large multimodal data streams is automatic image description (image classification, object segmentation and classification). Although the number and the diversity of image datasets is constantly expanding, still there is a huge demand for more datasets in terms of variety of domains and object classes covered. The goal of the project Multilingual Image Corpus (MIC 21) is to provide a large image dataset with annotated objects and object descriptions in 24 languages. The Multilingual Image Corpus consists of an Ontology of visual objects (based on WordNet) and a collection of thematically related images whose objects are annotated with segmentation masks and labels describing the ontology classes. The dataset is designed both for image classification and object detection and for semantic segmentation. The main contributions of our work are: a) the provision of large collection of high quality copyright-free images; b) the formulation of the Ontology of visual objects based on WordNet noun hierarchies; c) the precise manual correction of automatic object segmentation within the images and the annotation of object classes; and d) the association of objects and images with extended multilingual descriptions based on WordNet inner- and interlingual relations. The dataset can be used also for multilingual image caption generation, image-to-text alignment and automatic question answering for images and videos.},

abstract   = {Sign language production (SLP) is the process of
generating sign language videos from spoken language expressions.
Since sign languages are highly under-resourced, existing vision-
based SLP approaches suffer from out-of-vocabulary (OOV) and test-
time generalization problems and thus generate low-quality
translations. To address these problems, we introduce an avatar-
based SLP system composed of a sign language translation (SLT) model
and an avatar animation generation module. Our Transformer-based SLT
model utilizes two additional strategies to resolve these problems:
named entity transformation to reduce OOV tokens and context vector
generation using a pretrained language model (e.g., BERT) to
reliably train the decoder. Our system is validated on a new Korean-
Korean Sign Language (KSL) dataset of weather forecasts and
emergency announcements. Our SLT model achieves an 8.77 higher
BLEU-4 score and a 4.57 higher ROUGE-L score over those of our
baseline model. In a user evaluation, 93.48\% of named entities were
successfully identified by participants, demonstrating marked
improvement on OOV issues.},

  abstract    = {Posting and sharing memes have become a powerful  
expedient of expressing opinions on social media in recent days.  
Analysis of sentiment from memes has gained much attention to  
researchers due to its substantial implications in various domains  
like finance and politics. Past studies on sentiment analysis of  
memes have primarily been conducted in English, where low-resource  
languages gain little or no attention. However, due to the  
proliferation of social media usage in recent years, sentiment  
analysis of memes is also a crucial research issue in low resource  
languages. The scarcity of benchmark datasets is a significant  
barrier to performing multimodal sentiment analysis research in  
resource-constrained languages like Bengali. This paper presents a  
novel multimodal dataset (named MemoSen) for Bengali containing 4417  
memes with three annotated labels positive, negative, and neutral. A  
detailed annotation guideline is provided to facilitate further  
resource development in this domain. Additionally, a set of  
experiments are carried out on MemoSen by constructing twelve  
unimodal (i.e., visual, textual) and ten multimodal (image+text)  
models. The evaluation exhibits that the integration of multimodal  
information significantly improves (about 1.2\%) the meme sentiment  
classification compared to the unimodal counterparts and thus  
elucidate the novel aspects of multimodality.},

  abstract    = {We present a new audio-visual speech corpus (RUSAVIC)  
recorded in a car environment and designed for noise-robust speech  
recognition. Our goal was to produce a speech corpus which is  
natural (recorded in real driving conditions), controlled (providing
```

different SNR levels by windows open/closed, moving/parked vehicle, etc.), and adequate size (the amount of data is enough to train state-of-the-art NN approaches). We focus on the problem of audio-visual speech recognition: with the use of automated lip-reading to improve the performance of audio-based speech recognition in the presence of severe acoustic noise caused by road traffic. We also describe the equipment and procedures used to create RUSAVIC corpus. Data are collected in a synchronous way through several smartphones located at different angles and equipped with FullHD video camera and microphone. The corpus includes the recordings of 20 drivers with minimum of 10 recording sessions for each. Besides providing a detailed description of the dataset and its collection pipeline, we evaluate several popular audio and visual speech recognition methods and present a set of baseline recognition results. At the moment RUSAVIC is a unique audio-visual corpus for the Russian language that is recorded in-the-wild condition and we make it publicly available.},

```

```
abstract = {This paper presents a corpus of AZee discourse  
expressions, i.e. expressions which formally describe Sign Language  
utterances of any length using the AZee approach and language. The  
construction of this corpus had two main goals: a first reference  
corpus for AZee, and a test of its coverage on a significant sample  
of real-life utterances. We worked on productions from an existing  
corpus, namely the "40 breves", containing an hour of French Sign  
Language. We wrote the corresponding AZee discourse expressions for  
the entire video content, i.e. expressions capturing the forms  
produced by the signers and their associated meaning by combining  
known production rules, a basic building block for these  
expressions. These are made available as a version 2 extension of  
the "40 breves". We explain the way in which these expressions can  
be built, present the resulting corpus and set of production rules  
used, and perform first measurements on it. We also propose an  
evaluation of our corpus: for one hour of discourse, AZee allows to  
describe 94\% of it, while ongoing studies are increasing this  
coverage. This corpus offers a lot of future prospects, for instance  
concerning synthesis with virtual signers, machine translation or  
formal grammars for Sign Language.},

abstract  = {Evaluating video captioning systems is a challenging
task as there are multiple factors to consider; for instance: the
fluency of the caption, multiple actions happening in a single
scene, and the human bias of what is considered important. Most
metrics try to measure how similar the system generated captions are
to a single or a set of human-annotated captions. This paper
presents a new method based on a deep learning model to evaluate
these systems. The model is based on BERT, which is a language model
that has been shown to work well in multiple NLP tasks. The aim is
for the model to learn to perform an evaluation similar to that of a
human. To do so, we use a dataset that contains human evaluations of
system generated captions. The dataset consists of the human
judgments of the captions produces by the system participating in
various years of the TRECvid video to text task. BERTHA obtain
favourable results, outperforming the commonly used metrics in some
setups.},

publisher = {European Language Resources Association},
pages     = {1576--1583},
abstract  = {This paper presents Gesture AMR, an extension to
Abstract Meaning Representation (AMR), that captures the meaning of
gesture. In developing Gesture AMR, we consider how gesture form and
meaning relate; how gesture packages meaning both independently and
in interaction with speech; and how the meaning of gesture is
temporally and contextually determined. Our case study for
developing Gesture AMR is a focused human-human shared task to build
block structures. We develop an initial taxonomy of gesture act
relations that adheres to AMR's existing focus on predicate-argument
structure while integrating meaningful elements unique to gesture.
Pilot annotation shows Gesture AMR to be more challenging than
standard AMR, and illustrates the need for more work on
representation of dialogue and multimodal meaning. We discuss

```

challenges of adapting an existing meaning representation to non-speech-based modalities and outline several avenues for expanding Gesture AMR.},

abstract = {This paper is framed in the context of the SSHOC project and aims at exploring how Language Technologies can help in promoting and facilitating multilingualism in the Social Sciences and Humanities (SSH). Although most SSH researchers produce culturally and societally relevant work in their local languages, metadata and vocabularies used in the SSH domain to describe and index research data are currently mostly in English. We thus investigate Natural Language Processing and Machine Translation approaches in view of providing resources and tools to foster multilingual access and discovery to SSH content across different languages. As case studies, we create and deliver as freely, openly available data a set of multilingual metadata concepts and an automatically extracted multilingual Data Stewardship terminology. The two case studies allow as well to evaluate performances of state-of-the-art tools and to derive a set of recommendations as to how best apply them. Although not adapted to the specific domain, the employed tools prove to be a valid asset to translation tasks. Nonetheless, validation of results by domain experts proficient in the language is an unavoidable phase of the whole workflow.},

abstract = {With the emergence of neural end-to-end approaches for spoken language understanding (SLU), a growing number of studies have been presented during these last three years on this topic. The major part of these works addresses the spoken language understanding domain through a simple task like speech intent detection. In this context, new benchmark datasets have also been produced and shared with the community related to this task. In this paper, we focus on the French MEDIA SLU dataset, distributed since 2005 and used as a benchmark dataset for a large number of research works. This dataset has been shown as being the most challenging one among those accessible to the research community. Distributed by ELRA, this corpus is free for academic research since 2019. Unfortunately, the MEDIA dataset is not really used beyond the French research community. To facilitate its use, a complete recipe, including data preparation, training and evaluation scripts, has been built and integrated to SpeechBrain, an already popular open-source and all-in-one conversational AI toolkit based on PyTorch. This recipe is presented in this paper. In addition, based on the feedback of some researchers who have worked on this dataset for several years, some corrections have been brought to the initial manual annotation: the new version of the data will also be integrated into the ELRA catalogue, as the original one. More, a significant amount of data collected during the construction of the

MEDIA corpus in the 2000s was never used until now: we present the first results reached on this subset – also included in the MEDIA SpeechBrain recipe – , that will be used for now as the MEDIA test2. Last, we discuss evaluation issues.},

  abstract  = {Progress in sentence simplification has been hindered
by a lack of labeled parallel simplification data, particularly in
languages other than English. We introduce MUSS, a Multilingual
Unsupervised Sentence Simplification system that does not require
labeled simplification data. MUSS uses a novel approach to sentence
simplification that trains strong models using sentence-level
paraphrase data instead of proper simplification data. These models
leverage unsupervised pretraining and controllable generation
mechanisms to flexibly adjust attributes such as length and lexical
complexity at inference time. We further present a method to mine
such paraphrase data in any language from Common Crawl using
semantic sentence embeddings, thus removing the need for labeled
data. We evaluate our approach on English, French, and Spanish
simplification benchmarks and closely match or outperform the
previous best supervised results, despite not using any labeled
simplification data. We push the state of the art further by
incorporating labeled simplification data.},

  abstract  = {Women are often perceived as junior to their male  
counterparts, even within the same job titles. While there has been  
significant progress in the evaluation of gender bias in natural  
language processing (NLP), existing studies seldom investigate how  
biases toward gender groups change when compounded with other  
societal biases. In this work, we investigate how seniority impacts  
the degree of gender bias exhibited in pretrained neural generation  
models by introducing a novel framework for probing compound bias.  
We contribute a benchmark robustness-testing dataset spanning two  
domains, U.S. senatorship and professorship, created using a  
distant-supervision method. Our dataset includes human-written text  
with underlying ground truth and paired counterfactuals. We then  
examine GPT-2 perplexity and the frequency of gendered language in  
generated text. Our results show that GPT-2 amplifies bias by  
considering women as junior and men as senior more often than the  
ground truth in both domains. These results suggest that NLP  
applications built using GPT-2 may harm women in professional  
capacities.},

  abstract  = {Our discourses are full of potential lexical
ambiguities, due in part to the pervasive use of words having
multiple senses. Sometimes, one word may even be used in more than
one sense throughout a text. But, to what extent is this true for
different kinds of texts? Does the use of polysemous words change
when a discourse involves two people, or when speakers have time to
plan what to say? We investigate these questions by comparing the
polysemy level of texts of different nature, with a focus on
spontaneous spoken dialogs; unlike previous work which examines
solely scripted, written, monolog-like data. We compare multiple
metrics that presuppose different conceptualizations of text
polysemy, i.e., they consider the observed or the potential number
of senses of words, or their sense distribution in a discourse. We
show that the polysemy level of texts varies greatly depending on
the kind of text considered, with dialog and spoken discourses
having generally a higher polysemy level than written monologs.
Additionally, our results emphasize the need for relaxing the
popular "one sense per discourse" hypothesis.},

abstract = {Cross-Level Semantic Similarity (CLSS) is a measure of the level of semantic overlap between texts of different lengths. Although this problem was formulated almost a decade ago, research on it has been sparse, and limited exclusively to the English language. In this paper, we present the first CLSS dataset in another language, in the form of CLSS.news.sr – a corpus of 1000 phrase-sentence and 1000 sentence-paragraph newswire text pairs in Serbian, manually annotated with fine-grained semantic similarity scores using a 0-4 similarity scale. We describe the methodology of data collection and annotation, and compare the resulting corpus to its preexisting counterpart in English, SemEval CLSS, following up with a preliminary linguistic analysis of the newly created dataset. State-of-the-art pre-trained language models are then fine-tuned and evaluated on the CLSS task in Serbian using the produced data, and their settings and results are discussed. The CLSS.news.sr corpus and the guidelines used in its creation are made publicly available.},

abstract = {Semantic role labeling (SRL) represents the meaning of a sentence in the form of predicate-argument structures. Such shallow semantic analysis is helpful in a wide range of downstream NLP tasks and real-world applications. As treebanks enabled the development of powerful syntactic parsers, the accurate predicate-argument analysis demands training data in the form of propbanks. Unfortunately, most languages simply do not have corresponding propbanks due to the high cost required to construct such resources. To overcome such challenges, Universal Proposition Bank 1.0 (UP1.0) was released in 2017, with high-quality propbank data generated via a two-stage method exploiting monolingual SRL and multilingual parallel data. In this paper, we introduce Universal Proposition Bank 2.0 (UP2.0), with significant enhancements over UP1.0: (1) propbanks with higher quality by using a state-of-the-art monolingual SRL and improved auto-generation of annotations; (2) expanded language coverage (from 7 to 9 languages); (3) span annotation for the decoupling of syntactic analysis; and (4) Gold data for a subset of the languages. We also share our experimental results that confirm the significant quality improvements of the generated propbanks. In addition, we present a comprehensive experimental evaluation on how different implementation choices impact the quality of the resulting data. We release these resources to the research community and hope to encourage more research on cross-lingual SRL.},

  abstract = {Corpus-based studies on acceptability judgements have  
always stimulated the interest of researchers, both in theoretical  
and computational fields. Some approaches focused on spontaneous  
judgements collected through different types of tasks, others on  
data annotated through crowd-sourcing platforms, still others relied  
on expert annotated data available from the literature. The release  
of CoLA corpus, a large-scale corpus of sentences extracted from  
linguistic handbooks as examples of acceptable/non acceptable  
phenomena in English, has revived interest in the reliability of  
judgements of linguistic experts vs. non-experts. Several issues are  
still open. In this work, we contribute to this debate by presenting  
a 3D video game that was used to collect acceptability judgments on  
Italian sentences. We analyse the resulting annotations in terms of  
agreement among players and by comparing them with experts'  
acceptability judgments. We also discuss different game settings to  
assess their impact on participants' motivation and engagement. The  
final dataset containing 1,062 sentences, which were selected based  
on majority voting, is released for future research and  
comparisons.},

abstract   = {This paper describes a new corpus of human
translations which contains both professional and students
translations. The data consists of English sources -- texts from
news and reviews -- and their translations into Russian and
Croatian, as well as of the subcorpus containing translations of the
review texts into Finnish. All target languages represent mid-
resourced and less or mid-investigated ones. The corpus will be
valuable for studying variation in translation as it allows a direct
comparison between human translations of the same source texts. The
corpus will also be a valuable resource for evaluating machine
translation systems. We believe that this resource will facilitate
understanding and improvement of the quality issues in both human
and machine translation. In the paper, we describe how the data was
collected, provide information on translator groups and summarise
the differences between the human translations at hand based on our
preliminary results with shallow features.},

pages       = {1761--1770},
abstract    = {Automatic identification of cyberbullying from
textual content is known to be a challenging task. The challenges
arise from the inherent structure of cyberbullying and the lack of
labeled large-scale corpus, enabling efficient machine-learning-
based tools including neural networks. This paper advocates a data
augmentation-based approach that could enhance the automatic
detection of cyberbullying in social media texts. We use both word
sense disambiguation and synonymy relation in WordNet lexical
database to generate coherent equivalent utterances of cyberbullying
input data. The disambiguation and semantic expansion are intended
to overcome the inherent limitations of social media posts, such as
an abundance of unstructured constructs and limited semantic
content. Besides, to test the feasibility, a novel protocol has been
employed to collect cyberbullying traces data from AskFm forum,
where about a 10K-size dataset has been manually labeled. Next, the
problem of cyberbullying identification is viewed as a binary
classification problem using an elaborated data augmentation
strategy and an appropriate classifier. For the latter, a
Convolutional Neural Network (CNN) architecture with FastText and
BERT was put forward, whose results were compared against commonly
employed Naïve Bayes (NB) and Logistic Regression (LR) classifiers
with and without data augmentation. The research outcomes were
```

```
promising and yielded almost 98.4\% of classifier accuracy, an
improvement of more than 4\% over baseline results.},

abstract  = {Stuttering is a complex speech disorder that
negatively affects an individual's ability to communicate
effectively. Persons who stutter (PWS) often suffer considerably
under the condition and seek help through therapy. Fluency shaping
is a therapy approach where PWSs learn to modify their speech to
help them to overcome their stutter. Mastering such speech
techniques takes time and practice, even after therapy. Shortly
after therapy, success is evaluated highly, but relapse rates are
high. To be able to monitor speech behavior over a long time, the
```

ability to detect stuttering events and modifications in speech could help PWSs and speech pathologists to track the level of fluency. Monitoring could create the ability to intervene early by detecting lapses in fluency. To the best of our knowledge, no public dataset is available that contains speech from people who underwent stuttering therapy that changed the style of speaking. This work introduces the Kassel State of Fluency (KSoF), a therapy-based dataset containing over 5500 clips of PWSs. The clips were labeled with six stuttering-related event types: blocks, prolongations, sound repetitions, word repetitions, interjections, and – specific to therapy – speech modifications. The audio was recorded during therapy sessions at the Institut der Kasseler Stottertherapie. The data will be made available for research purposes upon request.},

abstract = {Given the benefits of syntactically annotated  
collections of transcribed speech in spoken language research and  
applications, many spoken language treebanks have been developed in  
the last decades, with divergent annotation schemes posing important  
limitations to cross-resource explorations, such as comparing data  
across languages, grammatical frameworks, and language domains. As a  
consequence, there has been a growing number of spoken language  
treebanks adopting the Universal Dependencies (UD) annotation  
scheme, aimed at cross-linguistically consistent morphosyntactic  
annotation. In view of the non-central role of spoken language data  
within the scheme and with little in-domain consolidation to date,  
this paper presents a comparative overview of spoken language  
treebanks in UD to support cross-treebank data explorations on the  
one hand, and encourage further treebank harmonization on the other.  
Our results show that the spoken language treebanks differ  
considerably with respect to the inventory and the format of  
transcribed phenomena, as well as the principles adopted in their  
morphosyntactic annotation. This is particularly true for the  
dependency annotation of speech disfluencies, where conflicting data  
annotations suggest an underspecification of the guidelines  
pertaining to speech repairs in general and the reparandum  
dependency relation in particular.},

abstract = {This paper describes our efforts to extend the PARSEME framework to Modern Standard Arabic. The applicability of the PARSEME guidelines was tested by measuring the inter-annotator agreement in the early annotation stage. A subset of 1,062 sentences from the Prague Arabic Dependency Treebank PADT was selected and annotated by two Arabic native speakers independently. Following their annotations, a new Arabic corpus with over 1,250 annotated VMWEs has been built. This corpus already exceeds the smallest corpora of the PARSEME suite, and enables first observations. We discuss our annotation guide-line schema that shows full MWE annotation is realizable in Arabic where we get good inter-annotator agreement.},

month = {June},
year = {2022},
address = {Marseille, France},
publisher = {European Language Resources Association},
pages = {1849--1859},
abstract = {There has been a lot of work on predicting the timing of feedback in conversational systems. However, there has been less focus on predicting the prosody and lexical form of feedback given their communicative function. Therefore, in this paper we present our preliminary annotations of the communicative functions of 1627 short feedback tokens from the Switchboard corpus and an analysis of their lexical realizations and prosodic characteristics. Since there is no standard scheme for annotating the communicative function of

feedback we propose our own annotation scheme. Although our work is ongoing, our preliminary analysis revealed lexical tokens such as "yeah" are ambiguous and therefore lexical forms alone are not indicative of the function. Both the lexical form and prosodic characteristics need to be taken into account in order to predict the communicative function. We also found that feedback functions have distinguishable prosodic characteristics in terms of duration, mean pitch, pitch slope, and pitch range.},

booktitle = {Proceedings of the Language Resources and Evaluation Conference},
month = {June},
year = {2022},
address = {Marseille, France},
publisher = {European Language Resources Association},
pages = {1870--1884},
abstract = {Gender bias in natural language processing (NLP) applications, particularly machine translation, has been receiving

increasing attention. Much of the research on this issue has focused on mitigating gender bias in English NLP models and systems. Addressing the problem in poorly resourced, and/or morphologically rich languages has lagged behind, largely due to the lack of datasets and resources. In this paper, we introduce a new corpus for gender identification and rewriting in contexts involving one or two target users (I and/or You) – first and second grammatical persons with independent grammatical gender preferences. We focus on Arabic, a gender-marking morphologically rich language. The corpus has multiple parallel components: four combinations of 1st and 2nd person in feminine and masculine grammatical genders, as well as English, and English to Arabic machine translation output. This corpus expands on Habash et al. (2019)’s Arabic Parallel Gender Corpus (APGC v1.0) by adding second person targets as well as increasing the total number of sentences over 6.5 times, reaching over 590K words. Our new dataset will aid the research and development of gender identification, controlled text generation, and post-editing rewrite systems that could be used to personalize NLP applications and provide users with the correct outputs based on their grammatical gender preferences. We make the Arabic Parallel Gender Corpus (APGC v2.0) publicly available},

 title = {HOPE: A Task-Oriented and Human-Centric Evaluation Framework Using Professional Post-Editing Towards More Effective MT Evaluation},
 booktitle = {Proceedings of the Language Resources and Evaluation Conference},
 month = {June},
 year = {2022},
 address = {Marseille, France},
 publisher = {European Language Resources Association},
 pages = {13--21},
 abstract = {Traditional automatic evaluation metrics for machine translation have been widely criticized by linguists due to their low accuracy, lack of transparency, focus on language mechanics rather than semantics, and low agreement with human quality evaluation. Human evaluations in the form of MQM-like scorecards have always been carried out in real industry setting by both clients and translation service providers (TSPs). However, traditional human translation quality evaluations are costly to perform and go into great linguistic detail, raise issues as to inter-rater reliability (IRR) and are not designed to measure quality of worse than premium quality translations. In this work, we introduce **HOPE**, a task-oriented and **h**uman-centric evaluation framework for machine translation output based **o**n professional **p**ost-**e**ditng annotations. It contains only a limited number of commonly occurring error types, and uses a scoring model with geometric progression of error penalty points (EPPs) reflecting error severity level to each translation unit. The initial

experimental work carried out on English–Russian language pair MT outputs on marketing content type of text from highly technical domain reveals that our evaluation framework is quite effective in reflecting the MT output quality regarding both overall system–level performance and segment–level transparency, and it increases the IRR for error type interpretation. The approach has several key advantages, such as ability to measure and compare less than perfect MT output from different systems, ability to indicate human perception of quality, immediate estimation of the labor effort required to bring MT output to premium quality, low–cost and faster application, as well as higher IRR. Our experimental data is available at [url{https://github.com/lHan87/HOPE}.}](https://github.com/lHan87/HOPE),

abstract = {In this paper, we provide an overview of current technologies for cross–lingual link discovery, and we discuss challenges, experiences and prospects of their application to under–resourced languages. We first introduce the goals of cross–lingual linking and associated technologies, and in particular, the role that the Linked Data paradigm (Bizer et al., 2011) applied to language data can play in this context. We define under–resourced languages with a specific focus on languages actively used on the internet, i.e., languages with a digitally versatile speaker community, but limited support in terms of language technology. We argue that languages for which considerable amounts of textual data and (at least) a bilingual word list are available, techniques for cross–lingual linking can be readily applied, and that these enable the implementation of downstream applications for under–resourced languages via the localisation and adaptation of existing technologies and resources.},

  abstract      = {Social media platforms play an increasingly important
role as forums for public discourse. Many platforms use
recommendation algorithms that funnel users to online groups with
the goal of maximizing user engagement, which many commentators have
pointed to as a source of polarization and misinformation.
Understanding the role of NLP in recommender systems is an
interesting research area, given the role that social media has
played in world events. However, there are few standardized
resources which researchers can use to build models that predict
engagement with online groups on social media; each research group
constructs datasets from scratch without releasing their version for
reuse. In this work, we present a dataset drawn from posts and
comments on the online message board Reddit. We develop baseline
models for recommending subreddits to users, given the user's post
and comment history. We also study the behavior of our recommender
models on subreddits that were banned in June 2020 as part of
Reddit's efforts to stop the dissemination of hate speech.},

abstract       = {Our knowledge on speech is historically built on data
comparing different speakers or data averaged across speakers.
Consequently, little is known on the variability in the speech of a
single individual. Experimental studies have shown that speakers
adapt to the linguistic and the speaking contexts, and modify their
speech according to their emotional or biological condition, etc.
However, it is unclear how much speakers vary from one repetition to
the next, and how comparable are recordings that are collected days,
months or years apart. In this paper, we introduce two French
databases which contain recordings of 9 to 11 speakers recorded over
9 to 18 sessions, allowing comparisons of speech tasks with a
different delay between the repetitions: 3 repetitions within the
same session, 6 to 10 repetitions on different days during a two
months period, 5 to 9 repetitions on different years. Speakers are
recorded on a large set of speech tasks including read and
spontaneous speech as well as speech-like performance tasks. In this
paper, we provide detailed descriptions of the two databases and
available annotations. We conclude by an illustration on how these
data can inform on within-speaker variability of speech.},

publisher = {European Language Resources Association},
pages = {1960--1969},
abstract = {Inserting fillers (such as "um", "like") to clean speech text has a rich history of study. One major application is to make dialogue systems sound more spontaneous. The ambiguity of filler occurrence and inter-speaker difference make both modeling and evaluation difficult. In this paper, we study sampling-based filler insertion, a simple yet unexplored approach to inserting fillers. We propose an objective score called Filler Perplexity (FPP). We build three models trained on two single-speaker spontaneous corpora, and evaluate them with FPP and perceptual tests. We implement two innovations in perceptual tests, (1) evaluating filler insertion on dialogue systems output, (2) synthesizing speech with neural spontaneous TTS engines. FPP proves to be useful in analysis but does not correlate well with perceptual MOS. Perceptual results show little difference between compared filler insertion models including with ground-truth, which may be due to the ambiguity of what is good filler insertion and a strong neural spontaneous TTS that produces natural speech irrespective of input. Results also show preference for filler-inserted speech synthesized with spontaneous TTS. The same test using TTS based on read speech obtains the opposite results, which shows the importance of using spontaneous TTS in evaluating filler insertions.  pages = {1978--1984},
 abstract = {We present SNUC, the first published corpus of spoken
 alphanumeric identifiers of the sort typically used as serial and
 part numbers in the manufacturing sector. The dataset contains
 recordings and transcriptions of over 50 native British English
 speakers, speaking over 13,000 multi-character alphanumeric
 sequences and totalling almost 20 hours of recorded speech. We
 describe requirements taken into account in the designing the corpus
 and the methodology used to construct it. We present summary
 statistics describing the corpus contents, as well as a preliminary
 investigation into errors in spoken alphanumeric identifiers. We
 validate the corpus by showing how it can be used to adapt a deep
 learning neural network based ASR system, resulting in improved
 recognition accuracy on the task of spoken alphanumeric identifier
 recognition. Finally, we discuss further potential uses for the
 corpus and for the tools developed to construct it.},

  pages    = {1985--1990},  
  abstract = {In the present paper, we introduce the ManDi Corpus,  
a spoken corpus of regional Mandarin dialects and Standard Mandarin.  
The corpus currently contains 357 recordings (about 9.6 hours) of  
monosyllabic words, disyllabic words, short sentences, a short  
passage and a poem, each produced in Standard Mandarin and in one of  
six regional Mandarin dialects: Beijing, Chengdu, Jinan, Taiyuan,  
Wuhan, and Xi'an Mandarin from 36 speakers. The corpus was collected  
remotely using participant-controlled smartphone recording apps.  
Word- and phone-level alignments were generated using Praat and the  
Montreal Forced Aligner. The pilot study of dialect-specific tone  
systems showed that with practicable design and decent recording  
quality, remotely collected speech data can be suitable for analysis  
of relative patterns in acoustic-phonetic realization. The corpus is  
available on OSF (https://osf.io/fgv4w/) for non-commercial use  
under a CC BY-NC 3.0 license.},

  abstract = {Conversations (normal speech) or professional  
interactions (e.g., projected speech in the classroom) have been  
identified as situations with increased risk of exposure to SARS-  
CoV-2 due to the high production of droplets in the exhaled air.  
However, it is still unclear to what extent speech properties  
influence droplets emission during everyday life conversations.  
Here, we report the experimental protocol of three experiments  
aiming at measuring the velocity and the direction of the airflow,
```

the number and size of droplets spread during speech interactions in French. We consider different phonetic conditions, potentially leading to a modulation of speech droplets production, such as voice intensity (normal vs. loud voice), articulation manner of phonemes (type of consonants and vowels) and prosody (i.e., the melody of the speech). Findings from these experiments will allow future simulation studies to predict the transport, dispersion and evaporation of droplets emitted under different speech conditions.},

publisher = {European Language Resources Association},
pages = {2000--2006},
abstract = {The growing popularity of various forms of Spoken Dialogue Systems (SDS) raises the demand for their capability of implicitly assessing the speaker's sentiment from speech only. Mapping the latter on user preferences enables to adapt to the user and individualize the requested information while increasing user satisfaction. In this paper, we explore the integration of rank consistent ordinal regression into a speech-only sentiment prediction task performed by ResNet-like systems. Furthermore, we use speaker verification extractors trained on larger datasets as low-level feature extractors. An improvement of performance is shown by fusing sentiment and pre-extracted speaker embeddings reducing the speaker bias of sentiment predictions. Numerous experiments on Multimodal Opinion Sentiment and Emotion Intensity (CMU-MOSEI) databases show that we beat the baselines of state-of-the-art unimodal approaches. Using speech as the only modality combined with optimizing an order-sensitive objective function gets significantly closer to the sentiment analysis results of state-of-the-art multimodal systems.},

abstract    = {This research explores automated text classification
using data from Low- and Middle-Income Countries (LMICs). In
particular, we explore enhancing text representations with
demographic information of speakers in a privacy-preserving manner.
We introduce the Demographic-Rich Qualitative UPV-Interviews Dataset
(DR-QI), a rich dataset of qualitative interviews from rural
communities in India and Uganda. The interviews were conducted
following the latest standards for respectful interactions with
illiterate speakers (Hirmer et al., 2021a). The interviews were
later sentence-annotated for Automated User-Perceived Value (UPV)
Classification (Conforti et al., 2020), a schema that classifies
values expressed by speakers, resulting in a dataset of 5,333
sentences. We perform the UPV classification task, which consists of
predicting which values are expressed in a given sentence, on the
new DR-QI dataset. We implement a classification model using
DistilBERT (Sanh et al., 2019), which we extend with demographic
information. In order to preserve the privacy of speakers, we
investigate encoding demographic information using autoencoders. We
find that adding demographic information improves performance, even
if such information is encoded. In addition, we find that the
performance per UPV is linked to the number of occurrences of that
value in our data.},

abstract   = {For research in audiovisual interview archives often
it is not only of interest what is said but also how. Sentiment
analysis and emotion recognition can help capture, categorize and
make these different facets searchable. In particular, for oral
history archives, such indexing technologies can be of great
interest. These technologies can help understand the role of
emotions in historical remembering. However, humans often perceive
sentiments and emotions ambiguously and subjectively. Moreover, oral
history interviews have multi-layered levels of complex, sometimes
contradictory, sometimes very subtle facets of emotions. Therefore,
the question arises of the chance machines and humans have capturing
```

and assigning these into predefined categories. This paper investigates the ambiguity in human perception of emotions and sentiment in German oral history interviews and the impact on machine learning systems. Our experiments reveal substantial differences in human perception for different emotions. Furthermore, we report from ongoing machine learning experiments with different modalities. We show that the human perceptual ambiguity and other challenges, such as class imbalance and lack of training data, currently limit the opportunities of these technologies for oral history archives. Nonetheless, our work uncovers promising observations and possibilities for further research.},

abstract = {Finding the polarity of feelings in texts is a far-reaching task. Whilst the field of natural language processing has established sentiment analysis as an alluring problem, many feelings are left uncharted. In this study, we analyze the optimism and pessimism concepts from Twitter posts to effectively understand the broader dimension of psychological phenomenon. Towards this, we carried a systematic study by first exploring the linguistic peculiarities of optimism and pessimism in user-generated content. Later, we devised a multi-task knowledge distillation framework to simultaneously learn the target task of optimism detection with the help of the auxiliary task of sentiment analysis and hate speech detection. We evaluated the performance of our proposed approach on the benchmark Optimism/Pessimism Twitter dataset. Our extensive experiments show the superiority of our approach in correctly differentiating between optimistic and pessimistic users. Our human and automatic evaluation shows that sentiment analysis and hate speech detection are beneficial for optimism/pessimism detection.},

  abstract  = {Multiword expression (MWE) identification in tweets
is a complex task due to the complex linguistic nature of MWEs
combined with the non-standard language use in social networks. MWE
features were shown to be helpful for hate speech detection (HSD).
In this article, we present joint experiments on these two related
tasks on English Twitter data: first we focus on the MWE
identification task, and then we observe the influence of MWE-based
features on the HSD task. For MWE identification, we compare the
performance of two systems: lexicon-based and deep neural networks-
based (DNN). We experimentally evaluate seven configurations of a
state-of-the-art DNN system based on recurrent networks using pre-
trained contextual embeddings from BERT. The DNN-based system
outperforms the lexicon-based one thanks to its superior
generalisation power, yielding much better recall. For the HSD task,
we propose a new DNN architecture for incorporating MWE features. We
confirm that MWE features are helpful for the HSD task. Moreover,
the proposed DNN architecture beats previous MWE-based HSD systems
by 0.4 to 1.1 F-measure points on average on four Twitter HSD
corpora.},

  abstract    = {This paper describes a method of semi-automatic word
spotting in minority languages, from one and the same Aesop fable
"The North Wind and the Sun" translated in Romance languages/
dialects from Hexagonal (i.e. Metropolitan) France and languages
from French Polynesia. The first task consisted of finding out how a
dozen words such as "wind" and "sun" were translated in over 200
versions collected in the field - taking advantage of orthographic
similarity, word position and context. Occurrences of the
translations were then extracted from the phone-aligned recordings.
The results were judged accurate in 96-97\% of cases, both on the
development corpus and a test set of unseen data. Corrected
alignments were then mapped and basemaps were drawn to make various

```

linguistic phenomena immediately visible. The paper exemplifies how regular expressions may be used for this purpose. The final result, which takes the form of an online speaking atlas (enriching the <https://atlas.limsi.fr> website), enables us to illustrate lexical, morphological or phonetic variation.},

abstract   = {Although information on the Internet can be shared in
many languages, the language presence on the World Wide Web is very
disproportionate. The problem of multilingualism on the Web, in
particular access, availability and quality of information in the
world's languages, has been the subject of UNESCO focus for several
decades. Making European websites more multilingual is also one of
the focal targets of the Connecting Europe Facility Automated
Translation (CEF AT) digital service infrastructure. In order to
monitor this goal, alongside other possible solutions, CEF AT needs
a methodology and easy to use tool to assess the degree of
multilingualism of a given website. In this paper we investigate
methods and tools that automatically analyse the language diversity
of the Web and propose indicators and methodology on how to measure
the multilingualism of European websites. We also introduce a
prototype tool based on open-source software that helps to assess
multilingualism of the Web and can be independently run at set
intervals. We also present initial results obtained with our tool
that allows us to conclude that multilingualism on the Web is still
a problem not only at the world level, but also at the European and
regional level.},

publisher  = {European Language Resources Association},
pages      = {2117--2125},
abstract   = {Different algorithms have been proposed to detect
semantic shifts (changes in a word meaning over time) in a
diachronic corpus. Yet, and somehow surprisingly, no reference
corpus has been designed so far to evaluate them, leaving
researchers to fallback to troublesome evaluation strategies. In
this work, we introduce a methodology for the construction of a
reference dataset for the evaluation of semantic shift detection,
that is, a list of words where we know for sure whether they present
a word meaning change over a period of interest. We leverage a
state-of-the-art word-sense disambiguation model to associate a date
of first appearance to all the senses of a word. Significant changes
in sense distributions as well as clear stability are detected and
the resulting words are inspected by experts using a dedicated
interface before populating a reference dataset. As a proof of
concept, we apply this methodology to a corpus of newspapers from
Quebec covering the whole 20th century. We manually verified a
subset of candidates, leading to QC-FR-Diac-V1.0, a corpus of 151

abstract = {Understanding the needs and fears of citizens, especially during a pandemic such as COVID-19, is essential for any government or legislative entity. An effective COVID-19 strategy further requires that the public understand and accept the restriction plans imposed by these entities. In this paper, we explore a causal mediation scenario in which we want to emphasize the use of NLP methods in combination with methods from economics and social sciences. Based on sentiment analysis of Tweets towards the current COVID-19 situation in the UK and Sweden, we conduct several causal inference experiments and attempt to decouple the effect of government restrictions on mobility behavior from the effect that occurs due to public perception of the COVID-19 strategy in a country. To avoid biased results we control for valid country specific epidemiological and time-varying confounders. Comprehensive experiments show that not all changes in mobility are caused by countries implemented policies but also by the support of individuals in the fight against this pandemic. We find that social

media texts are an important source to capture citizens' concerns and trust in policy makers and are suitable to evaluate the success of government policies.},

pages = {2141--2147},
abstract = {The scientific community is increasingly aware of the necessity to embrace pluralism and consistently represent major and minor social groups. Currently, there are no standard evaluation techniques for different types of biases. Accordingly, there is an urgent need to provide evaluation sets and protocols to measure existing biases in our automatic systems. Evaluating the biases should be an essential step towards mitigating them in the systems. This paper introduces WinoST, a new freely available challenge set for evaluating gender bias in speech translation. WinoST is the speech version of WinoMT, an MT challenge set, and both follow an evaluation protocol to measure gender accuracy. Using an S-Transformer end-to-end speech translation system, we report the gender bias evaluation on four language pairs, and we reveal the inaccuracies in translations generating gender-stereotyped translations.},

address = {Marseille, France},
publisher = {European Language Resources Association},
pages = {2148--2156},
abstract = {Obtaining linguistic annotation from novice crowdworkers is far from trivial. A case in point is the annotation of discourse relations, which is a complicated task. Recent methods have obtained promising results by extracting relation labels from either discourse connectives (DCs) or question-answer (QA) pairs that participants provide. The current contribution studies the effect of worker selection and training on the agreement on implicit

relation labels between workers and gold labels, for both the DC and the QA method. In Study 1, workers were not specifically selected or trained, and the results show that there is much room for improvement. Study 2 shows that a combination of selection and training does lead to improved results, but the method is cost- and time-intensive. Study 3 shows that a selection-only approach is a viable alternative; it results in annotations of comparable quality compared to annotations from trained participants. The results generalized over both the DC and QA method and therefore indicate that a selection-only approach could also be effective for other crowdsourced discourse annotation tasks.},

booktitle = {Proceedings of the Language Resources and Evaluation Conference},

month = {June},

year = {2022},

address = {Marseille, France},

publisher = {European Language Resources Association},

pages = {2157--2165},

abstract = {Social media are heavily used by many users to share their mental health concerns and diagnoses. This trend has turned social media into a large-scale resource for researchers focused on detecting mental health conditions. Social media usage varies considerably across individuals. Thus, classification of patterns, including detecting signs of depression, must account for such variation. We address the disparity in classification effectiveness for users with little activity (e.g., new users). Our evaluation, performed on a large-scale dataset, shows considerable detection discrepancy based on user posting frequency. For instance, the F1 detection score of users with an above-median versus below-median number of posts is greater than double (0.803 vs 0.365) using a conventional CNN-based model; similar results were observed on lexical and transformer-based classifiers. To complement this evaluation, we propose a dynamic thresholding technique that adjusts the classifier's sensitivity as a function of the number of posts a user has. This technique alone reduces the margin between users with many and few posts, on average, by 45% across all methods and increases overall performance, on average, by 33%. These findings emphasize the importance of evaluating and tuning natural language systems for potentially vulnerable populations.},

abstract   = {Can NLP assist in building formal models for
verifying complex systems? We study this challenge in the context of
parsing Network File System (NFS) specifications. We define a
semantic-dependency problem over SpecIR, a representation language
we introduce to model sentences appearing in NFS specification
documents (RFCs) as IF-THEN statements, and present an annotated
dataset of 1,198 sentences. We develop and evaluate semantic-
dependency parsing systems for this problem. Evaluations show that
even when using a state-of-the-art language model, there is
significant room for improvement, with the best models achieving an
F1 score of only 60.5 and 33.3 in the named-entity-recognition and
dependency-link-prediction sub-tasks, respectively. We also release
additional unlabeled data and other domain-related texts.
Experiments show that these additional resources increase the F1
measure when used for simple domain-adaption and transfer-learning-
based approaches, suggesting fruitful directions for further
research},

abstract    = {NLP technologies such as text similarity assessment,
question answering and text classification are increasingly being
used to develop intelligent educational applications. The long-term
goal of our work is an intelligent tutoring system for German
secondary schools, which will support students in a school exercise
that requires them to identify arguments in an argumentative source
text. The present paper presents our work on a central subtask, viz.
the automatic assessment of similarity between a pair of
argumentative text snippets in German. In the designated use case,
students write out key arguments from a given source text; the
tutoring system then evaluates them against a target reference,
assessing the similarity level between student work and the
reference. We collect a dataset for our similarity assessment task
through crowdsourcing as authentic German student data are scarce;
```

we label the collected text pairs with similarity scores on a 5-point scale and run first experiments on the task. We see that a model based on BERT shows promising results, while we also discuss some challenges that we observe.},

abstract = {Studying and mitigating gender and other biases in natural language have become important areas of research from both algorithmic and data perspectives. This paper explores the idea of reducing gender bias in a language generation context by generating gender variants of sentences. Previous work in this field has either been rule-based or required large amounts of gender balanced training data. These approaches are however not scalable across multiple languages, as creating data or rules for each language is costly and time-consuming. This work explores a light-weight method to generate gender variants for a given text using pre-trained language models as the resource, without any task-specific labelled data. The approach is designed to work on multiple languages with minimal changes in the form of heuristics. To showcase that, we have tested it on a high-resourced language, namely Spanish, and a low-resourced language from a different family, namely Serbian. The approach proved to work very well on Spanish, and while the results were less positive for Serbian, it showed potential even for languages where pre-trained models are less effective.},

abstract = {Hate speech detection is a prominent and challenging task, since hate messages are often expressed in subtle ways and with characteristics that may vary depending on the author. Hence,
```

many models suffer from the generalization problem. However, retrieving and monitoring hateful content on social media is a current necessity. In this paper, we propose an unsupervised approach using Graph Auto-Encoders (GAE), which allows us to avoid using labeled data when training the representation of the texts. Specifically, we represent texts as nodes of a graph, and use a transformer layer together with a convolutional layer to encode these nodes in a low-dimensional space. As a result, we obtain embeddings that can be decoded into a reconstruction of the original network. Our main idea is to learn a model with a set of texts without supervision, in order to generate embeddings for the nodes: nodes with the same label should be close in the embedding space, which, in turn, should allow us to distinguish among classes. We employ this strategy to detect hate speech in multi-domain and multilingual sets of texts, where our method shows competitive results on small datasets.},

  abstract = {Question Answering, including Reading Comprehension,  
  is one of the NLP research areas that has seen significant  
  scientific breakthroughs over the past few years, thanks to the  
  concomitant advances in Language Modeling. Most of these  
  breakthroughs, however, are centered on the English language. In  
  2020, as a first strong initiative to bridge the gap to the French  
  language, Illuin Technology introduced FQuAD1.1, a French Native  
  Reading Comprehension dataset composed of 60,000+ questions and  
  answers samples extracted from Wikipedia articles. Nonetheless,  
  Question Answering models trained on this dataset have a major  
  drawback: they are not able to predict when a given question has no  
  answer in the paragraph of interest, therefore making unreliable  
  predictions in various industrial use-cases. We introduce FQuAD2.0,  
  which extends FQuAD with 17,000+ unanswerable questions, annotated  
  adversarially, in order to be similar to answerable ones. This new  
  dataset, comprising a total of almost 80,000 questions, makes it  
  possible to train French Question Answering models with the ability  
  of distinguishing unanswerable questions from answerable ones. We  
  benchmark several models with this dataset: our best model, a fine-  
  tuned CamemBERT-large, achieves a F1 score of 82.3\% on this  
  classification task, and a F1 score of 83\% on the Reading  
  Comprehension task.},

  address     = {Marseille, France},  
  publisher   = {European Language Resources Association},  
  pages       = {2215--2225},  
  abstract    = {The performance of hate speech detection models  
relies on the datasets on which the models are trained. Existing  
datasets are mostly prepared with a limited number of instances or  
hate domains that define hate topics. This hinders large-scale  
analysis and transfer learning with respect to hate domains. In this  
study, we construct large-scale tweet datasets for hate speech  
detection in English and a low-resource language, Turkish,  
consisting of human-labeled 100k tweets per each. Our datasets are  
designed to have equal number of tweets distributed over five  
domains. The experimental results supported by statistical tests  
show that Transformer-based language models outperform conventional  
bag-of-words and neural models by at least 5% in English and 10%  
in Turkish for large-scale hate speech detection. The performance is  
also scalable to different training sizes, such that 98% of  
performance in English, and 97% in Turkish, are recovered when 20%  
of training instances are used. We further examine the  
generalization ability of cross-domain transfer among hate domains.  
We show that 96% of the performance of a target domain in average  
is recovered by other domains for English, and 92% for Turkish.  
Gender and religion are more successful to generalize to other  
domains, while sports fail most.},

  abstract = {Entity linking in dialogue is the task of mapping  
entity mentions in utterances to a target knowledge base. Prior work  
on entity linking has mainly focused on well-written articles such  
as Wikipedia, annotated newswire, or domain-specific datasets. We  
extend the study of entity linking to open domain dialogue by  
presenting the OpenEL corpus: an annotated multi-domain corpus for  
linking entities in natural conversation to Wikidata. Each dialogic  
utterance in 179 dialogues over 12 topics from the EDINA dataset has  
been annotated for entities realized by definite referring  
expressions as well as anaphoric forms such as he, she, it and they.  
This dataset supports training and evaluation of entity linking in  
open-domain dialogue, as well as analysis of the effect of using  
dialogue context and anaphora resolution in model training. It could  
also be used for fine-tuning a coreference resolution algorithm. To  
the best of our knowledge, this is the first substantial entity  
linking corpus publicly available for open-domain dialogue. We also  
establish baselines for this task using several existing entity  
linking systems. We found that the Transformer-based system Flair +  
BLINK has the best performance with a 0.65 F1 score. Our results  
show that dialogue context is extremely beneficial for entity  
linking in conversations, with Flair + Blink achieving an F1 of 0.61  
without discourse context. These results also demonstrate the  
remaining performance gap between the baselines and human  
performance, highlighting the challenges of entity linking in open-  
domain dialogue, and suggesting many avenues for future research  
using OpenEL.},

  abstract       = {An idealized, though simplistic, view of the
referring expression production and grounding process in (situated)
dialogue assumes that a speaker must merely appropriately specify
their expression so that the target referent may be successfully
identified by the addressee. However, referring in conversation is a
collaborative process that cannot be aptly characterized as an
exchange of minimally-specified referring expressions. Concerns have
been raised regarding assumptions made by prior work on visually-
grounded dialogue that reveal an oversimplified view of conversation
and the referential process. We address these concerns by
introducing a collaborative image ranking task, a grounded agreement
game we call "A Game Of Sorts". In our game, players are tasked with
reaching agreement on how to rank a set of images given some sorting
criterion through a largely unrestricted, role-symmetric dialogue.
By putting emphasis on the argumentation in this mixed-initiative
interaction, we collect discussions that involve the collaborative
referential process. We describe results of a small-scale data
collection experiment with the proposed task. All discussed
materials, which includes the collected data, the codebase, and a
containerized version of the application, are publicly available.},

  pages     = {2282--2291},
  abstract  = {The use of misogynistic and sexist language has
increased in recent years in social media, and is increasing in the
Arabic world in reaction to reforms attempting to remove
restrictions on women lives. However, there are few benchmarks for
Arabic misogyny and sexism detection, and in those the annotations
are in aggregated form even though misogyny and sexism judgments are
found to be highly subjective. In this paper we introduce an Arabic
misogyny and sexism dataset (ArMIS) characterized by providing
annotations from annotators with different degree of religious
beliefs, and provide evidence that such differences do result in
disagreements. To the best of our knowledge, this is the first
dataset to study in detail the effect of beliefs on misogyny and
sexism annotation. We also discuss proof-of-concept experiments
showing that a dataset in which disagreements have not been
reconciled can be used to train state-of-the-art models for misogyny
and sexism detection; and consider different ways in which such
models could be evaluated.},

  abstract  = {Despite the importance of understanding causality,
corpora addressing causal relations are limited. There is a
discrepancy between existing annotation guidelines of event
causality and conventional causality corpora that focus more on
linguistics. Many guidelines restrict themselves to include only
explicit relations or clause-based arguments. Therefore, we propose
an annotation schema for event causality that addresses these
concerns. We annotated 3,559 event sentences from protest event news
with labels on whether it contains causal relations or not. Our
corpus is known as the Causal News Corpus (CNC). A neural network
built upon a state-of-the-art pre-trained language model performed
well with 81.20\% F1 score on test set, and 83.46\% in 5-folds
cross-validation. CNC is transferable across two external corpora:
CausalTimeBank (CTB) and Penn Discourse Treebank (PDTB). Leveraging
each of these external datasets for training, we achieved up to
approximately 64\% F1 on the CNC test set without additional fine-
tuning. CNC also served as an effective training and pre-training
dataset for the two external corpora. Lastly, we demonstrate the
difficulty of our task to the layman in a crowd-sourced annotation
exercise. Our annotated corpus is publicly available, providing a
valuable resource for causal text mining researchers.},

abstract = {In recent years, machine learning for clinical  
decision support has gained more and more attention. In order to  
introduce such applications into clinical practice, a good  
performance might be essential, however, the aspect of trust should  
not be underestimated. For the treating physician using such a  
system and being (legally) responsible for the decision made, it is  
particularly important to understand the system's recommendation. To  
provide insights into a model's decision, various techniques from  
the field of explainability (XAI) have been proposed whose output is  
often enough not targeted to the domain experts that want to use the  
model. To close this gap, in this work, we explore how explanations  
could possibly look like in future. To this end, this work presents  
a dataset of textual explanations in context of decision support.  
Within a reader study, human physicians estimated the likelihood of  
possible negative patient outcomes in the near future and justified  
each decision with a few sentences. Using those sentences, we  
created a novel corpus, annotated with different semantic layers.  
Moreover, we provide an analysis of how those explanations are  
constructed, and how they change depending on physician, on the  
estimated risk and also in comparison to an automatic clinical  
decision support system with feature importance.},

abstract  = {Disfluency detection is a critical task in real-time
dialogue systems. However, despite its importance, it remains a
relatively unexplored field, mainly due to the lack of appropriate
datasets. At the same time, existing datasets suffer from various
issues, including class imbalance issues, which can significantly
affect the performance of the model on rare classes, as it is
demonstrated in this paper. To this end, we propose LARD, a method
for generating complex and realistic artificial disfluencies with
little effort. The proposed method can handle three of the most
common types of disfluencies: repetitions, replacements, and
restarts. In addition, we release a new large-scale dataset with
disfluencies that can be used on four different tasks: disfluency
detection, classification, extraction, and correction. Experimental
results on the LARD dataset demonstrate that the data produced by
the proposed method can be effectively used for detecting and
removing disfluencies, while also addressing limitations of existing
datasets.},

abstract  = {Psychiatry and people suffering from mental disorders
have often been given a pejorative label that induces social
rejection. Many studies have addressed discourse content about
psychiatry on social media, suggesting that they convey
stigmatizing representations of mental health disorders. In this
paper, we focus for the first time on the use of psychiatric terms
in tweets in French. We first describe the annotated dataset that we
use. Then we propose several deep learning models to
detect automatically (1) the different types of use of psychiatric
terms (medical use, misuse or irrelevant use), and (2) the
polarity of the tweet. We show that polarity detection can be

```

improved when done in a multitask framework in combination with type of use detection. This confirms the observations made manually on several datasets, namely that the polarity of a tweet is correlated to the type of term use (misuses are mostly negative whereas medical uses are neutral). The results are interesting for both tasks and it allows to consider the possibility for performing automatic approaches in order to conduct real-time surveys on social media, larger and less expensive than existing manual ones},

abstract   = {In recent years, the focus on developing natural
language processing (NLP) tools for Arabic has shifted from Modern
Standard Arabic to various Arabic dialects. Various corpora of
various sizes and representing different genres, have been created
for a number of Arabic dialects. As far as Gulf Arabic is concerned,
Gumar Corpus (Khalifa et al., 2016) is the largest corpus, to date,
that includes data representing the dialectal Arabic of the six Gulf
Cooperation Council countries (Bahrain, Kuwait, Saudi Arabia, Qatar,
United Arab Emirates, and Oman), particularly in the genre of
"online forum novels". In this paper, we present the Bahrain Corpus.
Our objective is to create a specialized corpus of the Bahraini
Arabic dialect, which includes written texts as well as transcripts
of audio files, belonging to a different genre (folktales, comedy
shows, plays, cooking shows, etc.). The corpus comprises 620K words,
carefully curated. We provide automatic morphological annotations of
the full corpus using state-of-the-art morphosyntactic
disambiguation for Gulf Arabic. We validate the quality of the
annotations on a 7.6K word sample. We plan to make the annotated
sample as well as the full corpus publicly available to support
researchers interested in Arabic NLP.},

abstract = {Discourse marker inventories are important tools for the development of both discourse parsers and corpora with discourse annotations. In this paper we explore the potential of massively multilingual lexical knowledge graphs to induce multilingual discourse marker lexicons using concept propagation methods as previously developed in the context of translation inference across dictionaries. Given one or multiple source languages with discourse marker inventories that discourse relations as senses of potential discourse markers, as well as a large number of bilingual dictionaries that link them -- directly or indirectly -- with the target language, we specifically study to what extent discourse marker induction can benefit from the integration of information from different sources, the impact of sense granularity and what limiting factors may need to be considered. Our study uses discourse marker inventories from nine European languages normalized against the discourse relation inventory of the Penn Discourse Treebank (PDTB), as well as three collections of machine-readable dictionaries with different characteristics, so that the interplay of a large number of factors can be studied.},

  abstract   = {In argumentative discourse, persuasion is often
achieved by refuting or attacking others' arguments. Attacking an
argument is not always straightforward and often consists of complex
rhetorical moves in which arguers may agree with a logic of an
argument while attacking another logic. Furthermore, an arguer may
neither deny nor agree with any logics of an argument, instead
ignore them and attack the main stance of the argument by providing
new logics and presupposing that the new logics have more value or
importance than the logics presented in the attacked argument.
However, there are no studies in computational argumentation that
capture such complex rhetorical moves in attacks or the
presuppositions or value judgments in them. To address this gap, we
introduce LPAttack, a novel annotation scheme that captures the
common modes and complex rhetorical moves in attacks along with the
implicit presuppositions and value judgments. Our annotation study
shows moderate inter-annotator agreement, indicating that human
annotation for the proposed scheme is feasible. We publicly release
our annotated corpus and the annotation guidelines.},

    abstract   = {MOTIF (Multimodal Contextualized Images For Language
Learners) is a multimodal dataset that consists of 1125
comprehension texts retrieved from Wikipedia Simple Corpus. Allowing
multimodal processing or enriching the context with multimodal
information has proven imperative for many learning tasks,
specifically for second language (L2) learning. In this respect,
several traditional NLP approaches can assist L2 readers in text
comprehension processes, such as simplifying text or giving
dictionary descriptions for complex words. As nicely stated in the
well-known proverb, sometimes "a picture is worth a thousand words"
and an image can successfully complement the verbal message by
enriching the representation, like in Pictionary books. This
multimodal support can also assist on-the-fly text reading
experience by providing a multimodal tool that chooses and displays
the most relevant images for the difficult words, given the text
context. This study mainly focuses on one of the key components to
achieving this goal; collecting a multimodal dataset enriched with
complex word annotation and validated image match.},

    abstract   = {Sign Languages (SLs) are the primary means of
communication for at least half a million people in Europe alone.
However, the development of SL recognition and translation tools is
slowed down by a series of obstacles concerning resource scarcity
and standardization issues in the available data. The former
challenge relates to the volume of data available for machine
learning as well as the time required to collect and process new
data. The latter obstacle is linked to the variety of the data,
i.e., annotation formats are not unified and vary amongst different
resources. The available data formats are often not suitable for
machine learning, obstructing the provision of automatic tools based

```

on neural models. In the present paper, we give an overview of these challenges by comparing various SL corpora and SL machine learning datasets. Furthermore, we propose a framework to address the lack of standardization at format level, unify the available resources and facilitate SL research for different languages. Our framework takes ELAN files as inputs and returns textual and visual data ready to train SL recognition and translation models. We present a proof of concept, training neural translation models on the data produced by the proposed framework.},

abstract = {The automatic translation of sign language videos  
into transcribed texts is rarely approached in its whole, as it  
implies to finely model the grammatical mechanisms that govern these  
languages. The presented work is a first step towards the  
interpretation of French sign language (LSF) by specifically  
targeting iconicity and spatial referencing. This paper describes  
the LSF-SHELVES corpus as well as the original technology that was  
designed and implemented to collect it. Our goal is to use deep  
learning methods to circumvent the use of models in spatial  
referencing recognition. In order to obtain training material with  
sufficient variability, we designed a light-weight (and low-cost)  
capture protocol that enabled us to collect data from a large panel  
of LSF signers. This protocol involves the use of a portable device  
providing a 3D skeleton, and of a software developed specifically  
for this application to facilitate the post-processing of  
handshapes. The LSF-SHELVES includes simple and compound iconic and  
spatial dynamics, organized in 6 complexity levels, representing a  
total of 60 sequences signed by 15 LSF signers.},

  abstract    = {Given our society's increased exposure to multimedia
formats on social media platforms, efforts to understand how digital
content impacts people's emotions are burgeoning. As such, we
introduce a U.S. gun violence news dataset that contains news
headline and image pairings from 840 news articles with 15K high-
quality, crowdsourced annotations on emotional responses to the news
pairings. We created three experimental conditions for the
annotation process: two with a single modality (headline or image
only), and one multimodal (headline and image together). In contrast
to prior works on affectively-annotated data, our dataset includes
annotations on the dominant emotion experienced with the content,
the intensity of the selected emotion and an open-ended, written
component. By collecting annotations on different modalities of the
same news content pairings, we explore the relationship between
image and text influence on human emotional response. We offer
initial analysis on our dataset, showing the nuanced affective
differences that appear due to modality and individual factors such
as political leaning and media consumption habits. Our dataset is
made publicly available to facilitate future research in affective
computing.},

  abstract  = {We present RoomReader, a corpus of multimodal,
  multiparty conversational interactions in which participants
  followed a collaborative student-tutor scenario designed to elicit
  spontaneous speech. The corpus was developed within the wider
  RoomReader Project to explore multimodal cues of conversational
  engagement and behavioural aspects of collaborative interaction in
  online environments. However, the corpus can be used to study a wide
  range of phenomena in online multimodal interaction. The publicly-
  shared corpus consists of over 8 hours of video and audio recordings
  from 118 participants in 30 gender-balanced sessions, in the "in-
  the-wild" online environment of Zoom. The recordings have been
  edited, synchronised, and fully transcribed. Student participants
  have been continuously annotated for engagement with a novel
  continuous scale. We provide questionnaires measuring engagement and
  group cohesion collected from the annotators, tutors and
  participants themselves. We also make a range of accompanying data
  available such as personality tests and behavioural assessments. The
  dataset and accompanying psychometrics present a rich resource
  enabling the exploration of a range of downstream tasks across
  diverse fields including linguistics and artificial intelligence.
  This could include the automatic detection of student engagement,
  analysis of group interaction and collaboration in online
  conversation, and the analysis of conversational behaviours in an
  online setting.},

    abstract   = {In this article, we present Quevedo, a software tool
we have developed for the task of automatic processing of graphical
languages. These are languages which use images to convey meaning,
relying not only on the shape of symbols but also on their spatial
arrangement in the page, and relative to each other. When presented
in image form, these languages require specialized computational
processing which is not the same as usually done either for natural
language processing or for artificial vision. Quevedo enables this
specialized processing, focusing on a data-based approach. As a
command line application and library, it provides features for the
collection and management of image datasets, and their machine
learning recognition using neural networks and recognizer pipelines.
This processing requires careful annotation of the source data, for
which Quevedo offers an extensive and visual web-based annotation
interface. In this article, we also briefly present a case study
centered on the task of SignWriting recognition, the original
motivation for writing the software. Quevedo is written in Python,
and distributed freely under the Open Software License version
3.0.},

abstract   = {We introduce the Merkel Podcast Corpus, an audio-
visual-text corpus in German collected from 16 years of (almost)
weekly Internet podcasts of former German chancellor Angela Merkel.
To the best of our knowledge, this is the first single speaker
corpus in the German language consisting of audio, visual and text
modalities of comparable size and temporal extent. We describe the
methods used with which we have collected and edited the data which
involves downloading the videos, transcripts and other metadata,
forced alignment, performing active speaker recognition and face
detection to finally curate the single speaker dataset consisting of
utterances spoken by Angela Merkel. The proposed pipeline is general
and can be used to curate other datasets of similar nature, such as
talk show contents. Through various statistical analyses and
applications of the dataset in talking face generation and TTS, we
show the utility of the dataset. We argue that it is a valuable
contribution to the research community, in particular, due to its
realistic and challenging material at the boundary between prepared
and spontaneous speech.},

abstract = {The Petit Larousse illustré is a French dictionary  
first published in 1905. Its division in two main parts on language  
and on history and geography corresponds to a major milestone in  
French lexicography as well as a repository of general knowledge  
from this period. Although the value of many entries from 1905  
remains intact, some descriptions now have a dimension that is more  
historical than contemporary. They are nonetheless significant to  
analyze and understand cultural representations from this time. A  
comparison with more recent information or a verification of these  
entries would require a tedious manual work. In this paper, we  
describe a new lexical resource, where we connected all the  
dictionary entries of the history and geography part to current data  
sources. For this, we linked each of these entries to a wikidata  
identifier. Using the wikidata links, we can automate more easily  
the identification, comparison, and verification of historically-  
situated representations. We give a few examples on how to process  
wikidata identifiers and we carried out a small analysis of the  
entities described in the dictionary to outline possible  
applications. The resource, i.e. the annotation of 20,245 dictionary  
entries with wikidata links, is available from GitHub (https://  
github.com/pnugues/petit\_larousse\_1905/)},

abstract = {The paper presents current work on a German corpus
```

annotated for metaphor. Metaphors denote entities or situations that are in some sense similar to the literal referent, e.g., when "Handschrift" 'signature' is used in the sense of 'distinguishing mark' or the suppression of hopes is introduced by the verb "verschütten" 'bury'. The corpus is part of a project on register, hence, includes material from different registers that represent register variation along a number of important dimensions, but we believe that it is of interest to research on metaphor in general. The corpus extends previous annotation initiatives in that it not only annotates the metaphoric expressions themselves but also their respective relevant contexts that trigger a metaphorical interpretation of the expressions. For the corpus, we developed extended annotation guidelines, which specifically focus not only on the identification of these metaphoric contexts but also analyse in detail specific linguistic challenges for metaphor annotation that emerge due to the grammar of German.},

abstract    = {We explored transformer-based language models for
ranking instances of Portuguese lexico-semantic relations. Weights
were based on the likelihood of natural language sequences that
transmitted the relation instances, and expectations were that they
would be useful for filtering out noisier instances. However, after
analysing the weights, no strong conclusions were taken. They are
not correlated with redundancy, but are lower for instances with
longer and more specific arguments, which may nevertheless be a
consequence of their sensitivity to the frequency of such arguments.
They did also not reveal to be useful when computing word similarity
with network embeddings. Despite the negative results, we see the
reported experiments and insights as another contribution for better
understanding transformer language models like BERT and GPT, and we
make the weighted instances publicly available for further
research.},

abstract   = {While contextual language models are now dominant in
the field of Natural Language Processing, the representations they
build at the token level are not always suitable for all uses. In
this article, we propose a new method for building word or type-
level embeddings from contextual models. This method combines the
generalization and the aggregation of token representations. We
evaluate it for a large set of English nouns from the perspective of
the building of distributional thesauri for extracting semantic
similarity relations. Moreover, we analyze the differences between
static embeddings and type-level embeddings according to features
such as the frequency of words or the type of semantic relations
these embeddings account for, showing that the properties of these
two types of embeddings can be complementary and exploited for
further improving distributional thesauri.},

abstract    = {We provide a novel dataset – DiaWUG – with judgements
on diatopic lexical semantic variation for six Spanish variants in
Europe and Latin America. In contrast to most previous meaning-based
resources and studies on semantic diatopic variation, we collect
annotations on semantic relatedness for Spanish target words in
their contexts from both a semasiological perspective (i.e.,
exploring the meanings of a word given its form, thus including
polysemy) and an onomasiological perspective (i.e., exploring
identical meanings of words with different forms, thus including
synonymy). In addition, our novel dataset exploits and extends the
existing framework DUREl for annotating word senses in context (Erk
et al., 2013; Schlechtweg et al., 2018) and the framework-embedded
Word Usage Graphs (WUGs) – which up to now have mainly be used for
semasiological tasks and resources – in order to distinguish,
visualize and interpret lexical semantic variation of contextualized
words in Spanish from these two perspectives, i.e., semasiological
and onomasiological language variation.},

  pages   = {267--276},
  abstract = {Natural language processing (NLP) has been shown to
perform well in various tasks, such as answering questions,
ascertaining natural language inference and anomaly detection.
However, there are few NLP-related studies that touch upon the moral
context conveyed in text. This paper studies whether state-of-the-
art, pre-trained language models are capable of passing moral
judgments on posts retrieved from a popular Reddit user board.
Reddit is a social discussion website and forum where posts are
promoted by users through a voting system. In this work, we
construct a dataset that can be used for moral judgement tasks by
collecting data from the AITA? (Am I the A*****?) subreddit. To
model our task, we harnessed the power of pre-trained language
models, including BERT, RoBERTa, RoBERTa-large, ALBERT and
Longformer. We then fine-tuned these models and evaluated their
ability to predict the correct verdict as judged by users for each
post in the datasets. RoBERTa showed relative improvements across
the three datasets, exhibiting a rate of 87\% accuracy and a
Matthews correlation coefficient (MCC) of 0.76, while the use of the
Longformer model slightly improved the performance when used with
longer sequences, achieving 87\% accuracy and 0.77 MCC.},

  pages       = {2617--2625},
  abstract    = {Target Sense Verification (TSV) describes the binary
disambiguation task of deciding whether the intended sense of a
target word in a context corresponds to a given target sense. In
this paper, we introduce WiC-TSV-de, a multi-domain dataset for
German Target Sense Verification. While the training and development
sets consist of domain-independent instances only, the test set
contains domain-bound subsets, originating from four different
domains, being Gastronomy, Medicine, Hunting, and Zoology. The
domain-bound subsets incorporate adversarial examples such as in-
domain ambiguous target senses and context-mixing (i.e., using the
target sense in an out-of-domain context) which contribute to the
challenging nature of the presented dataset. WiC-TSV-de allows for
the development of sense-inventory-independent disambiguation models
that can generalise their knowledge for different domain settings.
By combining it with the original English WiC-TSV benchmark, we
performed monolingual and cross-lingual analysis, where the
evaluated baseline models were not able to solve the dataset to a
satisfying degree, leaving a big gap to human performance.},

pages = {2642--2651},
abstract = {DBLP is the largest open-access repository of scientific articles on computer science and provides metadata associated with publications, authors, and venues. We retrieved more than 6 million publications from DBLP and extracted pertinent metadata (e.g., abstracts, author affiliations, citations) from the publication texts to create the DBLP Discovery Dataset (D3). D3 can be used to identify trends in research activity, productivity, focus, bias, accessibility, and impact of computer science research.

We present an initial analysis focused on the volume of computer science research (e.g., number of papers, authors, research activity), trends in topics of interest, and citation patterns. Our findings show that computer science is a growing research field (15% annually), with an active and collaborative researcher community. While papers in recent years present more bibliographical entries in comparison to previous decades, the average number of citations has been declining. Investigating papers' abstracts reveals that recent topic trends are clearly reflected in D3. Finally, we list further applications of D3 and pose supplemental research questions. The D3 dataset, our findings, and source code are publicly available for research purposes.},

abstract     = {Euphemisms have not received much attention in
natural language processing, despite being an important element of
polite and figurative language. Euphemisms prove to be a difficult
topic, not only because they are subject to language change, but
also because humans may not agree on what is a euphemism and what is
not. Nonetheless, the first step to tackling the issue is to collect
and analyze examples of euphemisms. We present a corpus of
potentially euphemistic terms (PETs) along with example texts from
the GloWbE corpus. Additionally, we present a subcorpus of texts
where these PETs are not being used euphemistically, which may be
useful for future applications. We also discuss the results of
multiple analyses run on the corpus. Firstly, we find that sentiment
analysis on the euphemistic texts supports that PETs generally
decrease negative and offensive sentiment. Secondly, we observe
cases of disagreement in an annotation task, where humans are asked
to label PETs as euphemistic or not in a subset of our corpus text
examples. We attribute the disagreement to a variety of potential
reasons, including if the PET was a commonly accepted term (CAT).},

  abstract  = {Mental health remains a significant challenge of
public health worldwide. With increasing popularity of online
platforms, many use the platforms to share their mental health
conditions, express their feelings, and seek help from the community
and counselors. Some of these platforms, such as Reachout, are
dedicated forums where the users register to seek help. Others such
as Reddit provide subreddits where the users publicly but
anonymously post their mental health distress. Although posts are of
varying length, it is beneficial to provide a short, but informative
summary for fast processing by the counselors. To facilitate
research in summarization of mental health online posts, we
introduce Mental Health Summarization dataset, MentSum, containing
over 24k carefully selected user posts from Reddit, along with their
short user-written summary (called TLDR) in English from 43 mental
health subreddits. This domain-specific dataset could be of interest
not only for generating short summaries on Reddit, but also for
generating summaries of posts on the dedicated mental health forums
such as Reachout. We further evaluate both extractive and
abstractive state-of-the-art summarization baselines in terms of
Rouge scores, and finally conduct an in-depth human evaluation study
of both user-written and system-generated summaries, highlighting
challenges in this research.},

  abstract  = {Traditionally, Text Simplification is treated as a
```

monolingual translation task where sentences between source texts and their simplified counterparts are aligned for training. However, especially for longer input documents, summarizing the text (or dropping less relevant content altogether) plays an important role in the simplification process, which is currently not reflected in existing datasets. Simultaneously, resources for non-English languages are scarce in general and prohibitive for training new solutions. To tackle this problem, we pose core requirements for a system that can jointly summarize and simplify long source documents. We further describe the creation of a new dataset for joint Text Simplification and Summarization based on German Wikipedia and the German children's encyclopedia "Klexikon", consisting of almost 2,900 documents. We release a document-aligned version that particularly highlights the summarization aspect, and provide statistical evidence that this resource is well suited to simplification as well. pages = {2702--2713},
abstract = {The distribution of fake news is not a new but a rapidly growing problem. The shift to news consumption via social media has been one of the drivers for the spread of misleading and deliberately wrong information, as in addition to its ease of use there is rarely any veracity monitoring. Due to the harmful effects of such fake news on society, the detection of these has become increasingly important. We present an approach to the problem that combines the power of transformer-based language models while simultaneously addressing one of their inherent problems. Our framework, CMTR-BERT, combines multiple text representations, with the goal of circumventing sequential limits and related loss of information the underlying transformer architecture typically suffers from. Additionally, it enables the incorporation of contextual information. Extensive experiments on two very different, publicly available datasets demonstrates that our approach is able to set new state-of-the-art performance benchmarks. Apart from the benefit of using automatic text summarization techniques we also find that the incorporation of contextual information contributes to performance gains.},

  publisher      = {European Language Resources Association},
  pages         = {2721--2729},
  abstract       = {The QUEST (QUality ESTablished) project aims at
ensuring the reusability of audio-visual datasets (Wamprechtshammer
et al., 2022) by devising quality criteria and curating processes.
RefCo (Reference Corpora) is an initiative within QUEST in
collaboration with DoReCo (Documentation Reference Corpus, Paschen
et al. (2020)) focusing on language documentation projects.
Previously, Aznar and Seifart (2020) introduced a set of quality
criteria dedicated to documenting fieldwork corpora. Based on these
criteria, we establish a semi-automatic review process for existing
and work-in-progress corpora, in particular for language
documentation. The goal is to improve the quality of a corpus by
increasing its reusability. A central part of this process is a
template for machine-readable corpus documentation and automatic
data verification based on this documentation. In addition to the
documentation and automatic verification, the process involves a
human review and potentially results in a RefCo certification of the
corpus. For each of these steps, we provide guidelines and manuals.
We describe the evaluation process in detail, highlight the current
limits for automatic evaluation and how the manual review is
organized accordingly.},

abstract = {Discourse markers carry information about the discourse structure and organization, and also signal local dependencies or epistemological stance of speaker. They provide instructions on how to interpret the discourse, and their study is paramount to understand the mechanism underlying discourse organization. This paper presents a new language resource, an ISO-based annotated multilingual parallel corpus for discourse markers. The corpus comprises nine languages, Bulgarian, Lithuanian, German, European Portuguese, Hebrew, Romanian, Polish, and Macedonian, with English as a pivot language. In order to represent the meaning of the discourse markers, we propose an annotation scheme of discourse relations from ISO 24617-8 with a plug-in to ISO 24617-2 for communicative functions. We describe an experiment in which we applied the annotation scheme to assess its validity. The results reveal that, although some extensions are required to cover all the multilingual data, it provides a proper representation of discourse markers value. Additionally, we report some relevant contrastive phenomena concerning discourse markers interpretation and role in discourse. This first step will allow us to develop deep learning methods to identify and extract discourse relations and communicative functions, and to represent that information as Linguistic Linked Open Data (LLOD).},

abstract  = {Speech is considered as a multi-modal process where
hearing and vision are two fundamentals pillars. In fact, several
studies have demonstrated that the robustness of Automatic Speech
Recognition systems can be improved when audio and visual cues are
combined to represent the nature of speech. In addition, Visual
Speech Recognition, an open research problem whose purpose is to
interpret speech by reading the lips of the speaker, has been a
focus of interest in the last decades. Nevertheless, in order to
estimate these systems in the currently Deep Learning era, large-
scale databases are required. On the other hand, while most of these
databases are dedicated to English, other languages lack sufficient
resources. Thus, this paper presents a semi-automatically annotated
audiovisual database to deal with unconstrained natural Spanish,
providing 13 hours of data extracted from Spanish television.
Furthermore, baseline results for both speaker-dependent and
speaker-independent scenarios are reported using Hidden Markov
Models, a traditional paradigm that has been widely used in the
field of Speech Technologies.},

abstract  = {Video-and-Language learning, such as video question
answering or video captioning, is the next challenge in the deep
learning society, as it pursues the way how human intelligence
perceives everyday life. These tasks require the ability of multi-
modal reasoning which is to handle both visual information and text
information simultaneously across time. In this point of view, a
cross-modality attention module that fuses video representation and
text representation takes a critical role in most recent approaches.
However, existing Video-and-Language models merely compute the
attention weights without considering the different characteristics
of video modality and text modality. Such naïve attention module

```

hinders the current models to fully enjoy the strength of cross-modality. In this paper, we propose a novel Modality Alignment method that benefits the cross-modality attention module by guiding it to easily amalgamate multiple modalities. Specifically, we exploit Centered Kernel Alignment (CKA) which was originally proposed to measure the similarity between two deep representations. Our method directly optimizes CKA to make an alignment between video and text embedding representations, hence it aids the cross-modality attention module to combine information over different modalities. Experiments on real-world Video QA tasks demonstrate that our method outperforms conventional multi-modal methods significantly with +3.57\% accuracy increment compared to the baseline in a popular benchmark dataset. Additionally, in a synthetic data environment, we show that learning the alignment with our method boosts the performance of the cross-modality attention.},

  pages       = {2771--2780},
  abstract    = {This paper investigates the correlation between mutual gaze and linguistic repetition, a form of alignment, which we take as evidence of mutual understanding. We focus on a multimodal corpus made of three-party conversations and explore the question of whether mutual gaze events correspond to moments of repetition or non-repetition. Our results, although mainly significant on word unigrams and bigrams, suggest positive correlations between the presence of mutual gaze and the repetitions of tokens, lemmas, or parts-of-speech, but negative correlations when it comes to paired levels of representation (tokens or lemmas associated with their part-of-speech). No compelling correlation is found with duration of mutual gaze. Results are strongest when ignoring punctuation as representations of pauses, intonation, etc. in counting aligned tokens.},

  abstract   = {In natural language settings, many interactions
include more than two speakers, and real-life interpretation is
based on all types of information available in all modalities. This
constitutes a challenge for corpus-based analyses because the
information in the audio and visual channels must be included in the
coding. The goal of the DINLANG project is to tackle that challenge
and analyze spontaneous interactions in family dinner settings (two
adults and two to three children). The families use either French,
or LSF (French sign language). Our aim is to compare how
participants share language across the range of modalities found in
vocal and visual languaging in coordination with dining. In order to
pinpoint similarities and differences, we had to find a common
coding tool for all situations (variations from one family to
another) and modalities. Our coding procedure incorporates the use
of the ELAN software. We created a template organized around
participants, situations, and modalities, rather than around
language forms. Spoken language transcription can be integrated,
when it exists, but it is not mandatory. Data that has been created
with another software can be injected in ELAN files if it is linked
using time stamps. Analyses performed with the coded files rely on
ELAN's structured search functionalities, which allow to achieve
fine-grained temporal analyses and which can be completed by using
spreadsheets or R language.},

abstract = {In recent years, Large Language Models such as GPT-3 showed remarkable capabilities in performing NLP tasks in the zero and few shot settings. On the other hand, the experiments highlighted the difficulty of GPT-3 in carrying out tasks that require a certain degree of reasoning, such as arithmetic operations. In this paper we evaluate the ability of Transformer Language Models to perform arithmetic operations following a pipeline that, before performing computations, decomposes numbers in units, tens, and so on. We denote the models fine-tuned with this pipeline with the name Calculon and we test them in the task of performing additions, subtractions and multiplications on the same test sets of GPT-3. Results show an increase of accuracy of 63\% in the five-digit addition task. Moreover, we demonstrate the importance of the decomposition pipeline introduced, since fine-tuning the same Language Model without decomposing numbers results in 0\% accuracy in the five-digit addition task.},

pages      = {2826--2832},
abstract   = {This paper describes how a newly published Danish
sentiment lexicon with a high lexical coverage was compiled by use
of lexicographic methods and based on the links between groups of
words listed in semantic order in a thesaurus and the corresponding
word sense descriptions in a comprehensive monolingual dictionary.
The overall idea was to identify negative and positive sections in a
thesaurus, extract the words from these sections and combine them
with the dictionary information via the links. The annotation task
of the dataset included several steps, and was based on the
comparison of synonyms and near synonyms within a semantic field. In
the cases where one of the words were included in the smaller Danish
sentiment lexicon AFINN, its value there was used as inspiration and
expanded to the synonyms when appropriate. In order to obtain a more
practical lexicon with overall polarity values at lemma level, all
the senses of the lemma were afterwards compared, taking into
consideration dictionary information such as usage, style and
frequency. The final lexicon contains 13,859 Danish polarity lemmas
and includes morphological information. It is freely available at
https://github.com/dsldk/danish-sentiment-lexicon (licence CC-BY-SA

  pages      = {2841--2849},
  abstract   = {While pre-trained language models play a vital role
in modern language processing tasks, but not every language can
benefit from them. Most existing research on pre-trained language
models focuses primarily on widely-used languages such as English,
Chinese, and Indo-European languages. Additionally, such schemes
usually require extensive computational resources alongside a large
amount of data, which is infeasible for less-widely used languages.
We aim to address this research niche by building a language model
that understands the linguistic phenomena in the target language
which can be trained with low-resources. In this paper, we discuss
Korean language modeling, specifically methods for language
representation and pre-training methods. With our Korean-specific
language representation, we are able to build more powerful language
models for Korean understanding, even with fewer resources. The
paper proposes chunk-wise reconstruction of the Korean language
based on a widely used transformer architecture and bidirectional
language representation. We also introduce morphological features
such as Part-of-Speech (PoS) into the language understanding by
leveraging such information during the pre-training. Our experiment
results prove that the proposed methods improve the model
performance of the investigated Korean language understanding
tasks.},

abstract = {The paper gives an account of an infrastructure that
will be integrated into a platform aimed at providing a multi-
faceted experience to visitors of Northern Greece using mythology as
a starting point. This infrastructure comprises a multi-lingual and
multi-modal corpus (i.e., a corpus of textual data supplemented with
images, and video) that belongs to the humanities domain along with
a dedicated database (content management system) with advanced
indexing, linking and search functionalities. We will present the
corpus itself focusing on the content, the methodology adopted for
its development, and the steps taken towards rendering it accessible
via the database in a way that also facilitates useful
visualizations. In this context, we tried to address three main
challenges: (a) to add a novel annotation layer, namely geotagging,
(b) to ensure the long-term maintenance of and accessibility to the
highly heterogeneous primary data – even after the life cycle of the
current project – by adopting a metadata schema that is compatible
to existing standards; and (c) to render the corpus a useful
resource to scholarly research in the digital humanities by adding a
minimum set of linguistic annotations.},

abstract     = {The present data formats proposed by authentic
organizations are based on a so-called standoff-style data format in
XML, which represents a semantic data model through an instance
structure and a link structure. However, this type of data formats
intended to enhance the power of representation of an XML format
injures the mobility of data because an abstract data structure
denoted by multiple link paths is hard to be converted into other
data structures. This difficulty causes a problem in the reuse of
data to convert into other data formats especially in a personal
data management environment. In this paper, in order to compensate
for the drawback, we propose a new concept of transforming a link
structure to an instance structure on a new marked-up scheme. This
approach to language data brings a new architecture of language data
management to realize a personal data management environment in
daily and long-life use.},

  abstract    = {Political authorities in democratic countries
regularly consult the public in order to allow citizens to voice
their ideas and concerns on specific issues. When trying to evaluate
the (often large number of) contributions by the public in order to
inform decision-making, authorities regularly face challenges due to
restricted resources. We identify several tasks whose automated
support can help in the evaluation of public participation. These
are i) the recognition of arguments, more precisely premises and
their conclusions, ii) the assessment of the concreteness of
arguments, iii) the detection of textual descriptions of locations
in order to assign citizens' ideas to a spatial location, and iv)
the thematic categorization of contributions. To enable future
research efforts to develop techniques addressing these four tasks,
we introduce the CIMT PartEval Corpus, a new publicly-available
German-language corpus that includes several thousand citizen
contributions from six mobility-related planning processes in five
German municipalities. The corpus provides annotations for each of
these tasks which have not been available in German for the domain
of public participation before either at all or in this scope and
```

```
variety.},

  abstract  = {Typological databases can contain a wealth of  
information beyond the collection of linguistic properties across  
languages. This paper shows how information often overlooked in  
typological databases can inform the research community about the  
state of description of the world's languages. We illustrate this  
using Grambank, a morphosyntactic typological database covering  
2,467 language varieties and based on 3,951 grammatical  
descriptions. We classify and quantify the comments that accompany  
coded values in Grambank. We then aggregate these comments and the  
coded values to derive a level of description for 17 grammatical  
domains that Grambank covers (negation, adnominal modification,  
participant marking, tense, aspect, etc.). We show that the  
description level of grammatical domains varies across space and  
time. Information about gaps and uncertainties in the descriptive  
knowledge of grammatical domains within and across languages is  
essential for a correct analysis of data in typological databases  
and for the study of grammatical diversity more generally. When  
collected in a database, such information feeds into disciplines  
that focus on primary data collection, such as grammaticography and  
language documentation.},

succinctly summarize a dialogue transcript while correctly linking  
the speakers and their speech, which distinguishes this task from a
```

conventional document summarization. To address this issue and reduce the ``who said what''-related errors in a summary, we propose embedding the speaker identity information in the input embedding into the dialogue transcript encoder. Unlike the speaker embedding proposed by Gu et al. (2020), our proposal takes into account the informativeness of position embedding. By experimentally comparing several embedding methods, we confirmed that the scores of ROUGE and a human evaluation of the generated summaries were substantially increased by embedding speaker information at the less informative part of the fixed position embedding with sinusoidal functions.},

abstract = {This paper is based on a collection of 16th century
letters from and to the Zurich reformer Heinrich Bullinger. Around

12,000 letters of this exchange have been preserved, out of which 3100 have been professionally edited, and another 5500 are available as provisional transcriptions. We have investigated code-switching in these 8600 letters, first on the sentence-level and then on the word-level. In this paper we give an overview of the corpus and its language mix (mostly Early New High German and Latin, but also French, Greek, Italian and Hebrew). We report on our experiences with a popular language identifier and present our results when training an alternative identifier on a very small training corpus of only 150 sentences per language. We use the automatically labeled sentences in order to bootstrap a word-based language classifier which works with high accuracy. Our research around the corpus building and annotation involves automatic handwritten text recognition, text normalisation for ENH German, and machine translation from medieval Latin into modern German.},

publisher = {European Language Resources Association},
pages = {2909--2918},
abstract = {This paper presents an analysis of annotation using an automatic pre-annotation for a mid-level annotation complexity task - dependency syntax annotation. It compares the annotation efforts made by annotators using a pre-annotated version (with a high-accuracy parser) and those made by fully manual annotation. The aim of the experiment is to judge the final annotation quality when pre-annotation is used. In addition, it evaluates the effect of automatic linguistically-based (rule-formulated) checks and another annotation on the same data available to the annotators, and their influence on annotation quality and efficiency. The experiment confirmed that the pre-annotation is an efficient tool for faster manual syntactic annotation which increases the consistency of the resulting annotation without reducing its quality.},

abstract     = {TimeML is an annotation scheme for capturing temporal
information in text. The developers of TimeML built the TimeBank
corpus to both validate the scheme and provide a rich dataset of
events, temporal expressions, and temporal relationships for
training and testing temporal analysis systems. In our own work we
have been developing methods aimed at TimeML graphs for detecting
(and eventually automatically correcting) temporal inconsistencies,
extracting timelines, and assessing temporal indeterminacy. In the
course of this investigation we identified numerous previously
unrecognized issues in the TimeBank corpus, including multiple
violations of TimeML annotation guide rules, incorrectly
disconnected temporal graphs, as well as inconsistent, redundant,
missing, or otherwise incorrect annotations. We describe our methods
for detecting and correcting these problems, which include: (a)
automatic guideline checking (109 violations); (b) automatic
inconsistency checking (65 inconsistent files); (c) automatic
disconnectivity checking (625 incorrect breakpoints); and (d) manual
comparison with the output of state-of-the-art automatic annotators
to identify missing annotations (317 events, 52 temporal
expressions). We provide our code as well as a set of patch files
that can be applied to the TimeBank corpus to produce a corrected
version for use by other researchers in the field.},

  abstract    = {In this paper, we present an evaluation of sentence
representation models on the paraphrase detection task. The
evaluation is designed to simulate a real-world problem of
plagiarism and is based on one of the most important cases of
forgery in modern history: the so-called "Protocols of the Elders of
Zion". The sentence pairs for the evaluation are taken from the
infamous forged text "Protocols of the Elders of Zion" (Protocols)
by unknown authors; and by "Dialogue in Hell between Machiavelli and
Montesquieu" by Maurice Joly. Scholars have demonstrated that the
first text plagiarizes from the second, indicating all the forged
parts on qualitative grounds. Following this evidence, we organized
the rephrased texts and asked native speakers to quantify the level
of similarity between each pair. We used this material to evaluate

```

sentence representation models in two languages: English and French, and on three tasks: similarity correlation, paraphrase identification, and paraphrase retrieval. Our evaluation aims at encouraging the development of benchmarks based on real-world problems, as a means to prevent problems connected to AI hypes, and to use NLP technologies for social good. Through our evaluation, we are able to confirm that the infamous Protocols are actually a plagiarized text but, as we will show, we encounter several problems connected with the convoluted nature of the task, that is very different from the one reported in standard benchmarks of paraphrase detection and sentence similarity. Code and data available at <https://github.com/roccotrip/protocols.>},

abstract = {Reference annotated (or gold-standard) datasets are required for various common tasks such as training for machine learning systems or system validation. They are necessary to analyse or compare occurrences or items annotated by experts, or to compare objects resulting from any computational process to objects annotated by experts. But, even if reference annotated gold-standard corpora are required, their production is known as a difficult problem, from both a theoretical and practical point of view. Many studies devoted to these issues conclude that multi-annotation is most of the time a necessity. That inter-annotator agreement measure, which is required to check the reliability of data and the reproducibility of an annotation task, and thus to establish a gold standard, is another thorny problem. Fine analysis of available metrics for this specific task then becomes essential. Our work is part of this effort and more precisely focuses on several problems, which are rarely discussed, although they are intrinsically linked with the interpretation of metrics. In particular, we focus here on the complex relations between agreement and reference (of which agreement among annotators is supposed to be an indicator), and the emergence of consensus. We also introduce the notion of consensuality as another relevant indicator.},

 abstract = {Pretrained models through self-supervised learning
 have been recently introduced for both acoustic and language
 modeling. Applied to spoken language understanding tasks, these
 models have shown their great potential by improving the state-of-
 the-art performances on challenging benchmark datasets. In this
 paper, we present an error analysis reached by the use of such
 models on the French MEDIA benchmark dataset, known as being one of
 the most challenging benchmarks for the slot filling task among all
 the benchmarks accessible to the entire research community. One year
 ago, the state-of-art system reached a Concept Error Rate (CER) of
 13.6\% through the use of a end-to-end neural architecture. Some
 months later, a cascade approach based on the sequential use of a
 fine-tuned wav2vec2.0 model and a fine-tuned BERT model reaches a
 CER of 11.2\%. This significant improvement raises questions about
 the type of errors that remain difficult to treat, but also about
 those that have been corrected using these models pre-trained
 through self-supervision learning on a large amount of data. This
 study brings some answers in order to better understand the limits
 of such models and open new perspectives to continue improving the
 performance.},

  abstract  = {A popular idea in Computer Assisted Language Learning
(CALL) is to use multimodal annotated texts, with annotations
typically including embedded audio and translations, to support L2
learning through reading. An important question is how to create
good quality audio, which can be done either through human recording
or by a Text-To-Speech (TTS) engine. We may reasonably expect TTS to
be quicker and easier, but human to be of higher quality. Here, we
report a study using the open source LARA platform and ten
languages. Samples of audio totalling about five minutes,
representing the same four passages taken from LARA versions of
Saint-Exupéry's "Le petit prince", were provided for each language
in both human and TTS form; the passages were chosen to instantiate
the 2x2 cross product of the conditions {dialogue, not-dialogue} and
{humour, not-humour}. 251 subjects used a web form to compare human
and TTS versions of each item and rate the voices as a whole. For
the three languages where TTS did best, English, French and Irish,
the evidence from this study and the previous one it extended
suggest that TTS audio is now pedagogically adequate and roughly
comparable with a non-professional human voice in terms of
exemplifying correct pronunciation and prosody. It was however still
judged substantially less natural and less pleasant to listen to. No
clear evidence was found to support the hypothesis that dialogue and
humour pose special problems for TTS. All data and software will be
made freely available.},

  abstract   = {A limited amount of studies investigates the role of
model-agnostic adversarial behavior in toxic content classification.
As toxicity classifiers predominantly rely on lexical cues,
(deliberately) creative and evolving language-use can be detrimental
to the utility of current corpora and state-of-the-art models when
they are deployed for content moderation. The less training data is
available, the more vulnerable models might become. This study is,
to our knowledge, the first to investigate the effect of adversarial
behavior and augmentation for cyberbullying detection. We
demonstrate that model-agnostic lexical substitutions significantly
hurt classifier performance. Moreover, when these perturbed samples
are used for augmentation, we show models become robust against
word-level perturbations at a slight trade-off in overall task
performance. Augmentations proposed in prior work on toxicity prove
to be less effective. Our results underline the need for such
evaluations in online harm areas with small corpora.},

pages = {3008--3016},
abstract = {We present a multi-task learning framework for cross-lingual abstractive summarization to augment training data. Recent studies constructed pseudo cross-lingual abstractive summarization data to train their neural encoder-decoders. Meanwhile, we introduce existing genuine data such as translation pairs and monolingual abstractive summarization data into training. Our proposed method, Transum, attaches a special token to the beginning of the input sentence to indicate the target task. The special token enables us to incorporate the genuine data into the training data easily. The experimental results show that Transum achieves better performance than the model trained with only pseudo cross-lingual summarization data. In addition, we achieve the top ROUGE score on Chinese-English and Arabic-English abstractive summarization. Moreover, Transum also has a positive effect on machine translation. Experimental results indicate that Transum improves the performance from the strong baseline, Transformer, in Chinese-English, Arabic-English, and English-Japanese translation datasets.},

abstract = {Document-level Neural Machine Translation aims to increase the quality of neural translation models by taking into account contextual information. Properly modelling information beyond the sentence level can result in improved machine translation output in terms of coherence, cohesion and consistency. Suitable corpora for context-level modelling are necessary to both train and evaluate context-aware systems, but are still relatively scarce. In this work we describe TANDO, a document-level corpus for the under-resourced Basque-Spanish language pair, which we share with the scientific community. The corpus is composed of parallel data from three different domains and has been prepared with context-level information. Additionally, the corpus includes contrastive test sets for fine-grained evaluations of gender and register contextual phenomena on both source and target language sides. To establish the usefulness of the corpus, we trained and evaluated baseline Transformer models and context-aware variants based on context concatenation. Our results indicate that the corpus is suitable for fine-grained evaluation of document-level machine translation systems.},

abstract      = {This paper introduces a multi-lingual database
containing translated texts of COVID-19 mythbusters. The database
has translations into 115 languages as well as the original English
texts, of which the original texts are published by World Health
Organization (WHO). This paper then presents preliminary analyses on
latin-alphabet-based texts to see the potential of the database as a
resource for multilingual linguistic analyses. The analyses on
latin-alphabet-based texts gave interesting insights into the
resource. While the amount of translated texts in each language was
small, character bi-grams with normalization (lowercasing and
removal of diacritics) was turned out to be an effective proxy for
measuring the similarity of the languages, and the affinity ranking
of language pairs could be obtained. Additionally, the hierarchical
clustering analysis is performed using the character bigram overlap
ratio of every possible pair of languages. The result shows the
cluster of Germanic languages, Romance languages, and Southern Bantu
languages. In sum, the multilingual database not only offers fixed
set of materials in numerous languages, but also serves as a
preliminary tool to identify the language family using text-based

  abstract  = {Generative Pre-trained Transformers (GPTs) have
recently been scaled to unprecedented sizes in the history of
machine learning. These models, solely trained on the language
modeling objective, have been shown to exhibit outstanding zero,
one, and few-shot learning capabilities in a number of different
tasks. Nevertheless, aside from anecdotal experiences, little is
known regarding their multilingual capabilities, given the fact that
the pre-training corpus is almost entirely composed of English text.
In this work, we investigate its potential and limits in three
tasks: extractive question-answering, text summarization and natural
language generation for five different languages, as well as the
effect of scale in terms of model size. Our results show that GPT-3
can be almost as useful for many languages as it is for English,
with room for improvement if optimization of the tokenization is
addressed.},

  abstract  = {Subtitles appear on screen as short pieces of text,
segmented based on formal constraints (length) and syntactic/
semantic criteria. Subtitle segmentation can be evaluated with
sequence segmentation metrics against a human reference. However,
standard segmentation metrics cannot be applied when systems
generate outputs different than the reference, e.g. with end-to-end
subtitling systems. In this paper, we study ways to conduct
reference-based evaluations of segmentation accuracy irrespective of
```

the textual content. We first conduct a systematic analysis of existing metrics for evaluating subtitle segmentation. We then introduce Sigma, a Subtitle Segmentation Score derived from an approximate upper-bound of BLEU on segmentation boundaries, which allows us to disentangle the effect of good segmentation from text quality. To compare Sigma with existing metrics, we further propose a boundary projection method from imperfect hypotheses to the true reference. Results show that all metrics are able to reward high quality output but for similar outputs system ranking depends on each metric's sensitivity to error type. Our thorough analyses suggest Sigma is a promising segmentation candidate but its reliability over other segmentation metrics remains to be validated through correlations with human judgements.},

  abstract  = {Despite impressive progress in machine translation in  
recent years, it has occasionally been argued that current systems  
are still mainly based on pattern recognition and that further  
progress may be possible by using text understanding techniques,  
thereby e.g. looking at semantics of the type "Who is doing what to  
whom?". In the current research we aim to take a small step into  
this direction. Assuming that semantic role labeling (SRL) grasps  
some of the relevant semantics, we automatically annotate the source  
language side of a standard parallel corpus, namely Europarl, with  
semantic roles. We then train a neural machine translation (NMT)  
system using the annotated corpus on the source language side, and  
the original unannotated corpus on the target language side. New  
text to be translated is first annotated by the same SRL system and  
then fed into the translation system. We compare the results to  
those of a baseline NMT system trained with unannotated text on both  
sides and find that the SRL-based system yields small improvements  
in terms of BLEU scores for each of the four language pairs under  
investigation, involving English, French, German, Greek and  
Spanish.},

abstract      = {Natural Language Inference (NLI), also known as
Recognizing Textual Entailment (RTE), has been one of the central
tasks in Artificial Intelligence (AI) and Natural Language
Processing (NLP). RTE between the two pieces of texts is a crucial
problem, and it adds further challenges when involving two different
languages, i.e., in the cross-lingual scenario. This paper proposes
an effective transfer learning approach for cross-lingual NLI. We
perform experiments on English-Hindi language pairs in the cross-
lingual setting to find out that our novel loss formulation could
enhance the performance of the baseline model by up to 2%. To
assess the effectiveness of our method further, we perform
additional experiments on every possible language pair using four
European languages, namely French, German, Bulgarian, and Turkish,
on top of XNLI dataset. Evaluation results yield up to 10%
performance improvement over the respective baseline models, in some
cases surpassing the state-of-the-art (SOTA). It is also to be noted
that our proposed model has 110M parameters which is much lesser
than the SOTA model having 220M parameters. Finally, we argue that

```

our transfer learning-based loss objective is model agnostic and thus can be used with other deep learning-based architectures for cross-lingual NLI.},

abstract = {Recent work has demonstrated the importance of dealing with Multi-Word Terms (MWTs) in several Natural Language Processing applications. In particular, MWTs pose serious challenges

for alignment and machine translation systems because of their syntactic and semantic properties. Thus, developing algorithms that handle MWTs is becoming essential for many NLP tasks. However, the availability of bilingual and more generally multi-lingual resources is limited, especially for low-resourced languages and in specialized domains. In this paper, we propose an approach for building comparable corpora and bilingual term dictionaries that help evaluate bilingual term alignment in comparable corpora. To that aim, we exploit parallel corpora to perform automatic bilingual MWT extraction and comparable corpus construction. Parallel information helps to align bilingual MWTs and makes it easier to build comparable specialized sub-corpora. Experimental validation on an existing dataset and on manually annotated data shows the interest of the proposed methodology.},

pages = {3113--3121},
abstract = {This paper examines machine bias in language technology. Machine bias can affect machine learning algorithms when language models trained on large corpora include biased human decisions or reflect historical or social inequities, e.g. regarding gender and race. The focus of the paper is on gender bias in machine translation and we discuss a study conducted on Icelandic translations in the translation systems Google Translate and Vélþýðing.is. The results show a pattern which corresponds to certain societal ideas about gender. For example it seems to depend on the meaning of adjectives referring to people whether they appear in the masculine or feminine form. Adjectives describing positive personality traits were more likely to appear in masculine gender whereas the negative ones frequently appear in feminine gender. However, the opposite applied to appearance related adjectives. These findings unequivocally demonstrate the importance of being vigilant towards technology so as not to maintain societal inequalities and outdated views – especially in today’s digital world.},

abstract      = {This paper presents an analysis of how dialogue act
sequences vary across different datasets in order to anticipate the
potential degradation in the performance of learned models during
domain adaptation. We hypothesize the following: 1) dialogue
sequences from related domains will exhibit similar n-gram frequency
distributions 2) this similarity can be expressed by measuring the
average Hamming distance between subsequences drawn from different
datasets. Our experiments confirm that when dialogue acts sequences
from two datasets are dissimilar they lie further away in embedding
space, making it possible to train a classifier to discriminate
between them even when the datasets are corrupted with noise. We
present results from eight different datasets: SwDA, AMI (DialSum),
GitHub, Hate Speech, Teams, Diplomacy Betrayal, SAMsum, and Military
(Army). Our datasets were collected from many types of human
communication including strategic planning, informal discussion, and
social media exchanges. Our methodology provides intuition on the
generalizability of dialogue models trained on different datasets.
Based on our analysis, it is problematic to assume that machine
learning models trained on one type of discourse will generalize
well to other settings, due to contextual differences.},

pages = {3158--3163},

abstract = {The main objective of this work is the elaboration and public release of BaSCo, the first corpus with annotated linguistic resources encompassing Basque-Spanish code-switching. The mixture of Basque and Spanish languages within the same utterance is popularly referred to as Euskañol, a widespread phenomenon among bilingual speakers in the Basque Country. Thus, this corpus has been created to meet the demand of annotated linguistic resources in Euskañol in research areas such as multilingual dialogue systems. The presented resource is the result of translating to Euskañol a compilation of texts in Basque and Spanish that were used for training the Natural Language Understanding (NLU) models of several task-oriented bilingual chatbots. Those chatbots were meant to answer specific questions associated with the administration, fiscal, and transport domains. In addition, they had the transverse potential to answer to greetings, requests for help, and chit-chat questions asked to chatbots. BaSCo is a compendium of 1377 tagged utterances with every sample annotated at three levels: (i) NLU semantic labels, considering intents and entities, (ii) code-switching proportion, and (iii) domain of origin.},

```
pages      = {3164--3173},
abstract   = {Robots will eventually enter our daily lives and
assist with a variety of tasks. Especially in the household domain,
robots may become indispensable helpers by overtaking tedious tasks,
e.g. keeping the place tidy. Their effectiveness and efficiency,
however, depend on their ability to adapt to our needs, routines,
and personal characteristics. Otherwise, they may not be accepted
and trusted in our private domain. For enabling adaptation, the
interaction between a human and a robot needs to be personalized.
Therefore, the robot needs to collect personal information from the
user. However, it is unclear how such sensitive data can be
collected in an understandable way without losing a user's trust in
the system. In this paper, we present a conversational approach for
explicitly collecting personal user information using natural
dialogue. For creating a sound interactive personalization, we have
developed an empathy-augmented dialogue strategy. In an online
study, the empathy-augmented strategy was compared to a baseline
dialogue strategy for interactive personalization. We have found the
empathy-augmented strategy to perform notably friendlier. Overall,
using dialogue for interactive personalization has generally shown
positive user reception.},

abstract    = {We introduce document retrieval and comment
generation tasks for automating horizon scanning. This is an
important task in the field of futurology that collects sufficient
information for predicting drastic societal changes in the mid- or
long-term future. The steps used are: 1) retrieving news articles
that imply drastic changes, and 2) writing subjective comments on
each article for others' ease of understanding. As a first step in
automating these tasks, we create a dataset that contains 2,266
manually collected news articles with comments written by experts.
We analyze the collected documents and comments regarding
characteristic words, the distance to general articles, and contents
in the comments. Furthermore, we compare several methods for
automating horizon scanning. Our experiments show that 1) manually
collected articles are different from general articles regarding the
words used and semantic distances, 2) the contents in the comment
can be classified into several categories, and 3) a supervised model
trained on our dataset achieves a better performance. The
contributions are: 1) we propose document retrieval and comment
```

```
generation tasks for horizon scanning, 2) create and analyze a new
dataset, and 3) report the performance of several models and show
that comment generation tasks are challenging.},

  title     = {ELITR Minuting Corpus: A Novel Dataset for Automatic
Minuting from Multi-Party Meetings in English and Czech},
  booktitle = {Proceedings of the Language Resources and
Evaluation Conference},
  month     = {June},
  year      = {2022},
  address   = {Marseille, France},
  publisher = {European Language Resources Association},
  pages     = {3174--3182},
  abstract  = {Taking minutes is an essential component of every
meeting, although the goals, style, and procedure of this activity
(`minuting' for short) can vary. Minuting is a rather unstructured
writing activity and is affected by who is taking the minutes and
for whom the intended minutes are. With the rise of online meetings,
automatic minuting would be an important benefit for the meeting
participants as well as for those who might have missed the meeting.
However, automatically generating meeting minutes is a challenging
problem due to a variety of factors including the quality of
automatic speech recorders (ASRs), availability of public meeting
data, subjective knowledge of the minuter, etc. In this work, we
present the first of its kind dataset on \textit{Automatic
Minuting}. We develop a dataset of English and Czech technical
project meetings which consists of transcripts generated from ASRs,
manually corrected, and minuted by several annotators. Our dataset,
AutoMin, consists of 113 (English) and 53 (Czech) meetings, covering
more than 160 hours of meeting content. Upon acceptance, we will
publicly release (aaa.bbb.ccc) the dataset as a set of meeting
transcripts and minutes, excluding the recordings for privacy
reasons. A unique feature of our dataset is that most meetings are
equipped with more than one minute, each created independently. Our
corpus thus allows studying differences in what people find
important while taking the minutes. We also provide baseline
experiments for the community to explore this novel problem further.
To the best of our knowledge \textbf{AutoMin} is probably the first
resource on minuting in English and also in a language other than
English (Czech).}},

  pages      = {3183--3194},
  abstract   = {Age-related stereotypes are pervasive in our society,
and yet have been under-studied in the NLP community. Here, we
present a method for extracting age-related stereotypes from Twitter
data, generating a corpus of 300,000 over-generalizations about four
contemporary generations (baby boomers, generation X, millennials,
and generation Z), as well as "old" and "young" people more
generally. By employing word-association metrics, semi-supervised
topic modelling, and density-based clustering, we uncover many
common stereotypes as reported in the media and in the psychological
literature, as well as some more novel findings. We also observe
trends consistent with the existing literature, namely that
definitions of "young" and "old" age appear to be context-dependent,
stereotypes for different generations vary across different topics
(e.g., work versus family life), and some age-based stereotypes are
distinct from generational stereotypes. The method easily extends to
other social group labels, and therefore can be used in future work
to study stereotypes of different social categories. By better
understanding how stereotypes are formed and spread, and by tracking
emerging stereotypes, we hope to eventually develop mitigating
measures against such biased statements.},

  abstract  = {Mental disorders are a serious and increasingly
relevant public health issue. NLP methods have the potential to
assist with automatic mental health disorder detection, but building
annotated datasets for this task can be challenging; moreover,
annotated data is very scarce for disorders other than depression.
Understanding the commonalities between certain disorders is also
important for clinicians who face the problem of shifting standards
of diagnosis. We propose that transfer learning with linguistic
features can be useful for approaching both the technical problem of
improving mental disorder detection in the context of data scarcity,
and the clinical problem of understanding the overlapping symptoms
between certain disorders. In this paper, we target four disorders:
depression, PTSD, anorexia and self-harm. We explore multi-aspect
transfer learning for detecting mental disorders from social media
texts, using deep learning models with multi-aspect representations
of language (including multiple types of interpretable linguistic
features). We explore different transfer learning strategies for
cross-disorder and cross-platform transfer, and show that transfer
learning can be effective for improving prediction performance for
disorders where little annotated data is available. We offer
insights into which linguistic features are the most useful vehicles
for transferring knowledge, through ablation experiments, as well as
error analysis.},

```

global infodemic have changed our lives in many different ways. We relied on social media to get the latest information about COVID-19 pandemic and at the same time to disseminate information. The content in social media consisted not only health related advice, plans, and informative news from policymakers, but also contains conspiracies and rumors. It became important to identify such information as soon as they are posted to make an actionable decision (e.g., debunking rumors, or taking certain measures for traveling). To address this challenge, we develop and publicly release the first largest manually annotated Arabic tweet dataset, ArCovidVac, for COVID-19 vaccination campaign, covering many countries in the Arab region. The dataset is enriched with different layers of annotation, including, (i) Informativeness more vs. less importance of the tweets); (ii) fine-grained tweet content types (e.g., advice, rumors, restriction, authenticate news/information); and (iii) stance towards vaccination (pro-vaccination, neutral, anti-vaccination). Further, we performed in-depth analysis of the data, exploring the popularity of different vaccines, trending hashtags, topics, and presence of offensiveness in the tweets. We studied the data for individual types of tweets and temporal changes in stance towards vaccine. We benchmarked the ArCovidVac dataset using transformer architectures for informativeness, content types, and stance detection.},

address = {Marseille, France},
publisher = {European Language Resources Association},
pages = {3231--3241},
abstract = {Proactively identifying misinformation spreaders is an important step towards mitigating the impact of fake news on our society. In this paper, we introduce a new contemporary Reddit dataset for fake news spreader analysis, called FACTOID, monitoring political discussions on Reddit since the beginning of 2020. The dataset contains over 4K users with 3.4M Reddit posts, and includes, beyond the users' binary labels, also their fine-grained credibility level (very low to very high) and their political bias strength (extreme right to extreme left). As far as we are aware, this is the first fake news spreader dataset that simultaneously captures both the long-term context of users' historical posts and the interactions between them. To create the first benchmark on our data, we provide methods for identifying misinformation spreaders by utilizing the social connections between the users along with their psycho-linguistic features. We show that the users' social

interactions can, on their own, indicate misinformation spreading, while the psycho-linguistic features are mostly informative in non-neural classification settings. In a qualitative analysis we observe that detecting affective mental processes correlates negatively with right-biased users, and that the openness to experience factor is lower for those who spread fake news.},

  pages = {3242--3249},  
  abstract = {Anglicisms are a challenge in German speech  
recognition. Due to their irregular pronunciation compared to native  
German words, automatically generated pronunciation dictionaries  
often contain incorrect phoneme sequences for Anglicisms. In this  
work, we propose a multitask sequence-to-sequence approach for  
grapheme-to-phoneme conversion to improve the phonetization of  
Anglicisms. We extended a grapheme-to-phoneme model with a  
classification task to distinguish Anglicisms from native German  
words. With this approach, the model learns to generate different  
pronunciations depending on the classification result. We used our  
model to create supplementary Anglicism pronunciation dictionaries  
to be added to an existing German speech recognition model. Tested  
on a special Anglicism evaluation set, we improved the recognition  
of Anglicisms compared to a baseline model, reducing the word error  
rate by a relative 1 \% and the Anglicism error rate by a relative 3  
\%. With our experiment, we show that multitask learning can help  
solving the challenge of Anglicisms in German speech recognition.},

abstract     = {This paper builds upon recent work in leveraging the
corpora and tools originally used to develop speech technologies for
corpus-based linguistic studies. We address the non-canonical
realization of consonants in connected speech and we focus on
voicing alternation phenomena of stops in 5 standard varieties of
Romance languages (French, Italian, Spanish, Portuguese, Romanian).
For these languages, both large scale corpora and speech recognition
systems were available for the study. We use forced alignment with
pronunciation variants and machine learning techniques to examine to
what extent such frequent phenomena characterize languages and what
are the most triggering factors. The results confirm that voicing
alternations occur in all Romance languages. Automatic
classification underlines that surrounding contexts and segment
duration are recurring contributing factors for modeling voicing
alternation. The results of this study also demonstrate the new role
that machine learning techniques such as classification algorithms
can play in helping to extract linguistic knowledge from speech and
to suggest interesting research directions.},

abstract = {This paper presents a semi-automatic approach to create a diachronic corpus of voices balanced for speaker's age, gender, and recording period, according to 32 categories (2 genders, 4 age ranges and 4 recording periods). Corpora were selected at French National Institute of Audiovisual (INA) to obtain at least 30 speakers per category (a total of 960 speakers; only 874 have been found yet). For each speaker, speech excerpts were extracted from audiovisual documents using an automatic pipeline consisting of speech detection, background music and overlapped speech removal and speaker diarization, used to present clean speaker segments to human annotators identifying target speakers. This pipeline proved highly effective, cutting down manual processing by a factor of ten. Evaluation of the quality of the automatic processing and of the final output is provided. It shows the automatic processing compared to up-to-date process, and that the output provides high quality speech for most of the selected excerpts. This method is thus recommendable for creating large corpora of known target speakers.},

abstract = {We present DiscoGeM, a crowdsourced corpus of 6,505 implicit discourse relations from three genres: political speech, literature, and encyclopedic texts. Each instance was annotated by 10 crowd workers. Various label aggregation methods were explored to evaluate how to obtain a label that best captures the meaning inferred by the crowd annotators. The results show that a significant proportion of discourse relations in DiscoGeM are ambiguous and can express multiple relation senses. Probability distribution labels better capture these interpretations than single labels. Further, the results emphasize that text genre crucially affects the distribution of discourse relations, suggesting that genre should be included as a factor in automatic relation classification. We make available the newly created DiscoGeM corpus, as well as the dataset with all annotator-level labels. Both the corpus and the dataset can facilitate a multitude of applications and research purposes, for example to function as training data to improve the performance of automatic discourse relation parsers, as well as facilitate research into non-connective signals of discourse relations.},

  abstract  = {The empirical quantification of the quality of a  
contribution to a political discussion is at the heart of  
deliberative theory, the subdiscipline of political science which  
investigates decision-making in deliberative democracy. Existing  
annotation on deliberative quality is time-consuming and carried out  
by experts, typically resulting in small datasets which also suffer  
from strong class imbalance. Scaling up such annotations with  
automatic tools is desirable, but very challenging. We take up this  
challenge and explore different strategies to improve the prediction  
of deliberative quality dimensions (justification, common good,  
interactivity, respect) in a standard dataset. Our results show that  
simple data augmentation techniques successfully alleviate data  
imbalance. Classifiers based on linguistic features (textual  
complexity and sentiment/polarity) and classifiers integrating  
argument quality annotations (from the argument mining community in  
NLP) were consistently outperformed by transformer-based models,  
with or without data augmentation.},

abstract = {The paper presents a multilingual database aimed to be used as a tool for typological analysis of response constructions called discourse formulae (DF), cf. English `No way!` or French `Ça va!` (~ `all right'). The two primary qualities that make DF of theoretical interest for linguists are their idiomaticity and the special nature of their meanings (cf. consent, refusal, negation), determined by their dialogical function. The formal and semantic structures of these items are language-specific. Compiling a database with DF from various languages would help estimate the diversity of DF in both of these aspects, and, at the same time, establish some frequently occurring patterns. The DF in the database are accompanied with glosses and assigned with multiple tags, such as pragmatic function, additional semantics, the illocutionary type of the context, etc. As a starting point, Russian, Serbian and Slovene DF are included into the database. This data already shows substantial grammatical and lexical variability.},

abstract = {Automatizing the process of understanding the global narrative structure of long texts and stories is still a major challenge for state-of-the-art natural language understanding systems, particularly because annotated data is scarce and existing annotation workflows do not scale well to the annotation of complex narrative phenomena. In this work, we focus on the identification of narrative levels in texts corresponding to stories that are embedded in stories. Lacking sufficient pre-annotated training data, we explore a solution to deal with data scarcity that is common in machine learning: the automatic augmentation of an existing small data set of annotated samples with the help of data synthesis. We present a workflow for narrative level detection, that includes the operationalization of the task, a model, and a data augmentation protocol for automatically generating narrative texts annotated with breaks between narrative levels. Our experiments suggest that narrative levels in long text constitute a challenging phenomenon for state-of-the-art NLP models, but generating training data synthetically does improve the prediction results considerably.},

abstract      = {Graph convolutional networks (GCNs) are a powerful
architecture for representation learning on documents that naturally
occur as graphs, e.g., citation or social networks. However,
sensitive personal information, such as documents with people's
profiles or relationships as edges, are prone to privacy leaks, as
the trained model might reveal the original input. Although
differential privacy (DP) offers a well-founded privacy-preserving
framework, GCNs pose theoretical and practical challenges due to
their training specifics. We address these challenges by adapting
differentially-private gradient-based training to GCNs and conduct
experiments using two optimizers on five NLP datasets in two
languages. We propose a simple yet efficient method based on random
graph splits that not only improves the baseline privacy bounds by a
factor of 2.7 while retaining competitive F1 scores, but also
provides strong privacy guarantees of  $\epsilon = 1.0$ . We show that,
under certain modeling choices, privacy-preserving GCNs perform up
to 90\% of their non-private variants, while formally guaranteeing
strong privacy measures.},

pages        = {3375--3381},
abstract     = {Identifying the high level structure of texts
provides important information when performing distant reading
analysis. The structure of texts is not necessarily linear, as
transitions, such as changes in the scenery or flashbacks, can be
present. As a first step in identifying this structure, we aim to
identify transitions in texts. Previous work (Heyns and van Zaanen,
2021) proposed a system that can successfully identify one
transition in literary texts. The text is split in snippets and LDA
is applied, resulting in a sequence of topics. A transition is
introduced at the point that separates the topics (before and after
the point) best. In this article, we extend the existing system such
that it can detect multiple transitions. Additionally, we introduce
a new system that inherently handles multiple transitions in texts.
The new system also relies on LDA information, but is more robust
than the previous system. We apply these systems to texts with known
transitions (as they are constructed by concatenating text snippets
stemming from different source texts) and evaluation both systems on
texts with one transition and texts with two transitions. As both
systems rely on LDA to identify transitions between snippets, we
also show the impact of varying the number of LDA topics on the
results as well. The new system consistently outperforms the
```

previous system, not only on texts with multiple transitions, but also on single boundary texts.},

abstract = {Parliamentary transcripts provide a valuable resource to understand the reality and know about the most important facts that occur over time in our societies. Furthermore, the political debates captured in these transcripts facilitate research on political discourse from a computational social science perspective. In this paper we release the first version of a newly compiled corpus from Basque parliamentary transcripts. The corpus is characterized by heavy Basque-Spanish code-switching, and represents an interesting resource to study political discourse in contrasting languages such as Basque and Spanish. We enrich the corpus with metadata related to relevant attributes of the speakers and speeches (language, gender, party...) and process the text to obtain named entities and lemmas. The obtained metadata is then used to perform a detailed corpus analysis which provides interesting insights about the language use of the Basque political representatives across time, parties and gender.},

publisher = {European Language Resources Association},
pages = {3398--3406},
abstract = {Classifying citations according to their purpose and importance is a challenging task that has gained considerable interest in recent years. This interest has been primarily driven by the need to create more transparent, efficient, merit-based reward systems in academia; a system that goes beyond simple bibliometric measures and considers the semantics of citations. Such systems that quantify and classify the influence of citations can act as edges that link knowledge nodes to a graph and enable efficient knowledge discovery. While a number of researchers have experimented with a variety of models, these experiments are typically limited to single-domain applications and the resulting models are hardly comparable. Recently, two Citation Context Classification (3C) shared tasks (at WOSP2020 and SDP2021) created the first benchmark enabling direct comparison of citation classification approaches, revealing the crucial impact of supplementary data on the performance of models. Reflecting from the findings of these shared tasks, we are releasing a new multi-disciplinary dataset, ACT2, an extended SDP 3C shared task dataset. This modified corpus has annotations for both citation function and importance classes newly enriched with supplementary contextual and non-contextual feature sets the selection of which follows from the lists of features used by the more successful teams in these shared tasks. Additionally, we include contextual features for cited papers (e.g. Abstract of the cited paper), which most existing datasets lack, but which have a lot of potential to improve results. We describe the methodology used for feature extraction and the challenges involved in the

process. The feature enriched ACT2 dataset is available at <https://github.com/oacore/ACT2.>},

abstract     = {This paper studies solving Arabic Math Word Problems
by deep learning. A Math Word Problem (MWP) is a text description of
a mathematical problem that can be solved by deriving a math
equation to reach the answer. Effective models have been developed
for solving MWPs in English and Chinese. However, Arabic MWPs are
rarely studied. This paper contributes the first large-scale dataset
for Arabic MWPs, which contains 6,000 samples of primary-school math
problems, written in Modern Standard Arabic (MSA). Arabic MWP
solvers are then built with deep learning models and evaluated on
this dataset. In addition, a transfer learning model is built to let
the high-resource Chinese MWP solver promote the performance of the
low-resource Arabic MWP solver. This work is the first to use deep
learning methods to solve Arabic MWP and the first to use transfer
learning to solve MWP across different languages. The transfer
learning enhanced solver has an accuracy of 74.15%, which is 3%
higher than the solver without using transfer learning. We make the
dataset and solvers available in public for encouraging more
research of Arabic MWPs: https://github.com/reem-codes/ArMATH},

  publisher = {European Language Resources Association},  
  pages     = {3461--3470},  
  abstract  = {Formal documents often are organized into sections of  
text, each with a title, and extracting this structure remains an  
under-explored aspect of natural language processing. This iterative  
title-text structure is valuable data for building models for  
headline generation and section title generation, but there is no  
corpus that contains web documents annotated with titles and prose  
texts. Therefore, we propose the first title-text dataset on web  
documents that incorporates a wide variety of domains to facilitate  
downstream training. We also introduce STAPI (Section Title And  
Prose text Identifier), a two-step system for labeling section  
titles and prose text in HTML documents. To filter out unrelated  
content like document footers, its first step involves a filter that  
reads HTML documents and proposes a set of textual candidates. In  
the second step, a typographic classifier takes the candidates from  
the filter and categorizes each one into one of the three pre-  
defined classes (title, prose text, and miscellany). We show that  
STAPI significantly outperforms two baseline models in terms of  
title-text identification. We release our dataset along with a web  
application to facilitate supervised and semi-supervised training in

publisher  = {European Language Resources Association},
pages      = {3500--3508},
abstract   = {The Story Cloze Test (SCT) is designed for training
and evaluating machine learning algorithms for narrative
understanding and inferences. The SOTA models can achieve over 90\%
accuracy on predicting the last sentence. However, it has been shown
that high accuracy can be achieved by merely using surface-level
features. We suspect these models may not {\it truly} understand the
story. Based on the SCT dataset, we constructed a human-labeled and
human-verified commonsense knowledge inference dataset. Given the
first four sentences of a story, we asked crowd-source workers to
choose from four types of narrative inference for deciding the
ending sentence and which sentence contributes most to the
inference. We accumulated data on 1871 stories, and three human
workers labeled each story. Analysis of the intra-category and
inter-category agreements show a high level of consensus. We present
two new tasks for predicting the narrative inference categories and
contributing sentences. Our results show that transformer-based
models can reach SOTA performance on the original SCT task using
transfer learning but don't perform well on these new and more
challenging tasks.},

address = {Marseille, France},
publisher = {European Language Resources Association},
pages = {3519--3529},
abstract = {This paper describes a system for interactive poem generation, which combines neural language models (LMs) for poem generation with explicit constraints that can be set by users on form, topic, emotion, and rhyming scheme. LMs cannot learn such constraints from the data, which is scarce with respect to their needs even for a well-resourced language such as French. We propose a method to generate verses and stanzas by combining LMs with rule-based algorithms, and compare several approaches for adjusting the words of a poem to a desired combination of topics or emotions. An approach to automatic rhyme setting using a phonetic dictionary is proposed as well. Our system has been demonstrated at public events, and log analysis shows that users found it engaging.},

abstract = {Online trolls increase social costs and cause psychological damage to individuals. With the proliferation of automated accounts making use of bots for trolling, it is difficult for targeted individual users to handle the situation both quantitatively and qualitatively. To address this issue, we focus on automating the method to counter trolls, as counter responses to combat trolls encourage community users to maintain ongoing discussion without compromising freedom of expression. For this purpose, we propose a novel dataset for automatic counter response generation. In particular, we constructed a pair-wise dataset that includes troll comments and counter responses with labeled response strategies, which enables models fine-tuned on our dataset to generate responses by varying counter responses according to the specified strategy. We conducted three tasks to assess the effectiveness of our dataset and evaluated the results through both automatic and human evaluation. In human evaluation, we demonstrate

```
that the model fine-tuned with our dataset shows a significantly
improved performance in strategy-controlled sentence generation.},

  pages     = {3542--3551},
  abstract  = {Numerical tables are widely employed to communicate
or report the classification performance of machine learning (ML)
models with respect to a set of evaluation metrics. For non-experts,
domain knowledge is required to fully understand and interpret the
information presented by numerical tables. This paper proposes a new
natural language generation (NLG) task where neural models are
trained to generate textual explanations, analytically describing
the classification performance of ML models based on the metrics'
scores reported in the tables. Presenting the generated texts along
with the numerical tables will allow for a better understanding of
the classification performance of ML models. We constructed a
dataset comprising numerical tables paired with their corresponding
textual explanations written by experts to facilitate this NLG task.
Experiments on the dataset are conducted by fine-tuning pre-trained
language models (T5 and BART) to generate analytical textual
explanations conditioned on the information in the tables.
Furthermore, we propose a neural module, Metrics Processing Unit
(MPU), to improve the performance of the baselines in terms of
correctly verbalising the information in the corresponding table.
Evaluation and analysis conducted indicate, that exploring pre-
trained models for data-to-text generation leads to better
generalisation performance and can produce high-quality textual
explanations.},

```
pages      = {363--373},
abstract   = {Training transformer language models requires vast
amounts of text and computational resources. This drastically limits
the usage of these models in niche domains for which they are not
optimized, or where domain-specific training data is scarce. We
focus here on the clinical domain because of its limited access to
training data in common tasks, while structured ontological data is
often readily available. Recent observations in model compression of
transformer models show optimization potential in improving the
representation capacity of attention heads. We propose KIMERA
(Knowledge Injection via Mask Enforced Retraining of Attention) for
detecting, retraining and instilling attention heads with
complementary structured domain knowledge. Our novel multi-task
training scheme effectively identifies and targets individual
attention heads that are least useful for a given downstream task
and optimizes their representation with information from structured
data. KIMERA generalizes well, thereby building the basis for an
efficient fine-tuning. KIMERA achieves significant performance
boosts on seven datasets in the medical domain in Information
Retrieval and Clinical Outcome Prediction settings. We apply KIMERA
to BERT-base to evaluate the extent of the domain transfer and also
improve on the already strong results of BioBERT in the clinical
domain.},

  pages     = {3561--3570},  
  abstract  = {We tackle the problem of neural headline generation  
in a low-resource setting, where only limited amount of data is  
available to train a model. We compare the ideal high-resource  
scenario on English with results obtained on a smaller subset of the  
same data and also run experiments on two small news corpora  
covering low-resource languages, Croatian and Estonian. Two options  
for headline generation in a multilingual low-resource scenario are  
investigated: a pretrained multilingual encoder-decoder model and a  
combination of two pretrained language models, one used as an  
encoder and the other as a decoder, connected with a cross-attention  
layer that needs to be trained from scratch. The results show that  
the first approach outperforms the second one by a large margin. We  
explore several data augmentation and pretraining strategies in  
order to improve the performance of both models and show that while  
we can drastically improve the second approach using these  
strategies, they have little to no effect on the performance of the  
pretrained encoder-decoder model. Finally, we propose two new  
measures for evaluating the performance of the models besides the  
classic ROUGE scores.},

  pages     = {3571--3581},  
  abstract  = {Pre-trained language models have established the  
state-of-the-art on various natural language processing tasks,  
including dialogue summarization, which allows the reader to quickly  
access key information from long conversations in meetings,  
interviews or phone calls. However, such dialogues are still  
difficult to handle with current models because the spontaneity of  
the language involves expressions that are rarely present in the  
corpora used for pre-training the language models. Moreover, the
```

vast majority of the work accomplished in this field has been focused on English. In this work, we present a study on the summarization of spontaneous oral dialogues in French using several language specific pre-trained models: BARThez, and BelGPT-2, as well as multilingual pre-trained models: mBART, mBARThez, and mT5. Experiments were performed on the DECODA (Call Center) dialogue corpus whose task is to generate abstractive synopses from call center conversations between a caller and one or several agents depending on the situation. Results show that the BARThez models offer the best performance far above the previous state-of-the-art on DECODA. We further discuss the limits of such pre-trained models and the challenges that must be addressed for summarizing spontaneous dialogues.},

pages = {3601--3609},
abstract = {Named Entity Recognition (NER) is an important task in information extraction. However, due to the lack of labelled corpora, biomedical NER has scarcely been studied in Vietnamese compared to English. To address this situation, we have constructed VietBioNER, a labelled NER corpus of Vietnamese academic biomedical text. The corpus focuses specifically on supporting tuberculosis surveillance, and was constructed by collecting scientific papers and grey literature related to tuberculosis symptoms and diagnostics. We manually annotated a small set of the collected documents with five categories of named entities: Organisation, Location, Date and Time, Symptom and Disease, and Diagnostic Procedure. Inter-annotator agreement ranges from 70.59\% and 95.89\% F-score according to entity category. In this paper, we make available two splits of the corpus, corresponding to traditional supervised learning and few-shot learning settings. We also provide baseline results for both of these settings, in addition to a dictionary-based approach, as a means to stimulate further research into Vietnamese biomedical NER. Although supervised methods produce results that are far superior to the other two approaches, the fact that even one-shot learning can outperform the dictionary-based method provides evidence that further research into few-shot learning on this text type would be worthwhile.},

abstract       = {Forced labour is the most common type of modern
slavery, and it is increasingly gaining the attention of the
research and social community. Recent studies suggest that
artificial intelligence (AI) holds immense potential for augmenting
anti-slavery action. However, AI tools need to be developed
transparently in cooperation with different stakeholders. Such tools
are contingent on the availability and access to domain-specific
data, which are scarce due to the near-invisible nature of forced
labour. To the best of our knowledge, this paper presents the first
openly accessible English corpus annotated for multi-class and
multi-label forced labour detection. The corpus consists of 989 news
articles retrieved from specialised data sources and annotated
according to risk indicators defined by the International Labour
Organization (ILO). Each news article was annotated for two aspects:
(1) indicators of forced labour as classification labels and (2)
snippets of the text that justify labelling decisions. We hope that
our data set can help promote research on explainability for multi-
class and multi-label text classification. In this work, we explain
our process for collecting the data underpinning the proposed
corpus, describe our annotation guidelines and present some
statistical analysis of its content. Finally, we summarise the
results of baseline experiments based on different variants of the
Bidirectional Encoder Representation from Transformer (BERT)
model.},

abstract    = {Despite remarkable advances in the development of
language resources over the recent years, there is still a shortage
of annotated, publicly available corpora covering (German) medical
language. With the initial release of the German Guideline Program
in Oncology NLP Corpus (GGPONC), we have demonstrated how such
corpora can be built upon clinical guidelines, a widely available
resource in many natural languages with a reasonable coverage of
medical terminology. In this work, we describe a major new release
for GGPONC. The corpus has been substantially extended in size and
re-annotated with a new annotation scheme based on SNOMED CT top
level hierarchies, reaching high inter-annotator agreement ( $\gamma=.94$ ).
Moreover, we annotated elliptical coordinated noun phrases and their
resolutions, a common language phenomenon in (not only German)
scientific documents. We also trained BERT-based named entity
recognition models on this new data set, which achieve high
performance on short, coarse-grained entity spans ( $F1=.89$ ), while
the rate of boundary errors increases for long entity spans. GGPONC
is freely available through a data use agreement. The trained named
entity recognition models, as well as the detailed annotation guide,
are also made publicly available.},

abstract  = {Running large-scale pre-trained language models in
computationally constrained environments remains a challenging
problem yet to be addressed, while transfer learning from these
models has become prevalent in Natural Language Processing tasks.
Several solutions, including knowledge distillation, network
quantization, or network pruning have been previously proposed;
however, these approaches focus mostly on the English language, thus
widening the gap when considering low-resource languages. In this
work, we introduce three light and fast versions of distilled BERT
models for the Romanian language: Distil-BERT-base-ro, Distil-
RoBERT-base, and DistilMulti-BERT-base-ro. The first two models
resulted from the individual distillation of knowledge from two base
versions of Romanian BERTs available in literature, while the last
one was obtained by distilling their ensemble. To our knowledge,
this is the first attempt to create publicly available Romanian
```

distilled BERT models, which were thoroughly evaluated on five tasks: part-of-speech tagging, named entity recognition, sentiment analysis, semantic textual similarity, and dialect identification. Our experimental results argue that the three distilled models offer performance comparable to their teachers, while being twice as fast on a GPU and ~35\% smaller. In addition, we further test the similarity between the predictions of our students versus their teachers by measuring their label and probability loyalty, together with regression loyalty – a new metric introduced in this work.},

title = {MuLD: The Multitask Long Document Benchmark},
booktitle = {Proceedings of the Language Resources and Evaluation Conference},
month = {June},
year = {2022},
address = {Marseille, France},
publisher = {European Language Resources Association},
pages = {3675--3685},
abstract = {The impressive progress in NLP techniques has been driven by the development of multi-task benchmarks such as GLUE and SuperGLUE. While these benchmarks focus on tasks for one or two input sentences, there has been exciting work in designing efficient techniques for processing much longer inputs. In this paper, we present MuLD: a new long document benchmark consisting of only documents over 10,000 tokens. By modifying existing NLP tasks, we create a diverse benchmark which requires models to successfully model long-term dependencies in the text. We evaluate how existing models perform, and find that our benchmark is much more challenging than their 'short document' equivalents. Furthermore, by evaluating both regular and efficient transformers, we show that models with increased context length are better able to solve the tasks presented, suggesting that future improvements in these models are vital for solving similar long document problems. We release the data and code for baselines to encourage further research on efficient NLP models.},

abstract = {This paper proposes a new cross-document coreference resolution (CDCR) dataset for identifying co-referring radiological findings and medical devices across a patient's radiology reports. Our annotated corpus contains 5872 mentions (findings and devices)

spanning 638 MIMIC-III radiology reports across 60 patients, covering multiple imaging modalities and anatomies. There are a total of 2292 mention chains. We describe the annotation process in detail, highlighting the complexities involved in creating a sizable and realistic dataset for radiology CDCR. We apply two baseline methods—string matching and transformer language models (BERT)—to identify cross-report coreferences. Our results indicate the requirement of further model development targeting better understanding of domain language and context to address this challenging and unexplored task. This dataset can serve as a resource to develop more advanced natural language processing CDCR methods in the future. This is one of the first attempts focusing on CDCR in the clinical domain and holds potential in benefiting physicians and clinical research through long-term tracking of radiology findings.},

abstract = {The business world has changed due to the 21st century economy, where borders have melted and trades became free. Nowadays, competition is no longer only at the local market level but also at the global level. In this context, the World Wide Web has become a major source of information for companies and professionals to keep track of their complex, rapidly changing, and competitive business environment. A lot of effort is nonetheless needed to collect and analyze this information due to information overload problem and the huge number of web pages to process and analyze. In this paper, we propose the BizRel resource, the first multilingual (French, English, Spanish, and Chinese) dataset for automatic extraction of binary business relations involving organizations from the web. This dataset is used to train several monolingual and cross-lingual deep learning models to detect these relations in texts. Our results are encouraging, demonstrating the effectiveness of such a resource for both research and business communities. In particular, we believe multilingual business relation extraction systems are crucial tools for decision makers to identify links between specific market stakeholders and build business networks which enable to anticipate changes and discover new threats or opportunities. Our work is therefore an important direction toward such tools.},

  abstract  = {With their Discovery of Inference Rules from Text  
(DIRT) algorithm, Lin and Pantel (2001) made a seminal contribution  
to the field of rule acquisition from text, by adapting the  
distributional hypothesis of Harris (1954) to rules that model  
binary relations such as X treat Y. DIRT's relevance is renewed in  
today's neural era given the recent focus on interpretability in the  
field of natural language processing. We propose a novel take on the  
DIRT algorithm, where we implement the distributional hypothesis  
using the contextualized embeddings provided by BERT, a transformer-  
network-based language model (Vaswani et al. 2017; Devlin et al.  
2018). In particular, we change the similarity measure between pairs  
of slots (i.e., the set of words matched by a rule) from the  
original formula that relies on lexical items to a formula computed  
using contextualized embeddings. We empirically demonstrate that  
this new similarity method yields a better implementation of the  
distributional hypothesis, and this, in turn, yields rules that  
outperform the original algorithm in the question answering-based  
evaluation proposed by Lin and Pantel (2001).},

abstract = {Modern approaches in Natural Language Processing (NLP) require, ideally, large amounts of labelled data for model training. However, new language resources, for example, for Named Entity Recognition (NER), Co-reference Resolution (CR), Entity Linking (EL) and Relation Extraction (RE), naming a few of the most popular tasks in NLP, have always been challenging to create since manual text annotations can be very time-consuming to acquire. While

there may be an acceptable amount of labelled data available for some of these tasks in one language, there may be a lack of datasets in another. WEXEA is a tool to exhaustively annotate entities in the English Wikipedia. Guidelines for editors of Wikipedia articles result, on the one hand, in only a few annotations through hyperlinks, but on the other hand, make it easier to exhaustively annotate the rest of these articles with entities than starting from scratch. We propose the following main improvements to WEXEA: Creating multi-lingual corpora, improved entity annotations using a proven NER system, annotating dates and times. A brief evaluation of the annotation quality of WEXEA is added.

abstract = {We present EpidBioBERT, a biosurveillance epidemiological document tagger for disease surveillance over PADI-Web system. Our model is trained on PADI-Web corpus which contains news articles on Animal Diseases Outbreak extracted from the web. We train a classifier to discriminate between relevant and irrelevant documents based on their epidemiological thematic feature content in preparation for further epidemiology information extraction. Our approach proposes a new way to perform epidemiological document classification by enriching epidemiological thematic features namely disease, host, location and date, which are used as inputs to our epidemiological document classifier. We adopt a pre-trained biomedical language model with a novel fine tuning approach that enriches these epidemiological thematic features. We find these thematic features rich enough to improve epidemiological document classification over a smaller data set than initially used in PADI-Web classifier. This improves the classifiers ability to avoid false positive alerts on disease surveillance systems. To further understand information encoded in EpidBioBERT, we experiment the impact of each epidemiology thematic feature on the classifier under ablation studies. We compare our biomedical pre-trained approach with a general language model based model finding that thematic feature embeddings pre-trained on general English documents are not rich enough for epidemiology classification task. Our model achieves an F1-score of 95.5% over an unseen test set, with an improvement of +5.5 points on F1-Score on the PADI-Web classifier with nearly half the training data set.},

  abstract  = {In this paper, we propose a method to generate  
personalized filled pauses (FPs) with group-wise prediction models.  
Compared with fluent text generation, disfluent text generation has  
not been widely explored. To generate more human-like texts, we  
addressed disfluent text generation. The usage of disfluency, such  
as FPs, rephrases, and word fragments, differs from speaker to  
speaker, and thus, the generation of personalized FPs is required.  
However, it is difficult to predict them because of the sparsity of  
position and the frequency difference between more and less  
frequently used FPs. Moreover, it is sometimes difficult to adapt FP
```

prediction models to each speaker because of the large variation of the tendency within each speaker. To address these issues, we propose a method to build group-dependent prediction models by grouping speakers on the basis of their tendency to use FPs. This method does not require a large amount of data and time to train each speaker model. We further introduce a loss function and a word embedding model suitable for FP prediction. Our experimental results demonstrate that group-dependent models can predict FPs with higher scores than a non-personalized one and the introduced loss function and word embedding model improve the prediction performance.},

pages       = {3761--3770},
abstract    = {Recent advancements in natural language processing
(NLP) have reshaped the industry, with powerful language models such
as GPT-3 achieving superhuman performance on various tasks. However,
the increasing complexity of such models turns them into "black
boxes'', creating uncertainty about their internal operation and
decision-making. Tsetlin Machine (TM) employs human-interpretable
conjunctive clauses in propositional logic to solve complex pattern
recognition problems and has demonstrated competitive performance in
various NLP tasks. In this paper, we propose ConvTextTM, a novel
convolutional TM architecture for text classification. While legacy
TM solutions treat the whole text as a corpus-specific set-of-words
(SOW), ConvTextTM breaks down the text into a sequence of text
fragments. The convolution over the text fragments opens up for
local position-aware analysis. Further, ConvTextTM eliminates the
dependency on a corpus-specific vocabulary. Instead, it employs a
generic SOW formed by the tokenization scheme of the Bidirectional
Encoder Representations from Transformers (BERT). The convolution
binds together the tokens, allowing ConvTextTM to address the out-
of-vocabulary problem as well as spelling errors. We investigate the
local explainability of our proposed method using clause-based
features. Extensive experiments are conducted on seven datasets, to
demonstrate that the accuracy of ConvTextTM is either superior or
comparable to state-of-the-art baselines.},

abstract = {Relation extraction is a core problem for natural
language processing in the biomedical domain. Recent research on
relation extraction showed that prompt-based learning improves the
performance on both fine-tuning on full training set and few-shot
training. However, less effort has been made on domain-specific
tasks where good prompt design can be even harder. In this paper, we
investigate prompting for biomedical relation extraction, with
experiments on the ChemProt dataset. We present a simple yet
effective method to systematically generate comprehensive prompts
that reformulate the relation extraction task as a cloze-test task
under a simple prompt formulation. In particular, we experiment with
different ranking scores for prompt selection. With BioMed-RoBERTa-
base, our results show that prompting-based fine-tuning obtains
gains by 14.21 F1 over its regular fine-tuning baseline, and 1.14 F1
over SciFive-Large, the current state-of-the-art on ChemProt.
Besides, we find prompt-based learning requires fewer training
examples to make reasonable predictions. The results demonstrate the
potential of our methods in such a domain-specific relation
extraction task.},

  pages     = {393--399},  
  abstract  = {In several ASR use cases, training and adaptation of  
  domain-specific LMs can only rely on a small amount of manually  
  verified text transcriptions and sometimes a limited amount of in-  
  domain speech. Training of LSTM LMs in such limited data scenarios  
  can benefit from alternate uncertain ASR hypotheses, as observed in  
  our recent work. In this paper, we propose a method to train  
  Transformer LMs on ASR confusion networks. We evaluate whether these  
  self-attention based LMs are better at exploiting alternate ASR  
  hypotheses as compared to LSTM LMs. Evaluation results show that  
  Transformer LMs achieve 3-6\% relative reduction in perplexity on  
  the AMI scenario meetings but perform similar to LSTM LMs on the  
  smaller Verbmobil conversational corpus. Evaluation on ASR N-best  
  rescoring shows that LSTM and Transformer LMs trained on ASR  
  confusion networks do not bring significant WER reductions. However,  
  a qualitative analysis reveals that they are better at predicting  
  less frequent words.},

abstract = {The paper presents novel resources and experiments  
for Buddhist Sanskrit, broadly defined here including all the  
varieties of Sanskrit in which Buddhist texts have been transmitted.  
We release a novel corpus of Buddhist texts, a novel corpus of  
general Sanskrit and word similarity and word analogy datasets for  
intrinsic evaluation of Buddhist Sanskrit embeddings models. We  
compare the performance of word2vec and fastText static embeddings  
models, with default and optimized parameter settings, as well as  
contextual models BERT and GPT-2, with different training regimes  
(including a transfer learning approach using the general Sanskrit  
corpus) and different embeddings construction regimes (given the  
encoder layers). The results show that for semantic similarity the  
fastText embeddings yield the best results, while for word analogy  
tasks BERT embeddings work the best. We also show that for  
contextual models the optimal layer combination for embedding  
construction is task dependant, and that pretraining the contextual  
embeddings models on a reference corpus of general Sanskrit is  
beneficial, which is a promising finding for future development of  
embeddings for less-resourced languages and domains.},

abstract    = {This paper describes the process of data processing
and training of an automatic speech recognition (ASR) system for
Cook Islands Māori (CIM), an Indigenous language spoken by
approximately 22,000 people in the South Pacific. We transcribed
four hours of speech from adults and elderly speakers of the
language and prepared two experiments. First, we trained three ASR
systems: one statistical, Kaldi; and two based on Deep Learning,
DeepSpeech and XLSR-Wav2Vec2. Wav2Vec2 tied with Kaldi for lowest
character error rate (CER=6±1) and was slightly behind in word error
rate (WER=23±2 versus WER=18±2 for Kaldi). This provides evidence
that Deep Learning ASR systems are reaching the performance of
statistical methods on small datasets, and that they can work
effectively with extremely low-resource Indigenous languages like
CIM. In the second experiment we used Wav2Vec2 to train models with
held-out speakers. While the performance decreased (CER=15±7,
WER=46±16), the system still showed considerable learning. We intend
to use ASR to accelerate the documentation of CIM, using newly
transcribed texts to improve the ASR and also generate teaching and
language revitalization materials. The trained model is available
under a license based on the Kaitiakitanga License, which provides
for non-commercial use while retaining control of the model by the
Indigenous community.},

abstract   = {Protest events provide information about social and
political conflicts, the state of social cohesion and democratic
conflict management, as well as the state of civil society in
general. Social scientists are therefore interested in the
systematic observation of protest events. With this paper, we
release the first German language resource of protest event related
article excerpts published in local news outlets. We use this
dataset to train and evaluate transformer-based text classifiers to
automatically detect relevant newspaper articles. Our best approach
reaches a binary F1-score of 93.3 \%, which is a promising result
for our goal to support political science research. However, in a
second experiment, we show that our model does not generalize
equally well when applied to data from time periods and localities
other than our training sample. To make protest event detection more
```

robust, we test two ways of alternative preprocessing. First, we find that letting the classifier concentrate on sentences around protest keywords improves the F1-score for out-of-sample data up to +4 percentage points. Second, against our initial intuition, masking of named entities during preprocessing does not improve the generalization in terms of F1-scores. However, it leads to a significantly improved recall of the models.},

abstract = {This paper presents text mining approaches on German-speaking job advertisements to enable social science research on the development of the labour market over the last 30 years. In order to build text mining applications providing information about profession and main task of a job, as well as experience and ICT skills needed, we experiment with transfer learning and domain adaptation. Our main contribution consists in building language models which are adapted to the domain of job advertisements, and their assessment on a broad range of machine learning problems. Our findings show the large value of domain adaptation in several respects. First, it boosts the performance of fine-tuned task-specific models consistently over all evaluation experiments. Second, it helps to mitigate rapid data shift over time in our special domain, and enhances the ability to learn from small updates with new, labeled task data. Third, domain-adaptation of language models is efficient: With continued in-domain pre-training we are able to outperform general-domain language models pre-trained on ten times more data. We share our domain-adapted language models and data with the research community.},

abstract      = {Patronizing and Condescending Language (PCL) is a
subtle but harmful type of discourse, yet the task of recognizing
PCL remains under-studied by the NLP community. Recognizing PCL is
challenging because of its subtle nature, because available datasets
are limited in size, and because this task often relies on some form
of commonsense knowledge. In this paper, we study to what extent PCL
detection models can be improved by pre-training them on other, more
established NLP tasks. We find that performance gains are indeed
possible in this way, in particular when pre-training on tasks
focusing on sentiment, harmful language and commonsense morality. In
contrast, for tasks focusing on political speech and social justice,
no or only very small improvements were witnessed. These findings
improve our understanding of the nature of PCL.},

  abstract    = {This paper introduces HeLI-OTS, an off-the-shelf text
language identification tool using the HeLI language identification
method. The HeLI-OTS language identifier is equipped with language
models for 200 languages and licensed for academic as well as
commercial use. We present the HeLI method and its use in our
previous research. Then we compare the performance of the HeLI-OTS
language identifier with that of fastText on two different data
sets, showing that fastText favors the recall of common languages,
whereas HeLI-OTS reaches both high recall and high precision for all
languages. While introducing existing off-the-shelf language
identification tools, we also give a picture of digital humanities-
related research that uses such tools. The validity of the results
of such research depends on the results given by the language
identifier used, and especially for research focusing on the less
common languages, the tendency to favor widely used languages might
be very detrimental, which Heli-OTS is now able to remedy.},

publisher = {European Language Resources Association},
pages = {3950--3959},
abstract = {Robot-Assisted minimally invasive robotic surgery is the gold standard for the surgical treatment of many pathological conditions, and several manuals and academic papers describe how to perform these interventions. These high-quality, often peer-reviewed texts are the main study resource for medical personnel and consequently contain essential procedural domain-specific knowledge. The procedural knowledge therein described could be extracted, e.g., on the basis of semantic parsing models, and used to develop clinical decision support systems or even automation methods for some procedure's steps. However, natural language understanding algorithms such as, for instance, semantic role labelers have lower efficacy and coverage issues when applied to domain others than those they are typically trained on (i.e., newswire text). To overcome this problem, starting from PropBank frames, we propose a new linguistic resource specific to the robotic-surgery domain, named Robotic Surgery Procedural Framebank (RSPF). We extract from robotic-surgical texts verbs and nouns that describe surgical actions and extend PropBank frames by adding any of new lemmas, frames or role sets required to cover missing lemmas, specific frames describing the surgical significance, or new semantic roles used in procedural surgical language. Our resource is publicly available and can be used to annotate corpora in the surgical domain to train and evaluate Semantic Role Labeling (SRL) systems in a challenging fine-grained domain setting.},

```
pages      = {3960--3968},
abstract   = {Understanding child language development requires
accurately representing children's lexicons. However, much of the
past work modeling children's vocabulary development has utilized
adult-based measures. The present investigation asks whether using
corpora that captures the language input of young children more
accurately represents children's vocabulary knowledge. We present a
newly-created toddler corpus that incorporates transcripts of child-
directed conversations, the text of picture books written for
preschoolers, and dialog from G-rated movies to approximate the
language input a North American preschooler might hear. We evaluate
the utility of the new corpus for modeling children's vocabulary
development by building and analyzing different semantic network
models and comparing them to norms based on vocabulary norms for
toddlers in this age range. More specifically, the relations between
words in our semantic networks were derived from skip-gram neural
networks (Word2Vec) trained on our toddler corpus or on Google news.
Results revealed that the models built from the toddler corpus were
more accurate at predicting toddler vocabulary growth than the
adult-based corpus. These results speak to the importance of
selecting a corpus that matches the population of interest.},

  abstract    = {A commonsense knowledge resource organizes common
sense that is not necessarily correct all the time, but most people
are expected to know or believe. Such knowledge resources have
recently been actively built and utilized in artificial
intelligence, particularly natural language processing. In this
paper, we discuss an important but not significantly discussed the
issue of semantic gaps potentially existing in a commonsense
knowledge graph and propose a machine learning-based approach to
detect a semantic gap that may inhibit the proper chaining of
knowledge triples. In order to establish this line of research, we
created a pilot dataset from ConceptNet, in which chains consisting
of two adjacent triples are sampled, and the validity of each chain
is human-annotated. We also devised a few baseline methods for
detecting the semantic gaps and compared them in small-scale
experiments. Although the experimental results suggest that the
detection of semantic gaps may not be a trivial task, we achieved
several insights to further push this research direction, including
the potential efficacy of sense embeddings and contextualized word
representations enabled by a pre-trained language model.},

  pages       = {4001--4010},
  abstract    = {GRh00T, the German Rhetorical Ontology, is a domain
ontology of 110 rhetorical figures in the German language. The
overall goal of building an ontology of rhetorical figures in German
is not only the formal representation of different rhetorical
figures, but also allowing for their easier detection, thus
improving sentiment analysis, argument mining, detection of hate
speech and fake news, machine translation, and many other tasks in
which recognition of non-literal language plays an important role.
The challenge of building such ontologies lies in classifying the
figures and assigning adequate characteristics to group them, while
considering their distinctive features. The ontology of rhetorical
figures in the Serbian language was used as a basis for our work.
Besides transferring and extending the concepts of the Serbian
ontology, we ensured completeness and consistency by using
description logic and SPARQL queries. Furthermore, we show a

```

```
decision tree to identify figures and suggest a usage scenario on
how the ontology can be utilized to collect and annotate data.},

  abstract  = {Large-scale diachronic corpus studies covering longer
time periods are difficult if more than one corpus are to be
consulted and, as a result, different formats and annotation schemas
need to be processed and queried in a uniform, comparable and
replicable manner. We describes the application of the Flexible
Integrated Transformation and Annotation eNginering (Fintan)
platform for studying word order in German using syntactically
annotated corpora that represent its entire written history.
Focusing on nominal dative and accusative arguments, this study
hints at two major phases in the development of scrambling in modern
German. Against more recent assumptions, it supports the traditional
view that word order flexibility decreased over time, but it also
indicates that this was a relatively sharp transition in Early New
High German. The successful case study demonstrates the potential of
Fintan and the underlying LLOD technology for historical
linguistics, linguistic typology and corpus linguistics. The
technological contribution of this paper is to demonstrate the
applicability of Fintan for querying across heterogeneously
annotated corpora, as previously, it had only been applied for
transformation tasks. With its focus on quantitative analysis,
Fintan is a natural complement for existing multi-layer technologies
that focus on query and exploration.},

abstract  = {Olfactory references play a crucial role in our memory and, more generally, in our experiences, since researchers have shown that smell is the sense that is most directly connected with emotions. Nevertheless, only few works in NLP have tried to capture this sensory dimension from a computational perspective. One of the main challenges is the lack of a systematic and consistent taxonomy of olfactory information, where concepts are organised also in a multi-lingual perspective. WordNet represents a valuable starting point in this direction, which can be semi-automatically extended taking advantage of Google n-grams and of existing language models. In this work we describe the process that has led to the semi-automatic development of a taxonomy for olfactory information in four languages (English, French, German and Italian), detailing the different steps and the intermediate evaluations. Along with being multi-lingual, the taxonomy also encloses temporal marks for olfactory terms thus making it a valuable resource for historical content analysis. The resource has been released and is freely available.},

abstract       = {Research suggests that using generic language models
in specialized domains may be sub-optimal due to significant domain
differences. As a result, various strategies for developing domain-
specific language models have been proposed, including techniques
for adapting an existing generic language model to the target
domain, e.g. through various forms of vocabulary modifications and
continued domain-adaptive pretraining with in-domain data. Here, an
empirical investigation is carried out in which various strategies
for adapting a generic language model to the clinical domain are
compared to pretraining a pure clinical language model. Three
clinical language models for Swedish, pretrained for up to ten
epochs, are fine-tuned and evaluated on several downstream tasks in
the clinical domain. A comparison of the language models' downstream
performance over the training epochs is conducted. The results show
that the domain-specific language models outperform a general-domain
language model; however, there is little difference in performance
of the various clinical language models. However, compared to
pretraining a pure clinical language model with only in-domain data,
leveraging and adapting an existing general-domain language model
requires fewer epochs of pretraining with in-domain data.},

abstract      = {Today, natural language processing heavily relies on
pre-trained large language models. Even though such models are
criticized for the poor interpretability, they still yield state-of-
the-art solutions for a wide set of very different tasks. While lots
of probing studies have been conducted to measure the models'
awareness of grammatical knowledge, semantic probing is less
popular. In this work, we introduce the probing pipeline to study
the representedness of semantic relations in transformer language
models. We show that in this task, attention scores are nearly as
expressive as the layers' output activations, despite their lesser
ability to represent surface cues. This supports the hypothesis that
attention mechanisms are focusing not only on the syntactic
relational information but also on the semantic one.},

  abstract  = {Recently, many studies have focused on developing
dialogue systems that enable collaborative work; however, they
rarely focus on creative tasks. Collaboration for creative work, in
which humans and systems collaborate to create new value, will be
essential for future dialogue systems. In this study, we collected
500 dialogues of human-human collaboration in Minecraft as a basis
for developing a dialogue system that enables creative collaborative
work. We conceived the Collaborative Garden Task, where two workers
interact and collaborate in Minecraft to create a garden, and we
collected dialogue, action logs, and subjective evaluations. We also
collected third-person evaluations of the gardens and analyzed the
relationship between dialogue and collaborative work that received
high scores on the subjective and third-person evaluations in order
to identify dialogic factors for high-quality collaborative work. We
found that two essential aspects in creative collaborative work are
performing more processes to ask for and agree on suggestions
between workers and agreeing on a particular image of the final
product in the early phase of work and then discussing changes and
details.},

  abstract = {In this paper, we present the methodology of corpus design that will be used to study the comparison of influence between linguistic nudges with positive or negative influences and
```

three conversational agents: robot, smart speaker, and human. We recruited forty-nine participants to form six groups. The conversational agents first asked the participants about their willingness to adopt five ecological habits and invest time and money in ecological problems. The participants were then asked the same questions but preceded by one linguistic nudge with positive or negative influence. The comparison of standard deviation and mean metrics of differences between these two notes (before the nudge and after) showed that participants were mainly affected by nudges with positive influence, even though several nudges with negative influence decreased the average note. In addition, participants from all groups were willing to spend more money than time on ecological problems. In general, our experiment's early results suggest that a machine agent can influence participants to the same degree as a human agent. A better understanding of the power of influence of different conversational machines and the potential of influence of nudges of different polarities will lead to the development of ethical norms of human-computer interactions.},

abstract = {Building common ground with users is essential for  
dialogue agent systems and robots to interact naturally with people.  
While a few previous studies have investigated the process of  
building common ground in human-human dialogue, most of them have  
been conducted on the basis of text chat. In this study, we  
constructed a dialogue corpus to investigate the process of building  
common ground with a particular focus on the modality of dialogue  
and the social relationship between the participants in the process  
of building common ground, which are important but have not been  
investigated in the previous work. The results of our analysis  
suggest that adding the modality or developing the relationship  
between workers speeds up the building of common ground.  
Specifically, regarding the modality, the presence of video rather  
than only audio may unconsciously facilitate work, and as for the  
relationship, it is easier to convey information about emotions and  
turn-taking among friends than in first meetings. These findings and  
the corpus should prove useful for developing a system to support  
remote communication.},

  year      = {2022},  
  address   = {Marseille, France},  
  publisher = {European Language Resources Association},  
  pages     = {4096--4113},  
  abstract  = {The ability to recognise emotions lends a  
conversational artificial intelligence a human touch. While emotions  
in chit-chat dialogues have received substantial attention, emotions  
in task-oriented dialogues remain largely unaddressed. This is  
despite emotions and dialogue success having equally important roles  
in a natural system. Existing emotion-annotated task-oriented  
corpora are limited in size, label richness, and public  
availability, creating a bottleneck for downstream tasks. To lay a  
foundation for studies on emotions in task-oriented dialogues, we  
introduce EmoWOZ, a large-scale manually emotion-annotated corpus of  
task-oriented dialogues. EmoWOZ is based on MultiWOZ, a multi-domain  
task-oriented dialogue dataset. It contains more than 11K dialogues  
with more than 83K emotion annotations of user utterances. In  
addition to Wizard-of-Oz dialogues from MultiWOZ, we collect human-  
machine dialogues within the same set of domains to sufficiently  
cover the space of various emotions that can happen during the  
lifetime of a data-driven dialogue system. To the best of our  
knowledge, this is the first large-scale open-source corpus of its  
kind. We propose a novel emotion labelling scheme, which is tailored  
to task-oriented dialogues. We report a set of experimental results  
to show the usability of this corpus for emotion recognition and  
state tracking in task-oriented dialogues.},

pages = {4126--4134},

abstract = {To build a well-founded opinion it is natural for humans to gather and exchange new arguments. Especially when being confronted with an overwhelming amount of information, people tend to focus on only the part of the available information that fits into their current beliefs or convenient opinions. To overcome this "self-imposed filter bubble" (SFB) in the information seeking process, it is crucial to identify influential indicators for the former. Within this paper we propose and investigate indicators for the the user's SFB, mainly their Reflective User Engagement (RUE), their Personal Relevance (PR) ranking of content-related subtopics as well as their False (FK) and True Knowledge (TK) on the topic. Therefore, we analysed the answers of 202 participants of an online conducted user study, who interacted with our argumentative dialogue system BEA ("Building Engaging Argumentation"). Moreover, also the influence of different input/output modalities (speech/speech and drop-down menu/text) on the interaction with regard to the suggested indicators was investigated.},

  abstract    = {In this paper, we discuss the development of a  
multilingual dataset annotated with a hierarchical, fine-grained  
tagset marking different types of aggression and the "context" in  
which they occur. The context, here, is defined by the  
conversational thread in which a specific comment occurs and also  
the "type" of discursive role that the comment is performing with  
respect to the previous comment. The initial dataset, being  
discussed here consists of a total 59,152 annotated comments in four
```

languages – Meitei, Bangla, Hindi, and Indian English – collected from various social media platforms such as YouTube, Facebook, Twitter and Telegram. As is usual on social media websites, a large number of these comments are multilingual, mostly code-mixed with English. The paper gives a detailed description of the tagset being used for annotation and also the process of developing a multi-label, fine-grained tagset that has been used for marking comments with aggression and bias of various kinds including sexism (called gender bias in the tagset), religious intolerance (called communal bias in the tagset), class/caste bias and ethnic/racial bias. We also define and discuss the tags that have been used for marking the different discursive role being performed through the comments, such as attack, defend, etc. Finally, we present a basic statistical analysis of the dataset. The dataset is being incrementally made publicly available on the project website\footnote{\url{https://sites.google.com/view/comma-ctrans}}.},

booktitle = {Proceedings of the Language Resources and Evaluation Conference},
month = {June},
year = {2022},
address = {Marseille, France},
publisher = {European Language Resources Association},
pages = {4162--4176},
abstract = {Over the last decade, Twitter has emerged as one of the most influential forums for social, political, and health discourse. In this paper, we introduce a massive dataset of more than 45 million geo-located tweets posted between 2015 and 2021 from US and Canada (TUSC), especially curated for natural language analysis. We also introduce Tweet Emotion Dynamics (TED) – metrics to capture patterns of emotions associated with tweets over time. We use TED and TUSC to explore the use of emotion-associated words across US and Canada; across 2019 (pre-pandemic), 2020 (the year the pandemic hit), and 2021 (the second year of the pandemic); and across individual tweeters. We show that Canadian tweets tend to have higher valence, lower arousal, and higher dominance than the US tweets. Further, we show that the COVID-19 pandemic had a marked impact on the emotional signature of tweets posted in 2020, when compared to the adjoining years. Finally, we determine metrics of TED for 170,000 tweeters to benchmark characteristics of TED metrics at an aggregate level. TUSC and the metrics for TED will enable a wide variety of research on studying how we use language to express ourselves, persuade, communicate, and influence, with particularly promising applications in public health, affective science, social science, and psychology.},

  pages     = {4177--4185},  
  abstract  = {Social media posts containing hate speech are  
reproduced and redistributed at an accelerated pace, reaching  
greater audiences at a higher speed. We present a machine learning  
system for automatic detection of hate speech in Turkish, along with  
a hate speech dataset consisting of tweets collected in two separate  
domains. We first adopted a definition for hate speech that is in  
line with our goals and amenable to easy annotation; then designed  
the annotation schema for annotating the collected tweets. The  
Istanbul Convention dataset consists of tweets posted following the  
withdrawal of Turkey from the Istanbul Convention. The Refugees  
dataset was created by collecting tweets about immigrants by  
filtering based on commonly used keywords related to immigrants.  
Finally, we have developed a hate speech detection system using the  
transformer architecture (BERTurk), to be used as a baseline for the  
collected dataset. The binary classification accuracy is 77\% when  
the system is evaluated using 5-fold cross-validation on the  
Istanbul Convention dataset and 71\% for the Refugee dataset. We  
also tested a regression model with 0.66 and 0.83 RMSE on a scale of  
[0-4], for the Istanbul Convention and Refugees datasets.},

booktitle = {Proceedings of the Language Resources and Evaluation Conference},

month = {June},

year = {2022},

address = {Marseille, France},

publisher = {European Language Resources Association},

pages = {4193--4204},

abstract = {Transformer models have achieved significant improvements in multiple downstream tasks in recent years. One of the main contributions of Transformers is their ability to create new representations for out-of-vocabulary (OOV) words. In this paper, we have evaluated three categories of OOVs: (A) new domain-specific terms (e.g., "eucaryote" in microbiology), (B) misspelled words containing typos, and (C) cross-domain homographs (e.g., "arm" has different meanings in a clinical trial and anatomy). We use three French domain-specific datasets on the legal, medical, and energetical domains to robustly analyze these categories. Our experiments have led to exciting findings that showed: (1) It is easier to improve the representation of new words (A and B) than it is for words that already exist in the vocabulary of the Transformer models (C), (2) To ameliorate the representation of OOVs, the most effective method relies on adding external morpho-syntactic context rather than improving the semantic understanding of the words directly (fine-tuning) and (3) We cannot foresee the impact of minor misspellings in words because similar misspellings have different impacts on their representation. We believe that tackling the challenges of processing OOVs regarding their specificities will significantly help the domain adaptation aspect of BERT.},

publisher      = {European Language Resources Association},
pages         = {427--435},
abstract      = {In recent years, natural language inference has been
an emerging research area. In this paper, we present a novel data
augmentation technique and combine it with a unique learning
procedure for that task. Our so-called automatic contextual data
augmentation (acda) method manages to be fully automatic, non-
trivially contextual, and computationally efficient at the same
time. When compared to established data augmentation methods, it is
substantially more computationally efficient and requires no manual
annotation by a human expert as they usually do. In order to
increase its efficiency, we combine acda with two learning
optimization techniques: contrastive learning and a hybrid loss
function. The former maximizes the benefit of the supervisory signal
generated by acda, while the latter incentivises the model to learn
the nuances of the decision boundary. Our combined approach is shown
experimentally to provide an effective way for mitigating spurious
data correlations within a dataset, called dataset artifacts, and as
a result improves performance. Specifically, our experiments verify
that acda-boosted pre-trained language models that employ our
learning optimization techniques, consistently outperform the
respective fine-tuned baseline pre-trained language models across
both benchmark datasets and adversarial examples.},

publisher    = {European Language Resources Association},
pages        = {4235--4244},
abstract     = {Event identification in technical logbooks poses
challenges given the limited logbook data available in specific
technical domains, the large set of possible classes, and logbook
entries typically being in short form and non-standard technical
language. Technical logbook data typically has both a domain, the
field it comes from (e.g., automotive), and an application, what it
is used for (e.g., maintenance). In order to better handle the
problem of data scarcity, using a variety of technical logbook
datasets, this paper investigates the benefits of using transfer
learning from sources within the same domain (but different
applications), from within the same application (but different
domains) and from all available data. Results show that performing
transfer learning within a domain provides statistically significant
improvements, and in all cases but one the best performance.
Interestingly, transfer learning from within the application or
across the global dataset degrades results in all cases but one,
```

which benefited from adding as much data as possible. A further analysis of the dataset similarities shows that the datasets with higher similarity scores performed better in transfer learning tasks, suggesting that this can be utilized to determine the effectiveness of adding a dataset in a transfer learning task for technical logbooks.},

year = {2022},

address = {Marseille, France},

publisher = {European Language Resources Association},

pages = {4245--4252},

abstract = {Automatic de-identification is a cost-effective and straightforward way of removing large amounts of personally identifiable information from large and sensitive corpora. However, these systems also introduce errors into datasets due to their imperfect precision. These corruptions of the data may negatively impact the utility of the de-identified dataset. This paper de-identifies a very large clinical corpus in Swedish either by removing entire sentences containing sensitive data or by replacing sensitive words with realistic surrogates. These two datasets are used to perform domain adaptation of a general Swedish BERT model. The impact of the de-identification techniques is assessed by training and evaluating the models using six clinical downstream tasks. The results are then compared to a similar BERT model domain-adapted using an unaltered version of the clinical corpus. The results show that using an automatically de-identified corpus for domain adaptation does not negatively impact downstream performance. We argue that automatic de-identification is an efficient way of reducing the privacy risks of domain-adapted models and that the models created in this paper should be safe to distribute to other academic researchers.},

    pages      = {4253--4259},
    abstract   = {Diacritics restoration has become a ubiquitous task
in the Latin-alphabet-based English-dominated Internet language
environment. In this paper, we describe a small footprint 1D dilated
convolution-based approach which operates on a character-level. We
find that neural networks based on 1D dilated convolutions are
competitive alternatives to solutions based on recurrent neural
networks or linguistic modeling for the task of diacritics
restoration. Our approach surpasses the performance of similarly
sized models and is also competitive with larger models. A special
feature of our solution is that it even runs locally in a web
browser. We also provide a working example of this browser-based
implementation. Our model is evaluated on different corpora, with
emphasis on the Hungarian language. We performed comparative
measurements about the generalization power of the model in relation
to three Hungarian corpora. We also analyzed the errors to
understand the limitation of corpus-based self-supervised
training.},

    abstract   = {This article presents the first results of the
CLARIAH-funded project 'Patterns in Translation: Using Colibri Core
for the Syriac Bible' (PaTraCoSy). This project seeks to use Colibri
Core to detect translation patterns in the Peshitta, the Syriac
translation of the Hebrew Bible. We first describe how we
constructed word and phrase alignment between these two texts. This
step is necessary to successfully implement the functionalities of
Colibri Core. After this, we further describe our first
investigations with the software. We describe how we use the built-
in pattern modeller to detect n-gram and skipgram patterns in both
Hebrew and Syriac texts. Colibri Core does not allow the creation of
a bilingual model, which is why we compare the separate models.
After a presentation of a few general insights on the overall
translation behaviour of the Peshitta, we delve deeper into the
concrete patterns we can detect by the n-gram/skipgram analysis. We
provide multiple examples from the book of Genesis, a book which has
been treated broadly in scholarly research into the Syriac
translation, but which also appears to have interesting features
based on our Colibri Core research.},

abstract = {In recent years there have been considerable advances in pre-trained language models, where non-English language versions have also been made available. Due to their increasing use, many lightweight versions of these models (with reduced parameters) have also been released to speed up training and inference times. However, versions of these lighter models (e.g., ALBERT, DistilBERT) for languages other than English are still scarce. In this paper we present ALBETO and DistilBETO, which are versions of ALBERT and DistilBERT pre-trained exclusively on Spanish corpora. We train several versions of ALBETO ranging from 5M to 223M parameters and one of DistilBETO with 67M parameters. We evaluate our models in the GLUES benchmark that includes various natural language understanding tasks in Spanish. The results show that our lightweight models achieve competitive results to those of BETO (Spanish-BERT) despite having fewer parameters. More specifically, our larger ALBETO model outperforms all other models on the MLDoc, PAWS-X, XNLI, MLQA, SQAC and XQuAD datasets. However, BETO remains unbeaten for POS and NER. As a further contribution, all models are publicly available to the community for future research.},

pages      = {4306--4315},
abstract   = {Modern Natural Language Processing relies on the
availability of annotated corpora for training and evaluating
models. Such resources are scarce, especially for specialized
domains in languages other than English. In particular, there are
very few resources for semantic similarity in the clinical domain in
French. This can be useful for many biomedical natural language
processing applications, including text generation. We introduce a
definition of similarity that is guided by clinical facts and apply
it to the development of a new French corpus of 1,000 sentence pairs
manually annotated according to similarity scores. This new sentence
similarity corpus is made freely available to the community. We
further evaluate the corpus through experiments of automatic
similarity measurement. We show that a model of sentence embeddings
can capture similarity with state-of-the-art performance on the DEFT
STS shared task evaluation data set (Spearman=0.8343). We also show
that the \corpus corpus is complementary to DEFT STS.},

abstract     = {Discovered by (Austin,1962) and extensively promoted  
by (Searle, 1975), speech acts (SA) have been the object of  
extensive discussion in the philosophical and the linguistic  
literature, as well as in computational linguistics where the  
detection of SA have shown to be an important step in many down  
stream NLP applications. In this paper, we attempt to measure for  
the first time the role of SA on urgency detection in tweets,  
focusing on natural disasters. Indeed, SA are particularly relevant  
to identify intentions, desires, plans and preferences towards  
action, providing therefore actionable information that will help to  
set priorities for the human teams and decide appropriate rescue  
actions. To this end, we come up here with four main contributions:  
(1) A two-layer annotation scheme of SA both at the tweet and  
subtweet levels, (2) A new French dataset of 6,669 tweets annotated  
for both urgency and SA, (3) An in-depth analysis of the annotation  
campaign, highlighting the correlation between SA and urgency  
categories, and (4) A set of deep learning experiments to detect SA  
in a crisis corpus. Our results show that SA are correlated with  
urgency which is a first important step towards SA-aware NLP-based  
crisis management on social media.},

abstract = {We train several language models for Icelandic, including IceBERT, that achieve state-of-the-art performance in a variety of downstream tasks, including part-of-speech tagging, named entity recognition, grammatical error detection and constituency parsing. To train the models we introduce a new corpus of Icelandic text, the Icelandic Common Crawl Corpus (IC3), a collection of high quality texts found online by targeting the Icelandic top-level-domain .is. Several other public data sources are also collected for a total of 16GB of Icelandic text. To enhance the evaluation of model performance and to raise the bar in baselines for Icelandic, we manually translate and adapt the WinoGrande commonsense reasoning dataset. Through these efforts we demonstrate that a properly cleaned crawled corpus is sufficient to achieve state-of-the-art results in NLP applications for low to medium resource languages, by comparison with models trained on a curated corpus. We further show that initializing models using existing multilingual models can lead to state-of-the-art results for some downstream tasks.},

abstract = {In recent years, voice-controlled personal assistants

have revolutionized the interaction with smart devices and mobile applications. The collected data are then used by system providers to train language models (LMs). Each spoken message reveals personal information, hence removing private information from the input sentences is necessary. Our data sanitization process relies on recognizing and replacing named entities by other words from the same class. However, this may harm LM training because privacy-transformed data is unlikely to match the test distribution. This paper aims to fill the gap by focusing on the adaptation of LMs initially trained on privacy-transformed sentences using a small amount of original untransformed data. To do so, we combine class-based LMs, which provide an effective approach to overcome data sparsity in the context of n-gram LMs, and neural LMs, which handle longer contexts and can yield better predictions. Our experiments show that training an LM on privacy-transformed data result in a relative 11\% word error rate (WER) increase compared to training on the original untransformed data, and adapting that model on a limited amount of original untransformed data leads to a relative 8\% WER improvement over the model trained solely on privacy-transformed data.},

abstract = {We introduce a new benchmark for assessing the
quality of text-to-text models for Polish. The benchmark consists of
diverse tasks and datasets: KLEJ benchmark adapted for text-to-text,
en-pl translation, summarization, and question answering. In
particular, since summarization and question answering lack
benchmark datasets for the Polish language, we describe in detail
their construction and make them publicly available. Additionally,
we present plT5 - a general-purpose text-to-text model for Polish
that can be fine-tuned on various Natural Language Processing (NLP)
tasks with a single training objective. Unsupervised denoising pre-
training is performed efficiently by initializing the model weights
with a multi-lingual T5 (mT5) counterpart. We evaluate the
performance of plT5, mT5, Polish BART (plBART), and Polish GPT-2
(papuGaPT2). The plT5 scores top on all of these tasks except
summarization, where plBART is best. In general (except
summarization), the larger the model, the better the results. The
encoder-decoder architectures prove to be better than the decoder-
only equivalent.},

  pages     = {4395--4404},
  abstract  = {The evaluation of Handwritten Text Recognition (HTR)
  models during their development is straightforward: because HTR is a
  supervised problem, the usual data split into training, validation,
  and test data sets allows the evaluation of models in terms of
  accuracy or error rates. However, the evaluation process becomes
  tricky as soon as we switch from development to application. A
  compilation of a new (and forcibly smaller) ground truth (GT) from a
  sample of the data that we want to apply the model on and the
  subsequent evaluation of models thereon only provides hints about
  the quality of the recognised text, as do confidence scores (if
  available) the models return. Moreover, if we have several models at
  hand, we face a model selection problem since we want to obtain the
  best possible result during the application phase. This calls for
  GT-free metrics to select the best model, which is why we
  (re-)introduce and compare different metrics, from simple, lexicon-
  based to more elaborate ones using standard language models and
  masked language models (MLM). We show that MLM-based evaluation can
  compete with lexicon-based methods, with the advantage that large
  and multilingual transformers are readily available, thus making
  compiling lexical resources for other metrics superfluous.},

  abstract  = {In this paper, we present a semi-automated workflow
  for live interlingual speech-to-text communication which seeks to
```

reduce the shortcomings of existing ASR systems: a human respeaker works with a speaker-dependent speech recognition software (e.g., Dragon Naturally Speaking) to deliver punctuated same-language output of superior quality than obtained using out-of-the-box automatic speech recognition of the original speech. This is fed into a machine translation engine (the EU's eTranslation) to produce live-caption ready text. We benchmark the quality of the output against the output of best-in-class (human) simultaneous interpreters working with the same source speeches from plenary sessions of the European Parliament. To evaluate the accuracy and facilitate the comparison between the two types of output, we use a tailored annotation approach based on the NTR model (Romero-Fresco and Pöschhacker, 2017). We find that the semi-automated workflow combining intralingual respeaking and machine translation is capable of generating outputs that are similar in terms of accuracy and completeness to the outputs produced in the benchmarking workflow, although the small scale of our experiment requires caution in interpreting this result.},

abstract = {Word embedding methods allow to represent words as vectors in a space that is structured using word co-occurrences so that words with close meanings are close in this space. These vectors are then provided as input to automatic systems to solve natural language processing problems. Because interpretability is a necessary condition to trusting such systems, interpretability of embedding spaces, the first link in the chain is an important issue. In this paper, we thus evaluate the interpretability of vectors extracted with two approaches: SPINE a k-sparse auto-encoder, and SINr, a graph-based method. This evaluation is based on a Word Intrusion Task with human annotators. It is operated using a large French corpus, and is thus, as far as we know, the first large-scale experiment regarding word embedding interpretability on this language. Furthermore, contrary to the approaches adopted in the literature where the evaluation is done on a small sample of frequent words, we consider a more realistic use-case where most of the vocabulary is kept for the evaluation. This allows to show how difficult this task is, even though SPINE and SINr show some promising results. In particular, SINr results are obtained with a very low amount of computation compared to SPINE, while being similarly interpretable.},

  abstract  = {Legal texts are often difficult to interpret, and
people who interpret them need to make choices about the
interpretation. To improve transparency, the interpretation of a
legal text can be made explicit by formalising it. However, creating
formalised representations of legal texts manually is quite labour-
intensive. In this paper, we describe a method to extract structured
representations in the Flint language (van Doesburg and van Engers,
2019) from natural language. Automated extraction of knowledge
representation not only makes the interpretation and modelling
efforts more efficient, it also contributes to reducing inter-coder
dependencies. The Flint language offers a formal model that enables
the interpretation of legal text by describing the norms in these
texts as acts, facts and duties. To extract the components of a
Flint representation, we use a rule-based method and a transformer-
based method. In the transformer-based method we fine-tune the last
layer with annotated legal texts. The results show that the
transformer-based method (80\% accuracy) outperforms the rule-based
method (42\% accuracy) on the Dutch Aliens Act. This indicates that
the transformer-based method is a promising approach of
automatically extracting Flint frames.},

```
publisher      = {European Language Resources Association},
pages         = {4439--4450},
abstract      = {Text mining and information extraction for the
medical domain has focused on scientific text generated by
researchers. However, their access to individual patient experiences
or patient-doctor interactions is limited. On social media, doctors,
patients and their relatives also discuss medical information.
Individual information provided by laypeople complements the
knowledge available in scientific text. It reflects the patient's
journey making the value of this type of data twofold: It offers
direct access to people's perspectives, and it might cover
information that is not available elsewhere, including self-
treatment or self-diagnose. Named entity recognition and relation
extraction are methods to structure information that is available in
unstructured text. However, existing medical social media corpora
focused on a comparably small set of entities and relations. In
contrast, we provide rich annotation layers to model patients'
experiences in detail. The corpus consists of medical tweets
annotated with a fine-grained set of medical entities and relations
between them, namely 14 entity (incl. environmental factors,
diagnostics, biochemical processes, patients' quality-of-life
descriptions, pathogens, medical conditions, and treatments) and 20
relation classes (incl. prevents, influences, interactions, causes).
The dataset consists of 2,100 tweets with approx. 6,000 entities and
2,200 relations.},

abstract     = {Understanding event duration is essential for
understanding natural language. However, the amount of training data
for tasks like duration question answering, i.e., McTACO, is very
limited, suggesting a need for external duration information to
improve this task. The duration information can be obtained from
existing temporal information extraction tasks, such as UDS-T and
TimeBank, where more duration data is available. A straightforward
two-stage fine-tuning approach might be less likely to succeed given
the discrepancy between the target duration question answering task
and the intermediary duration classification task. This paper
resolves this discrepancy by automatically recasting an existing
event duration classification task from UDS-T to a question
answering task similar to the target McTACO. We investigate the
transferability of duration information by comparing whether the
```

original UDS-T duration classification or the recast UDS-T duration question answering can be transferred to the target task. Our proposed model achieves a 13\% Exact Match score improvement over the baseline on the McTACO duration question answering task, showing that the two-stage fine-tuning approach succeeds when the discrepancy between the target and intermediary tasks are resolved.},

abstract = {Named Entity Recognition (NER) is a foundational NLP
task that aims to provide class labels like Person, Location,
Organisation, Time, and Number to words in free text. Named Entities
can also be multi-word expressions where the additional I-O-B
annotation information helps label them during the NER annotation
```

process. While English and European languages have considerable annotated data for the NER task, Indian languages lack on that front— both in terms of quantity and following annotation standards. This paper releases a significantly sized standard-abiding Hindi NER dataset containing 109,146 sentences and 2,220,856 tokens, annotated with 11 tags. We discuss the dataset statistics in all their essential detail and provide an in-depth analysis of the NER tag-set used with our data. The statistics of tag-set in our dataset shows a healthy per-tag distribution especially for prominent classes like Person, Location and Organisation. Since the proof of resource-effectiveness is in building models with the resource and testing the model on benchmark data and against the leader-board entries in shared tasks, we do the same with the aforesaid data. We use different language models to perform the sequence labelling task for NER and show the efficacy of our data by performing a comparative evaluation with models trained on another dataset available for the Hindi NER task. Our dataset helps achieve a weighted F1 score of 88.78 with all the tags and 92.22 when we collapse the tag-set, as discussed in the paper. To the best of our knowledge, no available dataset meets the standards of volume (amount) and variability (diversity), as far as Hindi NER is concerned. We fill this gap through this work, which we hope will significantly help NLP for Hindi. We release this dataset with our code and models for further research at <https://github.com/cfiltnlp/HiNER>,

  pages = {4477--4487},  
  abstract = {We propose a novel method to bootstrap text  
anonymization models based on distant supervision. Instead of  
requiring manually labeled training data, the approach relies on a  
knowledge graph expressing the background information assumed to be  
publicly available about various individuals. This knowledge graph  
is employed to automatically annotate text documents including  
personal data about a subset of those individuals. More precisely,  
the method determines which text spans ought to be masked in order  
to guarantee k-anonymity, assuming an adversary with access to both  
the text documents and the background information expressed in the  
knowledge graph. The resulting collection of labeled documents is  
then used as training data to fine-tune a pre-trained language model  
for text anonymization. We illustrate this approach using a  
knowledge graph extracted from Wikidata and short biographical texts  
from Wikipedia. Evaluation results with a RoBERTa-based model and a
```

manually annotated collection of 553 summaries showcase the potential of the approach, but also unveil a number of issues that may arise if the knowledge graph is noisy or incomplete. The results also illustrate that, contrary to most sequence labeling problems, the text anonymization task may admit several alternative solutions.},

  abstract  = {We present the first extractive question answering  
(QA) dataset for Icelandic, Natural Questions in Icelandic (NQiI).  
Developing such datasets is important for the development and  
evaluation of Icelandic QA systems. It also aids in the development  
of QA methods that need to work for a wide range of morphologically  
and grammatically different languages in a multilingual setting. The  
dataset was created by asking contributors to come up with questions  
they would like to know the answer to. Later, they were tasked with  
finding answers to each others questions following a previously  
published methodology. The questions are Natural in the sense that  
they are real questions posed out of interest in knowing the answer.  
The complete dataset contains 18 thousand labeled entries of which  
5,568 are directly suitable for training an extractive QA system for  
Icelandic. The dataset is a valuable resource for Icelandic which we  
demonstrate by creating and evaluating a system capable of  
extractive QA in Icelandic.},

abstract = {Recent progress in natural language processing has been impressive in many different areas with transformer-based approaches setting new benchmarks for a wide range of applications. This development has also lowered the barriers for people outside the NLP community to tap into the tools and resources applied to a variety of domain-specific applications. The bottleneck however still remains the lack of annotated gold-standard collections as soon as one's research or professional interest falls outside the scope of what is readily available. One such area is genocide-related research (also including the work of experts who have a professional interest in accessing, exploring and searching large-scale document collections on the topic, such as lawyers). We present GTC (Genocide Transcript Corpus), the first annotated corpus of genocide-related court transcripts which serves three purposes: (1) to provide a first reference corpus for the community, (2) to establish benchmark performances (using state-of-the-art transformer-based approaches) for the new classification task of paragraph identification of violence-related witness statements, (3) to explore first steps towards transfer learning within the domain. We consider our contribution to be addressing in particular this year's hot topic on Language Technology for All.},

title = {English Language Spelling Correction as an

```

Information Retrieval Task Using Wikipedia Search Statistics},
  booktitle      = {Proceedings of the Language Resources and
Evaluation Conference},
  month          = {June},
  year           = {2022},
  address        = {Marseille, France},
  publisher      = {European Language Resources Association},
  pages          = {458--464},
  abstract       = {Spelling correction utilities have become commonplace
during the writing process, however, many spelling correction
utilities suffer due to the size and quality of dictionaries
available to aid correction. Many terms, acronyms, and morphological
variations of terms are often missing, leaving potential spelling
errors unidentified and potentially uncorrected. This research
describes the implementation of WikiSpell, a dynamic spelling
correction tool that relies on the Wikipedia dataset search API
functionality as the sole source of knowledge to aid misspelled term
identification and automatic replacement. Instead of a traditional
matching process to select candidate replacement terms, the
replacement process is treated as a natural language information
retrieval process harnessing wildcard string matching and search
result statistics. The aims of this research include: 1) the
implementation of a spelling correction algorithm that utilizes the
wildcard operators in the Wikipedia dataset search API, 2) a review
of the current spell correction tools and approaches being utilized,
and 3) testing and validation of the developed algorithm against the
benchmark spelling correction tool, Hunspell. The key contribution
of this research is a robust, dynamic information retrieval-based
spelling correction algorithm that does not require prior training.
Results of this research show that the proposed spelling correction
algorithm, WikiSpell, achieved comparable results to an industry-
standard spelling correction algorithm, Hunspell.},

  abstract  = {In an era where social media platform users are
growing rapidly, there has been a marked increase in hateful content
being generated; to combat this, automatic hate speech detection
systems are a necessity. For this purpose, researchers have recently
focused their efforts on developing datasets, however, the vast
majority of them have been generated for the English language, with
only a few available for low-resource languages such as Roman Urdu.
Furthermore, what few are available have small number of samples
that pertain to hateful classes and these lack variations in topics
and content. Thus, deep learning models trained on such datasets
perform poorly when deployed in the real world. To improve
performance the option of collecting and annotating more data can be
very costly and time consuming. Thus, data augmentation techniques
need to be explored to exploit already available datasets to improve
model generalizability. In this paper, we explore different data
augmentation techniques for the improvement of hate speech detection
in Roman Urdu. We evaluate these augmentation techniques on two
datasets. We are able to improve performance in the primary metric
of comparison (F1 and Macro F1) as well as in recall, which is
impertinent for human-in-the-loop AI systems.},

abstract       = {Psycholinguistic knowledge resources have been widely
used in constructing features for text-based human trait and
behavior analysis. Recently, deep neural network (NN)-based text
analysis methods have gained dominance due to their high prediction
performance. However, NN-based methods may not perform well in low
resource scenarios where the ground truth data is limited (e.g.,
only a few hundred labeled training instances are available). In
this research, we investigate diverse methods to incorporate
Linguistic Inquiry and Word Count (LIWC), a widely-used
psycholinguistic lexicon, in NN models to improve human trait and
behavior analysis in low resource scenarios. We evaluate the
proposed methods in two tasks: predicting delay discounting and
predicting drug use based on social media posts. The results
demonstrate that our methods perform significantly better than
baselines that use only LIWC or only NN-based feature learning
methods. They also performed significantly better than published
results on the same dataset.},

abstract = {We propose an unsupervised method for the identification of bridge phrases in multi-hop question answering (QA). Our method constructs a graph of noun phrases from the question and the available context, and applies the Steiner tree algorithm to identify the minimal sub-graph that connects all question phrases. Nodes in the sub-graph that bridge loosely-connected or disjoint subsets of question phrases due to low-strength semantic relations are extracted as bridge phrases. The identified bridge phrases are then used to expand the query based on the initial question, helping in increasing the relevance of evidence that has little lexical overlap or semantic relation with the question. Through an evaluation on HotpotQA, a popular dataset for multi-hop QA, we show that our method yields: (a) improved evidence retrieval, (b) improved QA performance when using the retrieved sentences; and (c) effective and faithful explanations

  abstract  = {This paper introduces the question answering paradigm
  as a way to explore digitized archive collections for Social Science
  studies. In particular, we are interested in evaluating largely
  studied question generation and question answering approaches on a
  new type of documents, as a step forward beyond traditional
  benchmark evaluations. Question generation can be used as a way to
  provide enhanced training material for Machine Reading Question
  Answering algorithms but also has its own purpose in this paradigm,
  where relevant questions can be used as a way to create explainable
  links between documents. To this end, generating large amounts of
  question is not the only motivation, but we need to include
  qualitative and semantic control to the generation process. We
  propose a new approach for question generation, relying on a BART
  Transformer based generative model, for which input data are
  enriched by semantic constraints. Question generation and answering
  are evaluated on several French corpora, and the whole approach is
  validated on a new corpus of digitized archive collection of a
  French Social Science journal.},

abstract = {Electronic Health Records contain a lot of information in natural language that is not expressed in the structured clinical data. Especially in the case of new diseases such as COVID-19, this information is crucial to get a better understanding of patient recovery patterns and factors that may play a role in it. However, the language in these records is very different from standard language and generic natural language processing tools cannot easily be applied out-of-the-box. In this paper, we present a fine-tuned Dutch language model specifically developed for the language in these health records that can determine the functional level of patients according to a standard coding framework from the World Health Organization. We provide evidence that our classification performs at a sufficient level to generate patient recovery patterns that can be used in the future to analyse factors that contribute to the rehabilitation of COVID-19 patients and to predict individual patient recovery of functioning.},

abstract  = {In this paper, we present CrudeOilNews, a corpus of English Crude Oil news for event extraction. It is the first of its kind for Commodity News and serves to contribute towards resource building for economic and financial text mining. This paper describes the data collection process, the annotation methodology, and the event typology used in producing the corpus. Firstly, a seed set of 175 news articles were manually annotated, of which a subset of 25 news was used as the adjudicated reference test set for inter-annotator and system evaluation. The inter-annotator agreement was generally substantial, and annotator performance was adequate, indicating that the annotation scheme produces consistent event annotations of high quality. Subsequently, the dataset is expanded through (1) data augmentation and (2) Human-in-the-loop active learning. The resulting corpus has 425 news articles with approximately 11k events annotated. As part of the active learning process, the corpus was used to train basic event extraction models for machine labeling; the resulting models also serve as a validation or as a pilot study demonstrating the use of the corpus in machine learning purposes. The annotated corpus is made available for academic research purpose at https://github.com/meisin/CrudeOilNews-Corpus},

  address     = {Marseille, France},  
  publisher   = {European Language Resources Association},  
  pages       = {4606--4610},  
  abstract    = {We present a resource of German light verb  
constructions extracted from textual labels in graphical business  
process models. Those models depict the activities in processes in  
an organization in a semi-formal way. From a large range of sources,  
we compiled a repository of 2,301 business process models. Their  
textual labels (altogether 52,963 labels) were analyzed. This  
produced a list of 5,246 occurrences of 846 light verb  
constructions. We found that the light verb constructions that occur  
in business process models differ from light verb constructions that  
have been analyzed in other texts. Hence, we conclude that texts in  
graphical business process models represent a specific type of texts  
that is worth to be studied on its own. We think that our work is a  
step towards better automatic analysis of business process models  
because understanding the actual meaning of activity labels is a

publisher = {European Language Resources Association},

pages = {4637--4643},

abstract = {The biggest challenges we face in developing LR and

LT for Faroese is the lack of existing resources. A few resources already exist for Faroese, but many of them are either of insufficient size and quality or are not easily accessible. Therefore, the Faroese ASR project, Ravnur, set out to make a BLARK for Faroese. The BLARK is still in the making, but many of its resources have already been produced or collected. The LR status is framed by mentioning existing LR of relevant size and quality. The specific components of the BLARK are presented as well as the working principles behind the BLARK. The BLARK will be a pillar in Faroese LR, being relatively substantial in both size, quality, and diversity. It will be open-source, inviting other small languages to use it as an inspiration to create their own BLARK. We comment on the faulty yet sprouting LT situation in the Faroe Islands. The LR and LT challenges are not solved with just a BLARK. Some initiatives are therefore proposed to better the prospects of Faroese LT. The open-source principle of the project should facilitate further development.},

abstract = {A lack of datasets for spelling and grammatical error
correction in Icelandic, along with language-specific issues, has
caused a dearth of spell and grammar checking systems for the
language. We present the first open-source spell and grammar
checking tool for Icelandic, using an error corpus at all stages.
This error corpus was in part created to aid in the development of
the tool. The system is built with a rule-based tool stack
comprising a tokenizer, a morphological tagger, and a parser. For
token-level error annotation, tokenization rules, word lists, and a
trigram model are used in error detection and correction. For
sentence-level error annotation, we use specific error grammar rules
in the parser as well as regex-like patterns to search syntax trees.
The error corpus gives valuable insight into the errors typically
made when Icelandic text is written, and guided each development
phase in a test-driven manner. We assess the system's performance
with both automatic and human evaluation, using the test set in the
error corpus as a reference in the automatic evaluation. The data in
the error corpus development set proved useful in various ways for
error detection and correction.},

  abstract    = {Transcripts of teaching episodes can be effective
tools to understand discourse patterns in classroom instruction.
According to most educational experts, sustained classroom discourse
is a critical component of equitable, engaging, and rich learning
environments for students. This paper describes the TalkMoves
dataset, composed of 567 human-annotated K-12 mathematics lesson
transcripts (including entire lessons or portions of lessons)
derived from video recordings. The set of transcripts primarily
includes in-person lessons with whole-class discussions and/or small
group work, as well as some online lessons. All of the transcripts
are human-transcribed, segmented by the speaker (teacher or
student), and annotated at the sentence level for ten discursive
moves based on accountable talk theory. In addition, the transcripts
include utterance-level information in the form of dialogue act
labels based on the Switchboard Dialog Act Corpus. The dataset can
be used by educators, policymakers, and researchers to understand
the nature of teacher and student discourse in K-12 math classrooms.
Portions of this dataset have been used to develop the TalkMoves
application, which provides teachers with automated, immediate, and
actionable feedback about their mathematics instruction.},

  pages       = {4663--4673},
  abstract    = {In this paper, we approach summary evaluation from an
applied linguistics (AL) point of view. We provide computational
tools to AL researchers to simplify the process of Idea Unit (IU)
segmentation. The IU is a segmentation unit that can identify chunks
of information. These chunks can be compared across documents to
measure the content overlap between a summary and its source text.

```

We propose a full revision of the annotation guidelines to allow machine implementation. The new guideline also improves the inter-annotator agreement, rising from 0.547 to 0.785 (Cohen's Kappa). We release L2WS 2021, a IU gold standard corpus composed of 40 manually annotated student summaries. We propose IUExtract; i.e. the first automatic segmentation algorithm based on the IU. The algorithm was tested over the L2WS 2021 corpus. Our results are promising, achieving a precision of 0.789 and a recall of 0.844. We tested an existing approach to IU alignment via word embeddings with the state of the art model SBERT. The recorded precision for the top 1 aligned pair of IUs was 0.375. We deemed this result insufficient for effective automatic alignment. We propose "SAT", an online tool to facilitate the collection of alignment gold standards for future training.},

              Evaluation Conference},
  month     = {June},
  year      = {2022},
  address   = {Marseille, France},
  publisher = {European Language Resources Association},
  pages     = {4674--4683},
  abstract  = {The task of implicit reasoning generation aims to
              help machines understand arguments by inferring plausible reasonings
              (usually implicit) between argumentative texts. While this task is
              easy for humans, machines still struggle to make such inferences and
              deduce the underlying reasoning. To solve this problem, we
              hypothesize that as human reasoning is guided by innate collection
              of domain-specific knowledge, it might be beneficial to create such
              a domain-specific corpus for machines. As a starting point, we
              create the first domain-specific resource of implicit reasonings
              annotated for a wide range of arguments, which can be leveraged to
              empower machines with better implicit reasoning generation ability.
              We carefully design an annotation framework to collect them on a
              large scale through crowdsourcing and show the feasibility of
              creating a such a corpus at a reasonable cost and high-quality. Our
              experiments indicate that models trained with domain-specific
              implicit reasonings significantly outperform domain-general models
              in both automatic and human evaluations. To facilitate further
              research towards implicit reasoning generation in arguments, we
              present an in-depth analysis of our corpus and crowdsourcing
              methodology, and release our materials (i.e., crowdsourcing
              guidelines and domain-specific resource of implicit reasonings).},

pages     = {39--50},
abstract  = {This article presents the first output of the Dutch
FrameNet annotation tool, which facilitates both referential- and
frame annotations of language-independent corpora. On the
referential level, the tool links in-text mentions to structured
data, grounding the text in the real world. On the frame level,
those same mentions are annotated with respect to their semantic
sense. This way of annotating not only generates a rich linguistic
dataset that is grounded in real-world event instances, but also
guides the annotators in frame identification, resulting in high
inter-annotator-agreement and consistent annotations across
documents and at discourse level, exceeding traditional sentence
level annotations of frame elements. Moreover, the annotation tool
features a dynamic lexical lookup that increases the development of
a cross-domain FrameNet lexicon.},

abstract  = {To cope with the COVID-19 pandemic, many
jurisdictions have introduced new or altered existing legislation.
Even though these new rules are often communicated to the public in
news articles, it remains challenging for laypersons to learn about
what is currently allowed or forbidden since news articles typically
do not reference underlying laws. We investigate an automated
approach to extract legal claims from news articles and to match the
claims with their corresponding applicable laws. We examine the
feasibility of the two tasks concerning claims about COVID-19-
related laws from Berlin, Germany. For both tasks, we create and
make publicly available the data sets and report the results of
initial experiments. We obtain promising results with Transformer-
based models that achieve 46.7 F1 for claim extraction and 91.4 F1
for law matching, albeit with some conceptual limitations.

```

Furthermore, we discuss challenges of current machine learning approaches for legal language processing and their ability for complex legal reasoning tasks.},

publisher = {European Language Resources Association},
pages = {4684--4691},
abstract = {Conversational speech represents one of the most complex of automatic speech recognition (ASR) tasks owing to the high inter-speaker variation in both pronunciation and conversational dynamics. Such complexity is particularly sensitive to low-resourced (LR) scenarios. Recent developments in self-supervision have allowed such scenarios to take advantage of large amounts of otherwise unrelated data. In this study, we characterise an (LR) Austrian German conversational task. We begin with a non-pre-trained baseline and show that fine-tuning of a model pre-trained using self-supervision leads to improvements consistent with those in the literature; this extends to cases where a lexicon and language model are included. We also show that the advantage of pre-training indeed arises from the larger database rather than the self-supervision. Further, by use of a leave-one-conversation out technique, we demonstrate that robustness problems remain with respect to inter-speaker and inter-conversation variation. This serves to guide where future research might best be focused in light of the current state-of-the-art.},

abstract = {Automatic text generation based on neural language models has achieved performance levels that make the generated text almost indistinguishable from those written by humans. Despite the

value that text generation can have in various applications, it can also be employed for malicious tasks. The diffusion of such practices represent a threat to the quality of academic publishing. To address these problems, we propose in this paper two datasets comprised of artificially generated research content: a completely synthetic dataset and a partial text substitution dataset. In the first case, the content is completely generated by the GPT-2 model after a short prompt extracted from original papers. The partial or hybrid dataset is created by replacing several sentences of abstracts with sentences that are generated by the Arxiv-NLP model. We evaluate the quality of the datasets comparing the generated texts to aligned original texts using fluency metrics such as BLEU and ROUGE. The more natural the artificial texts seem, the more difficult they are to detect and the better is the benchmark. We also evaluate the difficulty of the task of distinguishing original from generated text by using state-of-the-art classification models.},

    abstract   = {HeidelTime is one of the most widespread and
successful tools for detecting temporal expressions in texts. Since
HeidelTime's pattern matching system is based on regular expression,
it can be extended in a convenient way. We present such an extension
for the German resources of HeidelTime: HeidelTimeExt. The extension
has been brought about by means of observing false negatives within
real world texts and various time banks. The gain in coverage is 2.7
\% or 8.5 \%, depending on the admitted degree of potential
overgeneralization. We describe the development of HeidelTimeExt,
its evaluation on text samples from various genres, and share some
linguistic observations. HeidelTimeExt can be obtained from https://
github.com/texttechnologylab/heideltime.},

```

```

    abstract  = {The aim of this study was to compare the
morphological complexity in a corpus representing the language
production of younger and older children across different languages.
The language samples were taken from the Frog Story subcorpus of the
CHILDES corpora, which comprises oral narratives collected by
various researchers between 1990 and 2005. We extracted narratives
by typically developing, monolingual, middle-class children.
Additionally, samples of Lithuanian language, collected according to
the same principles, were added. The corpus comprises 249 narratives
evenly distributed across eight languages: Croatian, English,
French, German, Italian, Lithuanian, Russian and Spanish. Two
subcorpora were formed for each language: a younger children corpus
and an older children corpus. Four measures of morphological
complexity were calculated for each subcorpus: Bane, Kolmogorov,
Word entropy and Relative entropy of word structure. The results
showed that younger children corpora had lower morphological

```

complexity than older children corpora for all four measures for Spanish and Russian. Reversed results were obtained for English and French, and the results for the remaining four languages showed variation. Relative entropy of word structure proved to be indicative of age differences. Word entropy and relative entropy of word structure show potential to demonstrate typological differences.},

abstract = {Field Specific Expert Scientific Writing in English as a Lingua Franca is essential for the effective research networking and dissemination worldwide. Extracting the linguistic profile of the research articles written in L2 English can help young researchers and expert scholars in various disciplines adapt to the scientific writing norms of their communities of practice. In this exploratory study, we present and test an automated linguistic assessment model that includes features relevant for the cross-disciplinary second language framework: Text Complexity Analysis features, such as Syntactic and Lexical Complexity, and Field Specific Academic Word Lists. We analyse how these features vary across four disciplinary fields (Economics, IT, Linguistics and Political Science) in a corpus of L2-English Expert Scientific Writing, part of the EXPRES corpus (Corpus of Expert Writing in Romanian and English). The variation in field specific writing is also analysed in groups of linguistic features extracted from the higher visibility (Hv) versus lower visibility (Lv) journals. After applying lexical sophistication, lexical variation and syntactic complexity formulae, significant differences between disciplines were identified, mainly that research articles from Lv journals have higher lexical complexity, but lower syntactic complexity than articles from Hv journals; while academic vocabulary proved to have discipline specific variation.},

  abstract    = {Detecting divergences in the applications of the law
(where the same legal text is applied differently by two rulings) is
an important task. It is the mission of the French Cour de
Cassation. The first step in the detection of divergences is to
detect similar cases, which is currently done manually by experts.
They rely on summarised versions of the rulings (syntheses and
keyword sequences), which are currently produced manually and are
not available for all rulings. There is also a high degree of
variability in the keyword choices and the level of granularity
used. In this article, we therefore aim to provide automatic tools
to facilitate the search for similar rulings. We do this by (i)
providing automatic keyword sequence generation models, which can be
used to improve the coverage of the analysis, and (ii) providing
measures of similarity based on the available texts and augmented
with predicted keyword sequences. Our experiments show that the
predictions improve correlations of automatically obtained
similarities against our specially collected human judgments of
similarity.},

  address   = {Marseille, France},  
  publisher = {European Language Resources Association},  
  pages     = {491--500},  
  abstract  = {Argumentation mining is a growing area of research  
and has several interesting practical applications of mining legal  
arguments. Support and Attack relations are the backbone of any  
legal argument. However, there is no publicly available dataset of  
these relations in the context of legal arguments expressed in court  
judgements. In this paper, we focus on automatically constructing  
such a dataset of Support and Attack relations between sentences in  
a court judgment with reasonable accuracy. We propose three sets of  
rules based on linguistic knowledge and distant supervision to  
identify such relations from Indian Supreme Court judgments. The  
first rule set is based on multiple discourse connectors, the second  
rule set is based on common semantic structures between  
argumentative sentences in a close neighbourhood, and the third rule  
set uses the information about the source of the argument. We also  
explore a BERT-based sentence pair classification model which is  
trained on this dataset. We release the dataset of 20506 sentence  
pairs - 10746 Support (precision 77.3\%) and 9760 Attack (precision  
65.8\%). We believe that this dataset and the ideas explored in  
designing the linguistic rules and will boost the argumentation  
mining research for legal arguments.},

publisher = {European Language Resources Association},
pages = {4808--4816},
abstract = {We present two comparable diachronic corpora of scientific English and German from the Late Modern Period (17th c.–19th c.) annotated with Universal Dependencies. We describe several steps of data pre-processing and evaluate the resulting parsing accuracy showing how our pre-processing steps significantly improve output quality. As a sanity check for the representativity of our data, we conduct a case study comparing previously gained insights

on grammatical change in the scientific genre with our data. Our results reflect the often reported trend of English scientific discourse towards heavy noun phrases and a simplification of the sentence structure (Halliday, 1988; Halliday and Martin, 1993; Biber and Gray, 2011; Biber and Gray, 2016). We also show that this trend applies to German scientific discourse as well. The presented corpora are valuable resources suitable for the contrastive analysis of syntactic diachronic change in the scientific genre between 1650 and 1900. The presented pre-processing procedures and their evaluations are applicable to other languages and can be useful for a variety of Natural Language Processing tasks such as syntactic parsing.},

  pages       = {4851--4858},
  abstract    = {Grounding the meaning of each symbol in math formulae
is important for automated understanding of scientific documents.
Generally speaking, the meanings of math symbols are not necessarily
constant, and the same symbol is used in multiple meanings.
Therefore, coreference relations between symbols need to be
identified for grounding, and the task has aspects of both
description alignment and coreference analysis. In this study, we
annotated 15 papers selected from arXiv.org with the grounding
information. In total, 12,352 occurrences of math identifiers in
these papers were annotated, and all coreference relations between
them were made explicit in each paper. The constructed dataset shows
that regardless of the ambiguity of symbols in math formulae,
coreference relations can be labeled with a high inter-annotator
agreement. The constructed dataset enables us to achieve automation
of formula grounding, and in turn, make deeper use of the knowledge
in scientific documents using techniques such as math information
extraction. The built grounding dataset is available at https://

  abstract  = {The aim of the Universal Anaphora initiative is to
push forward the state of the art in anaphora and anaphora
resolution by expanding the aspects of anaphoric interpretation
which are or can be reliably annotated in anaphoric corpora,
producing unified standards to annotate and encode these
annotations, deliver datasets encoded according to these standards,
and developing methods for evaluating models carrying out this type
of interpretation. Such expansion of the scope of anaphora
resolution requires a comparable expansion of the scope of the
scorers used to evaluate this work. In this paper, we introduce an
extended version of the Reference Coreference Scorer (Pradhan et
al., 2014) that can be used to evaluate the extended range of
anaphoric interpretation included in the current Universal Anaphora
proposal. The UA scorer supports the evaluation of identity anaphora
resolution and of bridging reference resolution, for which scorers
already existed but not integrated in a single package. It also
supports the evaluation of split antecedent anaphora and discourse
deixis, for which no tools existed. The proposed approach to the
evaluation of split antecedent anaphora is entirely novel; the
proposed approach to the evaluation of discourse deixis leverages
the encoding of discourse deixis proposed in Universal Anaphora to
enable the use for discourse deixis of the same metrics already used
for identity anaphora. The scorer was tested in the recent CODI-CRAC
2021 Shared Task on Anaphora Resolution in Dialogues.},

abstract = {Established cross-document coreference resolution (CDCR) datasets contain event-centric coreference chains of events and entities with identity relations. These datasets establish strict definitions of the coreference relations across related tests but typically ignore anaphora with more vague context-dependent loose coreference relations. In this paper, we qualitatively and quantitatively compare the annotation schemes of ECB+, a CDCR dataset with identity coreference relations, and NewsWCL50, a CDCR dataset with a mix of loose context-dependent and strict coreference relations. We propose a phrasing diversity metric (PD) that encounters for the diversity of full phrases unlike the previously proposed metrics and allows to evaluate lexical diversity of the CDCR datasets in a higher precision. The analysis shows that coreference chains of NewsWCL50 are more lexically diverse than those of ECB+ but annotating of NewsWCL50 leads to the lower inter-coder reliability. We discuss the different tasks that both CDCR datasets create for the CDCR models, i.e., lexical disambiguation and lexical diversity. Finally, to ensure generalizability of the CDCR models, we propose a direction for CDCR evaluation that combines CDCR datasets with multiple annotation schemes that focus of various properties of the coreference chains.},

abstract  = {The proliferation of fake news, i.e., news intentionally spread for misinformation, poses a threat to individuals and society. Despite various fact-checking websites such as PolitiFact, robust detection techniques are required to deal with the increase in fake news. Several deep learning models show promising results for fake news classification, however, their black-box nature makes it difficult to explain their classification decisions and quality-assure the models. We here address this problem by proposing a novel interpretable fake news detection framework based on the recently introduced Tsetlin Machine (TM). In brief, we utilize the conjunctive clauses of the TM to capture lexical and semantic properties of both true and fake news text. Further, we use clause ensembles to calculate the credibility of fake news. For evaluation, we conduct experiments on two publicly available datasets, PolitiFact and GossipCop, and demonstrate that the TM framework significantly outperforms previously published baselines by at least 5% in terms of accuracy, with the added benefit of an interpretable logic-based representation. In addition,
```

our approach provides a higher F1-score than BERT and XLNet, however, we obtain slightly lower accuracy. We finally present a case study on our model's explainability, demonstrating how it decomposes into meaningful words and their negations.},

abstract = {The introduction of word embedding models has remarkably changed many Natural Language Processing tasks. Word embeddings can automatically capture the semantics of words and other hidden features. Nonetheless, the Arabic language is highly complex, which results in the loss of important information. This paper uses Madamira, an external knowledge source, to generate additional word features. We evaluate the utility of adding these features to conventional word and character embeddings to perform the Named Entity Recognition (NER) task on Modern Standard Arabic (MSA). Our NER model is implemented using Bidirectional Long Short Term Memory and Conditional Random Fields (BiLSTM-CRF). We add morphological and syntactical features to different word embeddings to train the model. The added features improve the performance by different values depending on the used embedding model. The best performance is achieved by using Bert embeddings. Moreover, our best model outperforms the previous systems to the best of our knowledge.},

pages = {4913--4922},
abstract = {Search-Oriented Conversational AI (SCAI) is an established venue that regularly puts a spotlight upon the recent work advancing the field of conversational search. SCAI'21 was

organised as an independent online event and featured a shared task on conversational question answering, on which this paper reports. The shared task featured three subtasks that correspond to three steps in conversational question answering: question rewriting, passage retrieval, and answer generation. This report discusses each subtask, but emphasizes the answer generation subtask as it attracted the most attention from the participants and we identified evaluation of answer correctness in the conversational settings as a major challenge and a current research gap. Alongside the automatic evaluation, we conducted two crowdsourcing experiments to collect annotations for answer plausibility and faithfulness. As a result of this shared task, the original conversational QA dataset used for evaluation was further extended with alternative correct answers produced by the participant systems.},

 abstract = {The scarcity of parallel data is a major limitation
 for Neural Machine Translation (NMT) systems, in particular for
 translation into morphologically rich languages (MRLs). An important
 way to overcome the lack of parallel data is to leverage target
 monolingual data, which is typically more abundant and easier to
 collect. We evaluate a number of techniques to achieve this, ranging
 from back-translation to random token masking, on the challenging
 task of translating English into four typologically diverse MRLs,
 under low-resource settings. Additionally, we introduce Inflection
 Pre-Training (or PT-Inflect), a novel pre-training objective whereby
 the NMT system is pre-trained on the task of re-inflecting
 lemmatized target sentences before being trained on standard source-
 to-target language translation. We conduct our evaluation on four
 typologically diverse target MRLs, and find that PT-Inflect
 surpasses NMT systems trained only on parallel data. While PT-
 Inflect is outperformed by back-translation overall, combining the
 two techniques leads to gains in some of the evaluated language
 pairs.},

 pages = {4944--4954},
 abstract = {As vision processing and natural language processing
 continue to advance, there is increasing interest in multimodal
 applications, such as image retrieval, caption generation, and
 human-robot interaction. These tasks require close alignment between
 the information in the images and text. In this paper, we present a
 new multimodal dataset that combines state of the art semantic
 annotation for language with the bounding boxes of corresponding
 images. This richer multimodal labeling supports cross-modal
 inference for applications in which such alignment is useful. Our
 semantic representations, developed in the natural language
 processing community, abstract away from the surface structure of
 the sentence, focusing on specific actions and the roles of their
 participants, a level that is equally relevant to images. We then

utilize these representations in the form of semantic role labels in the captions and the images and demonstrate improvements in standard tasks such as image retrieval. The potential contributions of these additional labels is evaluated using a role-aware retrieval system based on graph convolutional and recurrent neural networks. The addition of semantic roles into this system provides a significant increase in capability and greater flexibility for these tasks, and could be extended to state-of-the-art techniques relying on transformers with larger amounts of annotated data.},

abstract = {This article presents a new French Sign Language (LSF) corpus called "Rosetta-LSF". It was created to support future studies on the automatic translation of written French into LSF, rendered through the animation of a virtual signer. An overview of the field highlights the importance of a quality representation of LSF. In order to obtain quality animations understandable by signers, it must surpass the simple "gloss transcription" of the LSF lexical units to use in the discourse. To achieve this, we designed a corpus composed of four types of aligned data, and evaluated its usability. These are: news headlines in French, translations of these headlines into LSF in the form of videos showing animations of a virtual signer, gloss annotations of the "traditional" type---although including additional information on the context in which each gestural unit is performed as well as their potential for adaptation to another context---and AZee representations of the videos, i.e. formal expressions capturing the necessary and sufficient linguistic information. This article describes this data, exhibiting an example from the corpus. It is available online for public research.},

pages = {4975--4983},
abstract = {Korean is a language with complex morphology that
uses spaces at larger-than-word boundaries, unlike other East-Asian
languages. While morpheme-based text generation can provide
significant semantic advantages compared to commonly used character-
level approaches, Korean morphological analyzers only provide a
sequence of morpheme-level tokens, losing information in the
tokenization process. Two crucial issues are the loss of spacing
information and subcharacter level morpheme normalization, both of
which make the tokenization result challenging to reconstruct the
original input string, deterring the application to generative
tasks. As this problem originates from the conventional scheme used
when creating a POS tagging corpus, we propose an improvement to the
existing scheme, which makes it friendlier to generative tasks. On
top of that, we suggest a fully-automatic annotation of a corpus by
leveraging public analyzers. We vote the surface and POS from the
outcome and fill the sequence with the selected morphemes, yielding
tokenization with a decent quality that incorporates space
information. Our scheme is verified via an evaluation done on an
external corpus, and subsequently, it is adapted to Korean Wikipedia
to construct an open, permissive resource. We compare morphological
analyzer performance trained on our corpus with existing methods,
then perform an extrinsic evaluation on a downstream task.},

  pages       = {5047--5053},
  abstract    = {We present three new corpora of urban varieties of
Portuguese spoken in Angola, Mozambique, and São Tomé and Príncipe,
where Portuguese is increasingly being spoken as first and second
language in different multilingual settings. Given the scarcity of
linguistic resources available for the African varieties of
Portuguese, these corpora provide new, contemporary data for the
study of each variety and for comparative research on African,
Brazilian and European varieties, hereby improving our understanding
of processes of language variation and change in postcolonial
societies. The corpora consist of transcribed spoken data,
complemented by a rich set of metadata describing the setting of the
audio recordings and sociolinguistic information about the speakers.
They are annotated with POS and lemma information and made available
on the CQPweb platform, which allows for sophisticated data
searches. The corpora are already being used for comparative
research on constructions in the domain of possession and location
involving the argument structure of intransitive, monotransitive and
ditransitive verbs that select Goals, Locatives, and Recipients.},

  pages     = {515--523},  
  abstract  = {In this paper, we present a new corpus of clickbait  
articles annotated by university students along with a corresponding  
shared task: clickbait articles use a headline or teaser that hides  
information from the reader to make them curious to open the  
article. We therefore propose to construct approaches that can  
automatically extract the relevant information from such an article,  
which we call clickbait resolving. We show why solving this task  
might be relevant for end users, and why clickbait can probably not  
be defeated with clickbait detection alone. Additionally, we argue  
that this task, although similar to question answering and some  
automatic summarization approaches, needs to be tackled with  
specialized models. We analyze the performance of some basic  
approaches on this task and show that models fine-tuned on our data  
can outperform general question answering models, while providing a  
systematic approach to evaluate the results. We hope that the data  
set and the task will help in giving users tools to counter  
clickbait in the future.},

  pages     = {5054--5062},  
  abstract  = {This study aims to create the very first dependency-  
to-constituency conversion algorithm optimised for Turkish language.  
For this purpose, a state-of-the-art morphologic analyser and a  
feature-based machine learning model was used. In order to enhance  
the performance of the conversion algorithm, bootstrap aggregating  
meta-algorithm was integrated. While creating the conversation  
algorithm, typological properties of Turkish were carefully  
considered. A comprehensive and manually annotated UD-style  
dependency treebank was the input, and constituency trees were the
```

output of the conversion algorithm. A team of linguists manually annotated a set of constituency trees. These manually annotated trees were used as the gold standard to assess the performance of the algorithm. The conversion process yielded more than 8000 constituency trees whose UD-style dependency trees are also available on GitHub. In addition to its contribution to Turkish treebank resources, this study also offers a viable and easy-to-implement conversion algorithm that can be used to generate new constituency treebanks and training data for NLP resources like constituency parsers.},

abstract = {In Switzerland, two thirds of the population speak Swiss German, a primarily spoken language with no standardised written form. It is widely used on Swiss TV, for example in news reports, interviews or talk shows, and subtitles are required for people who cannot understand this spoken language. This paper focuses on the task of automatic Standard German subtitling of spoken Swiss German, and more specifically on the translation of a normalised Swiss German speech recognition result into Standard German suitable for subtitles. Our contribution consists of a comparison of different statistical and deep learning MT systems for this task and an aligned corpus of normalised Swiss German and Standard German subtitles. Results of two evaluations, automatic and human, show that the systems succeed in improving the content, but are currently not capable of producing entirely correct Standard German.},

```
abstract = {Although Automatic Speech Recognition (ASR) systems have achieved human-like performance for a few languages, the majority of the world's languages do not have usable systems due to the lack of large speech datasets to train these models. Cross-lingual transfer is an attractive solution to this problem, because low-resource languages can potentially benefit from higher-resource languages either through transfer learning, or being jointly trained in the same multilingual model. The problem of cross-lingual transfer has been well studied in ASR, however, recent advances in Self Supervised Learning are opening up avenues for unlabeled speech data to be used in multilingual ASR models, which can pave the way for improved performance on low-resource languages. In this paper, we survey the state of the art in multilingual ASR models that are built with cross-lingual transfer in mind. We present best practices for building multilingual models from research across diverse languages and techniques, discuss open questions and provide recommendations for future work.},

abstract  = {Pre-trained Language Models such as BERT have become ubiquitous in NLP where they have achieved state-of-the-art performance in most NLP tasks. While these models are readily available for English and other widely spoken languages, they remain scarce for low-resource languages such as Luxembourgish. In this paper, we present LuxemBERT, a BERT model for the Luxembourgish language that we create using the following approach: we augment the pre-training dataset by considering text data from a closely related language that we partially translate using a simple and straightforward method. We are then able to produce the LuxemBERT model, which we show to be effective for various NLP tasks: it outperforms a simple baseline built with the available Luxembourgish text data as well the multilingual mBERT model, which is currently the only option for transformer-based language models in Luxembourgish. Furthermore, we present datasets for various downstream NLP tasks that we created for this study and will make available to researchers on request.},

  abstract  = {In this paper we introduce PerPaDa, a Persian  
paraphrase dataset that is collected from users' input in a  
plagiarism detection system. As an implicit crowdsourcing  
experience, we have gathered a large collection of original and  
paraphrased sentences from Hamtajoo; a Persian plagiarism detection  
system, in which users try to conceal cases of text re-use in their  
documents by paraphrasing and re-submitting manuscripts for  
analysis. The compiled dataset contains 2446 instances of  
paraphrasing. In order to improve the overall quality of the  
collected data, some heuristics have been used to exclude sentences  
that don't meet the proposed criteria. The introduced corpus is much  
larger than the available datasets for the task of paraphrase  
identification in Persian. Moreover, there is less bias in the data  
compared to the similar datasets, since the users did not try some  
fixed predefined rules in order to generate similar texts to their  
original inputs.},

pages = {5107--5113},
abstract = {Speech Recognition is an active research area where advances of technology have continuously driven the development of research work. However, due to the lack of adequate resources, certain languages such as Sinhala, are left to underutilize the technology. With techniques such as crowdsourcing and web scraping, several Sinhala corpora have been created and made publicly available. Despite them being large and generic, the correctness and consistency in their text data remain questionable, especially due to the lack of uniformity in the language used in the different sources of web scraped text. Addressing that requires a thorough understanding of technical and linguistic particulars pertaining to the language, which often leaves the issue unattended. We have followed a systematic approach to derive a refined corpus using a publicly available corpus for Sinhala speech recognition. In particular, we standardized the transcriptions of the corpus by removing noise in the text. Further, we applied corrections based on Sinhala linguistics. A comparative experiment shows a promising effect of the linguistic corrections by having a relative reduction of the Word-Error-Rate by 15.9\%.},

abstract = {Social media platforms and online streaming services have spawned a new breed of Hate Speech (HS). Due to the massive amount of user-generated content on these sites, modern machine learning techniques are found to be feasible and cost-effective to tackle this problem. However, linguistically diverse datasets covering different social contexts in which offensive language is typically used are required to train generalizable models. In this paper, we identify the shortcomings of existing Bangla HS datasets and introduce a large manually labeled dataset BD-SHS that includes HS in different social contexts. The labeling criteria were prepared following a hierarchical annotation process, which is the first of its kind in Bangla HS to the best of our knowledge. The dataset includes more than 50,200 offensive comments crawled from online social networking sites and is at least 60\% larger than any existing Bangla HS datasets. We present the benchmark result of our dataset by training different NLP models resulting in the best one achieving an F1-score of 91.0%. In our experiments, we found that a word embedding trained exclusively using 1.47 million comments from social media and streaming sites consistently resulted in better modeling of HS detection in comparison to other pre-trained embeddings. Our dataset and all accompanying codes is publicly available at github.com/naurosromim/hate-speech-dataset-for-Bengali-social-media},

  abstract  = {Modeling thematic fit (a verb-argument compositional semantics task) currently requires a very large burden of labeled data. We take a linguistically machine-annotated large corpus and replace corpus layers with output from higher-quality, more modern taggers. We compare the old and new corpus versions' impact on a verb-argument fit modeling task, using a high-performing neural approach. We discover that higher annotation quality dramatically reduces our data requirement while demonstrating better supervised predicate-argument classification. But in applying the model to psycholinguistic tasks outside the training objective, we see clear gains at scale, but only in one of two thematic fit estimation
```

tasks, and no clear gains on the other. We also see that quality improves with training size, but perhaps plateauing or even declining in one task. Last, we tested the effect of role set size. All this suggests that the quality/quantity interplay is not all you need. We replicate previous studies while modifying certain role representation details and set a new state-of-the-art in event modeling, using a fraction of the data. We make the new corpus version public.},

publisher = {European Language Resources Association},
pages = {5198--5205},
abstract = {Language acquisition research has benefitted from the use of annotated corpora of child-directed speech to examine key questions about how children learn and process language in real-world contexts. However, a lack of sense-annotated corpora has limited investigations of child word sense disambiguation in naturalistic contexts. In this work, we sense-tagged 53 corpora of American and English speech directed to 958 target children up to 59 months of age, comprising a large-scale sample of 15,581 utterances for 12 ambiguous words. Importantly, we carefully selected target senses that we know – from previous investigations – young children understand. As such work was part of a project focused on investigating the role of verbs in child word sense disambiguation, we additionally coded for verb instances which took a target ambiguous word as verb object. We present experimental work where we leveraged our sense-tagged corpus ChiSense-12 to examine the role of verb-event structure in child word sense disambiguation, and we outline our plan to use Transformer-based computational architectures to test hypotheses on the role of different learning mechanisms underlying children word sense disambiguation performance.},

abstract    = {Proper recognition and interpretation of negation
signals in text or communication is crucial for any form of full
natural language understanding. It is also essential for
computational approaches to natural language processing. In this
study we focus on negation detection in Dutch spoken human-computer
conversations. Since there exists no Dutch (dialogue) corpus
annotated for negation we have annotated a Dutch corpus sample to
evaluate our method for automatic negation detection. We use
transfer learning and trained NegBERT (an existing BERT
implementation used for negation detection) on English data with
multilingual BERT to detect negation in Dutch dialogues. Our results
show that adding in-domain training material improves the results.
We show that we can detect both negation cues and scope in Dutch
dialogues with high precision and recall. We provide a detailed
error analysis and discuss the effects of cross-lingual and cross-
domain transfer learning on automatic negation detection.},

abstract    = {COSMOS is a multidisciplinary research project
investigating schoolchildren's beliefs and representations of
specific concepts under control variables (age, gender, language
spoken at home). Seven concepts are studied: {\it friend, father,
mother, villain, work, television} and {\it dog}. We first present
the protocol used and the data collected from a survey of 184
children in two age groups (6-7 and 9-11 years) in four schools in
Brittany (France). A word-level lexical study shows that children's
linguistic proficiency and lexical diversity increase with age, and
we observe an interaction effect between gender and age on lexical
diversity as measured with MLR (Measure of Lexical Richness). In
contrast, none of the control variables affects lexical density. We
also present the lemmas that schoolchildren most often associate
with each concept. Generalized linear mixed-effects models reveal
significant effects of age, gender, and home language on some
concept-lemma associations and specific interactions between age and
gender. Most of the identified effects are documented in the child
development literature. To better understand the process of semantic
construction in children, additional lexical analyses at the n-gram,
chunk, and clause levels would be helpful. We briefly present
ongoing and planned work in this direction. The COSMOS data will
soon be made freely available to the scientific community.},

abstract  = {Research on metaphorical language has shown ties
between abstractness and emotionality with regard to metaphoricity;
prior work is however limited to the word and sentence levels, and
up to date there is no empirical study establishing the extent to
which this is also true on the discourse level. This paper explores
which textual and perceptual features human annotators perceive as
important for the metaphoricity of discourses and expressions, and
addresses two research questions more specifically. First, is a
metaphorically-perceived discourse more abstract and more emotional
in comparison to a literally-perceived discourse? Second, is a
metaphorical expression preceded by a more metaphorical/abstract/
emotional context than a synonymous literal alternative? We used a
dataset of 1,000 corpus-extracted discourses for which crowdsourced
annotators (1) provided judgements on whether they perceived the
discourses as more metaphorical or more literal, and (2)
```

systematically listed lexical terms which triggered their decisions in (1). Our results indicate that metaphorical discourses are more emotional and to a certain extent more abstract than literal discourses. However, neither the metaphoricity nor the abstractness and emotionality of the preceding discourse seem to play a role in triggering the choice between synonymous metaphorical vs. literal expressions. publisher = {European Language Resources Association},
pages = {5274--5285},
abstract = {Movies reflect society and also hold power to transform opinions. Social biases and stereotypes present in movies can cause extensive damage due to their reach. These biases are not always found to be the need of storyline but can creep in as the author's bias. Movie production houses would prefer to ascertain that the bias present in a script is the story's demand. Today, when deep learning models can give human-level accuracy in multiple tasks, having an AI solution to identify the biases present in the script at the writing stage can help them avoid the inconvenience of stalled release, lawsuits, etc. Since AI solutions are data intensive and there exists no domain specific data to address the problem of biases in scripts, we introduce a new dataset of movie scripts that are annotated for identity bias. The dataset contains dialogue turns annotated for (i) bias labels for seven categories, viz., gender, race/ethnicity, religion, age, occupation, LGBTQ, and other, which contains biases like body shaming, personality bias, etc. (ii) labels for sensitivity, stereotype, sentiment, emotion, emotion intensity, (iii) all labels annotated with context awareness, (iv) target groups and reason for bias labels and (v) expert-driven group-validation process for high quality annotations. We also report various baseline performances for bias identification and category detection on our dataset.},

abstract       = {Cross-linguistic phonetic analysis has long been
limited by data scarcity and insufficient computational resources.
In the past few years, the availability of large-scale cross-
linguistic spoken corpora has increased dramatically, but the data
still require considerable computational power and processing for
downstream phonetic analysis. To facilitate large-scale cross-
linguistic phonetic research in the field, we release the
VoxCommunis Corpus, which contains acoustic models, pronunciation
lexicons, and word- and phone-level alignments, derived from the
publicly available Mozilla Common Voice Corpus. The current release
includes data from 36 languages. The corpus also contains acoustic-
phonetic measurements, which currently consist of formant
frequencies (F1--F4) from all vowel quartiles. Major advantages of
this corpus for phonetic analysis include the number of available
languages, the large amount of speech per language, as well as the
fact that most language datasets have dozens to hundreds of
contributing speakers. We demonstrate the utility of this corpus for
downstream phonetic research in a descriptive analysis of language-
specific vowel systems, as well as an analysis of "uniformity" in
vowel realization across languages. The VoxCommunis Corpus is free
to download and use under a CC0 license.},

abstract = {This paper presents a new historical language resource, a corpus of Estonian Parish Court records from the years 1821–1920, annotated for named entities (NE), and reports on named entity recognition (NER) experiments using this corpus. The handwritten records have been transcribed manually via a crowdsourcing project, so the transcripts are of high quality, but the variation of language and spelling is high in these documents due to dialectal variation and the fact that there was a considerable change in Estonian spelling conventions during the time of their writing. The typology of NEs for manual annotation includes 7 categories, but the inter-annotator agreement is as good as 95.0 (mean F1-score). We experimented with fine-tuning BERT-like transfer learning approaches for NER, and found modern Estonian BERT models highly applicable, despite the difficulty of the historical material. Our best model, finetuned Est-RoBERTa, achieved microaverage F1 score of 93.6, which is comparable to state-of-the-art NER performance on the contemporary Estonian.},

abstract = {The Linguistic Data Consortium was founded in 1992 to solve the problem that limitations in access to shareable data was impeding progress in Human Language Technology research and development. At the time, DARPA had adopted the common task research management paradigm to impose additional rigor on their programs by also providing shared objectives, data and evaluation methods. Early successes underscored the promise of this paradigm but also the need for a standing infrastructure to host and distribute the shared data. During LDC's initial five year grant, it became clear that the demand for linguistic data could not easily be met by the existing providers and that a dedicated data center could add capacity first for data collection and shortly thereafter for annotation. The expanding purview required expansions of LDC's technical infrastructure including systems support and software development. An open question for the center would be its role in other kinds of research beyond data development. Over its 30 years history, LDC has performed multiple roles ranging from neutral, independent data provider to multisite programs, to creator of exploratory data in tight collaboration with system developers, to research group focused on data intensive investigations.},

  abstract  = {In this paper, we describe version 2.0 of the SLäNDa  
corpus. SLäNDa, the Swedish Literary corpus of Narrative and  
Dialogue, now contains excerpts from 19 novels, written between  
1809--1940. The main focus of the SLäNDa corpus is to distinguish  
between direct speech and the main narrative. In order to isolate  
the narrative, we also annotate everything else which does not  
belong to the narrative, such as thoughts, quotations, and letters.  
SLäNDa version 2.0 has a slightly updated annotation scheme from  
version 1.0. In addition, we added new texts from eleven authors and  
performed quality control on the previous version. We are  
specifically interested in different ways of marking speech  
segments, such as quotation marks, dashes, or no marking at all. To  
allow a detailed evaluation of this aspect, we added dedicated test  
sets to SLäNDa for these different types of speech marking. In a  
pilot experiment, we explore the impact of typographic speech  
marking by using these test sets, as well as artificially stripping  
the training data of speech markers.},

publisher = {European Language Resources Association},
pages = {5345--5355},
abstract = {We present the steps taken towards an exploration platform for a multi-modal corpus of German lyric poetry from the Romantic era developed in the project »textklang«. This interdisciplinary project develops a mixed-methods approach for the systematic investigation of the relationship between written text (here lyric poetry) and its potential and actual sonic realisation (in recitations, musical performances etc.). The multi-modal »textklang« platform will be designed to technically and analytically combine three modalities: the poetic text, the audio signal of a recorded recitation and, at a later stage, music scores of a musical setting of a poem. The methodological workflow will enable scholars to develop hypotheses about the relationship between textual form and sonic/prosodic realisation based on theoretical considerations, text interpretation and evidence from recorded recitations. The full workflow will support hypothesis testing either through systematic corpus analysis alone or with additional contrastive perception experiments. For the experimental track, researchers will be enabled to manipulate prosodic parameters in (re-)synthesised variants of the original recordings. The focus of this paper is on the design of the base corpus and on tools for systematic exploration – placing special emphasis on our response to challenges stemming from multi-modality and the methodologically diverse interdisciplinary setup.},

title = {MS-LaTTE: A Dataset of Where and When To-do Tasks are Completed},
booktitle = {Proceedings of the Language Resources and Evaluation Conference},
month = {June},
year = {2022},
address = {Marseille, France},

```

publisher      = {European Language Resources Association},
pages         = {5393--5403},
abstract      = {Tasks are a fundamental unit of work in the daily
lives of people, who are increasingly using digital means to keep
track of, organize, triage, and act on them. These digital tools --
such as task management applications -- provide a unique opportunity
to study and understand tasks and their connection to the real
world, and through intelligent assistance, help people be more
productive. By logging signals such as text, timestamp information,
and social connectivity graphs, an increasingly rich and detailed
picture of how tasks are created and organized, what makes them
important, and who acts on them, can be progressively developed. Yet
the context around actual task completion remains fuzzy, due to the
basic disconnect between actions taken in the real world and
telemetry recorded in the digital world. Thus, in this paper we
compile and release a novel, real-life, large-scale dataset called
MS-LaTTE that captures two core aspects of the context surrounding
task completion: location and time. We describe our annotation
framework and conduct a number of analyses on the data that were
collected, demonstrating that it captures intuitive contextual
properties for common tasks. Finally, we test the dataset on the two
problems of predicting spatial and temporal task co-occurrence,
concluding that predictors for co-location and co-time are both
learnable, with a BERT fine-tuned model outperforming several other
baselines. The MS-LaTTE dataset provides an opportunity to tackle
many new modeling challenges in contextual task understanding and we
hope that its release will spur future research in task intelligence
more broadly.},

abstract    = {We present an expanded version of our previously
released Kazakh text-to-speech (KazakhTTS) synthesis corpus. In the
new KazakhTTS2 corpus, the overall size has increased from 93 hours
to 271 hours, the number of speakers has risen from two to five
(three females and two males), and the topic coverage has been
diversified with the help of new sources, including a book and
Wikipedia articles. This corpus is necessary for building high-
quality TTS systems for Kazakh, a Central Asian agglutinative
language from the Turkic family, which presents several linguistic
challenges. We describe the corpus construction process and provide
the details of the training and evaluation procedures for the TTS

```

system. Our experimental results indicate that the constructed corpus is sufficient to build robust TTS models for real-world applications, with a subjective mean opinion score ranging from 3.6 to 4.2 for all the five speakers. We believe that our corpus will facilitate speech and language research for Kazakh and other Turkic languages, which are widely considered to be low-resource due to the limited availability of free linguistic data. The constructed corpus, code, and pretrained models are publicly available in our GitHub repository.},

  abstract = {The need for manual review of various financial texts, such as company filings and news, presents a major bottleneck in financial analysts' work. Thus, there is great potential for the application of NLP methods, tools and resources to fulfil a genuine industrial need in finance. In this paper, we show how this potential can be fulfilled by presenting an end-to-end, fully unsupervised method for knowledge discovery from financial texts. Our method creatively integrates existing resources to construct automatically a knowledge graph of companies and related entities as well as to carry out unsupervised analysis of the resulting graph to provide quantifiable and explainable insights from the produced knowledge. The graph construction integrates entity processing and semantic expansion, before carrying out open relation extraction. We illustrate our method by calculating automatically the environmental rating for companies in the S&P 500, based on company filings with the SEC (Securities and Exchange Commission). We then show the usefulness of our method in this setting by providing an assessment of our method's outputs with an independent MSCI source.},

abstract    = {This article highlights ELRA's latest achievements in
the field of Language Resources (LRs) identification, sharing and
production. It also reports on ELRA's involvement in several
national and international projects, as well as in the organization
of events for the support of LRs and related Language Technologies,
including for under-resourced languages. Over the past few years,
ELRA, together with its operational agency ELDA, has continued to
increase its catalogue offer of LRs, establishing worldwide
partnerships for the production of various types of LRs (SMS,
tweets, crawled data, MT aligned data, speech LRs, sentiment-based
data, etc.). Through their consistent involvement in EU-funded
projects, ELRA and ELDA have contributed to improve the access to
multilingual information in the context of the pandemic, develop
tools for the de-identification of texts in the legal and medical
domains, support the EU eTranslation Machine Translation system, and
set up a European platform providing access to both resources and
services. In December 2019, ELRA co-organized the LT4All conference,
whose main topics were Language Technologies for enabling linguistic
diversity and multilingualism worldwide. Moreover, although LREC was
cancelled in 2020, ELRA published the LREC 2020 proceedings for the
Main conference and Workshops papers, and carried on its
dissemination activities while targeting the new LREC edition for
2022.},

abstract   = {The number of depression and suicide risk cases on
social media platforms is ever-increasing, and the lack of
depression detection mechanisms on these platforms is becoming
increasingly apparent. A majority of work in this area has focused
on leveraging linguistic features while dealing with small-scale
datasets. However, one faces many obstacles when factoring into
account the vastness and inherent imbalance of social media content.
In this paper, we aim to optimize the performance of user-level
depression classification to lessen the burden on computational
resources. The resulting system executes in a quicker, more
efficient manner, in turn making it suitable for deployment. To
simulate a platform agnostic framework, we simultaneously replicate
```

the size and composition of social media to identify victims of depression. We systematically design a solution that categorizes post embeddings, obtained by fine-tuning transformer models such as RoBERTa, and derives user-level representations using hierarchical attention networks. We also introduce a novel mental health dataset to enhance the performance of depression categorization. We leverage accounts of depression taken from this dataset to infuse domain-specific elements into our framework. Our proposed methods outperform numerous baselines across standard metrics for the task of depression detection in text.},

```
pages      = {5436--5443},
abstract   = {With the growing access to the internet, the spoken
Arabic dialect language becomes informal languages written in social
media. Most users post comments using their own dialect. This
linguistic situation inhibits mutual understanding between internet
users and makes difficult to use computational approaches since most
Arabic resources are intended for the formal language: Modern
Standard Arabic (MSA). In this paper, we present a pipeline to
standardize the written texts in social networks by translating them
to the standard language MSA. We fine-tun at first an identification
bert-based model to select Tunisian Dialect (TD) from MSA and other
dialects. Then, we learned transformer model to translate TD to MSA.
The final system includes the translated TD text and the originally
text written in MSA. Each of these steps was evaluated on the same
test corpus. In order to test the effectiveness of the approach, we
compared two opinion analysis models, the first intended for the
Sentiment Analysis (SA) of dialect texts and the second for the MSA
texts. We concluded that through standardization we obtain the best
score.},

  abstract       = {This research has focused on evaluating the existing
open-source morphological analyzers for two of the most widely
spoken indigenous macrolanguages in South America, namely Quechua
and Aymara. Firstly, we have evaluated their performance (precision,
recall and F1 score) for the individual languages for which they
were developed (Cuzco Quechua and Aymara). Secondly, in order to
assess how these tools handle other individual languages of the
macrolanguage, we have extracted some sample text from school
textbooks and educational resources. This sample text was edited in
the different countries where these macrolanguages are spoken
(Colombia, Ecuador, Peru, Bolivia, Chile and Argentina for Quechua;
and Bolivia, Peru and Chile for Aymara), and it includes their
different standardized forms (10 individual languages of Quechua and
3 of Aymara). Processing this text by means of the tools, we have
(i) calculated their coverage (number of words recognized and
analyzed) and (ii) studied in detail the cases for which each tool
was unable to generate any output. Finally, we discuss different
ways in which these tools could be optimized, either to improve
their performances or, in the specific case of Quechua, to cover
more individual languages of this macrolanguage in future works as
well.},

  abstract      = {Over the past decade, researchers have started to
explore the use of NLP to develop tools aimed at helping the public,
vendors, and regulators analyze disclosures made in privacy
policies. With the introduction of new privacy regulations, the
language of privacy policies is also evolving, and disclosures made
by the same organization are not always the same in different

```

languages, especially when used to communicate with users who fall under different jurisdictions. This work explores the use of language technologies to capture and analyze these differences at scale. We introduce an annotation scheme designed to capture the nuances of two new landmark privacy regulations, namely the EU's GDPR and California's CCPA/CPRA. We then introduce the first bilingual corpus of mobile app privacy policies consisting of 64 privacy policies in English (292K words) and 91 privacy policies in German (478K words), respectively with manual annotations for 8K and 19K fine-grained data practices. The annotations are used to develop computational methods that can automatically extract "disclosures" from privacy policies. Analysis of a subset of 59 "semi-parallel" policies reveals differences that can be attributed to different regulatory regimes, suggesting that systematic analysis of policies using automated language technologies is indeed a worthwhile endeavor.},

  abstract  = {This paper motivates and presents the Twitter
Deliberative Politics dataset, a corpus of political tweets labeled
for its deliberative characteristics. The corpus was randomly
sampled from replies to US congressmen and women. It is expected to
be useful to a general community of computational linguists,
political scientists, and social scientists interested in the study
of online political expression, computer-mediated communication, and
political deliberation. The data sampling and annotation methods are
discussed and classical machine learning approaches are evaluated
for their predictive performance on the different deliberative
facets. The paper concludes with a discussion of future work aimed
at developing dictionaries for the quality assessment of online
political talk in English. The dataset and a demo dashboard are
available at https://github.com/kj2013/twitter-deliberative-
politics.},

  pages     = {559--563},
  abstract  = {Ethical issues in Language Resources and Language
Technology are often invoked, but rarely discussed. This is at least
partly because little work has been done to systematize ethical
issues and principles applicable in the fields of Language Resources
and Language Technology. This paper provides an overview of ethical
issues that arise at different stages of Language Resources and
Language Technology development, from the conception phase through
the construction phase to the use phase. Based on this overview, the
authors propose a tentative taxonomy of ethical issues in Language
```

Resources and Language Technology, built around five principles: Privacy, Property, Equality, Transparency and Freedom. The authors hope that this tentative taxonomy will facilitate ethical assessment of projects in the field of Language Resources and Language Technology, and structure the discussion on ethical issues in this domain, which may eventually lead to the adoption of a universally accepted Code of Ethics of the Language Resources and Language Technology community.},

month = {June},
year = {2022},
address = {Marseille, France},
publisher = {European Language Resources Association},
pages = {5511--5516},
abstract = {This paper describes the Bilinguals in the Midwest (BILinMID) Corpus, a comparable text corpus of the Spanish and English spoken in the US Midwest by various types of bilinguals. Unlike other areas within the US where language contact has been widely documented (e.g., the Southwest), Spanish-English bilingualism in the Midwest has been understudied despite an increase in its Hispanic population. The BILinMID Corpus contains short stories narrated in Spanish and in English by 72 speakers representing different types of bilinguals: early simultaneous bilinguals, early sequential bilinguals, and late second language learners. All stories have been transcribed and annotated using various natural language processing tools. Additionally, a user interface has also been created to facilitate searching for specific patterns in the corpus as well as to filter out results according to specified criteria. Guidelines and procedures followed to create the corpus and the user interface are described in detail in the paper. The corpus is fully available online and it might be particularly interesting for researchers working on language variation and contact.},

publisher    = {European Language Resources Association},
pages       = {5517--5524},
abstract     = {Document authoring involves a lengthy revision
process, marked by individual edits that are frequently linked to
comments. Modeling the relationship between edits and comments leads
to a better understanding of document evolution, potentially
benefiting applications such as content summarization, and task
triaging. Prior work on understanding revisions has primarily
focused on classifying edit intents, but falling short of a deeper
understanding of the nature of these edits. In this paper, we
present explore the challenge of describing an edit at two levels:
identifying the edit intent, and describing the edit using free-form
text. We begin by defining a taxonomy of general edit intents and
introduce a new dataset of full revision histories of Wikipedia
pages, annotated with each revision's edit intent. Using this
dataset, we train a classifier that achieves a 90\% accuracy in
identifying edit intent. We use this classifier to train a
distantly-supervised model that generates a high-level description
of a revision in free-form text. Our experimental results show that
incorporating edit intent information aids in generating better edit
descriptions. We establish a set of baselines for the edit
description task, achieving a best score of 28 ROUGE, thus
demonstrating the effectiveness of our layered approach to edit
understanding.},

pages = {5539--5547},
abstract = {Peer feedback in online education becomes increasingly important to meet the demand for feedback in large scale classes, such as e.g. Massive Open Online Courses (MOOCs). However, students are often not experts in how to write helpful feedback to their fellow students. In this paper, we introduce a corpus compiled from university students' peer feedback to be able to detect suggestions on how to improve the students' work and therefore being able to capture peer feedback helpfulness. To the best of our knowledge, this corpus is the first student peer feedback corpus in German which additionally was labelled with a new annotation scheme. The corpus consists of more than 600 written feedback (about 7,500 sentences). The utilisation of the corpus is broadly ranged from Dependency Parsing to Sentiment Analysis to Suggestion Mining, etc. We applied the latter to empirically validate the utility of the new corpus. Suggestion Mining is the extraction of sentences that contain suggestions from unstructured text. In this paper, we present a new annotation scheme to label sentences for Suggestion Mining. Two independent annotators labelled the corpus and achieved an inter-annotator agreement of 0.71. With the help of an expert arbitrator a gold standard was created. An automatic classification using BERT achieved an accuracy of 75.3\%.},

abstract    = {Anonymisation, that is identifying and neutralising
sensitive references, is a crucial part of dataset creation. In this
paper, we describe the anonymisation process of a Turkish-German
code-switching corpus, namely SAGT, which consists of speech data
and a treebank that is built on its transcripts. We employed a
selective pseudonymisation approach where we manually identified
sensitive references to anonymise and replaced them with surrogate
values on the treebank side. In addition to maintaining data
privacy, our primary concerns in surrogate selection were keeping
the integrity of code-switching properties, morphosyntactic
annotation layers, and semantics. After the treebank anonymisation,
we anonymised the speech data by mapping between the treebank
sentences and audio transcripts with the help of Praat scripts. The
treebank is publicly available for research purposes and the audio
files can be obtained via an individual licence agreement.},

abstract   = {We have constructed the Corpus of Everyday Japanese
Conversation (CEJC) and published it in March 2022. The CEJC is
designed to contain various kinds of everyday conversations in a
balanced manner to capture their diversity. The CEJC features not
only audio but also video data to facilitate precise understanding
of the mechanism of real-life social behavior. The publication of a
large-scale corpus of everyday conversations that includes video
data is a new approach. The CEJC contains 200 hours of speech, 577
conversations, about 2.4 million words, and a total of 1675
conversants. In this paper, we present an overview of the corpus,
including the recording method and devices, structure of the corpus,
formats of video and audio files, transcription, and annotations. We
then report some results of the evaluation of the CEJC in terms of
conversant and conversation attributes. We show that the CEJC
includes a good balance of adult conversants in terms of gender and
age, as well as a variety of conversations in terms of conversation
forms, places, activities, and numbers of conversants.},

  abstract  = {We present The Central Word Register for Danish  
(COR), which is an open source lexicon project for general AI  
purposes funded and initiated by the Danish Agency for Digitisation  
as part of an AI initiative embarked by the Danish Government in  
2020. We focus here on the lexical semantic part of the project  
(COR-S) and describe how we – based on the existing fine-grained  
sense inventory from Den Danske Ordbog (DDO) – compile a more AI  
suitable sense granularity level of the vocabulary. A three-step  
methodology is applied: We establish a set of linguistic principles  
for defining core senses in COR-S and from there, we generate a  
hand-crafted gold standard of 6,000 lemmas depicting how to come  
from the fine-grained DDO sense to the COR inventory. Finally, we  
experiment with a number of language models in order to automatize  
the sense reduction of the rest of the lexicon. The models comprise  
a ruled-based model that applies our linguistic principles in terms  
of features, a word2vec model using cosine similarity to measure the  
sense proximity, and finally a deep neural BERT model fine-tuned on  
our annotations. The rule-based approach shows best results, in  
particular on adjectives, however, when focusing on the average  
polysemous vocabulary, the BERT model shows promising results too.},

abstract      = {The grammatical framework for the mapping between
linguistic form and meaning representation known as Universal
Dependencies relies on a non-constituency syntactic analysis that is
centered on the notion of grammatical relation (e.g. Subject,
Object, etc.). Given its core goal of providing a common set of
analysis primitives suitable to every natural language, and its
practical objective of fostering their computational grammatical
processing, it keeps being an active domain of research in science
and technology of language. This paper presents a new collection of
quality language resources for the computational processing of the
Portuguese language under the Universal Dependencies framework (UD).
This is an all-encompassing, publicly available open collection of
mutually consistent and inter-operable scientific resources that
includes reliably annotated corpora, top-performing processing tools
and expert support services: a new UPOS-annotated corpus, CINTIL-
UPos, with 675K tokens and a new UD treebank, CINTIL-UDep Treebank,
with nearly 38K sentences; a UPOS tagger, LX-UTagger, and a UD
parser, LX-UDParser, trained on these corpora, available both as
local stand-alone tools and as remote web-based services; and
helpdesk support ensured by the Knowledge Center for the Science and
Technology of Portuguese of the CLARIN research infrastructure.},

  abstract    = {Text simplification is a method for improving the
accessibility of text by converting complex sentences into simple
sentences. Multiple studies have been done to create datasets for
text simplification. However, most of these datasets focus on high-
resource languages only. In this work, we proposed a complex word
dataset for Hindi, a language largely ignored in text simplification
literature. We used various Hindi knowledge annotators for
annotation to capture the annotator's language knowledge. Our
analysis shows a significant difference between native and non-
native annotators' perception of word complexity. We also built an
automatic complex word classifier using a soft voting approach based
on the predictions from tree-based ensemble classifiers. These
models behave differently for annotations made by different
categories of users, such as native and non-native speakers. Our
dataset and analysis will help simplify Hindi text depending on the
user's language understanding. The dataset is available at https://

evaluated overall, without taking into consideration performance on  
individual error types because system output is not annotated with  
respect to error type. We introduce a tool that automatically  
classifies errors in Russian learner texts. The tool takes an edit  
pair consisting of the original token(s) and the corresponding  
replacement and provides a grammatical error category. Manual  
evaluation of the output reveals that in more than 93\% of cases the  
error categories are judged as correct or acceptable. We apply the  
tool to carry out a fine-grained evaluation on the performance of  
two error correction systems for Russian.},

  publisher = {European Language Resources Association},  
  pages     = {5648--5653},  
  abstract  = {This paper presents a corpus of Polish texts  
annotated with metaphorical expressions. It is composed of two parts  
of comparable size, selected from two subcorpora of the Polish  
National Corpus: the subcorpus manually annotated on morphosyntactic  
level, named entities level etc., and the Polish Coreference Corpus,  
with manually annotated mentions and the coreference relations  
between them, but automatically annotated on the morphosyntactic  
level (only the second part is actually annotated). In the paper we  
briefly outline the method for identifying metaphorical expressions  
in a text, based on the MIPVU procedure. The main difference is the  
stress put on novel metaphors and considering neologicistic  
derivatives that have metaphorical properties. The annotation  
procedure is based on two notions: vehicle – a part of an expression  
used metaphorically, representing a source domain and its topic – a  
part referring to reality, representing a target domain. Next, we
```

propose several features (text form, conceptual structure, conventionality and contextuality) to classify metaphorical expressions identified in texts. Additionally, some metaphorical expressions are identified as concerning personal identity matters and classified w.r.t. their properties. Finally, we analyse and evaluate the results of the annotation.},

year = {2022},

address = {Marseille, France},

publisher = {European Language Resources Association},

pages = {5654--5664},

abstract = {Chinese word segmentation (CWS) and named entity recognition (NER) are two important tasks in Chinese natural language processing. To achieve good model performance on these tasks, existing neural approaches normally require a large amount of labeled training data, which is often unavailable for specific domains such as the Chinese medical domain due to privacy and legal issues. To address this problem, we have developed a Chinese medical corpus named ChiMST which consists of question-answer pairs collected from an online medical healthcare platform and is annotated with word boundary and medical term information. For word boundary, we mainly follow the word segmentation guidelines for the Penn Chinese Treebank (Xia, 2000); for medical terms, we define 9 categories and 18 sub-categories after consulting medical experts. To provide baselines on this corpus, we train existing state-of-the-art models on it and achieve good performance. We believe that the corpus and the baseline systems will be a valuable resource for CWS and NER research on the medical domain.},

publisher = {European Language Resources Association},

pages = {5665--5672},

abstract = {Citations are frequently used in publications to support the presented results and to demonstrate the previous

discoveries while also assisting the reader in following the chronological progression of information through publications. In scientific publications, a citation refers to the referenced document, but it makes no mention of the exact span of text that is being referred to. Connecting the citation to this span of text is called citation linkage. In this paper, to find these citation linkages in biomedical research publications using deep learning, we provide a synthetic silver standard corpus as well as the method to build this corpus. The motivation for building this corpus is to provide a training set for deep learning models that will locate the text spans in a reference article, given a citing statement, based on semantic similarity. This corpus is composed of sentence pairs, where one sentence in each pair is the citing statement and the other one is a candidate cited statement from the referenced paper. The corpus is annotated using an unsupervised sentence embedding method. The effectiveness of this silver standard corpus for training citation linkage models is validated against a human-annotated gold standard corpus.},

  publisher = {European Language Resources Association},
  pages     = {5673--5682},
  abstract  = {To augment datasets used for scientific-document
              writing support research, we extract texts from ``Related Work''
              sections and citation information in PDF-formatted papers published
              in English. The previous dataset was constructed entirely with Tex-
              formatted papers, from which it is easy to extract citation
              information. However, since many publicly available papers in
              various fields are provided only in PDF format, a dataset
              constructed using only Tex papers has limited utility. To resolve
              this problem, we augment the existing dataset by extracting the
              titles of sections using the visual features of PDF documents and
              extracting the Related Work section text using the explicit title
              information. Since text generated from the figures and footnotes
              appearing in the extraction target areas is considered noise, we
              remove instances of such text. Moreover, we map the cited paper's
              information obtained using existing tools to citation marks detected
              by regular expression rules, resulting in pairs of cited paper
              information and text of the Related Work section. By evaluating body
              text extraction and citation mapping in the constructed dataset, the
              accuracy of the proposed dataset was found to be close to that of
              the previous dataset. Accordingly, we demonstrated the possibility
```

```
of building a significantly augmented dataset.},

  abstract  = {While aspect-based sentiment analysis of user-  
generated content has received a lot of attention in the past years,  
emotion detection at the aspect level has been relatively  
unexplored. Moreover, given the rise of more visual content on  
social media platforms, we want to meet the ever-growing share of  
multimodal content. In this paper, we present a multimodal dataset  
for Aspect-Based Emotion Analysis (ABEA). Additionally, we take the  
first steps in investigating the utility of multimodal coreference  
resolution in an ABEA framework. The presented dataset consists of  
4,900 comments on 175 images and is annotated with aspect and  
emotion categories and the emotional dimensions of valence and  
arousal. Our preliminary experiments suggest that ABEA does not  
benefit from multimodal coreference resolution, and that aspect and  
emotion classification only requires textual information. However,  
when more specific information about the aspects is desired, image  
recognition could be essential.},

  abstract  = {This paper presents Atril, an XML visualization  
system for corpus texts, developed for, but not restricted to, the  
project Corpus de Audiências (CorAuDis), a corpus composed of  
transcripts of sessions of criminal proceedings recorded at the  
Coimbra Court. The main aim of the tool is to provide researchers  
with a web-based environment that allows for an easily customizable  
visualization of corpus texts with heavy structural annotation.  
Existing corpus analysis tools such as SketchEngine, TEITOK and  
CQPweb offer some kind of visualization mechanisms, but, to our  
knowledge, none meets our project's main needs. Our requirements are  
a system that is open-source; that can be easily connected to CQPweb  
and TEITOK, that provides a full text-view with switchable  
visualization templates, that allows for the visualization of  
overlapping utterances. To meet those requirements, we created  
Atril, a module with a corpus XML file viewer, a visualization  
management system, and a word alignment tool.},

abstract   = {Expert human annotation for summarization is
definitely an expensive task, and can not be done on huge scales.
But with this work, we show that even with a crowd sourced summary
generation approach, quality can be controlled by aggressive expert
informed filtering and sampling-based human evaluation. We propose a
pipeline that crowd-sources summarization data and then aggressively
```

filters the content via: automatic and partial expert evaluation. Using this pipeline we create a high-quality Telugu Abstractive Summarization dataset (TeSum) which we validate with sampling-based human evaluation. We also provide baseline numbers for various models commonly used for summarization. A number of recently released datasets for summarization, scraped the web-content relying on the assumption that summary is made available with the article by the publishers. While this assumption holds for multiple resources (or news-sites) in English, it should not be generalised across languages without thorough analysis and verification. Our analysis clearly shows that this assumption does not hold true for most Indian language news resources. We show that our proposed filtration pipeline can even be applied to these large-scale scraped datasets to extract better quality article-summary pairs.},

  address   = {Marseille, France},  
  publisher = {European Language Resources Association},  
  pages     = {5739--5748},  
  abstract  = {Humans sometimes anthropomorphize everyday objects,  
but especially robots that have human-like qualities and that are  
often able to interact with and respond to humans in ways that other  
objects cannot. Humans especially attribute emotion to robot  
behaviors, partly because humans often use and interpret emotions  
when interacting with other humans, and they apply that capability  
when interacting with robots. Moreover, emotions are a fundamental  
part of the human language system and emotions are used as  
scaffolding for language learning, making them an integral part of  
language learning and meaning. However, there are very few datasets  
that explore how humans perceive the emotional states of robots and  
how emotional behaviors relate to human language. To address this  
gap we have collected HADREB, a dataset of human appraisals and  
English descriptions of robot emotional behaviors collected from  
over 30 participants. These descriptions and human emotion  
appraisals are collected using the Mistyrobotics Misty II and the  
Digital Dream Labs Cozmo (formerly Anki) robots. The dataset  
contains English descriptions and emotion appraisals of more than  
500 descriptions and graded valence labels of 8 emotion pairs for  
each behavior and each robot. In this paper we describe the process  
of collecting and cleaning the data, give a general analysis of the  
data, and evaluate the usefulness of the dataset in two experiments,  
one using a language model to map descriptions to emotions, the  
other maps robot behaviors to emotions.},

  abstract  = {To develop a dialogue system that can build common  
ground with users, the process of building common ground through  
dialogue needs to be clarified. However, the studies on the process  
of building common ground have not been well conducted; much work  
has focused on finding the relationship between a dialogue in which  
users perform a collaborative task and its task performance  
represented by the final result of the task. In this study, to  
clarify the process of building common ground, we propose a data  
collection method for automatically recording the process of  
building common ground through a dialogue by using the intermediate  
result of a task. We collected 984 dialogues, and as a result of  
investigating the process of building common ground, we found that  
the process can be classified into several typical patterns and that  
conveying each worker's understanding through affirmation of a  
counterpart's utterances especially contributes to building common  
ground. In addition, toward dialogue systems that can build common  
ground, we conducted an automatic estimation of the degree of built  
common ground and found that its degree can be estimated quite  
accurately.},

abstract      = {In this work, we study entrainment of users playing a
creative reference resolution game with an autonomous dialogue
system. The language understanding module in our dialogue system
leverages annotated human-wizard conversational data, openly
available knowledge graphs, and crowd-augmented data. Unlike
previous entrainment work, our dialogue system does not attempt to
make the human conversation partner adopt lexical items in their
dialogue, but rather to adapt their descriptive strategy to one that
is simpler to parse for our natural language understanding unit. By
deploying this dialogue system through a crowd-sourced study, we
show that users indeed entrain on a "strategy-level" without the
change of strategy impinging on their creativity. Our work thus
presents a promising future research direction for developing
dialogue management systems that can strategically influence
people's descriptive strategy to ease the system's language
understanding in creative tasks.},

abstract      = {Incorporating multi-modal contexts in conversation is
an important step for developing more engaging dialogue systems. In
this work, we explore this direction by introducing MMChat: a large
scale Chinese multi-modal dialogue corpus (32.4M raw dialogues and
120.84K filtered dialogues). Unlike previous corpora that are crowd-
sourced or collected from fictitious movies, MMChat contains image-
grounded dialogues collected from real conversations on social
media, in which the sparsity issue is observed. Specifically, image-
initiated dialogues in common communications may deviate to some
non-image-grounded topics as the conversation proceeds. To better
investigate this issue, we manually annotate 100K dialogues from
MMChat and further filter the corpus accordingly, which yields
MMChat-hf. We develop a benchmark model to address the sparsity
issue in dialogue generation tasks by adapting the attention routing
mechanism on image features. Experiments demonstrate the usefulness
of incorporating image features and the effectiveness in handling
the sparsity of image features.},

address = {Marseille, France},
publisher = {European Language Resources Association},
pages = {5787--5796},
abstract = {There has been a growing interest in developing conversational recommendation system (CRS), which provides valuable recommendations to users through conversations. Compared to the traditional recommendation, it advocates wealthier interactions and provides possibilities to obtain users' exact preferences explicitly. Nevertheless, the corresponding research on this topic is limited due to the lack of broad-coverage dialogue corpus, especially real-world dialogue corpus. To handle this issue and facilitate our exploration, we construct E-ConvRec, an authentic Chinese dialogue dataset consisting of over 25k dialogues and 770k utterances, which contains user profile, product knowledge base (KB), and multiple sequential real conversations between users and recommenders. Next, we explore conversational recommendation in a real scene from multiple facets based on the dataset. Therefore, we particularly design three tasks: user preference recognition, dialogue management, and personalized recommendation. In the light of the three tasks, we establish baseline results on E-ConvRec to facilitate future studies.},

abstract = {We introduce SHONGLAP, a large annotated open-domain dialogue corpus in Bengali language. Due to unavailability of high-quality dialogue datasets for low-resource languages like Bengali, existing neural open-domain dialogue systems suffer from data scarcity. We propose a framework to prepare large-scale open-domain dialogue datasets from publicly available multi-party discussion podcasts, talk-shows and label them based on weak-supervision techniques which is particularly suitable for low-resource settings. Using this framework, we prepared our corpus, the first reported Bengali open-domain dialogue corpus (7.7k+ fully annotated dialogues

in total) which can serve as a strong baseline for future works. Experimental results show that our corpus improves performance of large language models (BanglaBERT) in case of downstream classification tasks during fine-tuning.},

abstract = {Praising behavior is considered to an important  
method of communication in daily life and social activities. An  
engineering analysis of praising behavior is therefore valuable.  
However, a dialogue corpus for this analysis has not yet been  
developed. Therefore, we develop corpuses for face-to-face and  
remote two-party dialogues with ratings of praising skills. The  
corpuses enable us to clarify how to use verbal and nonverbal  
behaviors for successfully praise. In this paper, we analyze the  
differences between the face-to-face and remote corpuses, in  
particular the expressions in adjudged praising scenes in both  
corpuses, and also evaluated praising skills. We also compare  
differences in head motion, gaze behavior, facial expression in  
high-rated praising scenes in both corpuses. The results showed that  
the distribution of praising scores was similar in face-to-face and  
remote dialogues, although the ratio of the number of praising  
scenes to the number of utterances was different. In addition, we  
confirmed differences in praising behavior in face-to-face and  
remote dialogues.},

  abstract    = {The long-standing goal of Artificial Intelligence
(AI) has been to create human-like conversational systems. Such
```

systems should have the ability to develop an emotional connection with the users, consequently, emotion recognition in dialogues has gained popularity. Emotion detection in dialogues is a challenging task because humans usually convey multiple emotions with varying degrees of intensities in a single utterance. Moreover, emotion in an utterance of a dialogue may be dependent on previous utterances making the task more complex. Recently, emotion recognition in low-resource languages like Hindi has been in great demand. However, most of the existing datasets for multi-label emotion and intensity detection in conversations are in English. To this end, we propose a large conversational dataset in Hindi named EmoInHindi for multi-label emotion and intensity recognition in conversations containing 1,814 dialogues with a total of 44,247 utterances. We prepare our dataset in a Wizard-of-Oz manner for mental health and legal counselling of crime victims. Each utterance of dialogue is annotated with one or more emotion categories from 16 emotion labels including neutral and their corresponding intensity. We further propose strong contextual baselines that can detect the emotion(s) and corresponding emotional intensity of an utterance given the conversational context.},

abstract     = {This paper presents a compositional annotation scheme
to capture the clusivity properties of personal pronouns in context,
that is their ability to construct and manage in-groups and out-
groups by including/excluding the audience and/or non-speech act
participants in reference to groups that also include the speaker.
We apply and test our schema on pronoun instances in speeches taken
from the German parliament. The speeches cover a time period from
2017-2021 and comprise manual annotations for 3,126 sentences. We
achieve high inter-annotator agreement for our new schema, with a
Cohen's  $\kappa$  in the range of 89.7-93.2 and a percentage agreement of >
96%. Our exploratory analysis of in/exclusive pronoun use in the
parliamentary setting provides some face validity for our new
schema. Finally, we present baseline experiments for automatically
predicting clusivity in political debates, with promising results
for many referential constellations, yielding an overall 84.9%
micro F1 for all pronouns.},

  abstract   = {This paper contributes to studying relationships
between Japanese topography and places featured in early modern
landscape prints, so-called ukiyo-e or 'pictures of the floating
world'. The printed inscriptions on these images feature diverse
place-names, both man-made and natural formations. However, due to
the corpus's richness and diversity, the precise nature of artistic
mediation of the depicted places remains little understood. In this
paper, we explored a new analytical approach based on the
macroanalysis of images facilitated by Natural Language Processing
technologies. This paper presents a small dataset with inscriptions
on prints that have been annotated by an art historian for included
place-name entities. Our dataset is released for public use. By
fine-tuning and applying a Japanese BERT-based Name Entity
Recogniser, we provide a use-case of a macroanalysis of a visual
dataset that is hosted by the digital database of the Art Research
Center at the Ritsumeikan University, Kyoto. Our work studies the
relationship between topography and its visual renderings in early
modern Japanese ukiyo-e landscape prints, demonstrating how an art
historian's work can be improved with Natural Language Processing
toward distant viewing of visual datasets. We release our dataset
and code for public use: https://github.com/connalia/ukiyo-

abstract = {Providing feedback on the argumentation of the learner is essential for developing critical thinking skills, however, it requires a lot of time and effort. To mitigate the overload on teachers, we aim to automate a process of providing feedback, especially giving diagnostic comments which point out the weaknesses inherent in the argumentation. It is recommended to give specific diagnostic comments so that learners can recognize the diagnosis without misinterpretation. However, it is not obvious how the task of providing specific diagnostic comments should be formulated. We present a formulation of the task as template selection and slot filling to make an automatic evaluation easier and the behavior of the model more tractable. The key to the formulation is the possibility of creating a template set that is sufficient for practical use. In this paper, we define three criteria that a template set should satisfy: expressiveness, informativeness, and uniqueness, and verify the feasibility of creating a template set that satisfies these criteria as a first trial. We will show that it is feasible through an annotation study that converts diagnostic comments given in a text to a template format. The corpus used in the annotation study is publicly available.},

abstract   = {Crowdsourcing the collection of speech provides a
scalable setting to access a customisable demographic according to
each dataset's needs. The correctness of speaker metadata is
especially relevant for speaker-centred collections – ones that
require the collection of a fixed amount of data per speaker. This
paper identifies two different types of misalignment present in
these collections: Multiple Accounts misalignment (different
contributors map to the same speaker), and Multiple Speakers
misalignment (multiple speakers map to the same contributor). Based
on state-of-the-art approaches to Speaker Verification, this paper
proposes an unsupervised method for measuring speaker metadata
plausibility of a collection, i.e., evaluating the match (or lack
thereof) between contributors and speakers. The solution presented
is composed of an embedding extractor and a clustering module.
Results indicate high precision in automatically classifying
contributor alignment (>0.94).},

  title    = {Align-smatch: A Novel Evaluation Method for Chinese
Abstract Meaning Representation Parsing based on Alignment of
Concept and Relation},
  booktitle = {Proceedings of the Language Resources and
Evaluation Conference},
  month    = {June},
  year     = {2022},
  address  = {Marseille, France},
  publisher = {European Language Resources Association},
  pages    = {5938--5945},
  abstract = {Abstract Meaning Representation is a sentence-level
meaning representation, which abstracts the meaning of sentences
into a rooted acyclic directed graph. With the continuous expansion
of Chinese AMR corpus, more and more scholars have developed parsing
systems to automatically parse sentences into Chinese AMR. However,
the current parsers can't deal with concept alignment and relation
alignment, let alone the evaluation methods for AMR parsing.
Therefore, to make up for the vacancy of Chinese AMR parsing
evaluation methods, based on AMR evaluation metric smatch, we have
improved the algorithm of generating triples so that to make it
compatible with concept alignment and relation alignment. Finally,
we obtain a new integrity metric align-smatch for paring evaluation.
A comparative research then was conducted on 20 manually annotated
AMR and gold AMR, with the result that align-smatch works well in
alignments and more robust in evaluating arcs. We also put forward
some fine-grained metric for evaluating concept alignment, relation

```

  abstract  = {Collecting human judgements is currently the most
reliable evaluation method for natural language generation systems.
Automatic metrics have reported flaws when applied to measure
quality aspects of generated text and have been shown to correlate
poorly with human judgements. However, human evaluation is time and
cost-intensive, and we lack consensus on designing and conducting
human evaluation experiments. Thus there is a need for streamlined
approaches for efficient collection of human judgements when
evaluating natural language generation systems. Therefore, we
present a dynamic approach to measure the required number of human
annotations when evaluating generated outputs in relative comparison
settings. We propose an agent-based framework of human evaluation to
assess multiple labelling strategies and methods to decide the
better model in a simulation and a crowdsourcing case study. The
main results indicate that a decision about the superior model can
be made with high probability across different labelling strategies,
where assigning a single random worker per task requires the least
overall labelling effort and thus the least cost.},

  abstract  = {Pronoun Coreference Resolution (PCR) is the task of  
resolving pronominal expressions to all mentions they refer to. The  
correct resolution of pronouns typically involves the complex  
inference over both linguistic knowledge and general world  
knowledge. Recently, with the help of pre-trained language  
representation models, the community has made significant progress
```

on various PCR tasks. However, as most existing works focus on developing PCR models for specific datasets and measuring the accuracy or F1 alone, it is still unclear whether current PCR systems are reliable in real applications. Motivated by this, we propose PCR4ALL, a new benchmark and a toolbox that evaluates and analyzes the performance of PCR systems from different perspectives (i.e., knowledge source, domain, data size, frequency, relevance, and polarity). Experiments demonstrate notable performance differences when the models are examined from different angles. We hope that PCR4ALL can motivate the community to pay more attention to solving the overall PCR problem and understand the performance comprehensively. All data and codes are available at: [https://github.com/HKUST-KnowComp/PCR4ALL.](https://github.com/HKUST-KnowComp/PCR4ALL)},

  pages     = {5974--5982},
  abstract  = {Genre identification is a kind of non-topic text
classification. The main difference between this task and topic
classification is that genre, unlike topic, usually cannot be
expressed just by some keywords and is defined as a functional
space. Neural models based on pre-trained transformers, such as BERT
or XLM-RoBERTa, demonstrate SOTA results in many NLP tasks,
including non-topical classification. However, in many cases, their
downstream application to very large corpora, such as those
extracted from social media, can lead to unreliable results because
of dataset shifts, when some raw texts do not match the profile of
the training set. To mitigate this problem, we experiment with
individual models as well as with their ensembles. To evaluate the
robustness of all models we use a prediction confidence metric,
which estimates the reliability of a prediction in the absence of a
gold standard label. We can evaluate robustness via the confidence
gap between the correctly classified texts and the misclassified
ones on a labeled test corpus, higher gaps make it easier to
identify whether a text is classified correctly. Our results show
that for all of the classifiers tested in this study, there is a
confidence gap, but for the ensembles, the gap is wider, meaning
that ensembles are more robust than their individual models.},

pages          = {5983--5993},
abstract       = {Named Entity Recognition (NER) is a well researched
NLP task and is widely used in real world NLP scenarios. NER
research typically focuses on the creation of new ways of training
NER, with relatively less emphasis on resources and evaluation.
Further, state of the art (SOTA) NER models, trained on standard
datasets, typically report only a single performance measure (F-
score) and we don't really know how well they do for different
entity types and genres of text, or how robust are they to new,
unseen entities. In this paper, we perform a broad evaluation of NER
using a popular dataset, that takes into consideration various text
genres and sources constituting the dataset at hand. Additionally,
we generate six new adversarial test sets through small
perturbations in the original test set, replacing select entities
while retaining the context. We also train and test our models on
randomly generated train/dev/test splits followed by an experiment
where the models are trained on a select set of genres but tested
genres not seen in training. These comprehensive evaluation
strategies were performed using three SOTA NER models. Based on our
results, we recommend some useful reporting practices for NER
researchers, that could help in providing a better understanding of
a SOTA model's performance in future.},

pages     = {6001--6008},  
abstract  = {We evaluate several publicly available off-the-shelf  
(commercial and research) automatic speech recognition (ASR) systems  
on dialogue agent-directed English speech from speakers with General  
American vs. non-American accents. Our results show that the  
performance of the ASR systems for non-American accents is  
considerably worse than for General American accents. Depending on  
the recognizer, the absolute difference in performance between  
General American accents and all non-American accents combined can  
vary approximately from 2% to 12%, with relative differences  
varying approximately between 16% and 49%. This drop in  
performance becomes even larger when we consider specific categories  
of non-American accents indicating a need for more diligent  
collection of and training on non-native English speaker data in  
order to narrow this performance gap. There are performance  
differences across ASR systems, and while the same general pattern  
holds, with more errors for non-American accents, there are some  
accents for which the best recognizer is different than in the  
overall case. We expect these results to be useful for dialogue  
system designers in developing more robust inclusive dialogue  
systems, and for ASR providers in taking into account performance  
requirements for different accents.},

remains an open problem in text generation. Widely used evaluation
```

metrics, like ROUGE and BLEU, are based on exact word matching and fail to capture semantic similarity. Recent works, such as BERTScore, MoverScore and, Sentence Mover's Similarity, are an improvement over these standard metrics as they use the contextualized word or sentence embeddings to capture semantic similarity. We in this work, propose a novel evaluation metric, Sentence Pair EmbEDdings (SPEED) Score, for text generation which is based on semantic similarity between sentence pairs as opposed to earlier approaches. To find semantic similarity between a pair of sentences, we obtain sentence-level embeddings from multiple transformer models pre-trained specifically on various sentence pair tasks such as Paraphrase Detection (PD), Semantic Text Similarity (STS), and Natural Language Inference (NLI). As these sentence pair tasks involve capturing the semantic similarity between a pair of input texts, we leverage these models in our metric computation. Our proposed evaluation metric shows an impressive performance in evaluating both abstractive and extractive summarization models and achieves state-of-the-art results on the SummEval dataset, demonstrating the effectiveness of our approach. Also, we perform the run-time analysis to show that our proposed metric is faster than the current state-of-the-art.},

  abstract   = {Due to the success of pre-trained language models,
versions of languages other than English have been released in
recent years. This fact implies the need for resources to evaluate
these models. In the case of Spanish, there are few ways to
systematically assess the models' quality. In this paper, we narrow
the gap by building two evaluation benchmarks. Inspired by previous
work (Conneau and Kiela, 2018; Chen et al., 2019), we introduce
Spanish SentEval and Spanish DiscoEval, aiming to assess the
capabilities of stand-alone and discourse-aware sentence
representations, respectively. Our benchmarks include considerable
pre-existing and newly constructed datasets that address different
tasks from various domains. In addition, we evaluate and analyze the
most recent pre-trained Spanish language models to exhibit their
capabilities and limitations. As an example, we discover that for
the case of discourse evaluation tasks, mBERT, a language model
trained on multiple languages, usually provides a richer latent
representation than models trained only with documents in Spanish.
We hope our contribution will motivate a fairer, more comparable,
and less cumbersome way to evaluate future Spanish language
models.},

  abstract   = {Feature Engineering consists in the application of
domain knowledge to select and transform relevant features to build
efficient machine learning models. In the Natural Language
Processing field, the state of the art concerning automatic document
classification tasks relies on word and sentence embeddings built
upon deep learning models based on transformers that have
outperformed the competition in several tasks. However, the models
built from these embeddings are usually difficult to interpret. On
the contrary, linguistic features are easy to understand, they

```

result in simpler models, and they usually achieve encouraging results. Moreover, both linguistic features and embeddings can be combined with different strategies which result in more reliable machine-learning models. The de facto tool for extracting linguistic features in Spanish is LIWC. However, this software does not consider specific linguistic phenomena of Spanish such as grammatical gender and lacks certain verb tenses. In order to solve these drawbacks, we have developed UMUTextStats, a linguistic extraction tool designed from scratch for Spanish. Furthermore, this tool has been validated to conduct different experiments in areas such as infodemiology, hate-speech detection, author profiling, authorship verification, humour or irony detection, among others. The results indicate that the combination of linguistic features and embeddings based on transformers are beneficial in automatic document classification.},

  abstract  = {In this paper we address the question of how to
integrate grammar and lexical-semantic knowledge within a single and
homogeneous knowledge graph. We introduce a graph modelling of
grammar knowledge which enables its merging with a lexical-semantic
network. Such an integrated representation is expected, for
instance, to provide new material for language-related graph
embeddings in order to model interactions between Syntax and
Semantics. Our base model relies on a phrase structure grammar. The
phrase structure is accounted for by both a Proof-Theoretical
representation, through a Context-Free Grammar, and a Model-
Theoretical one, through a constraint-based grammar. The constraint
types colour the grammar layer with syntactic relationships such as
Immediate Dominance, Linear Precedence, and more. We detail a
creation process which infers the grammar layer from a corpus
annotated in constituency and integrates it with a lexical-semantic
network through a shared POS tagset. We implement the process, and
experiment with the French Treebank and the JeuxDeMots lexical-
semantic network. The outcome is the HOLINET knowledge graph.},

  publisher   = {European Language Resources Association},
  pages       = {6059--6068},
  abstract    = {Multiple-choice question answering (MCQA) for machine
reading comprehension (MRC) is challenging. It requires a model to
select a correct answer from several candidate options related to
text passages or dialogue. To select the correct answer, such models
must have the ability to understand natural languages, comprehend
textual representations, and infer the relationship between
candidate options, questions, and passages. Previous models
calculated representations between passages and question-option
pairs separately, thereby ignoring the effect of other relation-
pairs. In this study, we propose a human reading comprehension
attention (HRCA) model and a passage-question-option (PQO) matrix-
guided HRCA model called HRCA+ to increase accuracy. The HRCA model
updates the information learned from the previous relation-pair to
the next relation-pair. HRCA+ utilizes the textual information and
the interior relationship between every two parts in a passage, a
question, and the corresponding candidate options. Our proposed
method outperforms other state-of-the-art methods. On the
Semeval-2018 Task 11 dataset, our proposed method improved accuracy
levels from 95.8\% to 97.2\%, and on the DREAM dataset, it improved
accuracy levels from 90.4\% to 91.6\% without extra training data,
from 91.8\% to 92.6\% with extra training data.},

  abstract  = {Data exploration is an important step of every data
science and machine learning project, including those involving
textual data. We provide a novel language tool, in the form of a
publicly available Python library for extracting patterns from
textual data. The library integrates a first public implementation
of the existing GrASP algorithm. It allows users to extract patterns
```

using a number of general-purpose built-in linguistic attributes (such as hypernyms, part-of-speech tags, and syntactic dependency tags), as envisaged for the original algorithm, as well as domain-specific custom attributes which can be incorporated into the library by implementing two functions. The library is equipped with a web-based interface empowering human users to conveniently explore data via the extracted patterns, using complementary pattern-centric and example-centric views: the former includes a reading in natural language and statistics of each extracted pattern; the latter shows applications of each extracted pattern to training examples. We demonstrate the usefulness of the library in classification (spam detection and argument mining), model analysis (machine translation), and artifact discovery in datasets (SNLI and 20NewsGroups).},

  abstract  = {How to obtain hierarchical representations with an  
increasing level of abstraction becomes one of the key issues of  
learning with deep neural networks. A variety of RNN models have  
recently been proposed to incorporate both explicit and implicit  
hierarchical information in modeling languages in the literature. In  
this paper, we propose a novel approach called the latent indicator  
layer to identify and learn implicit hierarchical information (e.g.,  
phrases), and further develop an EM algorithm to handle the latent  
indicator layer in training. The latent indicator layer further  
simplifies a text's hierarchical structure, which allows us to  
seamlessly integrate different levels of attention mechanisms into  
the structure. We called the resulting architecture as the EM-HRNN  
model. Furthermore, we develop two bootstrap strategies to  
effectively and efficiently train the EM-HRNN model on long text  
documents. Simulation studies and real data applications demonstrate  
that the EM-HRNN model with bootstrap training outperforms other  
RNN-based models in document classification tasks. The performance  
of the EM-HRNN model is comparable to a Transformer-based method  
called Bert-base, though the former is much smaller model and does  
not require pre-training.},

pages      = {6114--6120},
abstract   = {Existing question answering systems mainly focus on
dealing with text data. However, much of the data produced daily is
stored in the form of tables that can be found in documents and
relational databases, or on the web. To solve the task of question
answering over tables, there exist many datasets for table question
answering written in English, but few Korean datasets. In this
paper, we demonstrate how we construct Korean-specific datasets for
table question answering: Korean tabular dataset is a collection of
1.4M tables with corresponding descriptions for unsupervised pre-
training language models. Korean table question answering corpus
consists of 70k pairs of questions and answers created by crowd-
sourced workers. Subsequently, we then build a pre-trained language
model based on Transformer and fine-tune the model for table
question answering with these datasets. We then report the
evaluation results of our model. We make our datasets publicly
available via our GitHub repository and hope that those datasets
will help further studies for question answering over tables, and
for the transformation of table formats.},

pages       = {6121--6130},
abstract    = {While the field of argument mining has grown notably
in the last decade, research on the Twitter medium remains
relatively understudied. Given the difficulty of mining arguments in
tweets, recent work on creating annotated resources mainly utilized
simplified annotation schemes that focus on single argument
components, i.e., on claim or evidence. In this paper we strive to
fill this research gap by presenting GerCCT, a new corpus of German
tweets on climate change, which was annotated for a set of different
argument components and properties. Additionally, we labelled
sarcasm and toxic language to facilitate the development of tools
for filtering out non-argumentative content. This, to the best of
our knowledge, renders our corpus the first tweet resource annotated
for argumentation, sarcasm and toxic language. We show that a
```

comparatively complex annotation scheme can still yield promising inter-annotator agreement. We further present first good supervised classification results yielded by a fine-tuned BERT architecture.},

publisher = {European Language Resources Association},
pages = {623--632},
abstract = {State-of-the-art approaches for metaphor detection compare their literal - or core - meaning and their contextual meaning using metaphor classifiers based on neural networks. However, metaphorical expressions evolve over time due to various reasons, such as cultural and societal impact. Metaphorical expressions are known to co-evolve with language and literal word meanings, and even drive, to some extent, this evolution. This poses

the question of whether different, possibly time-specific, representations of literal meanings may impact the metaphor detection task. To the best of our knowledge, this is the first study that examines the metaphor detection task with a detailed exploratory analysis where different temporal and static word embeddings are used to account for different representations of literal meanings. Our experimental analysis is based on three popular benchmarks used for metaphor detection and word embeddings extracted from different corpora and temporally aligned using different state-of-the-art approaches. The results suggest that the usage of different static word embedding methods does impact the metaphor detection task and some temporal word embeddings slightly outperform static methods. However, the results also suggest that temporal word embeddings may provide representations of the core meaning of the metaphor even too close to their contextual meaning, thus confusing the classifier. Overall, the interaction between temporal language evolution and metaphor detection appears tiny in the benchmark datasets used in our experiments. This suggests that future work for the computational analysis of this important linguistic phenomenon should first start by creating a new dataset where this interaction is better represented.},

abstract = {Deep neural networks (DNNs) have a high capacity to  
completely memorize noisy labels given sufficient training time, and  
its memorization unfortunately leads to performance degradation.  
Recently, virtual adversarial training (VAT) attracts attention as  
it could further improve the generalization of DNNs in semi-  
supervised learning. The driving force behind VAT is to prevent the  
models from overfitting to data points by enforcing consistency  
between the inputs and the perturbed inputs. These strategy could be  
helpful in learning from noisy labels if it prevents neural models  
from learning noisy samples while encouraging the models to  
generalize clean samples. In this paper, we propose context-based  
virtual adversarial training (ConVAT) to prevent a text classifier  
from overfitting to noisy labels. Unlike the previous works, the  
proposed method performs the adversarial training in the context  
level rather than the inputs. It makes the classifier not only learn  
its label but also its contextual neighbors, which alleviate the  
learning from noisy labels by preserving contextual semantics on  
each data point. We conduct extensive experiments on four text
```

classification datasets with two types of label noises. Comprehensive experimental results clearly show that the proposed method works quite well even with extremely noisy settings.},

abstract = {Answering questions over financial reports containing both tabular and textual data (hybrid data) is challenging as it requires models to select information from financial reports and perform complex quantitative analyses. Although current models have demonstrated a solid capability to solve simple questions, they struggle with complex questions that require a multiple-step numerical reasoning process. This paper proposes a new framework named FinMath, which improves the model's numerical reasoning capacity by injecting a tree-structured neural model to perform multi-step numerical reasoning. Specifically, FinMath extracts supporting evidence from the financial reports given the question in the first phase. In the second phase, a tree-structured neural model is applied to generate a tree expression in a top-down recursive way. Experiments on the TAT-QA dataset show that our proposed approach improves the previous best result by 8.5\% absolute for Exact Match (EM) score (50.1\% to 58.6\%) and 6.1\% absolute for numeracy-focused F1 score (58.0\% to 64.1\%).},

pages = {6162--6169},
abstract = {The goal of text zoning is to segment a text into zones (i.e., Background, Conclusion) that serve distinct functions. Argumentative zoning, a specific text zoning scheme for the scientific domain, is considered as the antecedent for argument mining by many researchers. Surprisingly, however, little work is concerned with exploiting zoning information to improve the performance of argument mining models, despite the relatedness of the two tasks. In this paper, we propose two transformer-based models to incorporate zoning information into argumentative component identification and classification tasks. One model is for the sentence-level argument mining task and the other is for the token-level task. In particular, we add the zoning labels predicted by an off-the-shelf model to the beginning of each sentence, inspired by the convention commonly used biomedical abstracts. Moreover, we employ multi-head attention to transfer the sentence-level zoning information to each token in a sentence. Based on experiment results, we find a significant improvement in F1-scores for both sentence- and token-level tasks. It is worth mentioning that these zoning labels can be obtained with high accuracy by utilising readily available automated methods. Thus, existing argument mining models can be improved by incorporating zoning information without any additional annotation cost.},

  abstract  = {While deep learning approaches to information
extraction have had many successes, they can be difficult to augment
or maintain as needs shift. Rule-based methods, on the other hand,
can be more easily modified. However, crafting rules requires
expertise in linguistics and the domain of interest, making it
infeasible for most users. Here we attempt to combine the advantages
of these two directions while mitigating their drawbacks. We adapt
recent advances from the adjacent field of program synthesis to
information extraction, synthesizing rules from provided examples.
We use a transformer-based architecture to guide an enumerative
search, and show that this reduces the number of steps that need to
be explored before a rule is found. Further, we show that without
training the synthesis algorithm on the specific domain, our
synthesized rules achieve state-of-the-art performance on the 1-shot
scenario of a task that focuses on few-shot learning for relation
classification, and competitive performance in the 5-shot
scenario.},

  pages       = {6190--6199},
  abstract    = {Relation extraction (RE) is a sub-field of
information extraction, which aims to extract the relation between
two given named entities (NEs) in a sentence and thus requires a
good understanding of contextual information, especially the
entities and their surrounding texts. However, limited attention is
paid by most existing studies to re-modeling the given NEs and thus
lead to inferior RE results when NEs are sometimes ambiguous. In
this paper, we propose a RE model with two training stages, where
adversarial multi-task learning is applied to the first training
stage to explicitly recover the given NEs so as to enhance the main
relation extractor, which is trained alone in the second stage. In
doing so, the RE model is optimized by named entity recognition
(NER) and thus obtains a detailed understanding of entity-aware
context. We further propose the adversarial mechanism to enhance the
process, which controls the effect of NER on the main relation
extractor and allows the extractor to benefit from NER while keep
focusing on RE rather than the entire multi-task learning.
Experimental results on two English benchmark datasets for RE
demonstrate the effectiveness of our approach, where state-of-the-
art performance is observed on both datasets.},

  pages          = {6223--6231},
  abstract       = {This paper presents a toolkit that applies named-
entity extraction techniques to identify information related to
criminal activity in texts from the Polish Internet. The
methodological and technical assumptions were established following
the requirements of our application users from the Border Guard. Due
to the specificity of the users' needs and the specificity of web
texts, we used original methodologies related to the search for
desired texts, the creation of domain lexicons, the annotation of
the collected text resources, and the combination of rule-based and
machine-learning techniques for extracting the information desired
by the user. The performance of our tools has been evaluated on 6240
manually annotated text fragments collected from Internet sources.
Evaluation results and user feedback show that our approach is
feasible and has potential value for real-life applications in the
daily work of border guards. Lexical lookup combined with hand-
crafted rules and regular expressions, supported by text statistics,
can make a decent specialized entity recognition system in the
absence of large data sets required for training a good neural
network.},

  abstract  = {At present, more and more work has begun to pay  
attention to the long-term housekeeping robot scene. Naturally, we  
wonder whether the robot can answer the questions raised by the  
owner according to the actual situation at home. These questions  
usually do not have a clear text context, are directly related to  
the actual scene, and it is difficult to find the answer from the  
general knowledge base (such as Wikipedia). Therefore, the  
experience accumulated from the task seems to be a more natural  
choice. We present a corpus called TEQA (task-driven and experience-  
based question answering) in the long-term household task. Based on  
a popular in-house virtual environment (AI2-THOR) and agent task  
experiences of ALFRED, we design six types of questions along with  
answering including 24 question templates, 37 answer templates, and  
nearly 10k different question answering pairs. Our corpus aims at  
investigating the ability of task experience understanding of agents  
for the daily question answering scenario on the ALFRED dataset.},

address = {Marseille, France},
publisher = {European Language Resources Association},
pages = {6250--6259},
abstract = {We present a radiology question answering dataset, RadQA, with 3074 questions posed against radiology reports and annotated with their corresponding answer spans (resulting in a total of 6148 question-answer evidence pairs) by physicians. The questions are manually created using the clinical referral section of the reports that take into account the actual information needs of ordering physicians and eliminate bias from seeing the answer context (and, further, organically create unanswerable questions). The answer spans are marked within the Findings and Impressions sections of a report. The dataset aims to satisfy the complex clinical requirements by including complete (yet concise) answer phrases (which are not just entities) that can span multiple lines. We conduct a thorough analysis of the proposed dataset by examining the broad categories of disagreement in annotation (providing insights on the errors made by humans) and the reasoning requirements to answer a question (uncovering the huge dependence on medical knowledge for answering the questions). The advanced transformer language models achieve the best F1 score of 63.55 on the test set, however, the best human performance is 90.31 (with an average of 84.52). This demonstrates the challenging nature of RadQA that leaves ample scope for future method research.},

  publisher  = {European Language Resources Association},
  pages      = {6260--6270},
  abstract   = {In the commercial aviation domain, there are a large
number of documents, like accident reports of NTSB and ASRS, and
regulatory directives ADs. There is a need for a system to
efficiently access these diverse repositories to serve the demands
of the aviation industry, such as maintenance, compliance, and
safety. In this paper, we propose a Knowledge Graph (KG) guided Deep
Learning (DL) based Question Answering (QA) system to cater to these
requirements. We construct a KG from aircraft accident reports and
contribute this resource to the community of researchers. The
efficacy of this resource is tested and proved by the proposed QA
system. Questions in Natural Language are converted into SPARQL (the
interface language of the RDF graph database) queries and are
answered from the KG. On the DL side, we examine two different QA
models, BERT-QA and GPT3-QA, covering the two paradigms of answer
formulation in QA. We evaluate our system on a set of handcrafted
queries curated from the accident reports. Our hybrid KG + DL QA
system, KGQA + BERT-QA, achieves 7\% and 40.3\% increase in accuracy
over KGQA and BERT-QA systems respectively. Similarly, the other
combined system, KGQA + GPT3-QA, achieves 29.3\% and 9.3\% increase
in accuracy over KGQA and GPT3-QA systems respectively. Thus, we
infer that the combination of KG and DL is better than either KG or
DL individually for QA, at least in our chosen domain.},

  abstract    = {One desiderata of topic modeling is to produce
interpretable topics. Given a cluster of document-tokens comprising
a topic, we can order the topic by counting each word. It is natural
to think that each topic could easily be labeled by looking at the
words with the highest word count. However, this is not always the
case. A human evaluator can often have difficulty identifying a
single label that accurately describes the topic as many top words
seem unrelated. This paper aims to improve interpretability in topic
modeling by providing a novel, outperforming interpretable topic
model Our approach combines two previously established subdomains in
topic modeling: nonparametric and weakly-supervised topic models.
Given a nonparametric topic model, we can include weakly-supervised
```

input using novel modifications to the nonparametric generative model. These modifications lay the groundwork for a compelling setting---one in which most corpora, without any previous supervised or weakly-supervised input, can discover interpretable topics. This setting also presents various challenging sub-problems of which we provide resolutions. Combining nonparametric topic models with weakly-supervised topic models leads to an exciting discovery---a complete, self-contained and outperforming topic model for interpretability.},

  abstract = {In this paper, we report experiments on Few- and  
Zero-shot Knowledge Graph completion, where the objective is to add  
missing relational links between entities into an existing Knowledge  
Graph with few or no previous examples of the relation in question.  
While previous work has used pre-trained embeddings based on the  
structure of the graph as input for a neural network, nobody has, to  
the best of our knowledge, addressed the task by only using textual  
descriptive data associated with the entities and relations, much  
since current standard benchmark data sets lack such information. We  
therefore enrich the benchmark data sets for these tasks by  
collecting textual description data to provide a new resource for  
future research to bridge the gap between structural and textual  
Knowledge Graph completion. Our results show that we can improve the  
results for Knowledge Graph completion for both Few- and Zero-shot  
scenarios with up to a two-fold increase of all metrics in the Zero-  
shot setting. From a more general perspective, our experiments  
demonstrate the value of using textual resources to enrich more  
formal representations of human knowledge and in the utility of  
transfer learning from textual data and text collections to enrich  
and maintain knowledge resources.},

abstract      = {Several existing resources are available for
sentiment analysis (SA) tasks that are used for learning sentiment
specific embedding (SSE) representations. These resources are either
large, common-sense knowledge graphs (KG) that cover a limited
amount of polarities/emotions or they are smaller in size (e.g.:
lexicons), which require costly human annotation and cover fine-
grained emotions. Therefore using knowledge resources to learn SSE
representations is either limited by the low coverage of polarities/
emotions or the overall size of a resource. In this paper, we first
introduce a new directed KG called 'RELATE', which is built to
overcome both the issue of low coverage of emotions and the issue of
scalability. RELATE is the first KG of its size to cover Ekman's six
basic emotions that are directed towards entities. It is based on
linguistic rules to incorporate the benefit of semantics without
relying on costly human annotation. The performance of 'RELATE' is
evaluated by learning SSE representations using a Graph
Convolutional Neural Network (GCN).},

abstract = {Automatic Term Extraction (ATE) is a key component
for domain knowledge understanding and an important basis for
further natural language processing applications. Even with
persistent improvements, ATE still exhibits weak results exacerbated
by small training data inherent to specialized domain corpora.
Recently, transformers-based deep neural models, such as BERT, have
proven to be efficient in many downstream NLP tasks. However, no
systematic evaluation of ATE has been conducted so far. In this
paper, we run an extensive study on fine-tuning pre-trained BERT
models for ATE. We propose strategies that empirically show BERT's
effectiveness using cross-lingual and cross-domain transfer learning
to extract single and multi-word terms. Experiments have been
conducted on four specialized domains in three languages. The
obtained results suggest that BERT can capture cross-domain and
cross-lingual terminologically-marked contexts shared by terms,
opening a new design-pattern for ATE.},

abstract = {Constructions are direct form-meaning pairs with possible schematic slots. These slots are simultaneously constrained by the embedded construction itself and the sentential context. We propose that the constraint could be described by a conditional probability distribution. However, as this conditional probability is inevitably complex, we utilize language models to capture this distribution. Therefore, we build CxLM, a deep learning-based masked language model explicitly tuned to constructions' schematic slots. We first compile a construction dataset consisting of over ten thousand constructions in Taiwan Mandarin. Next, an experiment is conducted on the dataset to examine to what extent a pretrained masked language model is aware of the constructions. We then fine-tune the model specifically to perform a cloze task on the opening slots. We find that the fine-tuned model predicts masked slots more accurately than baselines and generates both structurally and semantically plausible word samples. Finally, we release CxLM and its dataset as publicly available resources and hope to serve as new quantitative tools in studying construction grammar.},

  abstract  = {Previous work concerning measurement of second
language learners has tended to focus on the knowledge of small
numbers of words, often geared towards measuring vocabulary size.
This paper presents a "tall" dataset containing information about a
few learners' knowledge of many words, suitable for evaluating
Vocabulary Inventory Prediction (VIP) techniques, including those
based on Computerised Adaptive Testing (CAT). In comparison to
previous comparable datasets, the learners are from varied
backgrounds, so as to reduce the risk of overfitting when used for
machine learning based VIP. The dataset contains both a self-rating
test and a translation test, used to derive a measure of reliability
for learner responses. The dataset creation process is documented,
and the relationship between variables concerning the participants,
such as their completion time, their language ability level, and the
triangulated reliability of their self-assessment responses, are
analysed. The word list is constructed by taking into account the
extensive derivation morphology of Finnish, and infrequent words are
included in order to account for explanatory variables beyond word
frequency.},

encoding models on exploring brain language processing using  
naturalistic stimuli. Neural encoding models are data-driven methods  
that require an encoding model to investigate the mystery of brain  
mechanisms hidden in the data. As a data-driven method, the  
performance of encoding models is very sensitive to the experimental  
setting. However, it is unknown how the experimental setting further  
affects the conclusions of neural encoding models. This paper
```

systematically investigated this problem and evaluated the influence of three experimental settings, i.e., the data size, the cross-validation training method, and the statistical testing method. Results demonstrate that inappropriate cross-validation training and small data size can substantially decrease the performance of encoding models, especially in the temporal lobe and the frontal lobe. And different null hypotheses in significance testing lead to highly different significant brain regions. Based on these results, we suggest a block-wise cross-validation training method and an adequate data size for increasing the performance of linear encoding models. We also propose two strict null hypotheses to control false positive discovery rates.},

pages = {6405--6419},

abstract = {In recent years, there has been increasing interest in automatic personality detection based on language. Progress in this area is highly contingent upon the availability of datasets and benchmark corpora. However, publicly available datasets for modeling and predicting personality traits are still scarce. While recent efforts to create such datasets from social media (Twitter, Reddit) are to be applauded, they often do not include continuous and contextualized language use. In this paper, we introduce SPADE, the first dataset with continuous samples of argumentative speech labeled with the Big Five personality traits and enriched with socio-demographic data (age, gender, education level, language background). We provide benchmark models for this dataset to facilitate further research and conduct extensive experiments. Our models leverage 436 (psycho)linguistic features extracted from transcribed speech and speaker-level meta-information with transformers. We conduct feature ablation experiments to investigate which types of features contribute to the prediction of individual personality traits.},

pages      = {6420--6428},
abstract   = {This contribution presents our efforts to develop the
automatic speech recognition (ASR) systems for three low resource
languages: Kurmanji Kurdish, Cree and Inuktut. As a first step, we
generate multilingual models from acoustic training data from 12
different languages in the hybrid DNN/HMM framework. We explore
different strategies for combining the phones from different
languages: either keep the phone labels separate for each language
or merge the common phones. For Kurmanji Kurdish and Inuktut,
keeping the phones separate gives much lower word error rate (WER),
while merging phones gives lower WER for Cree. These WER are lower
than training the acoustic models separately for each language. We
also compare two different DNN architectures: factored time delay
neural network (TDNN-F), and bidirectional long short-term memory
(BLSTM) acoustic models. The TDNN-F acoustic models give
significantly lower WER for Kurmanji Kurdish and Cree, while BLSTM
acoustic models give significantly lower WER for Inuktut. We also
show that for each language, training multilingual acoustic models
by one more epoch with acoustic data from that language reduces the
WER significantly. We also added 512-dimensional embedding features
from cross-lingual pre-trained wav2vec2.0 XLSR-53 models, but they
lead to only a small reduction in WER.},

publisher = {European Language Resources Association},
pages = {6429--6438},
abstract = {Candidate generation is a crucial module in entity linking. It also plays a key role in multiple NLP tasks that have been proven to beneficially leverage knowledge bases. Nevertheless, it has often been overlooked in the monolingual English entity linking literature, as naïve approaches obtain very good performance. Unfortunately, the existing approaches for English cannot be successfully transferred to poorly resourced languages. This paper constitutes an in-depth analysis of the candidate generation problem in the context of cross-lingual entity linking with a focus on low-resource languages. Among other contributions, we point out limitations in the evaluation conducted in previous works. We introduce a characterization of queries into types based on their difficulty, which improves the interpretability of the performance of different methods. We also propose a light-weight and simple solution based on the construction of indexes whose design is motivated by more complex transfer learning based neural approaches. A thorough empirical analysis on 9 real-world datasets under 2 evaluation settings shows that our simple solution outperforms the state-of-the-art approach in terms of both quality and efficiency for almost all datasets and query types.},

    abstract   = {In recent years, the natural language processing
(NLP) community has given increased attention to the disparity of
efforts directed towards high-resource languages over low-resource
ones. Efforts to remedy this delta often begin with translations of
existing English datasets into other languages. However, this
approach ignores that different language communities have different
needs. We consider a group of low-resource languages, creole
languages. Creoles are both largely absent from the NLP literature,
and also often ignored by society at large due to stigma, despite
these languages having sizable and vibrant communities. We
demonstrate, through conversations with creole experts and surveys
of creole-speaking communities, how the things needed from language
technology can change dramatically from one language to another,
even when the languages are considered to be very similar to each
other, as with creoles. We discuss the prominent themes arising from
these conversations, and ultimately demonstrate that useful language
technology cannot be built without involving the relevant
community.},

  pages       = {6450--6460},
  abstract    = {The Brahmic family of scripts is used to record some
of the most spoken languages in the world and is arguably the most
diverse family of writing systems. In this work, we present several
substantial extensions to Brahmic script functionality within the
open-source Nisaba library of finite-state script normalization and
processing utilities (Johny et al., 2021). First, we extend coverage
from the original ten scripts to an additional ten scripts of South
Asia and beyond, including some used to record endangered languages
such as Dogri. Second, we augment the language layer so that scripts
used by multiple languages in distinct ways can be processed
correctly for more languages, such as the Bengali script when used
for the low-resource language Santali. We document key changes to
the finite-state engine required to support these new languages and
scripts. Finally, we add new script processing utilities, including
lightweight script-level reading normalization that (unlike existing
visual normalization) does not preserve visual invariance, and a
fixed-input transliteration mechanism specifically tailored to
Brahmic text entry with ASCII characters.},

  abstract    = {This paper simulates a low-resource setting across 17  
languages in order to evaluate embedding similarity, stability, and  
reliability under different conditions. The goal is to use corpus  
similarity measures before training to predict properties of  
embeddings after training. The main contribution of the paper is to  
show that it is possible to predict downstream embedding similarity  
using upstream corpus similarity measures. This finding is then  
applied to low-resource settings by modelling the reliability of  
embeddings created from very limited training data. Results show  
that it is possible to estimate the reliability of low-resource  
embeddings using corpus similarity measures that remain robust on  
small amounts of data. These findings have significant implications  
for the evaluation of truly low-resource languages in which such  
systematic downstream validation methods are not possible because of  
data limitations.},

  abstract    = {Multi-modal Machine Translation (MMT) enables the use  
of visual information to enhance the quality of translations,  
especially where the full context is not available to enable the  
unambiguous translation in standard machine translation. Despite the  
increasing popularity of such technique, it lacks sufficient and  
qualitative datasets to maximize the full extent of its potential.  
Hausa, a Chadic language, is a member of the Afro-Asiatic language  
family. It is estimated that about 100 to 150 million people speak
```

the language, with more than 80 million indigenous speakers. This is more than any of the other Chadic languages. Despite the large number of speakers, the Hausa language is considered as a low resource language in natural language processing (NLP). This is due to the absence of enough resources to implement most of the tasks in NLP. While some datasets exist, they are either scarce, machine-generated or in the religious domain. Therefore, there is the need to create training and evaluation data for implementing machine learning tasks and bridging the research gap in the language. This work presents the Hausa Visual Genome (HaVG), a dataset that contains the description of an image or a section within the image in Hausa and its equivalent in English. The dataset was prepared by automatically translating the English description of the images in the Hindi Visual Genome (HVG). The synthetic Hausa data was then carefully postedited, taking into cognizance the respective images. The data is made of 32,923 images and their descriptions that are divided into training, development, test, and challenge test set. The Hausa Visual Genome is the first dataset of its kind and can be used for Hausa-English machine translation, multi-modal research, image description, among various other natural language processing and generation tasks.},

```

four formats: (1) transcriptions, (2) lemmatized transcriptions, (3) audio files and time-aligned phonetic transcriptions, and (4) an SQLite database. The transcription files are a digitized and corrected version of authentic transcriptions of tape-recorded narratives coming from a fieldwork trip conducted in the 1980s and published in the early 1990s (Arnold, 1991a, 1991b). They contain no annotation, except for some informative tagging (e.g. to mark loanwords and misspoken words). In the lemmatized version of the files, each word form is followed by its lemma in angled brackets. The time-aligned TextGrid annotations consist of four tiers: the sentence level (Tier 1), the word level (Tiers 2 and 3), and the segment level (Tier 4). These TextGrid files are downloadable together with their audio files (for the original source of the audio data see Arnold, 2003). The SQLite database enables users to access the data on the level of tokens, types, lemmas, sentences, narratives, or speakers. The corpus is now available to the scientific community at <https://doi.org/10.5281/zenodo.6496714>.,

  abstract  = {This paper provides language identification models  
for low- and under-resourced languages in the Pacific region with a  
focus on previously unavailable Austronesian languages. Accurate  
language identification is an important part of developing language  
resources. The approach taken in this paper combines 29 Austronesian  
languages with 171 non-Austronesian languages to create an  
evaluation set drawn from eight data sources. After evaluating six  
approaches to language identification, we find that a classifier  
based on skip-gram embeddings reaches a significantly higher  
performance than alternate methods. We then systematically increase  
the number of non-Austronesian languages in the model up to a total  
of 800 languages to evaluate whether an increased language inventory  
leads to less precise predictions for the Austronesian languages of  
interest. This evaluation finds that there is only a minimal impact  
on accuracy caused by increasing the inventory of non-Austronesian  
languages. Further experiments adapt these language identification  
models for code-switching detection, achieving high accuracy across  
all 29 languages.},

  abstract  = {This paper describes the development and evaluation  
of a FST-based analyser-generator for Mapudüngun language, which is  
publicly available through a web interface. As far as we know, it is  
the first system of this kind for Mapudüngun. Following the Mapuche  
grammar by Smeets, we have developed a machine including the  
morphological and phonological aspects of Mapudüngun. Through this  
computational approach we have produced a finite state morphological  
analyser-generator capable of classifying and appropriately tagging  
all the components (roots and suffixes) interacting in a Mapuche  
word-form. A double evaluation has been carried out showing a good
```

level of reliability. In order to face the lack of standardization of the language, additional components (an enhanced analyser, a spelling unifier and a root guesser) have been integrated in the tool. The generated corpora, the lexicons and the FST grammars are available for further development and comparison results.},

abstract = {Bodo is a scheduled Indian language spoken largely by the Bodo community of Assam and other northeastern Indian states. Due to a lack of resources, it is difficult for young languages to communicate more effectively with the rest of the world. This leads to a lack of research in low-resource languages. The creation of a dataset is a tedious and costly process, particularly for languages with no participatory research. This is more visible for languages that are young and have recently adopted standard writing scripts. In this paper, we present a methodology using Google Keep for OCR to generate a monolingual Bodo corpus from different books. In this work, a Bodo text corpus of 192,327 tokens and 32,268 unique tokens is generated using free, accessible, and daily-usable applications. Moreover, some essential characteristics of the Bodo language are discussed that are neglected by Natural Language Progressing (NLP) researchers.},

  pages       = {6578--6584},
  abstract    = {Language identification is one of the fundamental
tasks in natural language processing that is a prerequisite to data
processing and numerous applications. Low-resourced languages with
similar typologies are generally confused with each other in real-
world applications such as machine translation, affecting the user's
experience. In this work, we present a language identification
dataset for five typologically and phylogenetically related low-
resourced East African languages that use the Ge'ez script as a
writing system; namely Amharic, Blin, Ge'ez, Tigre, and Tigrinya.
The dataset is built automatically from selected data sources, but
we also performed a manual evaluation to assess its quality. Our
approach to constructing the dataset is cost-effective and
applicable to other low-resource languages. We integrated the
dataset into an existing language-identification tool and also fine-
tuned several Transformer based language models, achieving very
strong results in all cases. While the task of language
identification is easy for the informed person, such datasets can
make a difference in real-world deployments and also serve as part
of a benchmark for language understanding in the target languages.
The data and models are made available at https://github.com/fgaim/

    abstract   = {Today classicists are provided with a great number of
digital tools which, in turn, offer possibilities for further study
and new research goals. In this paper we explore the idea that old
Greek handwriting can be machine-readable and consequently,
researchers can study the target material fast and efficiently.
Previous studies have shown that Handwritten Text Recognition (HTR)
models are capable of attaining high accuracy rates. However,
achieving high accuracy HTR results for Greek manuscripts is still
considered to be a major challenge. The overall aim of this paper is
to assess HTR for old Greek manuscripts. To address this statement,
we study and use digitized images of the Oxford University Bodleian
Library Greek manuscripts. By manually transcribing 77 images, we
created and present here a new dataset for Handwritten Paleographic
Greek Text Recognition. The dataset instances were organized by
establishing as a leading factor the century to which the manuscript
and hence the image belongs. Experimenting then with an HTR model we
show that the error rate depends on the century of the image.},

pages = {6612--6619},
abstract = {Hate and offensive speech on social media is targeted to attack an individual or group of community based on protected characteristics such as gender, ethnicity, and religion. Hate and offensive speech on social media is a global problem that suffers the community especially, for an under-resourced language like Afaan Oromo language. One of the most widely spoken Cushitic language families is Afaan Oromo. Our objective is to develop and test a model used to detect and classify Afaan Oromo hate speech on social media. We developed numerous models that were used to detect and classify Afaan Oromo hate speech on social media by using different machine learning algorithms (classical, ensemble, and deep learning) with the combination of different feature extraction techniques such as BOW, TF-IDF, word2vec, and Keras Embedding layers. To perform the task, we required Afaan Oromo datasets, but the datasets were

unavailable. By concentrating on four thematic areas of hate speech, such as gender, religion, race, and offensive speech, we were able to collect a total of 12,812 posts and comments from Facebook.

BiLSTM with pre-trained word2vec feature extraction is an outperformed algorithm that achieves better accuracy of 0.84 and 0.88 for eight classes and two classes, respectively.},

abstract = {A semantic frame is a conceptual structure describing  
an event, relation, or object along with its participants. Several  
semantic frame resources have been manually elaborated, and there  
has been much interest in the possibility of applying semantic  
frames designed for a particular language to other languages, which  
has led to the development of cross-lingual frame knowledge.
```

```
However, manually developing such cross-lingual lexical resources is  
labor-intensive. To support the development of such resources, this  
paper presents an attempt at automatic cross-lingual linking of  
automatically constructed frames and manually crafted frames.
```

```
Specifically, we link automatically constructed example-based  
Japanese frames to English FrameNet by using cross-lingual word  
embeddings and a two-stage model that first extracts candidate  
FrameNet frames for each Japanese frame by taking only the frame-  
evoking words into account, then finds the best alignment of frames  
by also taking frame elements into account. Experiments using frame-  
annotated sentences in Japanese FrameNet indicate that our approach  
will facilitate the manual development of cross-lingual frame  
resources.},

abstract = {We present here the efforts of aligning two language resources for Romanian: the Romanian Reference Treebank and the Valence Lexicon of Romanian Verbs: for each occurrence of those verbs in the treebank that were included as entries in the lexicon, a set of valence frames is automatically assigned, then manually validated by two linguists and, when necessary, corrected. Validating a valence frame also means semantically disambiguating the verb in the respective context. The validation is done by two linguists, on complementary datasets. However, a subset of verbs were validated by both annotators and Cohen's  $\kappa$  is 0.87 for this subset. The alignment we have made also serves as a method of enhancing the quality of the two resources, as in the process we identify morpho-syntactic annotation mistakes, incomplete valence frames or missing ones. Information from each resource complements the information from the other, thus their value increases. The treebank and the lexicon are freely available, while the links discovered between them are also made available on GitHub.},

abstract   = {In this paper, we propose two neural machine
translation (NMT) systems (French-to-Wolof and Wolof-to-French)
based on sequence-to-sequence with attention and Transformer
architectures. We trained our models on the parallel French-Wolof
corpus (Nguer et al., 2020) of about 83k sentence pairs. Because of
the low-resource setting, we experimented with advanced methods for
handling data sparsity, including subword segmentation,
backtranslation and the copied corpus method. We evaluate the models
using BLEU score and find that the transformer outperforms the
classic sequence-to-sequence model in all settings, in addition to
being less sensitive to noise. In general, the best scores are
achieved when training the models on subword-level based units. For
such models, using backtranslation proves to be slightly beneficial
in low-resource Wolof to high-resource French language translation
for the transformer-based models. A slight improvement can also be
observed when injecting copied monolingual text in the target
language. Moreover, combining the copied method data with
backtranslation leads to a slight improvement of the translation

  abstract = {This paper presents a number of possible criteria for  
systems that transliterate South Asian languages from their native  
scripts into the Latin script, a process known as romanization.  
These criteria are related to either fidelity to human linguistic  
behavior (pronunciation transparency, naturalness and  
conventionality) or processing utility for people (ease of input) as  
well as under-the-hood in systems (invertibility and stability  
across languages and scripts). When addressing these differing  
criteria several linguistic considerations, such as modeling of  
prominent phonological processes and their relation to orthography,  
need to be taken into account. We discuss these key linguistic  
details in the context of Brahmic scripts and languages that use  
them, such as Hindi and Malayalam. We then present the core features  
of several romanization algorithms, implemented in a finite state  
transducer (FST) formalism, that address differing criteria.  
Implementations of these algorithms have been released as part of  
the Nisaba finite-state script processing library.},

analyze the performance of BERT's syntactic dependencies and their
```

impact on machine translation quality, exploring what kind of syntactic dependencies are difficult for NMT engines based on BERT. While our probing experiments confirm that pre-trained BERT “knows” about syntactic dependencies, its ability to recognize them often decreases after fine-tuning for NMT tasks. We also detect a relationship between syntactic dependencies in three languages and the quality of their translations, which shows which specific syntactic dependencies are likely to be a significant cause of low-quality translations.},

publisher = {European Language Resources Association},
pages = {689--696},
abstract = {We present a fairly large, Potential Idiomatic Expression (PIE) dataset for Natural Language Processing (NLP) in English. The challenges with NLP systems with regards to tasks such as Machine Translation (MT), word sense disambiguation (WSD) and information retrieval make it imperative to have a labelled idioms dataset with classes such as it is in this work. To the best of the authors' knowledge, this is the first idioms corpus with classes of idioms beyond the literal and the general idioms classification. In particular, the following classes are labelled in the dataset: metaphor, simile, euphemism, parallelism, personification, oxymoron, paradox, hyperbole, irony and literal. We obtain an overall inter-annotator agreement (IAA) score, between two independent annotators, of 88.89%. Many past efforts have been limited in the corpus size and classes of samples but this dataset contains over 20,100 samples with almost 1,200 cases of idioms (with their meanings) from 10 classes (or senses). The corpus may also be extended by researchers to meet specific needs. The corpus has part of speech (PoS) tagging from the NLTK library. Classification experiments performed on the corpus to obtain a baseline and comparison among three common models, including the BERT model, give good results. We also make publicly available the corpus and the relevant codes for working with it for NLP tasks.},

  pages          = {6691--6703},
  abstract       = {We introduce CVSS, a massively multilingual-to-
English speech-to-speech translation (S2ST) corpus, covering
sentence-level parallel S2ST pairs from 21 languages into English.
CVSS is derived from the Common Voice speech corpus and the CoVoST 2
speech-to-text translation (ST) corpus, by synthesizing the
translation text from CoVoST 2 into speech using state-of-the-art
TTS systems. Two versions of translation speech in English are
provided: 1) CVSS-C: All the translation speech is in a single high-
quality canonical voice; 2) CVSS-T: The translation speech is in
voices transferred from the corresponding source speech. In
addition, CVSS provides normalized translation text which matches
the pronunciation in the translation speech. On each version of
CVSS, we built baseline multilingual direct S2ST models and cascade
S2ST models, verifying the effectiveness of the corpus. To build
strong cascade S2ST baselines, we trained an ST model on CoVoST 2,
which outperforms the previous state-of-the-art trained on the
corpus without extra data by 5.8 BLEU. Nevertheless, the performance
of the direct S2ST models approaches the strong cascade baselines
when trained from scratch, and with only 0.1 or 0.7 BLEU difference
on ASR transcribed translation when initialized from matching ST
models.},

  abstract      = {Most current machine translation models are mainly
trained with parallel corpora, and their translation accuracy
largely depends on the quality and quantity of the corpora. Although
there are billions of parallel sentences for a few language pairs,
effectively dealing with most language pairs is difficult due to a
lack of publicly available parallel corpora. This paper creates a
large parallel corpus for English-Japanese, a language pair for
which only limited resources are available, compared to such
resource-rich languages as English-German. It introduces a new web-
based English-Japanese parallel corpus named JParaCrawl v3.0. Our
```

new corpus contains more than 21 million unique parallel sentence pairs, which is more than twice as many as the previous JParaCrawl v2.0 corpus. Through experiments, we empirically show how our new corpus boosts the accuracy of machine translation models on various domains. The JParaCrawl v3.0 corpus will eventually be publicly available online for research purposes.},

abstract = {South and North Korea both use the Korean language.  
However, Korean NLP research has focused on South Korean only, and  
existing NLP systems of the Korean language, such as neural machine  
translation (NMT) models, cannot properly handle North Korean  
inputs. Training a model using North Korean data is the most  
straightforward approach to solving this problem, but there is  
insufficient data to train NMT models. In this study, we create data  
for North Korean NMT models using a comparable corpus. First, we  
manually create evaluation data for automatic alignment and machine  
translation, and then, investigate automatic alignment methods  
suitable for North Korean. Finally, we show that a model trained by  
North Korean bilingual data without human annotation significantly  
boosts North Korean translation accuracy compared to existing South  
Korean models in zero-shot settings.},

abstract = {Previous research for adapting a general neural  
machine translation (NMT) model into a specific domain usually  
neglects the diversity in translation within the same domain, which
```

is a core problem for domain adaptation in real-world scenarios. One representative of such challenging scenarios is to deploy a translation system for a conference with a specific topic, e.g., global warming or coronavirus, where there are usually extremely less resources due to the limited schedule. To motivate wider investigation in such a scenario, we present a real-world fine-grained domain adaptation task in machine translation (FGraDA). The FGrADA dataset consists of Chinese-English translation task for four sub-domains of information technology: autonomous vehicles, AI education, real-time networks, and smart phone. Each sub-domain is equipped with a development set and test set for evaluation purposes. To be closer to reality, FGrADA does not employ any in-domain bilingual training data but provides bilingual dictionaries and wiki knowledge base, which can be easier obtained within a short time. We benchmark the fine-grained domain adaptation task and present in-depth analyses showing that there are still challenging problems to further improve the performance with heterogeneous resources.},

  abstract     = {This paper presents a new benchmark test dataset for
multi-level complexity-controllable machine translation (MLCC-MT),
which is MT controlling the complexity of the output at more than
two levels. In previous research, MLCC-MT models have been evaluated
on a test dataset automatically constructed from the Newsela corpus,
which is a document-level comparable corpus with document-level
complexity. The existing test dataset has the following three
problems: (i) A source language sentence and its target language
sentence are not necessarily an exact translation pair because they
are automatically detected. (ii) A target language sentence and its
simplified target language sentence are not necessarily exactly
parallel because they are automatically aligned. (iii) A sentence-
level complexity is not necessarily appropriate because it is
transferred from an article-level complexity attached to the Newsela
corpus. Therefore, we create a benchmark test dataset for Japanese-
to-English MLCC-MT from the Newsela corpus by introducing an
automatic filtering of data with inappropriate sentence-level
complexity, manual check for parallel target language sentences with
different complexity levels, and manual translation. Moreover, we
implement two MLCC-NMT frameworks with a Transformer architecture
and report their performance on our test dataset as baselines for
future research. Our test dataset and codes are released.},

  abstract  = {Machine Translation is a mature technology for many  
high-resource language pairs. However in the context of low-resource  
languages, there is a paucity of parallel data datasets available  
for developing translation models. Furthermore, the development of  
datasets for low-resource languages often focuses on simply creating  
the largest possible dataset for generic translation. The benefits  
and development of smaller in-domain datasets can easily be  
overlooked. To assess the merits of using in-domain data, a dataset  
for the specific domain of health was developed for the low-resource  
English to Irish language pair. Our study outlines the process used  
in developing the corpus and empirically demonstrates the benefits  
of using an in-domain dataset for the health domain. In the context  
of translating health-related data, models developed using the  
gaHealth corpus demonstrated a maximum BLEU score improvement of  
22.2 points (40\%) when compared with top performing models from the  
LoResMT2021 Shared Task. Furthermore, we define linguistic  
guidelines for developing gaHealth, the first bilingual corpus of  
health data for the Irish language, which we hope will be of use to  
other creators of low-resource data sets. gaHealth is now freely  
available online and is ready to be explored for further research.},

pages         = {6786--6793},
abstract      = {With the rise of deep learning and intelligent
vehicles, the smart assistant has become an essential in-car
component to facilitate driving and provide extra functionalities.
In-car smart assistants should be able to process general as well as
car-related commands and perform corresponding actions, which eases
driving and improves safety. However, there is a data scarcity issue
for low resource languages, hindering the development of research
and applications. In this paper, we introduce a new dataset,
Cantonese In-car Audio-Visual Speech Recognition (CI-AVSR), for in-
car command recognition in the Cantonese language with both video
and audio data. It consists of 4,984 samples (8.3 hours) of 200 in-
car commands recorded by 30 native Cantonese speakers. Furthermore,
we augment our dataset using common in-car background noises to
simulate real environments, producing a dataset 10 times larger than
the collected one. We provide detailed statistics of both the clean
and the augmented versions of our dataset. Moreover, we implement
two multimodal baselines to demonstrate the validity of CI-AVSR.
Experiment results show that leveraging the visual signal improves
the overall performance of the model. Although our best model can
achieve a considerable quality on the clean test set, the speech
recognition quality on the noisy data is still inferior and remains
an extremely challenging task for real in-car speech recognition
systems. The dataset and code will be released at https://github.com/HLTCHKUST/CI-AVSR.},

  abstract    = {This study investigates social-psychological
negotiation-outcome prediction (SPNOP), a novel task for estimating
various subjective evaluation scores of negotiation, such as
satisfaction and trust, from negotiation dialogue data. To
investigate SPNOP, a corpus with various psychological measurements
is beneficial because the interaction process of negotiation relates
to many aspects of psychology. However, current negotiation corpora
only include information related to objective outcomes or a single
aspect of psychology. In addition, most use the ``laboratory
setting'' that uses non-skilled negotiators and over simplified
negotiation scenarios. There is a concern that such a gap with
actual negotiation will intrinsically affect the behavior and

```

psychology of negotiators in the corpus, which can degrade the performance of models trained from the corpus in real situations. Therefore, we created a negotiation corpus with three features; 1) was assessed with various psychological measurements, 2) used skilled negotiators, and 3) used scenarios of context-rich negotiation. We recorded video and audio of negotiations in Japanese to investigate SPNOP in the context of social signal processing. Experimental results indicate that social-psychological outcomes can be effectively estimated from multimodal information.},

abstract   = {Multimodal combinations of writing and pictures have
become ubiquitous in contemporary society, and scholars have
increasingly been turning to analyzing these media. Here we present
a resource for annotating these complex documents: the Multimodal
Annotation Software Tool (MAST). MAST is an application that allows
users to analyze visual and multimodal documents by selecting and
annotating visual regions, and to establish relations between
annotations that create dependencies and/or constituent structures.
By means of schema publications, MAST allows annotation theories to
be citable, while evolving and being shared. Documents can be
annotated using multiple schemas simultaneously, offering more
comprehensive perspectives. As a distributed, client-server system
MAST allows for collaborative annotations across teams of users, and
features team management and resource access functionalities,
facilitating the potential for implementing open science practices.
Altogether, we aim for MAST to provide a powerful and innovative
annotation tool with application across numerous fields engaging
with multimodal media.},

  abstract  = {Large datasets as required for deep learning of lip
reading do not exist in many languages. In this paper we present the
dataset GLips (German Lips) consisting of 250,000 publicly available
videos of the faces of speakers of the Hessian Parliament, which was
processed for word-level lip reading using an automatic pipeline.
The format is similar to that of the English language LRW (Lip
Reading in the Wild) dataset, with each video encoding one word of
interest in a context of 1.16 seconds duration, which yields
compatibility for studying transfer learning between both datasets.
By training a deep neural network, we investigate whether lip
reading has language-independent features, so that datasets of
different languages can be used to improve lip reading models. We
demonstrate learning from scratch and show that transfer learning
from LRW to GLips and vice versa improves learning speed and
performance, in particular for the validation set.},

abstract = {For different reasons, text can be difficult to read and understand for many people, especially if the text's language is too complex. In order to provide suitable text for the target audience, it is necessary to measure its complexity. In this paper we describe subjective experiments to assess the readability of German text. We compile a new corpus of sentences provided by a German IT service provider. The sentences are annotated with the subjective complexity ratings by two groups of participants, namely experts and non-experts for that text domain. We then extract an extensive set of linguistically motivated features that are supposedly interacting with complexity perception. We show that a linear regression model with a subset of these features can be a very good predictor of text complexity.},

abstract = {This article presents SSR7000, a corpus of  
synchronized ultrasound tongue and lip images designed for end-to-  
end silent speech recognition (SSR). Although neural end-to-end  
models are successfully updating the state-of-the-art technology in  
the field of automatic speech recognition, SSR research based on  
ultrasound tongue imaging has still not evolved past cascaded DNN-  
HMM models due to the absence of a large dataset. In this study, we  
constructed a large dataset, namely SSR7000, to exploit the  
performance of the end-to-end models. The SSR7000 dataset contains  
ultrasound tongue and lip images of 7484 utterances by a single  
speaker. It contains more utterances per person than any other SSR  
corpus based on ultrasound imaging. We also describe preprocessing  
techniques to tackle data variances that are inevitable when  
collecting a large dataset and present benchmark results using an  
end-to-end model. The SSR7000 corpus is publicly available under the  
CC BY-NC 4.0 license.},

  abstract   = {Deletion-based sentence compression in the English
language has made significant progress over the past few decades.
However, there is a lack of large-scale and high-quality parallel
corpus (i.e., (sentence, compression) pairs) for the Chinese
language to train an efficient compression system. To remedy this
shortcoming, we present a dependency-tree-based method to construct
a Chinese corpus with 151k pairs of sentences and compression based
on Chinese language-specific characteristics. Subsequently, we
trained both extractive and generative neural compression models
using the constructed corpus. The experimental results show that our
compression model can generate high-quality compressed sentences on
both automatic and human evaluation metrics compared with the
baselines. The results of the faithfulness evaluation also indicated
that the Chinese compression model trained on our constructed corpus
can produce more faithful compressed sentences. Furthermore, a
dataset with 1,000 pairs of sentences and ground truth compression
was manually created for automatic evaluation, which, we believe,
will benefit future research on Chinese sentence compression.},

abstract = {As neural Text Generation Models (TGM) have become more and more capable of generating text indistinguishable from human-written ones, the misuse of text generation technologies can have serious ramifications. Although a neural classifier often achieves high detection accuracy, the reason for it is not well studied. Most previous work revolves around studying the impact of model structure and the decoding strategy on ease of detection, but little work has been done to analyze the forms of artifacts left by the TGM. We propose to systematically study the forms and scopes of artifacts by corrupting texts, replacing them with linguistic or statistical features, and applying the interpretable method of Integrated Gradients. Comprehensive experiments show artifacts a) primarily relate to token co-occurrence, b) feature more heavily at the head of vocabulary, c) appear more in content word than stopwords, d) are sometimes detrimental in the form of number of token occurrences, e) are less likely to exist in high-level semantics or syntaxes, f) manifest in low concreteness values for higher-order n-grams.},

abstract = {Natural language generation in real-time settings with raw sensor data is a challenging task. We find that formulating the task as an end-to-end problem leads to two major challenges in

content selection -- the sensor data is both redundant and diverse across environments, thereby making it hard for the encoders to select and reason on the data. We here present a new corpus for a specific domain that instantiates these properties. It includes handover utterances that an assistant for a semi-autonomous drone uses to communicate with humans during the drone flight. The corpus consists of sensor data records and utterances in 8 different environments. As a structured intermediary representation between data records and text, we explore the use of description logic (DL). We also propose a neural generation model that can alert the human pilot of the system state and environment in preparation of the handover of control.},

publisher = {European Language Resources Association},

pages = {6914--6921},

abstract = {Lexical substitution task requires to substitute a

target word by candidates in a given context. Candidates must keep meaning and grammatically of the sentence. The task, introduced in the SemEval 2007, has two objectives. The first objective is to find a list of substitutes for a target word. This list of substitutes can be obtained with lexical resources like WordNet or generated with a pre-trained language model. The second objective is to rank these substitutes using the context of the sentence. Most of the methods use vector space models or more recently embeddings to rank substitutes. Embedding methods use high contextualized representation. This representation can be over contextualized and in this way overlook good substitute candidates which are more similar on non-contextualized layers. SemDis 2014 introduced the lexical substitution task in French. We propose an application of the state-of-the-art method based on BERT in French and a novel method using contextualized and non-contextualized layers to increase the suggestion of words having a lower probability in a given context but that are more semantically similar. Experiments show our method increases the BERT based system on the OOT measure but decreases on the BEST measure in the SemDis 2014 benchmark.},

pages = {6922--6931},
abstract = {Can language models read biomedical texts and explain the biomedical mechanisms discussed? In this work we introduce a biomedical mechanism summarization task. Biomedical studies often investigate the mechanisms behind how one entity (e.g., a protein or a chemical) affects another in a biological context. The abstracts of these publications often include a focused set of sentences that present relevant supporting statements regarding such relationships, associated experimental evidence, and a concluding sentence that summarizes the mechanism underlying the relationship. We leverage this structure and create a summarization task, where the input is a collection of sentences and the main entities in an abstract, and the output includes the relationship and a sentence that summarizes the mechanism. Using a small amount of manually labeled mechanism sentences, we train a mechanism sentence classifier to filter a large biomedical abstract collection and create a summarization dataset with 22k instances. We also introduce conclusion sentence generation as a pretraining task with 611k instances. We benchmark the performance of large bio-domain language models. We find that while the pretraining task help improves performance, the best model produces acceptable mechanism outputs in only 32\% of the instances,

which shows the task presents significant challenges in biomedical language understanding and summarization.},

abstract = {Cross-lingual summarization, which produces the summary in one language from a given source document in another language, could be extremely helpful for humans to obtain information across the world. However, it is still a little-explored task due to the lack of datasets. Recent studies are primarily based on pseudo-cross-lingual datasets obtained by translation. Such an approach would inevitably lead to the loss of information in the original document and introduce noise into the summary, thus hurting the overall performance. In this paper, we present CATAMARAN, the first high-quality cross-lingual long text abstractive summarization dataset. It contains about 20,000 parallel news articles and corresponding summaries, all written by humans. The average lengths of articles are 1133.65 for English articles and 2035.33 for Chinese articles, and the average lengths of the summaries are 26.59 and 70.05, respectively. We train and evaluate an mBART-based cross-lingual abstractive summarization model using our dataset. The result shows that, compared with mono-lingual systems, the cross-lingual abstractive summarization system could also achieve solid performance.},

abstract = {In this paper, we address two problems in indexing and querying spoken language corpora with overlapping speaker contributions. First, we look into how token distance and token precedence can be measured when multiple primary data streams are

available and when transcriptions happen to be tokenized, but are not synchronized with the sound at the level of individual tokens. We propose and experiment with a speaker-based search mode that enables any speaker's transcription tier to be the basic tokenization layer whereby the contributions of other speakers are mapped to this given tier. Secondly, we address two distinct methods of how speaker overlaps can be captured in the TEI-based ISO Standard for Spoken Language Transcriptions (ISO 24624:2016) and how they can be queried by MTAS – an open source Lucene-based search engine for querying text with multilevel annotations. We illustrate the problems, introduce possible solutions and discuss their benefits and drawbacks.},

abstract      = {Emotion detection can provide us with a window into
understanding human behavior. Due to the complex dynamics of human
emotions, however, constructing annotated datasets to train
automated models can be expensive. Thus, we explore the efficacy of
cross-lingual approaches that would use data from a source language
to build models for emotion detection in a target language. We
compare three approaches, namely: i) using inherently multilingual
models; ii) translating training data into the target language; and
iii) using an automatically tagged parallel corpus. In our study, we
consider English as the source language with Arabic and Spanish as
target languages. We study the effectiveness of different
classification models such as BERT and SVMs trained with different
features. Our BERT-based monolingual models that are trained on
target language data surpass state-of-the-art (SOTA) by 4\% and 5\%
absolute Jaccard score for Arabic and Spanish respectively. Next, we
show that using cross-lingual approaches with English data alone, we
can achieve more than 90\% and 80\% relative effectiveness of the
Arabic and Spanish BERT models respectively. Lastly, we use LIME to
analyze the challenges of training cross-lingual models for
different language pairs.},

address     = {Marseille, France},
publisher   = {European Language Resources Association},
pages       = {6959--6966},
abstract    = {Quotation extraction and attribution are challenging
tasks, aiming at determining the spans containing quotations and
attributing each quotation to the original speaker. Applying this
task to news data is highly related to fact-checking, media
monitoring and news tracking. Direct quotations are more traceable
and informative, and therefore of great significance among different
types of quotations. Therefore, this paper introduces DirectQuote, a
corpus containing 19,760 paragraphs and 10,279 direct quotations
manually annotated from online news media. To the best of our
knowledge, this is the largest and most complete corpus that focuses
on direct quotations in news texts. We ensure that each speaker in
the annotation can be linked to a specific named entity on Wikidata,
benefiting various downstream tasks. In addition, for the first
time, we propose several sequence labeling models as baseline
methods to extract and attribute quotations simultaneously in an
end-to-end manner.},

  address   = {Marseille, France},  
  publisher = {European Language Resources Association},  
  pages     = {6967--6975},  
  abstract  = {Billions of COVID-19 vaccines have been administered,  
but many remain hesitant. Misinformation about the COVID-19 vaccines  
and other vaccines, propagating on social media, is believed to  
drive hesitancy towards vaccination. The ability to automatically  
recognize misinformation targeting vaccines on Twitter depends on  
the availability of data resources. In this paper we present  
VaccineLies, a large collection of tweets propagating misinformation  
about two vaccines: the COVID-19 vaccines and the Human  
Papillomavirus (HPV) vaccines. Misinformation targets are organized  
in vaccine-specific taxonomies, which reveal the misinformation  
themes and concerns. The ontological commitments of the  
misinformation taxonomies provide an understanding of which  
misinformation themes and concerns dominate the discourse about the  
two vaccines covered in VaccineLies. The organization into training,  
testing and development sets of VaccineLies invites the development  
of novel supervised methods for detecting misinformation on Twitter  
and identifying the stance towards it. Furthermore, VaccineLies can  
be a stepping stone for the development of datasets focusing on  
misinformation targeting additional vaccines.},

  publisher = {European Language Resources Association},  
  pages     = {6976--6984},  
  abstract  = {Automatic approaches to irony detection have been of  
interest to the NLP community for a long time, yet, state-of-the-art  
approaches still fall way short of what one would consider a  
desirable performance. In part this is due to the inherent  
difficulty of the problem. However, in recent years ensembles of  
transformer-based approaches have emerged as a promising direction  
to push the state of the art forward in a wide range of NLP  
applications. A different, more recent, development is the automatic  
augmentation of training data. In this paper we will explore both  
these directions for the task of irony detection in social media.
```

Using the common SemEval 2018 Task 3 benchmark collection we demonstrate that transformer models are well suited in ensemble classifiers for the task at hand. In the multi-class classification task we observe statistically significant improvements over strong baselines. For binary classification we achieve performance that is on par with state-of-the-art alternatives. The examined data augmentation strategies showed an effect, but are not decisive for good results.},

year = {2022},
address = {Marseille, France},
publisher = {European Language Resources Association},
pages = {6985--6991},
abstract = {Aspect-based sentiment analysis (ABSA) is a task that involves classifying the polarity of aspects of the products or services described in users' reviews. Most previous work on ABSA has focused on explicit aspects, which appear as explicit words or phrases in the sentences of the review. However, users often express their opinions toward the aspects indirectly or implicitly, in which case the specific name of an aspect does not appear in the review. The current datasets used for ABSA are mainly annotated with explicit aspects. This paper proposes a novel method for constructing a corpus that is automatically annotated with implicit aspects. The main idea is that sentences containing explicit and implicit aspects share a similar context. First, labeled sentences with explicit aspects and unlabeled sentences that include implicit aspects are collected. Next, clustering is performed on these sentences so that similar sentences are merged into the same cluster. Finally, the explicit aspects are propagated to the unlabeled sentences in the same cluster, in order to construct a labeled dataset containing implicit aspects. The results of our experiments on mobile phone reviews show that our method of identifying the labels of implicit aspects achieves a maximum accuracy of 82\%.},

title = {A Multimodal Corpus for Emotion Recognition in Sarcasm},
booktitle = {Proceedings of the Language Resources and Evaluation Conference},
month = {June},

```

year          = {2022},
address       = {Marseille, France},
publisher     = {European Language Resources Association},
pages        = {6992--7003},
abstract     = {While sentiment and emotion analysis have been
studied extensively, the relationship between sarcasm and emotion
has largely remained unexplored. A sarcastic expression may have a
variety of underlying emotions. For example, "I love being ignored"
believes sadness, while "my mobile is fabulous with a battery backup
of only 15 minutes!" expresses frustration. Detecting the emotion
behind a sarcastic expression is non-trivial yet an important task.
We undertake the task of detecting the emotion in a sarcastic
statement, which to the best of our knowledge, is hitherto
unexplored. We start with the recently released multimodal sarcasm
detection dataset (MUSStARD) pre-annotated with 9 emotions. We
identify and correct 343 incorrect emotion labels (out of 690). We
double the size of the dataset, label it with emotions along with
valence and arousal which are important indicators of emotional
intensity. Finally, we label each sarcastic utterance with one of
the four sarcasm types-Propositional, Embedded, Likeprefixed and
Illocutionary, with the goal of advancing sarcasm detection
research. Exhaustive experimentation with multimodal (text, audio,
and video) fusion models establishes a benchmark for exact emotion
recognition in sarcasm and outperforms the state-of-art sarcasm
detection. We release the dataset enriched with various annotations
and the code for research purposes: https://github.com/apoorva-
nunna/MUSStARD\\_Plus\\_Plus,

pages       = {7004--7013},
abstract    = {Personal Narrative (PN) is the recollection of
individuals' life experiences, events, and thoughts along with the
associated emotions in the form of a story. Compared to other genres
such as social media texts or microblogs, where people write about
experienced events or products, the spoken PNs are complex to
analyze and understand. They are usually long and unstructured,
involving multiple and related events, characters as well as
thoughts and emotions associated with events, objects, and persons.
In spoken PNs, emotions are conveyed by changing the speech signal
characteristics as well as the lexical content of the narrative. In
this work, we annotate a corpus of spoken personal narratives, with

```

the emotion valence using discrete values. The PNs are segmented into speech segments, and the annotators annotate them in the discourse context, with values on a 5-point bipolar scale ranging from -2 to +2 (0 for neutral). In this way, we capture the unfolding of the PNs events and changes in the emotional state of the narrator. We perform an in-depth analysis of the inter-annotator agreement, the relation between the label distribution w.r.t. the stimulus (positive/negative) used for the elicitation of the narrative, and compare the segment-level annotations to a baseline continuous annotation. We find that the neutral score plays an important role in the agreement. We observe that it is easy to differentiate the positive from the negative valence while the confusion with the neutral label is high. Keywords: Personal Narratives, Emotion Annotation, Segment Level Annotation},

abstract = {There has been significant progress in the field of sentiment analysis. However, aspect-based sentiment analysis (ABSA) has not been explored in the Japanese language even though it has a huge scope in many natural language processing applications such as 1) tracking sentiment towards products, movies, politicians etc; 2) improving customer relation models. The main reason behind this is that there is no standard Japanese dataset available for ABSA task. In this paper, we present the first standard Japanese dataset for the hotel reviews domain. The proposed dataset contains 53,192 review sentences with seven aspect categories and two polarity labels. We perform experiments on this dataset using popular ABSA approaches and report error analysis. Our experiments show that contextual models such as BERT works very well for the ABSA task in the Japanese language and also show the need to focus on other NLP tasks for better performance through our error analysis.},

publisher = {European Language Resources Association},
pages = {7029--7039},
abstract = {Aspect-based sentiment analysis (ABSA) aims to predict the sentiment polarity towards a given aspect term in a sentence on the fine-grained level, which usually requires a good understanding of contextual information, especially appropriately distinguishing of a given aspect and its contexts, to achieve good performance. However, most existing ABSA models pay limited attention to the modeling of the given aspect terms and thus result in inferior results when a sentence contains multiple aspect terms with contradictory sentiment polarities. In this paper, we propose to improve ABSA by complementary learning of aspect terms, which serves as a supportive auxiliary task to enhance ABSA by explicitly recovering the aspect terms from each input sentence so as to better understand aspects and their contexts. Particularly, a discriminator is also introduced to further improve the learning process by appropriately balancing the impact of aspect recovery to sentiment prediction. Experimental results on five widely used English benchmark datasets for ABSA demonstrate the effectiveness of our approach, where state-of-the-art performance is observed on all datasets.},

address = {Marseille, France},
publisher = {European Language Resources Association},
pages = {7040--7048},
abstract = {Hate speech detection for social media posts is considered as a binary classification problem in existing approaches, largely neglecting distinct attributes of hate speeches from other sentimental types such as ``aggressive'' and ``racist''.

As these sentimental types constitute a significant major portion of data, the classification performance is compromised. Moreover, those classifiers often do not generalize well across different datasets due to a relatively small number of hate-class samples. In this paper, we adopt a one-class perspective for hate speech detection, where the detection classifier is trained with hate-class samples only. Our model employs a BERT-BiLSTM module for feature extraction and a one-class SVM for classification. A comprehensive evaluation with four benchmarking datasets demonstrates the better performance of our model than existing approaches, as well as the advantage of training our model with a combination of the four datasets.},

address = {Marseille, France},

publisher = {European Language Resources Association},

pages = {7049--7055},

abstract = {In this paper, we present the process we used in order to collect new annotations of opinions over the multimodal corpus SEMAINE composed of dyadic interactions. The dataset had already been annotated continuously in two affective dimensions related to the emotions: Valence and Arousal. We annotated the part of SEMAINE called \textit{Solid SAL} composed of 79 interactions between a user and an operator playing the role of a virtual agent designed to engage a person in a sustained, emotionally colored conversation. We aligned the audio at the word level using the available high-quality manual transcriptions. The annotated dataset contains 5627 speech turns for a total of 73,944 words, corresponding to 6 hours 20 minutes of dyadic interactions. Each interaction has been labeled by three annotators at the speech turn level following a three-step process. This method allows us to obtain a precise annotation regarding the opinion of a speaker. We obtain thus a dataset dense in opinions, with more than 48\% of the annotated speech turns containing at least one opinion. We then propose a new baseline for the detection of opinions in interactions improving slightly a state of the art model with RoBERTa embeddings. The obtained results on the database are promising with a F1-score at 0.72.},

    pages      = {7056--7060},
    abstract   = {Due to the increased availability of online reviews,
sentiment analysis witnessed a thriving interest from researchers.
Sentiment analysis is a computational treatment of sentiment used to
extract and understand the opinions of authors. While many systems
were built to predict the sentiment of a document or a sentence,
many others provide the necessary detail on various aspects of the
entity (i.e., aspect-based sentiment analysis). Most of the
available data resources were tailored to English and the other
popular European languages. Although Farsi is a language with more
than 110 million speakers, to the best of our knowledge, there is a
lack of proper public datasets on aspect-based sentiment analysis
for Farsi. This paper provides a manually annotated Farsi dataset,
Pars-ABSA, annotated and verified by three native Farsi speakers.
The dataset consists of 5,114 positive, 3,061 negative and 1,827
neutral data samples from 5,602 unique reviews. Moreover, as a
baseline, this paper reports the performance of some aspect-based
sentiment analysis methods focusing on transfer learning on Pars-
ABSA.},

abstract = {Sentiment analysis studies are focused more on online customer reviews or social media, and less on literary studies. The problem is greater for ancient languages, where the linguistic expression of sentiments may diverge from modern linguistic forms. This work presents the outcome of a sentiment annotation task of the first Book of Iliad, an ancient Greek poem. The annotators were provided with verses translated into modern Greek and they annotated the perceived emotions and sentiments verse by verse. By estimating the fraction of annotators that found a verse as belonging to a specific sentiment class, we model the poem's perceived sentiment as a multi-variate time series. By experimenting with a state of the art deep learning masked language model, pre-trained on modern Greek and fine-tuned to estimate the sentiment of our data, we registered a mean squared error of 0.063. This low error indicates that sentiment estimators built on our dataset can potentially be used as mechanical annotators, hence facilitating the distant reading of Homeric text. Our dataset is released for public use.},

pages        = {7096--7105},
abstract     = {This paper presents the phonological, morphological,
and syntactic distinctions between formal and informal Persian,
showing that these two variants have fundamental differences that
cannot be attributed solely to pronunciation discrepancies. Given
that informal Persian exhibits particular characteristics, any
computational model trained on formal Persian is unlikely to
transfer well to informal Persian, necessitating the creation of
dedicated treebanks for this variety. We thus detail the development
of the open-source Informal Persian Universal Dependency Treebank, a
new treebank annotated within the Universal Dependencies scheme. We
then investigate the parsing of informal Persian by training two
dependency parsers on existing formal treebanks and evaluating them
on out-of-domain data, i.e. the development set of our informal
treebank. Our results show that parsers experience a substantial
performance drop when we move across the two domains, as they face
more unknown tokens and structures and fail to generalize well.
Furthermore, the dependency relations whose performance deteriorates
the most represent the unique properties of the informal variant.
The ultimate goal of this study that demonstrates a broader impact
is to provide a stepping-stone to reveal the significance of
informal variants of languages, which have been widely overlooked in
natural language processing tools across languages.},

abstract  = {Annotation inconsistencies between data sets can
cause problems for low-resource NLP, where noisy or inconsistent
data cannot be easily replaced. We propose a method for
automatically detecting annotation mismatches between dependency
parsing corpora, along with three related methods for automatically
converting the mismatches. All three methods rely on comparing
unseen examples in a new corpus with similar examples in an existing
corpus. These three methods include a simple lexical replacement
using the most frequent tag of the example in the existing corpus, a
GloVe embedding-based replacement that considers related examples,
```

and a BERT-based replacement that uses contextualized embeddings to provide examples fine-tuned to our data. We evaluate these conversions by retraining two dependency parsers---Stanza and Parsing as Tagging (PaT)---on the converted and unconverted data. We find that applying our conversions yields significantly better performance in many cases. Some differences observed between the two parsers are observed. Stanza has a more complex architecture with a quadratic algorithm, taking longer to train, but it can generalize from less data. The PaT parser has a simpler architecture with a linear algorithm, speeding up training but requiring more training data to reach comparable or better performance.},

abstract = {Although screen readers enable visually impaired people to read written text via speech, the ambiguities in pronunciations of heteronyms cause wrong reading, which has a
```

serious impact on the text understanding. Especially in Japanese, there are many common heteronyms expressed by logograms (Chinese characters or kanji) that have totally different pronunciations (and meanings). In this study, to improve the accuracy of pronunciation prediction, we construct two large-scale Japanese corpora that annotate kanji characters with their pronunciations. Using existing language resources on i) book titles compiled by the National Diet Library and ii) the books in a Japanese digital library called Aozora Bunko and their Braille translations, we develop two large-scale pronunciation-annotated corpora for training pronunciation prediction models. We first extract sentence-level alignments between the Aozora Bunko text and its pronunciation converted from the Braille data. We then perform dictionary-based pattern matching based on morphological dictionaries to find word-level pronunciation alignments. We have ultimately obtained the Book Title corpus with 336M characters (16.4M book titles) and the Aozora Bunko corpus with 52M characters (1.6M sentences). We analyzed pronunciation distributions for 203 common heteronyms, and trained a BERT-based pronunciation prediction model for 93 heteronyms, which achieved an average accuracy of 0.939.

abstract = {Paraphrasing is often performed with less concern for  
controlled style conversion. Especially for questions and commands,  
style-variant paraphrasing can be crucial in tone and manner, which  
also matters with industrial applications such as dialog systems. In  
this paper, we attack this issue with a corpus construction scheme  
that simultaneously considers the core content and style of  
directives, namely intent and formality, for the Korean language.  
Utilizing manually generated natural language queries on six daily  
topics, we expand the corpus to formal and informal sentences by  
human rewriting and transferring. We verify the validity and  
industrial applicability of our approach by checking the adequate  
classification and inference performance that fit with conventional  
fine-tuning approaches, at the same time proposing a supervised  
formality transfer task.},

  title      = {Syntax-driven Approach for Semantic Role Labeling},
  booktitle  = {Proceedings of the Language Resources and
Evaluation Conference},
  month      = {June},
  year       = {2022},
  address    = {Marseille, France},
  publisher  = {European Language Resources Association},
  pages      = {7129--7139},
  abstract   = {As an important task to analyze the semantic
structure of a sentence, semantic role labeling (SRL) aims to locate
the semantic role (e.g., agent) of noun phrases with respect to a
given predicate and thus plays an important role in downstream tasks
such as dialogue systems. To achieve a better performance in SRL, a
model is always required to have a good understanding of the context
information. Although one can use advanced text encoder (e.g., BERT)
to capture the context information, extra resources are also
required to further improve the model performance. Considering that
there are correlations between the syntactic structure and the
semantic structure of the sentence, many previous studies leverage
auto-generated syntactic knowledge, especially the dependencies, to
enhance the modeling of context information through graph-based
architectures, where limited attention is paid to other types of
auto-generated knowledge. In this paper, we propose map memories to
enhance SRL by encoding different types of auto-generated syntactic
knowledge (i.e., POS tags, syntactic constituencies, and word
dependencies) obtained from off-the-shelf toolkits. Experimental
results on two English benchmark datasets for span-style SRL (i.e.,
CoNLL-2005 and CoNLL-2012) demonstrate the effectiveness of our
approach, which outperforms strong baselines and achieves state-of-
the-art results on CoNLL-2005.},

  abstract  = {A variety of contextualised language models have been  
  proposed in the NLP community, which are trained on diverse corpora  
  to produce numerous Neural Language Models (NLMs). However,  
  different NLMs have reported different levels of performances in  
  downstream NLP applications when used as text representations. We  
  propose a sentence-level meta-embedding learning method that takes  
  independently trained contextualised word embedding models and
```

learns a sentence embedding that preserves the complementary strengths of the input source NLMs. Our proposed method is unsupervised and is not tied to a particular downstream task, which makes the learnt meta-embeddings in principle applicable to different tasks that require sentence representations. Specifically, we first project the token-level embeddings obtained by the individual NLMs and learn attention weights that indicate the contributions of source embeddings towards their token-level meta-embeddings. Next, we apply mean and max pooling to produce sentence-level meta-embeddings from token-level meta-embeddings. Experimental results on semantic textual similarity benchmarks show that our proposed unsupervised sentence-level meta-embedding method outperforms previously proposed sentence-level meta-embedding methods as well as a supervised baseline.},

abstract     = {Due to the severity of the social media offensive and
hateful comments in Brazil, and the lack of research in Portuguese,
this paper provides the first large-scale expert annotated corpus of
Brazilian Instagram comments for hate speech and offensive language
detection. The HateBR corpus was collected from the comment section
of Brazilian politicians' accounts on Instagram and manually
annotated by specialists, reaching a high inter-annotator agreement.
The corpus consists of 7,000 documents annotated according to three
different layers: a binary classification (offensive versus non-
offensive comments), offensiveness-level classification (highly,
moderately, and slightly offensive), and nine hate speech groups
(xenophobia, racism, homophobia, sexism, religious intolerance,
partyism, apology for the dictatorship, antisemitism, and
fatphobia). We also implemented baseline experiments for offensive
language and hate speech detection and compared them with a
literature baseline. Results show that the baseline experiments on
our corpus outperform the current state-of-the-art for the
Portuguese language.},

  pages       = {7191--7198},  
  abstract    = {With the increasing commercial and social importance  
of Instagram in recent years, more researchers begin to take  
multimodal approaches to predict popular content on Instagram.  
However, existing popularity prediction approaches often reduce  
hashtags to simple features such as hashtag length or number of  
hashtags in a post, ignoring the structural and textual information  
that entangles between hashtags. In this paper, we propose a  
multimodal framework using post captions, image, hashtag network,  
and topic model to predict popular influencer posts in Taiwan.  
Specifically, the hashtag network is constructed as a homogenous  
graph using the co-occurrence relationship between hashtags, and we  
extract its structural information with GraphSAGE and semantic  
information with BERTopic. Finally, the prediction process is  
defined as a binary classification task (popular/unpopular) using  
neural networks. Our results show that the proposed framework  
incorporating hashtag network outperforms all baselines and unimodal  
models, while information captured from the hashtag network and  
topic model appears to be complementary.},

title = {Annotating the Tweebank Corpus on Named Entity Recognition and Building NLP Models for Social Media Analysis},
booktitle = {Proceedings of the Language Resources and Evaluation Conference},
month = {June},
year = {2022},
address = {Marseille, France},
publisher = {European Language Resources Association},
pages = {7199--7208},
abstract = {Social media data such as Twitter messages ("tweets") pose a particular challenge to NLP systems because of their short, noisy, and colloquial nature. Tasks such as Named Entity Recognition (NER) and syntactic parsing require highly domain-matched training data for good performance. To date, there is no complete training corpus for both NER and syntactic analysis (e.g., part of speech tagging, dependency parsing) of tweets. While there are some publicly available annotated NLP datasets of tweets, they are only designed for individual tasks. In this study, we aim to create Tweebank-NER, an English NER corpus based on Tweebank V2 (TB2), train state-of-the-art (SOTA) Tweet NLP models on TB2, and release an NLP pipeline called Twitter-Stanza. We annotate named entities in TB2 using Amazon Mechanical Turk and measure the quality of our annotations. We train the Stanza pipeline on TB2 and compare with alternative NLP frameworks (e.g., FLAIR, spaCy) and transformer-based models. The Stanza tokenizer and lemmatizer achieve SOTA performance on TB2, while the Stanza NER tagger, part-of-speech (POS) tagger, and dependency parser achieve competitive performance against non-transformer models. The transformer-based models establish a strong baseline in Tweebank-NER and achieve the new SOTA performance in POS tagging and dependency parsing on TB2. We release the dataset and make both the Stanza pipeline and BERTweet-based models available "off-the-shelf" for use in future Tweet NLP research. Our source code, data, and pre-trained models are available at: \url{https://github.com/social-machines/TweebankNLP}.},

abstract  = {While popular Television (TV) shows are airing, some
users interested in these shows publish social media posts about the
show. Analyzing social media posts related to a TV show can be
beneficial for gaining insights about what happened during scenes of
the show. This is a challenging task partly because a significant
number of social media posts associated with a TV show or event may
not clearly describe what happened during the event. In this work,
we propose a method to predict social media posts (associated with
scenes of a TV show) that are indicative of what transpired during
the scenes of the show. We evaluate our method on social media
(Twitter) posts associated with an episode of a popular TV show,
Game of Thrones. We show that for each of the identified scenes,
with high AUC's, our method can predict posts that are indicative of
what happened in a scene from those that are not-indicative. Based
on Twitters policy, we will make the Tweeter ID's of the Twitter
posts used for this work publicly available.},

abstract  = {Hashtag segmentation is the task of breaking a
hashtag into its constituent tokens. Hashtags often encode the
essence of user-generated posts, along with information like topic
and sentiment, which are useful in downstream tasks. Hashtags
prioritize brevity and are written in unique ways - transliterating
and mixing languages, spelling variations, creative named entities.
Benchmark datasets used for the hashtag segmentation task - STAN,
BOUN - are small and extracted from a single set of tweets. However,
datasets should reflect the variations in writing styles of hashtags
and account for domain and language specificity, failing which the
results will misrepresent model performance. We argue that model

```

performance should be assessed on a wider variety of hashtags, and datasets should be carefully curated. To this end, we propose HashSet, a dataset comprising of: a) 1.9k manually annotated dataset; b) 3.3M loosely supervised dataset. HashSet dataset is sampled from a different set of tweets when compared to existing datasets and provides an alternate distribution of hashtags to build and validate hashtag segmentation models. We analyze the performance of SOTA models for Hashtag Segmentation, and show that the proposed dataset provides an alternate set of hashtags to train and assess models.},

abstract      = {Fake news provokes many societal problems; therefore,
there has been extensive research on fake news detection tasks to
counter it. Many fake news datasets were constructed as resources to
facilitate this task. Contemporary research focuses almost
exclusively on the factuality aspect of the news. However, this
aspect alone is insufficient to explain "fake news," which is a
complex phenomenon that involves a wide range of issues. To fully
understand the nature of each instance of fake news, it is important
to observe it from various perspectives, such as the intention of
the false news disseminator, the harmfulness of the news to our
society, and the target of the news. We propose a novel annotation
scheme with fine-grained labeling based on detailed investigations
of existing fake news datasets to capture these various aspects of
fake news. Using the annotation scheme, we construct and publish the
first Japanese fake news dataset. The annotation scheme is expected
to provide an in-depth understanding of fake news. We plan to build
datasets for both Japanese and other languages using our scheme. Our
Japanese dataset is published at https://hkefka385.github.io/
dataset/fakenews-japanese/.},

abstract   = {Since BERT appeared, Transformer language models and
transfer learning have become state-of-the-art for natural language
processing tasks. Recently, some works geared towards pre-training
specially-crafted models for particular domains, such as scientific
papers, medical documents, user-generated texts, among others. These
domain-specific models have been shown to improve performance
significantly in most tasks; however, for languages other than
English, such models are not widely available. In this work, we
present RoBERTuito, a pre-trained language model for user-generated
text in Spanish, trained on over 500 million tweets. Experiments on
a benchmark of tasks involving user-generated text showed that
RoBERTuito outperformed other pre-trained language models in
Spanish. In addition to this, our model has some cross-lingual
abilities, achieving top results for English-Spanish tasks of the
Linguistic Code-Switching Evaluation benchmark (LinCE) and also
competitive performance against monolingual models in English
Twitter tasks. To facilitate further research, we make RoBERTuito
publicly available at the HuggingFace model hub together with the

  abstract  = {In Japan, the number of single-person households,
particularly among the elderly, is increasing. Consequently,
opportunities for people to narrate are being reduced. To address
this issue, conversational agents, e.g., communication robots and
smart speakers, are expected to play the role of the listener. To
realize these agents, this paper describes the collection of
conversational responses by listeners that demonstrate attentive
listening attitudes toward narrative speakers, and a method to
annotate existing narrative speech with responsive utterances is
proposed. To summarize, 148,962 responsive utterances by 11
listeners were collected in a narrative corpus comprising 13,234
utterance units. The collected responsive utterances were analyzed
in terms of response frequency, diversity, coverage, and
naturalness. These results demonstrated that diverse and natural
responsive utterances were collected by the proposed method in an
efficient and comprehensive manner. To demonstrate the practical use
of the collected responsive utterances, an experiment was conducted,
in which response generation timings were detected in narratives.},

abstract = {The exploding amount of user-generated content has
spurred NLP research to deal with documents from various digital
communication formats (tweets, chats, emails, etc.). Using these
texts as language resources implies complying with legal data
privacy regulations. To protect the personal data of individuals and
preclude their identification, we employ pseudonymization. More
precisely, we identify those text spans that carry information
revealing an individual's identity (e.g., names of persons,
locations, phone numbers, or dates) and subsequently substitute them
with synthetically generated surrogates. Based on CodE Alltag, a
German-language email corpus, we address two tasks. The first task
is to evaluate various architectures for the automatic recognition
of privacy-sensitive entities in raw data. The second task examines
the applicability of pseudonymized data as training data for such
systems since models learned on original data cannot be published
for reasons of privacy protection. As outputs of both tasks, we,
first, generate a new pseudonymized version of CodE Alltag compliant
with the legal requirements of the General Data Protection
Regulation (GDPR). Second, we make accessible a tagger for
recognizing privacy-sensitive information in German emails and
similar text genres, which is trained on already pseudonymized
data.},

abstract  = {We present a preprocessed, ready-to-use automatic
speech recognition corpus, BembaSpeech, consisting over 24 hours of
read speech in the Bemba language, a written but low-resourced
language spoken by over 30\% of the population in Zambia. To assess
its usefulness for training and testing ASR systems for Bemba, we
explored different approaches; supervised pre-training (training
from scratch), cross-lingual transfer learning from a monolingual
English pre-trained model using DeepSpeech on the portion of the
dataset and fine-tuning large scale self-supervised Wav2Vec2.0 based
multilingual pre-trained models on the complete BembaSpeech corpus.
From our experiments, the 1 billion XLS-R parameter model gives the
best results. The model achieves a word error rate (WER) of 32.91\%,
results demonstrating that model capacity significantly improves
performance and that multilingual pre-trained models transfers
cross-lingual acoustic representation better than monolingual pre-
trained English model on the BembaSpeech for the Bemba ASR. Lastly,
results also show that the corpus can be used for building ASR
systems for Bemba language.},

  abstract  = {Psychosis is a clinical syndrome characterized by the
presence of symptoms such as hallucinations, thought disorder and
disorganized speech. Several studies have used machine learning,
combined with speech and natural language processing methods to aid
in the diagnosis process of this disease. This paper describes the
creation of the first European Portuguese corpus for the
```

identification of the presence of speech characteristics of psychosis, which contains samples of 92 participants, 56 controls and 36 individuals diagnosed with psychosis and medicated. The corpus was used in a set of experiments that allowed identifying the most promising feature set to perform the classification: the combination of acoustic and speech metric features. Several classifiers were implemented to study which ones entailed the best performance depending on the task and feature set. The most promising results obtained for the entire corpus were achieved when identifying individuals with a Multi-Layer Perceptron classifier and reached an 87.5\% accuracy. Focusing on the gender dependent results, the overall best results were 90.9\% and 82.9\% accuracy, for female and male subjects respectively. Lastly, the experiments performed lead us to conjecture that spontaneous speech presents more identifiable characteristics than read speech to differentiate healthy and patients diagnosed with psychosis.},

publisher = {European Language Resources Association},
pages = {7305--7313},
abstract = {Audiobook readers play with their voices to emphasize some text passages, highlight discourse changes or significant events, or in order to make listening easier and entertaining. A dialog is a central passage in audiobooks where the reader applies significant voice transformation, mainly prosodic modifications, to realize character properties and changes. However, these intra-speaker modifications are hard to reproduce with simple text-to-speech synthesis. The manner of vocalizing characters involved in a given story depends on the text style and differs from one speaker to another. In this work, this problem is investigated through the prism of voice conversion. We propose to explore modifying the narrator's voice to fit the context of the story, such as the character who is speaking, using voice conversion. To this end, two complementary experiments are designed: the first one aims to assess the quality of our Phonetic PosteriorGrams (PPG)-based voice conversion system using parallel data. Subjective evaluations with naive raters are conducted to estimate the quality of the signal generated and the speaker similarity. The second experiment applies an intra-speaker voice conversion, considering narration passages and direct speech passages as two distinct speakers. Data are then nonparallel and the dissimilarity between character and narrator is subjectively measured.},

  pages     = {7314--7320},  
  abstract  = {Despite recent advances in automatic speech  
recognition (ASR), the recognition of children's speech still  
remains a significant challenge. This is mainly due to the high  
acoustic variability and the limited amount of available training  
data. The latter problem is particularly evident in languages other  
than English, which are usually less-resourced. In the current  
paper, we address children ASR in a number of less-resourced  
languages by combining several small-sized children speech corpora  
from these languages. In particular, we address the following  
research question: Does a novel two-step training strategy in which  
multilingual learning is followed by language-specific transfer  
learning outperform conventional single language/task training for  
children speech, as well as multilingual and transfer learning  
alone? Based on previous experimental results with English, we  
hypothesize that multilingual learning provides a better  
generalization of the underlying characteristics of children's  
speech. Our results provide a positive answer to our research  
question, by showing that using transfer learning on top of a  
multilingual model for an unseen language outperforms conventional  
single language-specific learning.},

  abstract  = {Question-Answer (QA) is one of the effective methods  
for storing knowledge which can be used for future retrieval. As  
such, identifying mentions of questions and their answers in text is  
necessary for a knowledge construction and retrieval systems. In the  
literature, QA identification has been well studied in the NLP
```

community. However, most of the prior works are restricted to formal written documents such as papers or websites. As such, Questions and Answers that are presented in informal/noisy documents have not been adequately studied. One of the domains that can significantly benefit from QA identification is the domain of livestreaming video transcripts that involve abundant QA pairs to provide valuable knowledge for future users and services. Since video transcripts are often transcribed automatically for scale, they are prone to errors. Combined with the informal nature of discussion in a video, prior QA identification systems might not be able to perform well in this domain. To enable comprehensive research in this domain, we present a large-scale QA identification dataset annotated by human over transcripts of 500 hours of streamed videos. We employ Behance.net to collect the videos and their automatically obtained transcripts. Furthermore, we conduct extensive analysis on the annotated dataset to understand the complexity of QA identification for livestreaming video transcripts. Our experiments show that the annotated dataset presents unique challenges for existing methods and more research is necessary to explore more effective methods. The dataset and the models developed in this work will be publicly released for future research.},

abstract = {To improve computer-based recognition from video of  
isolated signs from American Sign Language (ASL), we propose a new  
skeleton-based method that involves explicit detection of the start  
and end frames of signs, trained on the ASLLVD dataset; it uses  
linguistically relevant parameters based on the skeleton input. Our  
method employs a bidirectional learning approach within a Graph  
Convolutional Network (GCN) framework. We apply this method to the  
WLASL dataset, but with corrections to the gloss labeling to ensure  
consistency in the labels assigned to different signs; it is  
important to have a 1-1 correspondence between signs and text-based  
gloss labels. We achieve a success rate of 77.43\% for top-1 and  
94.54\% for top-5 using this modified WLASL dataset. Our method,  
which does not require multi-modal data input, outperforms other  
state-of-the-art approaches on the same modified WLASL dataset,  
demonstrating the importance of both attention to the start and end  
frames of signs and the use of bidirectional data streams in the  
GCNs for isolated sign recognition.},

abstract = {The growth of social media has brought with it a massive channel for spreading and reinforcing stereotypes. This issue becomes critical when the affected targets are minority groups such as women, the LGBT+ community and immigrants. Although from the perspective of computational linguistics, the detection of this kind of stereotypes is steadily improving, most stereotypes are expressed implicitly and identifying them automatically remains a challenge. One of the problems we found for tackling this issue is the lack of an operationalised definition of implicit stereotypes that would allow us to annotate consistently new corpora by characterising the different forms in which stereotypes appear. In this paper, we present thirteen criteria for annotating implicitness which were

elaborated to facilitate the subjective task of identifying the presence of stereotypes. We also present NewsCom-Implicitness, a corpus of 1,911 sentences, of which 426 comprise explicit and implicit racial stereotypes. An experiment was carried out to evaluate the applicability of these criteria. The results indicate that different criteria obtain different inter-annotator agreement values and that there is a greater agreement when more criteria can be identified in one sentence.},

abstract = {We propose an enhanced adversarial training algorithm  
for fine-tuning transformer-based language models (i.e., RoBERTa)  
and apply it to the temporal reasoning task. Current adversarial  
training approaches for NLP add the adversarial perturbation only to  
the embedding layer, ignoring the other layers of the model, which  
might limit the generalization power of adversarial training.  
Instead, our algorithm searches for the best combination of layers  
to add the adversarial perturbation. We add the adversarial  
perturbation to multiple hidden states or attention representations  
of the model layers. Adding the perturbation to the attention  
representations performed best in our experiments. Our model can  
improve performance on several temporal reasoning benchmarks, and  
establishes new state-of-the-art results.},

abstract = {Transformer-based models have become the state-of-  
the-art for numerous natural language processing (NLP) tasks,  
especially for noisy data sets, including social media posts. For  
example, BERTweet, pre-trained RoBERTa on a large amount of Twitter  
data, has achieved state-of-the-art results on several Twitter NLP
```

tasks. We argue that it is not only important to have general pre-trained models for a social media platform, but also domain-specific ones that better capture domain-specific language context. Domain-specific resources are not only important for NLP tasks associated with a specific domain, but they are also useful for understanding language differences across domains. One domain that receives a large amount of attention is politics, more specifically political elections. Towards that end, we release PoliBERTweet, a pre-trained language model trained from BERTweet on over 83M US 2020 election-related English tweets. While the construction of the resource is fairly straightforward, we believe that it can be used for many important downstream tasks involving language, including political misinformation analysis and election public opinion analysis. To show the value of this resource, we evaluate PoliBERTweet on different NLP tasks. The results show that our model outperforms general-purpose language models in domain-specific contexts, highlighting the value of domain-specific models for more detailed linguistic analysis. We also extend other existing language models with a sample of these data and show their value for presidential candidate stance detection, a context-specific task. We release PoliBERTweet and these other models to the community to advance interdisciplinary research related to Election 2020.},

publisher = {European Language Resources Association},
pages = {7368--7376},
abstract = {We focus on the syntactic variation and measure syntactic distances between nine Slavic languages (Belarusian, Bulgarian, Croatian, Czech, Polish, Slovak, Slovene, Russian, and Ukrainian) using symmetric measures of insertion, deletion and movement of syntactic units in the parallel sentences of the fable "The North Wind and the Sun". Additionally, we investigate phonetic and orthographic asymmetries between selected languages by means of the information theoretical notion of surprisal. Syntactic distance and surprisal are, thus, considered as potential predictors of mutual intelligibility between related languages. In spoken and written cloze test experiments for Slavic native speakers, the presented predictors will be validated as to whether variations in syntax lead to a slower or impeded intercomprehension of Slavic texts.},

  abstract  = {This research provides the first comprehensive  
analysis of the performance of pre-trained language models for  
Sinhala text classification. We test on a set of different Sinhala  
text classification tasks and our analysis shows that out of the  
pre-trained multilingual models that include Sinhala (XLM-R, LaBSE,  
and LASER), XLM-R is the best model by far for Sinhala text  
classification. We also pre-train two RoBERTa-based monolingual  
Sinhala models, which are far superior to the existing pre-trained  
language models for Sinhala. We show that when fine-tuned, these  
pre-trained language models set a very strong baseline for Sinhala  
text classification and are robust in situations where labeled data  
is insufficient for fine-tuning. We further provide a set of  
recommendations for using pre-trained models for Sinhala text  
classification. We also introduce new annotated datasets useful for  
future research in Sinhala text classification and publicly release  
our pre-trained models.},

  address   = {Marseille, France},  
  publisher = {European Language Resources Association},  
  pages     = {7386--7391},  
  abstract  = {In this paper, we evaluate several Transformer-based  
language models for Icelandic on four downstream tasks: Part-of-  
Speech tagging, Named Entity Recognition, Dependency Parsing, and  
Automatic Text Summarization. We pre-train four types of monolingual  
ELECTRA and ConvBERT models and compare our results to a previously  
trained monolingual RoBERTa model and the multilingual mBERT model.  
We find that the Transformer models obtain better results, often by  
a large margin, compared to previous state-of-the-art models.  
Furthermore, our results indicate that pre-training larger language  
models results in a significant reduction in error rates in  
comparison to smaller models. Finally, our results show that the  
monolingual models for Icelandic outperform a comparably sized
```

  publisher = {European Language Resources Association},  
  pages    = {763--768},  
  abstract = {Current state of the art acoustic models can easily  
comprise more than 100 million parameters. This growing complexity  
demands larger training datasets to maintain a decent generalization  
of the final decision function. An ideal dataset is not necessarily  
large in size, but large with respect to the amount of unique  
speakers, utilized hardware and varying recording conditions. This  
enables a machine learning model to explore as much of the domain-  
specific input space as possible during parameter estimation. This  
work introduces Common Phone, a gender-balanced, multilingual corpus  
recorded from more than 76.000 contributors via Mozilla's Common  
Voice project. It comprises around 116 hours of speech enriched with  
automatically generated phonetic segmentation. A Wav2Vec 2.0  
acoustic model was trained with the Common Phone to perform phonetic  
symbol recognition and validate the quality of the generated  
phonetic annotation. The architecture achieved a PER of 18.1 \% on  
the entire test set, computed with all 101 unique phonetic symbols,  
showing slight differences between the individual languages. We  
conclude that Common Phone provides sufficient variability and  
reliable phonetic annotation to help bridging the gap between  
research and application of acoustic models.},

abstract = {This paper describes a comprehensive annotation study on Japanese judgment documents in civil cases. We aim to build an annotated corpus designed for Legal Judgment Prediction (LJP), especially for torts. Our annotation scheme contains annotations of whether tort is accepted by judges as well as its corresponding rationales for explainability purpose. Our annotation scheme extracts decisions and rationales at character-level. Moreover, the scheme can capture the explicit causal relation between judge's decisions and their corresponding rationales, allowing multiple decisions in a document. To obtain high-quality annotation, we developed an annotation scheme with legal experts, and confirmed its reliability by agreement studies with Krippendorff's alpha metric. The result of the annotation study suggests the proposed annotation scheme can produce a dataset of Japanese LJP at reasonable reliability.},

abstract     = {Even though hate speech (HS) online has been an
important object of research in the last decade, most HS-related
corpora over-simplify the phenomenon of hate by attempting to label
user comments as "hate" or "neutral". This ignores the complex and
subjective nature of HS, which limits the real-life applicability of
classifiers trained on these corpora. In this study, we present the
M-Phasis corpus, a corpus of ~9k German and French user comments
collected from migration-related news articles. It goes beyond the
"hate"- "neutral" dichotomy and is instead annotated with 23
features, which in combination become descriptors of various types
of speech, ranging from critical comments to implicit and explicit
expressions of hate. The annotations are performed by 4 native
speakers per language and achieve high ( $0.77 \leq k \leq 1$ ) inter-
annotator agreements. Besides describing the corpus creation and
presenting insights from a content, error and domain analysis, we
explore its data characteristics by training several classification
baselines.},

  pages       = {805--813},
  abstract    = {In this paper, we describe ParCorFull2.0, a parallel
corpus annotated with full coreference chains for multiple
languages, which is an extension of the existing corpus ParCorFull
(Lapshinova-Koltunski et al., 2018). Similar to the previous
version, this corpus has been created to address translation of
coreference across languages, a phenomenon still challenging for
machine translation (MT) and other multilingual natural language
processing (NLP) applications. The current version of the corpus
that we present here contains not only parallel texts for the
language pair English-German, but also for English-French and
English-Portuguese, which are all major European languages. The new
language pairs belong to the Romance languages. The addition of a
new language group creates a need of extension not only in terms of
texts added, but also in terms of the annotation guidelines. Both
French and Portuguese contain structures not found in English and
German. Moreover, Portuguese is a pro-drop language bringing even
more systemic differences in the realisation of coreference into our
cross-lingual resources. These differences cause problems for
multilingual coreference resolution and machine translation. Our
```

parallel corpus with full annotation of coreference will be a valuable resource with a variety of uses not only for NLP applications, but also for contrastive linguists and researchers in translation studies.},

  abstract   = {The Universal Morphology (UniMorph) project is a
collaborative effort providing broad-coverage instantiated
normalized morphological inflection tables for hundreds of diverse
world languages. The project comprises two major thrusts: a
language-independent feature schema for rich morphological
annotation, and a type-level resource of annotated data in diverse
languages realizing that schema. This paper presents the expansions
and improvements on several fronts that were made in the last couple
of years (since McCarthy et al. (2020)). Collaborative efforts by
numerous linguists have added 66 new languages, including 24
endangered languages. We have implemented several improvements to
the extraction pipeline to tackle some issues, e.g., missing gender
and macrons information. We have amended the schema to use a
hierarchical structure that is needed for morphological phenomena
like multiple-argument agreement and case stacking, while adding
some missing morphological features to make the schema more
inclusive. In light of the last UniMorph release, we also augmented
the database with morpheme segmentation for 16 languages. Lastly,
this new release makes a push towards inclusion of derivational
morphology in UniMorph by enriching the data and annotation schema
with instances representing derivational processes from MorphyNet.},

  abstract    = {We release an internationalized annotation and human
evaluation bundle, called Textinator, along with documentation and
video tutorials. Textinator allows annotating data for a wide
variety of NLP tasks, and its user interface is offered in multiple
languages, lowering the entry threshold for domain experts. The
latter is, in fact, quite a rare feature among the annotation tools,
that allows controlling for possible unintended biases introduced
due to hiring only English-speaking annotators. We illustrate the
rarity of this feature by presenting a thorough systematic
comparison of Textinator to previously published annotation tools
along 9 different axes (with internationalization being one of
them). To encourage researchers to design their human evaluation
before starting to annotate data, Textinator offers an easy-to-use
tool for human evaluations allowing importing surveys with
potentially hundreds of evaluation items in one click. We finish by
presenting several use cases of annotation and evaluation projects
conducted using pre-release versions of Textinator. The presented
```

use cases do not represent Textinator's full annotation or evaluation capabilities, and interested readers are referred to the online documentation for more information.},

booktitle = {Proceedings of the Language Resources and Evaluation Conference},
month = {June},
year = {2022},
address = {Marseille, France},
publisher = {European Language Resources Association},
pages = {867--875},
abstract = {Over the past decades, the number of episodes of cyber aggression occurring online has grown substantially, especially among teens. Most solutions investigated by the NLP community to curb such online abusive behaviors consist of supervised approaches relying on annotated data extracted from social media. However, recent studies have highlighted that private instant messaging platforms are major mediums of cyber aggression among teens. As such interactions remain invisible due to the app privacy policies, very few datasets collecting aggressive conversations are available for the computational analysis of language. In order to overcome this limitation, in this paper we present the CyberAgressionAdo-V1 dataset, containing aggressive multiparty chats in French collected through a role-playing game in high-schools, and annotated at different layers. We describe the data collection and annotation phases, carried out in the context of a EU and a national research projects, and provide insightful analysis on the different types of aggression and verbal abuse depending on the targeted victims (individuals or communities) emerging from the collected data.},

abstract = {There has been a lot of research in identifying hate posts from social media because of their detrimental effects on both

individuals and society. The majority of this research has concentrated on English, although one notices the emergence of multilingual detection tools such as multilingual-BERT (mBERT). However, there is a lack of hate speech datasets compared to English, and a multilingual pre-trained model often contains fewer tokens for other languages. This paper attempts to contribute to hate speech identification in Finnish by constructing a new hate speech dataset that is collected from a popular forum (Suomi24). Furthermore, we have experimented with FinBERT pre-trained model performance for Finnish hate speech detection compared to state-of-the-art mBERT and other practices. In addition, we tested the performance of FinBERT compared to fastText as embedding, which employed with Convolution Neural Network (CNN). Our results showed that FinBERT yields a 91.7\% accuracy and 90.8\% F1 score value, which outperforms all state-of-art models, including multilingual-BERT and CNN.},

abstract = {Automatic post-editing (APE) refers to a research  
field that aims to automatically correct errors included in the  
translation sentences derived by the machine translation system.  
This study has several limitations, considering the data  
acquisition, because there is no official dataset for most language  
pairs. Moreover, the amount of data is restricted even for language  
pairs in which official data has been released, such as WMT. To  
solve this problem and promote universal APE research regardless of  
APE data existence, this study proposes a method for automatically  
generating APE data based on a noising scheme from a parallel  
corpus. Particularly, we propose a human mimicking errors-based  
noising scheme that considers a practical correction process at the  
human level. We propose a precise inspection to attain high  
performance, and we derived the optimal noising schemes that show  
substantial effectiveness. Through these, we also demonstrate that  
depending on the type of noise, the noising scheme-based APE data  
generation may lead to inferior performance. In addition, we propose  
a dynamic noise injection strategy that enables the acquisition of a  
robust error correction capability and demonstrated its  
effectiveness by comparative analysis. This study enables obtaining  
a high performance APE model without human-generated data and can  
promote universal APE research for all language pairs targeting

  abstract  = {Cross-lingual transfer learning without labeled  
target language data or parallel text has been surprisingly  
effective in zero-shot cross-lingual classification, question  
answering, unsupervised machine translation, etc. However, some  
recent publications have claimed that domain mismatch prevents  
cross-lingual transfer, and their results show that unsupervised  
bilingual lexicon induction (UBLI) and unsupervised neural machine  
translation (UNMT) do not work well when the underlying monolingual  
corpora come from different domains (e.g., French text from  
Wikipedia but English text from UN proceedings). In this work, we  
show how a simple initialization regimen can overcome much of the  
effect of domain mismatch in cross-lingual transfer. We pre-train  
word and contextual embeddings on the concatenated domain-mismatched  
corpora, and use these as initializations for three tasks: MUSE  
UBLI, UN Parallel UNMT, and the SemEval 2017 cross-lingual word  
similarity task. In all cases, our results challenge the conclusions  
of prior work by showing that proper initialization can recover a  
large portion of the losses incurred by domain mismatch.},

  abstract  = {Clinical phenotyping enables the automatic extraction  
of clinical conditions from patient records, which can be beneficial  
to doctors and clinics worldwide. However, current state-of-the-art
```

models are mostly applicable to clinical notes written in English. We therefore investigate cross-lingual knowledge transfer strategies to execute this task for clinics that do not use the English language and have a small amount of in-domain data available. Our results reveal two strategies that outperform the state-of-the-art: Translation-based methods in combination with domain-specific encoders and cross-lingual encoders plus adapters. We find that these strategies perform especially well for classifying rare phenotypes and we advise on which method to prefer in which situation. Our results show that using multilingual data overall improves clinical phenotyping models and can compensate for data sparseness.},

  abstract  = {Translation of the noisy, informal language found in
social media has been an understudied problem, with a principal
factor being the limited availability of translation corpora in many
languages. To address this need we have developed a new corpus
containing over 200,000 translations of microblog posts that
supports translation of thirteen languages into English. The
languages are: Arabic, Chinese, Farsi, French, German, Hindi,
Korean, Pashto, Portuguese, Russian, Spanish, Tagalog, and Urdu. We
are releasing these data as the Multilingual Microblog Translation
Corpus to support further research in translation of informal
language. We establish baselines using this new resource, and we
further demonstrate the utility of the corpus by conducting
experiments with fine-tuning to improve translation quality from a
high performing neural machine translation (NMT) system. Fine-tuning
provided substantial gains, ranging from +3.4 to +11.1 BLEU. On
average, a relative gain of 21% was observed, demonstrating the
utility of the corpus.},

abstract     = {Humans constantly deal with multimodal information,
that is, data from different modalities, such as texts and images.
In order for machines to process information similarly to humans,
they must be able to process multimodal data and understand the
joint relationship between these modalities. This paper describes
the work performed on the VTLM (Visual Translation Language
Modelling) framework from (Caglayan et al., 2021) to test its
generalization ability for other language pairs and corpora. We use
the multimodal and multilingual corpus How2 (Sanabria et al., 2018)
in three parallel streams with aligned English-Portuguese-Visual
information to investigate the effectiveness of the model for this
new language pair and in more complex scenarios, where the sentence
associated with each image is not a simple description of it. Our
experiments on the Portuguese-English multimodal translation task
using the How2 dataset demonstrate the efficacy of cross-lingual
visual pretraining. We achieved a BLEU score of 51.8 and a METEOR
score of 78.0 on the test set, outperforming the MMT baseline by
about 14 BLEU and 14 METEOR. The good BLEU and METEOR values
obtained for this new language pair, regarding the original English-
German VTLM, establish the suitability of the model to other
languages.},

abstract    = {Recently, we have seen an increasing interest in the
area of speech-to-text translation. This has led to astonishing
improvements in this area. In contrast, the activities in the area
of speech-to-speech translation is still limited, although it is
essential to overcome the language barrier. We believe that one of
the limiting factors is the availability of appropriate training
data. We address this issue by creating LibriS2S, to our knowledge
the first publicly available speech-to-speech training corpus
between German and English. For this corpus, we used independently
created audio for German and English leading to an unbiased
pronunciation of the text in both languages. This allows the
creation of a new text-to-speech and speech-to-speech translation
model that directly learns to generate the speech signal based on
the pronunciation of the source language. Using this created corpus,
we propose Text-to-Speech models based on the example of the
```

recently proposed FastSpeech 2 model that integrates source language information. We do this by adapting the model to take information such as the pitch, energy or transcript from the source speech as additional input.},

abstract = {This paper presents a fine-grained test suite for the language pair German-English. The test suite is based on a number of linguistically motivated categories and phenomena and the semi-automatic evaluation is carried out with regular expressions. We describe the creation and implementation of the test suite in detail, providing a full list of all categories and phenomena. Furthermore, we present various exemplary applications of our test suite that have been implemented in the past years, like contributions to the Conference of Machine Translation, the usage of the test suite and MT outputs for quality estimation, and the expansion of the test suite to the language pair Portuguese-English. We describe how we tracked the development of the performance of various systems MT systems over the years with the help of the test suite and which categories and phenomena are prone to resulting in MT errors. For the first time, we also make a large part of our test suite publicly available to the research community.},
