HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

# Computing $\mathcal{E} \mathcal{L}$ minimal modules: a combined approach 

from atomic concepts $A \in \mathrm{~N}_{C}$ to a subset $A^{I} \subseteq \Delta^{I}$ and from roles $r \in \mathrm{~N}_{R}$ to a subset $r^{I} \subseteq \Delta^{I} \times \Delta^{I}$. For a concept $C$ built from the grammar rules, we define $C^{I}$ inductively by: $(T)^{I}=\Delta^{I},(C \sqcap D)^{I}=C^{I} \cap D^{I}$, $(\exists r . C)^{I}=\left\{a \in \Delta^{I} \mid \exists b \in C^{I},(a, b) \in r^{I}\right\}$. An interpretation is a model of $O$ if it is compatible with all axioms in $O$, i.e., for all $C \sqsubseteq D, C \equiv D$, we have $C^{I} \subseteq D^{I}, C^{I}=D^{I}$ respectively.

An $\mathcal{E} \mathcal{L}$-ontology $O$ is normalized if all its axioms are of the form $A \bowtie B_{1} \sqcap B_{2} \sqcap \cdots \sqcap B_{m}, A \bowtie \exists r . B$, where $\bowtie ₫ \in\{\equiv, \sqsubseteq\}, A, B, B_{i} \in \mathrm{~N}_{C}, r \in \mathrm{~N}_{R}$. Every $\mathcal{E} \mathcal{L}$-ontology can be normalised in polynomial time by introducing new atomic concepts. Moreover, we say the $O$ is a terminology if any atomic concept $A$ appears at most once on the left-hand side of axiom in $O$.

We say $O \models \alpha$ where $\alpha$ is an axiom if and only if each model of $O$ is compatible with $\alpha$.

Definition 1. (Justification) Given $O$ such that $O \equiv A \sqsubseteq B$. A justification of $A \sqsubseteq B$ is a minimal subset $J \subseteq O$ such that $J \mid=A \sqsubseteq B$.

Given two ontologies $O_{1}, O_{2}$ and a signature $\Sigma \subseteq \mathrm{N}_{C} \cup \mathrm{~N}_{R}$, the logical difference ${ }^{1}$ between $O_{1}, O_{2}$ over $\Sigma$ is the set:

$$
\mathcal{D}_{\Sigma}\left(O_{1}, O_{2}\right)=\left\{\alpha\left|\operatorname{sig}(\alpha) \subseteq \Sigma, O_{i}\right|=\alpha, O_{j} \mid \neq \alpha,\{i, j\}=\{1,2\}\right\}
$$

Definition 2. (Minimal module) A sub-ontology $\mathcal{M} \subseteq O$ is a minimal module for $\Sigma$ if $\mathcal{D}_{\Sigma}(\mathcal{M}, O)=\emptyset$ and there is no $\mathcal{M}^{\prime} \subset \mathcal{M}$ such that $\mathcal{D}_{\Sigma}\left(\mathcal{M}^{\prime}, O\right)=\emptyset$.

When $O_{1}, O_{2}$ are terminologies, we have:
Theorem 1. [13] Given two terminologies $O_{1}, O_{2}$ and a signature $\Sigma$. If $\mathcal{D}_{\Sigma}\left(O_{1}, O_{2}\right)$ is not empty, then there exists an axiom in $\mathcal{D}_{\Sigma}\left(O_{1}, O_{2}\right)$ of the form $A \sqsubseteq C$ or $C \sqsubseteq A$, where $A$ is an atomic concept.

## Example 1. For terminology

$O_{0}=\left\{\beta_{1}: B_{2} \sqsubseteq A_{1} \sqcap A_{2}, \beta_{2}: B_{1} \sqsubseteq A_{1}, \beta_{3}: A_{3} \equiv \exists s . A_{1}, \beta_{4}: A_{4} \equiv \exists s . A_{2}\right.$,

$$
\left.\beta_{5}: B_{3} \equiv A_{3} \sqcap A_{4}, \beta_{6}: A_{4} \sqsubseteq \exists s . A_{5}, \beta_{7}: A_{5} \sqsubseteq B_{4} \sqcap B_{5}\right\},
$$

we have $O_{0} \models B_{2} \sqsubseteq A_{1}$, and $J_{0}=\left\{\beta_{1}\right\}$ is the only justification for $B_{2} \sqsubseteq A_{1}$.
If we consider a signature $\Sigma_{0}=\left\{s, B_{1}, B_{2}, B_{3}, B_{4}, B_{5}\right\}$, there is only one minimal module for $\Sigma_{0}: \mathcal{M}_{0}=O_{0} \backslash\left\{\beta_{2}\right\}$.

### 2.2 Hyper-graph

In this paper, we associate $\mathcal{E} \mathcal{L}$-ontologies with hyper-graphs. A (directed) hyper-graph [4] $\mathcal{H}=\{\mathcal{V}, \mathcal{E}\}$ consists of a node set $\mathcal{V}=$ $\left\{v_{1}, v_{2}, \cdots, v_{n}\right\}$ and an edge set $\mathcal{E}=\left\{e_{1}, e_{2} \cdots, e_{m}\right\}, e_{i}=\left\langle T\left(e_{i}\right), f\left(e_{i}\right)\right\rangle$, where $T\left(e_{i}\right) \subseteq \mathcal{V}$ is a subset and $f\left(e_{i}\right) \in \mathcal{V}$ is a node.
Definition 3. Given a hyper-graph $\mathcal{H}=\{\mathcal{V}, \mathcal{E}\}$, assume $S \subseteq \mathcal{V}$ and $v \in \mathcal{V}$. A hyper-path from $S$ to $v$ is a sequence $h=\left[e_{1}, e_{2}, \cdots, e_{n}\right]$ of hyper-edges satisfying:
(1) $f\left(e_{n}\right)=\{v\}$;
(2) for $i=1, \cdots, n, T\left(e_{i}\right) \subseteq S \cup\left\{f\left(e_{1} ; \cdots, f\left(e_{i-1}\right)\right)\right\}$
(3) for $i=1, \cdots, n, f\left(e_{i}\right) \in \bigcup_{i<j \leq n} T\left(e_{j}\right)$.

If $v \in T\left(e_{1}\right)$, we say $h$ is a loop. If $h$ does not contain any loop, we say $h$ is loop-free.

For simplicity, in the following we also write edges $\left\langle\left\{v_{1}\right\}, v\right\rangle$, $\left\langle\left\{v_{1}, \cdots, v_{k}\right\}, v\right\rangle$ as $v_{1} \rightarrow v,\left\{v_{1}, \cdots, v_{k}\right\} \rightarrow v$.

[^0]
## 3 CONSTRUCTION OF INVARIANT

In this section, we propose the notion of invariant that provides means to characterize terminologies sharing the same logical information with respect to a given signature.

Definition 4. A map Inv taking as input a terminology and a signature is an invariant if for any two terminologies $O_{1} \subseteq O_{2}$,

$$
\mathcal{D}_{\Sigma}\left(O_{1}, O_{2}\right)=\emptyset i f f \operatorname{Inv}\left(O_{1}, \Sigma\right)=\operatorname{Inv}\left(O_{2}, \Sigma\right)
$$

Note that, the elements of $\operatorname{Inv}(O, \Sigma)$ can be of any kinds. For example, a trivial invariant can be defined by the set of axioms $\{\alpha|O|=\alpha, \operatorname{sig}(\alpha) \subseteq \Sigma\}$. Because this trivial invariant is infinite and thus has no practical interest, we introduce next another invariant (a finite one) set whose elements are triples $\left(A, S_{1}, S_{2}\right)$ where A is a concept and $S_{i}$ are finite sets.

### 3.1 Main idea

Similarly to [6], our construction of finite invariant is based on Theorem 1. Given two terminologies $O_{1}, O_{2}$, a signature $\Sigma$ and a concept $A$, we consider:

$$
\begin{aligned}
& \mathcal{D}_{\Sigma, A}^{r}\left(O_{1}, O_{2}\right)=\left\{C \sqsubseteq A \mid C \sqsubseteq A \in \mathcal{D}_{\Sigma}\left(O_{1}, O_{2}\right)\right\}, \\
& \mathcal{D}_{\Sigma, A}^{l}\left(O_{1}, O_{2}\right)=\left\{A \sqsubseteq C \mid A \sqsubseteq C \in \mathcal{D}_{\Sigma}\left(O_{1}, O_{2}\right)\right\} .
\end{aligned}
$$

Definition 5. A map from the tuple $(O, \Sigma, A)$ to a set $\operatorname{Inv}^{r}(O, \Sigma, A)$ is a right invariant if for any two terminologies $O_{1} \subseteq O_{2}$, we have:

$$
\mathcal{D}_{\Sigma, A}^{r}\left(O_{1}, O_{2}\right)=\emptyset \operatorname{iff} \operatorname{Inv}^{r}\left(O_{1}, \Sigma, A\right)=\operatorname{Inv}^{r}\left(O_{2}, \Sigma, A\right)
$$

The left invariant $\operatorname{Inv}^{1}(O, \Sigma, A)$ is defined in a dual manner based on $\mathcal{D}_{\Sigma, A}^{l}\left(O_{1}, O_{2}\right)$.

Then as a corollary of Theorem 1, we have:
Corollary 1. If $\operatorname{Inv}^{r}\left(r e s p . \mathrm{Inv}^{\mathcal{I}}\right)$ is a right (resp. left) invariant, then the map Inv defined below is an invariant:

$$
\operatorname{Inv}(O, \Sigma)=\left\{\left(A, \operatorname{Inv}^{\Upsilon}(O, \Sigma, A), \operatorname{Inv}^{1}(O, \Sigma, A)\right) \mid A \in \Sigma\right\}
$$

Thus, to construct a finite invariant, it is enough to build a finite right invariant and a finite left invariant, at first.

### 3.2 Building a finite right invariant

Given a terminology $O$, a signature $\Sigma$ and a concept $A$, in the following we associate a hyper-graph $\mathcal{H}^{O}$ to $O$ and then we construct a finite right invariant using the hyper-paths of $\mathcal{H}^{O}$.
3.2.1 (1) Hyper-graph and hyper-paths. The hyper-graph $\mathcal{H}^{O}=$ $(\mathcal{N}, \mathcal{E})$ associated to $O$ consists of the node set $\mathcal{N}:=\left\{N_{A} \mid A \in \mathrm{~N}_{C}\right\}$ and the edge set

$$
\begin{aligned}
\mathcal{E} & :=\left\{\left\{N_{A_{1}}, \cdots, N_{A_{n}}\right\} \rightarrow N_{A} \mid A \equiv A_{1} \sqcap A_{2} \sqcap \cdots \sqcap A_{n} \in O\right\} \\
& \cup\left\{N_{A} \xrightarrow{r} N_{B} \mid B \equiv \exists r . A \in O\right\} \cup\left\{N_{A} \rightarrow N_{B}|O|=A \sqsubseteq B\right\},
\end{aligned}
$$

where $N_{A} \xrightarrow{r} N_{B}$ is an edge with the index $r \in \mathrm{~N}_{\mathrm{R}}$.
Among the hyper-paths in $\mathcal{H}^{O}$, we specifically consider the set $P_{\Sigma, A}^{O}$ of all the hyper-paths $h$ from $S_{\Sigma}=\left\{N_{B} \mid B \in \Sigma\right\}$ to $N_{A}$ in $\mathcal{H}^{O}$ such that:
(1) for an edge $e \in h$, either $e$ has no index or its index $r \in \Sigma$;

2022-05-24 19:11. Page 2 of 1-7.
(2) $h$ does not contain trivial loops of the form:
$\left[\left\{N_{A_{1}}, \cdots, N_{A_{n}}\right\} \rightarrow N_{B}, N_{B} \rightarrow N_{A_{i}}\right]$ for some $i \in[1, n] ;$
(3) $h$ does not contain repeated edges.

Item 3 above implies that the length of an hyper-path $h \in P_{\Sigma, A}^{O}$ is at most \#|E| and therefore $P_{\Sigma, A}^{O}$ is finite.
Example 2 (Example 1 cont'd). The hyper-graph associated with the ontology $O_{0}$ is shown in Figure 1. Notice that $e_{6}=\left\{N_{A_{3}}, N_{A_{4}}\right\} \rightarrow N_{B_{3}}$ is the only complex edge in this hyper-graph. There are two hyperpaths in $P_{\sum_{0}, B_{3}}^{O_{0}}: h_{1}=\left[e_{1}, e_{4}, e_{3}, e_{5}, e_{6}\right]$, and $h_{2}=\left[e_{2}, e_{4}, e_{3}, e_{5}, e_{6}\right]$.

Figure 1: $\mathcal{H}^{O_{0}}$, concepts and roles in $\Sigma_{0}$ are in red.

Note that $l_{1}=\left[e_{6}, e_{9}\right], l_{2}=\left[e_{6}, e_{10}\right]$ are trivial loops. Thus any hyperpath containing $l_{1}$ or $l_{2}$ is excluded from $P_{\Sigma_{0}, B_{3}}^{O_{0}}$.
3.2.2 (2) Our finite right invariant. Each hyper-path $h \in P_{\Sigma, A}^{O}$ can be interpreted as an ontology:

$$
\begin{aligned}
O_{h}:= & \left\{A_{1} \sqcap A_{2} \cdots \sqcap A_{n} \sqsubseteq A \mid\left\{N_{A_{1}}, \cdots, N_{A_{n}}\right\} \rightarrow N_{A} \in h\right\} \cup \\
& \left\{A \sqsubseteq B \mid N_{A} \rightarrow N_{B} \in h\right\} \cup\left\{\exists r . A \sqsubseteq B \mid N_{A} \xrightarrow{r} N_{B} \in h\right\},
\end{aligned}
$$

Indeed, the existence of a hyper-path $h$ determines whether $O \mid=C \sqsubseteq A$ in the following sense:
Theorem 2. $O \models C \sqsubseteq A$, sig $(C) \subseteq \Sigma$ iff there exists a hyper-path $h \in P_{\Sigma, A}^{O}$ such that $O_{h}=C \sqsubseteq A$.

Now, one could expect that $P_{\Sigma, A}^{O}$ is a good candidate for defining a right invariant. However, we still need to refine it in order to avoid redundant and repetitive elements. Let us illustrates this with Example 3 for redundancy, and with Example 4 for repetition. Before, let us consider $I(h)$ to be the set of axioms entailed by $O_{h}$ : $I(h):=\left\{C \sqsubseteq A \mid O_{h}=C \sqsubseteq A, \operatorname{sig}(C) \in \Sigma\right\}$.

Example 3 (Example 1 and 2 cont'd). For terminology $O_{0}$, we have $P_{\Sigma_{0}, B_{3}}^{O_{0}}=\left\{h_{1}, h_{2}\right\}$. Note that $\beta_{2}$ is one of the axioms corresponding to $\left\{h_{1}, h_{2}\right\}$ but $\beta_{2}$ does not belong to the unique minimal module $\mathcal{M}_{0}$. The reason is that $I\left(h_{1}\right) \subset I\left(h_{2}\right)$, which means that $h_{2}$ provides strictly more logical information than $h_{1}$. Therefore, $h_{1}$ is redundant and should not be considered when computing the minimal module $\mathcal{M}_{0}$.
Example 4. Assume $O_{1}=\left\{\beta_{1}: B_{2} \sqsubseteq B_{1}, \beta_{2}: A \sqsubseteq B_{1}, \beta_{3}: B_{2} \sqsubseteq A\right\}$ and $\Sigma_{1}=$ $\left\{B_{1}, B_{2}\right\}$. Then

$$
P_{\Sigma_{1}, B_{1}}^{O_{1}}=\left\{h_{1}:\left[N_{B_{2}} \rightarrow N_{B_{1}}\right], h_{2}:\left[N_{B_{2}} \rightarrow N_{A}, N_{A} \rightarrow N_{B_{1}}\right]\right\} .
$$

We have $I\left(h_{1}\right)=I\left(h_{2}\right)$, meaning that $h_{1}, h_{2}$ provide the same logical information and thus a repetition. There are two minimal modules for $\Sigma_{1}: \mathcal{M}_{1}=\left\{\beta_{1}\right\}$ and $\mathcal{M}_{2}=\left\{\beta_{2}, \beta_{3}\right\}$ corresponding to $h_{1}$ and $h_{2}$, respectively. Indeed here, a minimal module should "contain" one and only one of $h_{1}, h_{2}$.
2022-05-24 19:11. Page 3 of 1-7.

Formally, for any two hyper-paths $h_{1}, h_{2} \in P_{\Sigma, A}^{O}$, we say:

- $h_{1}$ is redundant if $I\left(h_{1}\right) \subset I\left(h^{\prime}\right)$ for some $h^{\prime} \in P_{\Sigma, A}^{O}$;
- $h_{1}, h_{2}$ are equivalent if $I\left(h_{1}\right)=I\left(h_{2}\right)$.

Now, to eliminate redundancy and repetition, we extract from $P_{\Sigma, A}^{O}$ the set $\left\{\bar{h} \mid h \in P_{\Sigma, A}^{O}\right.$ is not redundant $\}$, where $\bar{h}$ denotes the class of all hyper-paths equivalent to $h$. Finally, our finite right invariant is defined by:

Theorem 3. The map $I^{r}{ }^{r}$ defined below is a right invariant:

$$
\operatorname{Inv}^{r}(O, \Sigma, A)=\left\{\bar{h} \mid h \in P_{\Sigma, A}^{O} \text { is not redundant }\right\} .
$$

Clearly, $\operatorname{Inv}{ }^{r}(O, \Sigma . A)$ is finite since $P_{\Sigma, A}^{O}$ is a finite set.
Example 5 (Example 3 cont'd). Since $I\left(h_{1}\right) \subset I\left(h_{2}\right)$, the hyper-path $h_{1}$ is redundant and $\operatorname{Inv}^{r}\left(O_{0}, \Sigma_{0}, B_{3}\right)=\left\{\bar{h}_{2}\right\}$.
3.2.3 (3) Checking equivalence and redundancy. Computing our right invariant requires an algorithm for checking the equivalence and the redundancy of hyper-paths (i.e., whether $I\left(h_{1}\right)=I\left(h_{2}\right)$ or $I\left(h_{1}\right) \subset I\left(h_{2}\right)$ ), thus indeed, an algorithm for checking $I\left(h_{1}\right) \subseteq I\left(h_{2}\right)$. In the general case, we can rely on an existing polynomial algorithm [7]. However, in the case of loop-free hyper-paths, we designed a specific straightforward algorithm. For details see supplementary materials.

### 3.3 Building a finite left invariant

The left invariant is constructed along the same lines as the right case. The main difference is that our left invariant is based on a graph $\mathcal{G}^{0}$ (instead of a hyper-graph) and on clusters (instead of hyper-paths).

The graph $\mathcal{G}^{O}=(\mathcal{N}, \mathcal{E})$ associated with $O$ consists of a node set $\mathcal{N}:=\left\{N_{A} \mid A \in \mathrm{~N}_{\mathrm{C}}\right\}$ and an edge set

$$
\begin{aligned}
\mathcal{E}:= & \left\{N_{A} \rightarrow N_{B} \mid O \models A \sqsubseteq B\right\} \\
& \cup\left\{N_{A} \xrightarrow{r} N_{B} \mid A \equiv \exists r . B \in O \text { or } A \sqsubseteq \exists r . B \in O\right\} .
\end{aligned}
$$

One may consider to construct a finite left invariant using paths in $\mathcal{G}^{O}$ as in Section 3.2. However, the paths in $\mathcal{G}^{O}$ are not sufficient for instance to capture the entailment $O \vDash A \sqsubseteq \exists r$. ( $B \sqcap C)$. Indeed, a path like $\left[N_{A} \rightarrow N_{A_{1}}, N_{A_{1}} \xrightarrow{r} N_{A_{2}}, N_{A_{2}} \xrightarrow{s} N_{B}\right]$ in $\mathcal{G}^{O}$ corresponds to $O=A \sqsubseteq \exists r . \exists s . B$, where $B$ is an atomic concept.

To overcome such limitation, we introduce clusters as unions of paths.
Definition 6. (Cluster) A cluster $t$ from $A$ to $\Sigma$, is a union of paths, which do not contain a loop twice ${ }^{2}$, from $N_{A}$ to some $N_{B}, B \in \Sigma$ in $\mathcal{G}{ }^{O}$. We say $t$ is loop-free if it does not contain loops.

Let us define $T_{\Sigma, A}^{O}$ as the collection of all clusters from $A$ to $\Sigma$. Then $T_{\Sigma, A}^{O}$ is finite, because the length of a path without repetitive loops is bounded ${ }^{3}$ and thus there are finitely many such paths.
Example 6 (Example 1 cont'd). For the terminology $O_{0}, \mathcal{G}^{O_{0}}$ is shown in Fig 2. There are two paths $p_{1}=\left[e_{10}, e_{13}, e_{7}\right], p_{2}=\left[e_{10}, e_{13}, e_{8}\right]$ from $N_{B_{3}}$ to some node in $\Sigma$ and three loop-free clusters $t_{1}=p_{1}, t_{2}=p_{2}$, $t_{3}=p_{1} \cup p_{2}$.

[^1]

Figure 2: $\mathcal{G}^{O_{0}}$, concepts and roles in $\Sigma_{0}$ are red.

Each cluster $t$ is a sub-graph of $\mathcal{G}^{O}$ and can be associated with an ontology:

$$
O_{t}:=\left\{A \sqsubseteq B \mid N_{A} \rightarrow N_{B} \in t\right\} \cup\left\{A \sqsubseteq \exists r . B \mid N_{A} \xrightarrow{r} N_{B} \in t\right\} .
$$

The following result is similar to Theorem 2 :
Theorem 4. $O \models A \sqsubseteq C$, sig $(C) \subseteq \Sigma$ iff there exists a cluster $t \in T_{\Sigma, A}^{O}$ such that $O_{t}=A \sqsubseteq C$.

To define a finite left invariant, we need to filter out repetitive and redundant clusters in $T_{\Sigma, A}^{O}$. Let us denote $I(t)=\{A \sqsubseteq C \mid$ $\left.O_{t}=A \sqsubseteq C, s i g(C) \subseteq \Sigma\right\}$ and say:

- $t_{1} \in T_{\Sigma, A}^{O}$ is redundant if there exists $t^{\prime} \in T_{\Sigma, A}^{O}$ such that $I\left(t_{1}\right) \subset I\left(t^{\prime}\right)$,
- $t_{1}, t_{2} \in T_{\Sigma, A}^{O}$ are equivalent if $I\left(t_{1}\right)=I\left(t_{2}\right)$.

Then, our finite left invariant is defined as follows:
Theorem 5. The map Inv $^{1}$ defined below is a left invariant.

$$
\operatorname{Inv}^{1}(O, \Sigma, A)=\left\{\bar{t} \mid t \in T_{\Sigma, A}^{O} \text { is not redundant }\right\}
$$

To compute $\operatorname{Inv}^{1}(O, \Sigma, A)$, as in Section 3.2, we need to determine whether $I\left(t_{1}\right) \subseteq I\left(t_{2}\right)$. The general case can be solved by a polynomial algorithm proposed in [7]. As for hyper-paths, we designed a specific straightforward algorithm for loop-free clusters (for details see supplementary materials).

Example 7. Continuing Example 6, since $I\left(t_{1}\right) \subset I\left(t_{3}\right)$ and $I\left(t_{2}\right) \subset I\left(t_{3}\right)$, the clusters $t_{1}$ and $t_{2}$ are redundant and $\operatorname{Inv}^{1}\left(O, \Sigma_{0}, B_{3}\right)=\left\{\bar{t}_{3}\right\}$.

In conclusion of this section, thanks to Corollary 1, we are able to exhibit a finite invariant Inv for $O, \Sigma$ using the finite right and left invariant above.

## 4 COMPUTING MINIMAL MODULES

Given a terminology $O$ and a signature $\Sigma$, in this section, we compute the minimal modules for $O$ and $\Sigma$ using a SAT-based approach as in PULi [11]. Thus minimal modules are computed in three steps:

Step 1. The right invariants $\operatorname{Inv}^{r}(O, \Sigma, A)$ and left invariants $\operatorname{Inv}^{l}(O, \Sigma, A)$ are computed for each $A \in \Sigma$ which, by Corollary 1, provides us with the invariant $\operatorname{Inv}(O, \Sigma)$.

Step 2. We build a set $\mathcal{C}_{\Sigma}$ of Horn clauses to encode the derivations of elements in $\operatorname{Inv}(O, \Sigma)$ from $O$. These clauses are given below:
(1) We add the clause $\wedge_{A \in \Sigma}\left(l_{A}^{r} \wedge l_{A}^{l}\right) \rightarrow l_{\Sigma}$, where $l_{\Sigma}$ captures a minimal module for $\Sigma$ and $l_{A}^{r} \wedge l_{A}^{l}$ a tuple

$$
\left(A, \operatorname{Inv}^{r}(O, \Sigma, A), \operatorname{Inv}^{1}(O, \Sigma, A)\right)
$$

of the invariant;
(2) We add two clauses

$$
\left.\wedge_{\bar{h} \in \operatorname{Inv}}(O, \Sigma, A)<l_{\bar{h}}\right) \rightarrow l_{A}^{r}, \wedge_{\bar{t} \in \operatorname{Inv}^{1}(O, \Sigma, A)}\left(l_{\bar{t}}\right) \rightarrow l_{A}^{l}
$$

for each $A \in \Sigma$;
(3) We add the clause $\wedge_{e \in h}\left(l_{e}\right) \rightarrow l_{\bar{h}}$ (resp. $\left.\wedge_{e \in t}\left(l_{e}\right) \rightarrow l_{\bar{t}}\right)$, for each non-redundant $h \in P_{\Sigma, A}^{O}$ (resp. $t \in T_{\Sigma, A}^{O}$ ) and $A \in \Sigma$;
(4) For each edge $e \in h$ (resp. $e \in t$ ), where $h \in P_{\Sigma, A}^{O}$ (resp. $t \in T_{\Sigma, A}^{O}$ ) is non-redundant and $A \in \Sigma$ :
(a) if $e=N_{A} \rightarrow N_{B}$, then we add clause $\wedge_{\beta \in J}\left(l_{\beta}\right) \rightarrow l_{e}$ for each justification $J$ of $A \sqsubseteq B$;
(b) if $e=N_{A} \xrightarrow{r} N_{B}$ or $\left\{N_{A_{1}}, \cdots, N_{A_{n}}\right\} \rightarrow N_{B}$, then we add the clause $l_{\beta} \rightarrow l_{e}$, where $\beta \in O$ is the axiom corresponding to $e$.

The answer literals are defined as the literals $l_{\beta}$ such that $\beta \in O$.
Step 3. We apply resolution over $\mathcal{C}_{\Sigma} \cup\left\{l_{\Sigma} \rightarrow \emptyset\right\}$. Then let us consider $\mathrm{M}_{\Sigma}$, the collection of resulting minimal ${ }^{4}$ clauses composed of answer literals only. From $M_{\Sigma}$, all minimal modules for $\Sigma$ are extracted easily as stated in Theorem 6.

Theorem 6. A subset $\mathcal{M}=\left\{\beta_{1}, \cdots, \beta_{k}\right\} \subseteq O$ is a minimal module for $\Sigma$ with respect to $O$ iff $\wedge_{i=1}^{k}\left(l_{\beta_{i}}\right) \rightarrow \emptyset \in M_{\Sigma}$.

Remark 1. In Step 2, Case 4(a), for the sake of simplicity, the added clauses are defined using justifications. Indeed, instead of computing justifications, we have developed a more efficient algorithm for computing these Horn clauses following a method similar to [11]. For details see supplementary materials.

Example 8. For our running example, the only non-empty right (left) invariants are $\operatorname{Inv}^{r}\left(O_{0}, \Sigma_{0}, B_{3}\right)=\left\{\bar{h}_{2}\right\}$, $\operatorname{Inv}^{1}\left(O_{0}, \Sigma_{0}, B_{3}\right)=\left\{\bar{t}_{3}\right\}$. Thus,

$$
\begin{aligned}
\operatorname{Inv}\left(O_{0}, \Sigma_{0}\right)=\{ & \left.\left(B_{3},\left\{\bar{h}_{2}\right\},\left\{\bar{t}_{3}\right\}\right)\right\} \cup \\
& \left\{\left(B_{k}, \emptyset, \emptyset\right) \mid k=1,2,4,5\right\}
\end{aligned}
$$

The set of clauses $\mathcal{C}_{\Sigma_{0}}$ is shown in Table 1. We obtain

$$
M_{\Sigma_{0}}=\left\{l_{\beta_{1}} \wedge l_{\beta_{3}} \wedge l_{\beta_{4}} \wedge l_{\beta_{5}} \wedge l_{\beta_{6}} \wedge l_{\beta_{7}} \rightarrow \emptyset\right\}
$$

by resolution over $\mathcal{C}_{\Sigma_{0}} \cup\left\{l_{\Sigma_{0}} \rightarrow \emptyset\right\}$. Therefore, the only minimal module for $\Sigma_{0}$ is $O_{0} \backslash\left\{\beta_{2}\right\}$.

Approximation. Now, let $O^{a p}=\left\{\beta \in O \mid l_{\beta}\right.$ appears in $\left.C_{\Sigma}\right\}$, then $O^{a p}$ contains all the minimal modules of $\Sigma$ and thus $\mathcal{D}_{\Sigma}\left(O^{a p}, O\right)=\emptyset$. Next, we regard $O^{a p}$ as an approximation of minimal modules. Indeed, $O^{a p}$ can be computed from the invariant without Step 3.
4.0.1 Optimization. In general, there can be exponentially many hyper-paths (resp. clusters) in $P_{\Sigma, A}^{O}$ (resp. $T_{\Sigma, A}^{O}$ ) with respect to the size of $\mathcal{H}^{O}$ (resp. $\mathcal{G}^{O}$ ). In order to reduce the computation cost, we can restrict the search space to hyper-paths (resp. clusters) having particular forms.

[^2]Table 1: Clause set $\mathcal{C}_{\Sigma_{0}}$

(1) Hyper-paths. We say a hyper-path $h$ over $\mathcal{H}^{O}$ is compact when it does not contain sub-paths of either form:
(1) $\left[\left\{N_{B_{1}}, \cdots, N_{B_{n}}\right\} \rightarrow N_{B}, N_{B} \rightarrow N_{A}\right]$, where $B \notin \Sigma$,
(2) $\left[N_{B_{1}} \xrightarrow{r} N_{B}, N_{B} \rightarrow N_{A}\right]$, where $B \notin \Sigma$.

When $O$ is a terminology, the hyper-paths over $\mathcal{H}^{O}$ satisfy the following property:

Proposition 2. For any hyper-path $h \in P_{\Sigma, A}^{O}$, there exists a compact hyper-path $h^{\prime} \in P_{\Sigma, A}^{O}$ such that $I(h) \subseteq I\left(h^{\prime}\right)$.

According to the above property, we can restrict $P_{\Sigma, A}^{O}$ to compact hyper-paths. Then, both Theorem 2 and 3 that define our right invariant still hold.
(2) Clusters. We say that a cluster $t=p_{1} \cup p_{2} \cup \cdots \cup p_{n}$ in $T_{\Sigma, A}^{O}$ is compact if either $n=1$ or the paths $p_{1}, \cdots, p_{n}$ have a common prefix path $\left[e_{1}, \cdots, e_{k}\right]$ with at least one indexed edge. For instance, in Example 6, the cluster $t_{3}$ is compact because $p_{1}, p_{2}$ share the prefix [ $e_{10}, e_{13}$ ] and $e_{13}$ is an indexed edge. Then, the following proposition holds:

Proposition 3. For $C$ with sig( $C) \subseteq \Sigma$ of the form B or $\exists r . C_{1}, O \models A \sqsubseteq C$ iff there exists a compact cluster $t \in T_{\Sigma, A}^{O}$ such that $O_{t}=A \sqsubseteq C$.

In proposition 3, we only consider concepts of the form $B$ or $\exists r . C_{1}$, because any concept $C$ can be written as $B_{1} \sqcap \cdots \sqcap B_{n} \sqcap \exists r_{1} . C_{1} \sqcap$ $\cdots \sqcap \exists r_{m} . C_{m}$, where $B_{1}, \cdots, B_{n}$ are atomic concepts. Thus, we know that $O=A \sqsubseteq C$ iff $O=A \sqsubseteq B_{i}, O \vDash A \sqsubseteq \exists r_{j} . C_{j}$ for any $1 \leq i \leq n, 1 \leq j \leq m$.

Therefore, by Proposition 3, we can require all clusters in $T_{\Sigma, A}^{O}$ to be compact: Theorem 5 that defines our left invariant still holds.

## 5 EXPERIMENT

To evaluate the efficiency of our algorithm for computing minimal modules and the quality of our approximation results, we implemented in Python a prototype called GIMM. We evaluated GIMM using the $\mathcal{E} \mathcal{L}$-fragment of two prominent biomedical ontologies: Snomed CT (version Jan 2016) ${ }^{5}$, a terminology with 317891 axioms, and NCI (version 16.03d) ${ }^{6}$, a terminology having 165341

[^3]Table 3: Successful rate

| Successful rate $(\%)$ | $\sum_{50,10}^{\text {snt }}$ | $\Sigma_{100,10}^{\text {snt }}$ | $\sum_{50,10}^{n c i}$ | $\Sigma_{100,10}^{n c i}$ |
| :---: | :---: | :---: | :---: | :---: |
| Zooms | 57.1 | 32.5 | 79.0 | 57.3 |
| GIMM | $\mathbf{8 4 . 2}(+27.1)$ | $\mathbf{7 8 . 5}(+46)$ | $\mathbf{9 1 . 8}(+12.8)$ | $\mathbf{7 4 . 3}(+17)$ |

Table 4: Time cost (max/min/mean/median)

| Time(s) | GIMM | Zooms |
| :---: | :---: | :---: |
| $\Sigma_{50,10}^{\text {snt }}$ | $7.57 / 5.13 / 6.13 / 6.12$ | $558.76 / 34.85 / 186.04 / 143.53$ |
| $\Sigma_{100,10}^{s n t}$ | $9.82 / 5.19 / 6.24 / 6.18$ | $563.24 / 71.38 / 302.24 / 294.19$ |
| $\Sigma_{50,10}^{n c l}$ | $29.54 / 2.03 / 2.56 / 2.43$ | $560.89 / 7.81 / 91.08 / 60.42$ |
| $\Sigma_{100,10}^{n c l}$ | $15.50 / 2.04 / 2.63 / 2.46$ | $576.35 / 15.49 / 145.32 / 105.92$ |

axioms. All the experiments are run on a machine with an Intel Xeon Core 4 Duo CPU 2.50 GHz with 64 GiB of RAM.
For each terminology, we run the experiments over 2 sets $\Sigma_{n, m}$ of 1000 signatures randomly generated, each one containing $n$ concepts and $m$ roles. We tested $\Sigma_{50,10}^{s n t}, \Sigma_{100,10}^{s n t}$ for Snomed CT and $\Sigma_{50,10}^{n c i}, \Sigma_{100,10}^{n c i}$ for NCI.

Next, we say a signature $\Sigma$ is loop-free if all hyper-paths (resp. clusters) in the right (resp. left) invariant of ( $\Sigma, A$ ), $A \in \Sigma$ are loop-free. A signature is trivial if its minimal module is empty. GIMM computes minimal modules for loop-free signatures. Table 2 (Column 2) shows the distribution of signatures among "with loop", "trivial", and "loop-free and non trivial". Then it provides the maximal, minimal, average number (Column 3) and size (Column 4) of the minimal modules with respect to the signatures.

Table 2: Running GIMM on the signature sets: statistics

|  | Signature <br> $($ loop/trivial/ <br> non-trivial) | Minimal modules |  |
| :---: | :---: | :---: | :---: |
|  |  | Size <br> $(\mathrm{max} / \mathrm{min} / \mathrm{mean})$ |  |
| $\sum_{50,10}^{\text {snt }}$ | $0 / 53 / 947$ | $935325 / 1 / 5046.82$ | $112 / 0 / 72.59$ |
| $\Sigma_{100,10}^{s n t}$ | $0 / 3 / 997$ | $322597 / 1 / 1330.87$ | $134 / 0 / 86.04$ |
| $\sum_{50,10}^{n c i}$ | $25 / 21 / 954$ | $10947030 / 1 / 63929.41$ | $110 / 0 / 47.42$ |
| $\sum_{100,10}^{n c i}$ | $47 / 4 / 949$ | $4334784 / 1 / 129078$ | $144 / 0 / 54.10$ |

Time cost: GIMM vs. Zooms. First, we compare GIMM with the state-of-the-art algorithm [6], called Zooms. For each signature, we set the run-time limit to 600s. For simplicity, we regard signatures with loop as timed out samples for GIMM. Zooms is actually unable to solve any of these signatures.
As shown in Table 3, the successful rate of GIMM is between $+12.8 \%$ and $+46 \%$ higher than Zooms. As shown in Table 4, for the signatures solved by both algorithms, GIMM is 30 to 50 times faster than Zooms on average. The maximal time-cost of GIMM is close to or even smaller than the minimal time-cost of Zooms except for the dataset $\sum_{50,10}^{n c i}$. Fig. 3 illustrates the time-cost of the two algorithms for all the signatures solved by them: GIMM is faster than Zooms on all the signatures.

One reason GIMM runs so fast is that the size of our invariants were usually small. On average, we have 0.95 non-redundant hyperpaths and 11.51 non-redundant clusters for each signature. For more than half of the cases, the set of non-redundant hyper-paths is empty. But in some rare cases, there exists up to 953 non-redundant hyperpaths.

(a) $\Sigma_{50,10}^{s n t}$

| Size | $\#\left\|O^{a p}\right\|$ | \#locality-based module |
| :---: | :---: | :---: |
| $\sum_{50,10}^{\text {snt }}$ | $1581 / 0 / 237.11 / 67.5$ | $10182 / 3426 / 6539.11 / 6506.5$ |
| $\Sigma_{100,10}^{s n t}$ | $2537 / 0 / 480.75 / 154$ | $18311 / 8515 / 13080.30 / 13033$ |
| $\sum_{50,10}^{n c i}$ | $285 / 0 / 58.94 / 51$ | $7746 / 256 / 5542.04 / 6874$ |
| $\sum_{100,10}^{n c l}$ | $332 / 0 / 101.59 / 90$ | $8571 / 1261 / 7337.73 / 7465$ |
| Time(s) | GIMM | locality-based module $($ OWL API) |
| $\sum_{50,10}^{\text {snt }}$ | $34.71 / 5.13 / 8.22 / 6.37$ | $13.23 / 4.08 / 7.48 / 7.88$ |
| $\sum_{100,10}^{s n t}$ | $259.39 / 5.19 / 10.24 / 6.79$ | $12.01 / 4.44 / 7.83 / 8.19$ |
| $\sum_{50,10}^{n c i}$ | $4.42 / 2.03 / 2.49 / 2.44$ | $3.99 / 1.72 / 2.85 / 2.93$ |
| $\sum_{100,10}^{n c i}$ | $5.17 / 2.04 / 2.63 / 2.52$ | $3.92 / 2.10 / 2.96 / 2.96$ |

(b) $\Sigma_{50,10}^{n c i}$

(d) $\Sigma_{100,10}^{n c i}$

Figure 3: x: Signatures, y: time cost (s). In each sub-figure, we arrange the order of signatures according to their time cost in Zooms

For the signatures solved by both algorithms, GIMM spent most of the time ( $96.8 \%$ on average) on computing our invariant. Besides,

Table 5: Comparison result (max/min/mean/median)

GIMM spent more time on computing right invariant ( $75.4 \%$ on average) than computing left invariant ( $21.4 \%$ on average). The reason is that the hyper-graph $\mathcal{H}^{O}$ is always much bigger than the graph $\mathcal{G}^{O}$. Thus extracting hyper-paths over $\mathcal{H}^{O}$ is more difficult than extracting clusters over $\mathcal{G}^{O}$, even if there are much more nonredundant clusters than hyper-paths on average.

Approximation: GIMM vs. locality-based module. Although GIMM is much more efficient than Zooms, as shown above, not all samples can be solved within 600s. For example, there are $25.7 \%$ timed out samples in $\Sigma_{100,10}^{n c i}$ for GIMM. This is not surprising as computing minimal modules is a complex task in general. In these cases, GIMM was able to compute the approximation result $O^{a p}$ instead, except for $0.5 \%$ of $\Sigma_{100,10}^{s n t}$ signatures, for which timing out took place during computing the invariant.

To evaluate the approximation results, we compared GIMM with the locality-based module as implemented by OWL API [9], which also provides an approximation of minimal modules. The results are summarized in Table 5. We can see that the sizes of our approximations ( $O^{a p}$ ) are usually much smaller than that of locality-based modules ( 27 to 90 times smaller on average). On the other hand, the computation time of our approximation results using GIMM is comparable to the computation time of the locality-based modules except for a few cases (see the maximal time for $\Sigma_{100,10}^{s n t}$ ).

## 6 FUTURE WORK

In this paper, we proposed an abstract notion of invariant to characterize sub-terminologies sharing the same logical information with respect to some signature. Based on the construction of a finite invariant, we translated the computation of minimal modules for $\mathcal{E} \mathcal{L}$-terminologies to a SAT problem. We developed GIMM, a prototype and the real-world ontologies experiments showed that our approach greatly improved the state-of-the-art method Zooms.

In the future, first, we will further optimize our algorithm for rightinvariant computation and extend it to support signatures with loops. Second, we expect that our method (invariant) can be extended to drop the constraint on terminologies $O_{1}, O_{2}$ requiring $O_{1} \subseteq O_{2}$. Third, we will investigate how to generalize our method to $\mathcal{E} \mathcal{L}$ ontologies or even more expressive languages.
