HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

## REVERSIBLE PRIMES

CÉCILE DARTYGE, BRUNO MARTIN, JOËL RIVAT, IGOR E. SHPARLINSKI, AND CATHY SWAENEPOEL

Abstract. For an $n$-bit positive integer $a$ written in binary as

$$
a=\sum_{j=0}^{n-1} \varepsilon_{j}(a) 2^{j},
$$

where $\varepsilon_{j}(a) \in\{0,1\}, j \in\{0, \ldots, n-1\}, \varepsilon_{n-1}(a)=1$, let us define

$$
\overleftarrow{a}=\sum_{j=0}^{n-1} \varepsilon_{j}(a) 2^{n-1-j}
$$

the digital reversal of $a$. Also let $\mathcal{B}_{n}=\left\{2^{n-1} \leqslant a<2^{n}\right.$ : $a$ odd $\}$. With a sieve argument, we obtain an upper bound of the expected order of magnitude for the number of $p \in \mathcal{B}_{n}$ such that $p$ and $\overleftarrow{p}$ are prime. We also prove that for sufficiently large $n$,

$$
\left|\left\{a \in \mathcal{B}_{n}: \max \{\Omega(a), \Omega(\overleftarrow{a})\} \leqslant 8\right\}\right| \geqslant c \frac{2^{n}}{n^{2}}
$$

where $\Omega(n)$ denotes the number of prime factors counted with multiplicity of $n$ and $c>0$ is an absolute constant. Finally, we provide an asymptotic formula for the number of $n$-bit integers $a$ such that $a$ and $\overleftarrow{a}$ are both squarefree. Our method leads us to provide various estimates for the exponential sum

$$
\sum_{a \in \mathcal{B}_{n}} \exp (2 \pi i(\alpha a+\vartheta \overleftarrow{a})) \quad(\alpha, \vartheta \in \mathbb{R}) .
$$

## Notation

Throughout the paper, the notations $U=O(V), U \ll V$ and $V \gg U$ all mean that there is an absolute constant $C>0$ such that $|U| \leqslant C V$. If the implicit constant $C$ is allowed to depend on a parameter $\alpha$ then this dependence is indicated by writing $U=O_{\alpha}(V), U \ll_{\alpha} V$ or $V>_{\alpha}$ $U$. We also write $U \asymp V$ if $U \ll V \ll U$ and similarly for $U \asymp{ }_{\alpha} V$.

For a real number $A>0$, we write $a \sim A$ to denote $a \in[A, 2 A)$.
For a finite set $\mathcal{S}$ we use $|\mathcal{S}|$ to denote its cardinality.
We use $\mu(d), \tau(d), \omega(d)$ and $\Omega(d)$ to denote the Möbius function, number of positive divisors, number of distinct prime factors and the number of prime factors counted with multiplicity of an integer $d \geqslant 1$. We denote by $P^{-}(d)$ and $P^{+}(d)$ the smallest and the largest prime factors of an integer $d \geqslant 2$, respectively.

For a real number $x$ we also set

$$
\mathrm{e}(x)=\exp (2 \pi i x) \quad \text { and } \quad\|x\|=\min \{|x-k|: k \in \mathbb{Z}\}
$$

For a certain property P , we define $\mathbf{1}_{\mathrm{P}}$ by $\mathbf{1}_{\mathrm{P}}=1$ if P is satisfied and $\mathbf{1}_{\mathrm{P}}=0$ otherwise.

The letter $p$, with or without indices, always denotes a prime number.

## 1. Introduction

1.1. Motivation and set-up. Since recently, a large body of research has appeared on arithmetic properties of integers with various digits restrictions in a given integer base. For example, this includes the work of Mauduit and Rivat [21] on the sum of digits of primes, the work of Bourgain [4, 5] and Swaenepoel [31] on primes with prescribed digits on a positive proportion of positions in their digital expansion, and the results of Maynard [22,23] on primes with missing digits, see also [6-11, $13,16,19,26,28]$ and references therein for a series of other results about primes and other interesting integers with various digit restrictions. In this direction, polynomial values with digital restrictions have been studied by Mauduit and Rivat [20], Maynard [23] and very recently by Spiegelhofer [29], see also [12, 15, 30].

In the present paper, we are interested in a question, which apparently has never been studied theoretically. Let $b \geqslant 2$ an integer. For a positive integer $k$ written in a base $b$ as

$$
k=\sum_{j=0}^{n-1} \varepsilon_{j}(k) b^{j}
$$

where $\varepsilon_{j}(k) \in\{0, \ldots, b-1\}$ for $j \in\{0, \ldots, n-1\}$ and $\varepsilon_{n-1}(k) \neq 0$, we define

$$
\overleftarrow{k}=\sum_{j=0}^{n-1} \varepsilon_{j}(k) b^{n-1-j}
$$

as the "reverse" of $k$ in base $b$ (throughout the paper, we make sure that there is no ambiguity on the base $b$ ). It is certainly interesting to understand whether there is any correlation between arithmetic properties of $k$ and $\overleftarrow{k}$. For instance, a natural question would be to evaluate the number of $n$-digits integers $a$ such that $a$ and $\overleftarrow{a}$ belong to a given set $\mathcal{S}$ defined by a multiplicative property.

We are especially interested in primality of both $k$ and $\overleftarrow{k}$. The prime numbers $p$ such that $\overleftarrow{p}$ is also a prime number are called reversible primes. Sometimes they are also referred as "emirps", "reversal primes" or "mirror primes". The first reversible primes in bases 2 and 10 can be found in [27, A074832] and [27, A007500], respectively.

Remarkable examples of reversible primes are of course palindromic primes, that is, primes $p$ such that $p=\overleftarrow{p}$. Unlike reversible primes, the distribution of palindromic primes has already been deeply investigated. Let us denote by $\mathcal{P}_{b}(x)$ the set of palindromes less than $x$ in
base $b$. Improving on results by Banks, Hart and Sakata [1], Col [9] has obtained an upper bound of the right order of magnitude for the number of palindromic primes in every base $b \geqslant 2$ : for $x \geqslant 2$, we have

$$
\left|\left\{p \in \mathcal{P}_{b}(x)\right\}\right|<_{b} \frac{\left|\mathcal{P}_{b}(x)\right|}{\log x} .
$$

Col [9] has also proved that for all $b \geqslant 2$, there exists $\kappa_{b} \geqslant 1$ such that for a sufficiently large $x$ (depending only on $b$ )

$$
\left|\left\{k \in \mathcal{P}_{b}(x): \Omega(k) \leqslant \kappa_{b}\right\}\right| \gg_{b} \frac{\left|\mathcal{P}_{b}(x)\right|}{\log x}
$$

and he computed some admissible values of $\kappa_{b}$. In particular, he showed that there are infinitely many binary palindromes $k$ such that $\Omega(k) \leqslant$ 60. We also mention that Irving [18] has proved that, for sufficiently large $b$, there exists a 3-digits palindrome in base $b$ with exactly 2 prime factors and Banks and Shparlinski [3] showed that in any base $b \geqslant 2$, for sufficiently large $n$, there exists a $n$-digit palindrome $k$ such that $\omega(k) \geqslant(\log \log k)^{1+o(1)}$ and a $n$-digit palindrome $m$ such that $P^{+}(m) \geqslant(\log m)^{2+o(1)}$.

In this paper, in order to emphasize our main ideas to handle reversible primes, we choose to concentrate on the emblematic case of binary expansions. So from now on, we consider $n$-bit integers $k$ such that

$$
k=\sum_{j=0}^{n-1} \varepsilon_{j}(k) 2^{j}, \quad \overleftarrow{k}=\sum_{j=0}^{n-1} \varepsilon_{j}(k) 2^{n-1-j}
$$

with $\varepsilon_{j}(k) \in\{0,1\}, j \in\{0, \ldots, n-1\}, \varepsilon_{n-1}(k)=1$. The sieve method developed by Col in [9] is not suitable to study reversible primes. Instead, we develop a two-dimensional sieve approach that enables us to obtain an upper bound of the expected order of magnitude for the number of reversible primes and to prove that there are infinitely many reversible almost primes. Furthermore, we are able to get an asymptotic formula for the number of reversible squarefree integers.

### 1.2. Main results.

1.2.1. Reversible primes. The $n$-bit prime numbers $p$ such that $\overleftarrow{p}$ is also prime must satisfy $\varepsilon_{0}(p)=\varepsilon_{n-1}(p)=1$, which implies that $p \in \mathcal{B}_{n}$, where

$$
\mathcal{B}_{n}=\left\{2^{n-1} \leqslant a<2^{n}: a \text { odd }\right\}
$$

is the set of $n$-bit odd integers. Clearly

$$
\left|\mathcal{B}_{n}\right|=2^{n-2} .
$$

We also note that if $a \in \mathcal{B}_{n}$, then

$$
\begin{equation*}
\overleftarrow{a} \equiv(-1)^{n-1} a \bmod 3 \tag{1.1}
\end{equation*}
$$

so that $3 \mid a$ if and only if $3 \mid \overleftarrow{a}$
We denote by $\Theta(n)$ the number of $n$-bit reversible primes:

$$
\Theta(n)=\mid\left\{2^{n-1} \leqslant p<2^{n}: p \text { and } \overleftarrow{p} \text { are prime }\right\} \mid
$$

It is certainly natural to expect that

$$
\begin{equation*}
\Theta(n)=(c+o(1)) \frac{2^{n}}{n^{2}} \quad(n \rightarrow \infty) \tag{1.2}
\end{equation*}
$$

for some absolute constant $c>0$. In Section 8, we present numerical investigations and a heuristic argument that permit us to formulate a conjecture regarding the value of $c$ in (1.2). We are not able to obtain such an asymptotic formula but we obtain an upper bound on $\Theta(n)$ of the expected order of magnitude. To achieve this, we use a sieve method based on the following trivial inequality. For any real number $z \leqslant 2^{n-1}$ we have

$$
\begin{equation*}
\Theta(n) \leqslant \Theta(n, z) \tag{1.3}
\end{equation*}
$$

where

$$
\Theta(n, z)=\left|\left\{a \in \mathcal{B}_{n}: p \mid a \overleftarrow{a} \Rightarrow p \geqslant z\right\}\right|
$$

We use the two-dimensional combinatorial sieve described in [14, p. 308-310], with the associated constant

$$
\beta_{2}=4.2664 \ldots
$$

from [14, Appendix III], to establish the following matching upper and lower bounds on $\Theta(n, z)$.
Theorem 1.1. Let $0<\gamma<1 /\left(2 \beta_{2}\right)$. There exists $n_{0} \geqslant 1$, which depends only on $\gamma$, such that for $n \geqslant n_{0}$, we have

$$
\Theta\left(n, 2^{\gamma n}\right) \asymp \gamma \frac{2^{n}}{n^{2}} .
$$

Hence, we immediately derive from (1.3) and Theorem 1.1 an upper bound on $\Theta(n)$ of the expected order of magnitude.
Corollary 1.2. For any integer $n \geqslant 1$, we have

$$
\Theta(n) \ll \frac{2^{n}}{n^{2}}
$$

Another direct consequence of Theorem 1.1 is the existence of infinitely many almost prime numbers whose reverse is also almost prime. If a $n$-bit integer $a$ is such that all prime factors of $a \overleftarrow{a}$ are bigger than $2^{\gamma n}$ then $\max \{\Omega(a), \Omega(\overleftarrow{a})\} \leqslant\lfloor 1 / \gamma\rfloor$. Our limit for the choice of $1 / \gamma$ is $2 \beta_{2}=8.53 \ldots$.

Corollary 1.3. There exists $n_{0} \geqslant 1$ such that for any integer $n \geqslant n_{0}$, we have

$$
\left|\left\{a \in \mathcal{B}_{n}: \max \{\Omega(a), \Omega(\overleftarrow{a})\} \leqslant 8\right\}\right| \gg \frac{2^{n}}{n^{2}}
$$

The lower bound in Corollary 1.3 is not of the expected order of magnitude. A power of $\log n$ is missing. This is due to the fact that the almost primes $a$ and $\overleftarrow{a}$ detected in Corollary 1.3 are without small prime factors.
1.2.2. Reversible squarefree integers. It is also interesting to consider simultaneously squarefree values of $a$ and $\overleftarrow{a}$. Thus, we define

$$
Q(n)=\left|\left\{a \in \mathcal{B}_{n}: \mu^{2}(a)=\mu^{2}(\overleftarrow{a})=1\right\}\right|
$$

as the cardinality of the set of the $a \in \mathcal{B}_{n}$ such that $a$ and its reverse $\overleftarrow{a}$ are both squarefree. This is related to the sequence [27, A077337] (in base $b=10$ ). In this case, we are able to obtain an asymptotic formula for $Q(n)$ which matches the following heuristic.

If we choose $a \in \mathcal{B}_{n}$ at random then the probability that $9 \nmid a$ and $9 \nmid \overleftarrow{a}$ is

$$
\begin{aligned}
\mathbb{P}(9 \nmid a \text { and } 9 \nmid \overleftarrow{a}) & =1-\mathbb{P}(9 \mid a \text { or } 9 \mid \overleftarrow{a}) \\
& =1-\mathbb{P}(9 \mid a)-\mathbb{P}(9 \mid \overleftarrow{a})+\mathbb{P}(9 \mid a \text { and } 9 \mid \overleftarrow{a})
\end{aligned}
$$

If $3 \mid a$ then $3 \mid \overleftarrow{a}$. Therefore, if $9 \mid a$ then $\overleftarrow{a} \equiv 0,3$ or $6 \bmod 9$. Hence we may expect that

$$
\mathbb{P}(9 \mid a \text { and } 9 \mid \overleftarrow{a}) \approx \frac{1}{9} \cdot \frac{1}{3}=\frac{1}{27}
$$

and

$$
\mathbb{P}(9 \nmid a \text { and } 9 \nmid \overleftarrow{a}) \approx 1-\frac{1}{9}-\frac{1}{9}+\frac{1}{27}=\frac{22}{27}
$$

Moreover, if $a \in \mathcal{B}_{n}$ then $a$ and $\overleftarrow{a}$ are both odd. Thus we may expect that

$$
\begin{aligned}
\frac{1}{\left|\mathcal{B}_{n}\right|} Q(n) & \approx \mathbb{P}(9 \nmid a \text { and } 9 \nmid \overleftarrow{a}) \prod_{p \geqslant 5} \mathbb{P}\left(p^{2} \nmid a \text { and } p^{2} \nmid \overleftarrow{a}\right) \\
& \approx \frac{22}{27} \prod_{p \geqslant 5}\left(1-\frac{1}{p^{2}}\right)^{2}=\frac{22}{27}\left(\frac{4}{3}\right)^{2}\left(\frac{9}{8}\right)^{2} \frac{1}{\zeta(2)^{2}} \\
& =\frac{11}{6} \frac{1}{\zeta(2)^{2}}=\frac{66}{\pi^{4}} .
\end{aligned}
$$

Therefore we expect that

$$
Q(n)=\left|\mathcal{B}_{n}\right|\left(\frac{66}{\pi^{4}}+o(1)\right)
$$

which we prove in a quantitative way.
We also define

$$
\widetilde{Q}(n)=\left|\left\{2^{n-1} \leqslant a<2^{n}: \mu^{2}(a)=\mu^{2}(\overleftarrow{a})=1\right\}\right|
$$

Theorem 1.4. There exists an absolute constant $c>0$ such that for any $n \geqslant 1$, we have

$$
\begin{equation*}
Q(n)=\left|\mathcal{B}_{n}\right|\left(\frac{66}{\pi^{4}}+O(\exp (-c \sqrt{n}))\right) \tag{1.4}
\end{equation*}
$$

and

$$
\begin{equation*}
\widetilde{Q}(n)=2^{n-1}\left(\frac{99}{2 \pi^{4}}+O(\exp (-c \sqrt{n}))\right) \tag{1.5}
\end{equation*}
$$

Examining the proof of Theorem 1.4 one can easily see that the value $c=0.0439$ is admissible.

To conclude this section, we point to the reader that so far, it is not known whether there exists infinitely many squarefree palindromes.

### 1.3. Our approach to estimate $\Theta(n, z)$.

1.3.1. Overview. Our proof follows the following sequence of steps and ideas.

- We rely on sieving, which means we have to establish a reasonable level of distribution of the products $a \overleftarrow{a}$ in arithmetic progressions, see (1.6). This naturally leads to two problems: evaluating the main term which is given by some explicit multiplicative function, see (1.7) and (1.8), and estimating the error term (on average over moduli in the sieving with some weights), which is done in Lemma 1.5.
- We handle the error term and prove Lemma 1.5 by establishing a connection with some exponential sums, see Section 5, and estimating these sums, see Sections 2 and 3.
- In particular, we study in Section 2 exponential sums with linear combinations of $a$ and $\overleftarrow{a}$. As for many other exponential sums involving digital functions, they can be decomposed in a product of elementary trigonometric sums, see Section 2.2. This product representation permits us to develop iterative arguments, see for instance the proof of Lemma 2.6, and obtain pointwise bounds, see Section 2.3, as well as bounds on average, see Sections 2.4 and 2.5.
1.3.2. Detailed description. As already mentioned, we rely on a classical sieve method. For $d \geqslant 1$, we put

$$
\begin{equation*}
T_{n}(d)=\left|\left\{a \in \mathcal{B}_{n}: d \mid a \overleftarrow{a}\right\}\right| \tag{1.6}
\end{equation*}
$$

Clearly $T_{n}(2)=0$. For $a \in \mathcal{B}_{n}$ randomly chosen, since $3 \mid \overleftarrow{a}$ is equivalent to $3 \mid a$ (by (1.1)), the probability that $3 \mid a \overleftarrow{a}$ is close to $1 / 3$ and for any prime $p \geqslant 5$, the events " $p \mid a$ " and " $p \mid \overleftarrow{a}$ " should be independent so that the probability that $p \mid a \overleftarrow{a}$ is expected to be $\frac{1}{p}+\frac{1}{p}-\frac{1}{p^{2}}=\frac{2 p-1}{p^{2}}$. Moreover for distinct prime numbers $p_{1}$ and $p_{2}$, the events " $p_{1} \mid a \overleftarrow{a}$ " and " $p_{2} \mid a \overleftarrow{a}$ " are expected to be independent. These heuristics lead us to define $R_{n}(d)$ for $d$ squarefree by

$$
\begin{equation*}
T_{n}(d)=\frac{f(d)}{d}\left|\mathcal{B}_{n}\right|+R_{n}(d) \tag{1.7}
\end{equation*}
$$

where $f$ is the multiplicative function defined for any prime number $p$ by

$$
f(p)= \begin{cases}0 & \text { if } p=2  \tag{1.8}\\ 1 & \text { if } p=3 \\ \frac{2 p-1}{p} & \text { if } p \geqslant 5\end{cases}
$$

and $f\left(p^{\nu}\right)=0$ for any $\nu \geqslant 2$ (it follows that $f(d) \neq 0$ if and only if $d$ is odd and squarefree).

Let

$$
V(w)=\prod_{2 \leqslant p<w}\left(1-\frac{f(p)}{p}\right) .
$$

If $w \leqslant 3$ then

$$
V(w)=1
$$

and if $w>3$ then

$$
V(w)=\frac{2}{3} \prod_{3<p<w}\left(1-\frac{2 p-1}{p^{2}}\right)=\frac{2}{3} \prod_{3<p<w}\left(1-\frac{1}{p}\right)^{2} .
$$

The Mertens formula, see, for example, [32, Part I, Theorem 1.12], implies that

$$
V(w) \asymp \frac{1}{(\log w)^{2}}
$$

and that there exists an absolute constant $C>0$ such that for any $2 \leqslant w_{1} \leqslant w$, we have

$$
\frac{V\left(w_{1}\right)}{V(w)} \leqslant\left(\frac{\log w}{\log w_{1}}\right)^{2}\left(1+\frac{C}{\log w_{1}}\right) .
$$

We are now ready to apply the sieve theorem stated in a more precise form in [14, Equations (1.17) and (1.18)] with

$$
\mathscr{A}=(a \overleftarrow{a})_{a \in \mathcal{B}_{n}}, \quad \mathscr{P}=\{p \geqslant 3: p \text { prime }\}, \quad \kappa=2
$$

For any $y \geqslant z \geqslant 3$, we have

$$
\begin{align*}
\Theta(n, z) \leqslant\left|\mathcal{B}_{n}\right| V(z)\left(h^{+}\left(\frac{\log y}{\log z}\right)\right. & \left.+O\left(\frac{\log \log y}{(\log y)^{1 / 6}}\right)\right) \\
& +O\left(\sum_{\substack{d \mid P(z) \\
d<y}} 4^{\omega(d)}\left|R_{n}(d)\right|\right) \tag{1.9}
\end{align*}
$$

where

$$
P(z)=\prod_{3 \leqslant p<z} p
$$

and $h^{+}(u)$ is some continuous function, which decreases monotonically towards 1 as $u \rightarrow+\infty$. Moreover, for any $y \geqslant z \geqslant 3$, we have a similar lower bound

$$
\begin{align*}
\Theta(n, z) \geqslant\left|\mathcal{B}_{n}\right| V(z)\left(h^{-}\left(\frac{\log y}{\log z}\right)\right. & \left.+O\left(\frac{\log \log y}{(\log y)^{1 / 6}}\right)\right) \\
& +O\left(\sum_{\substack{d \mid P(z) \\
d<y}} 4^{\omega(d)}\left|R_{n}(d)\right|\right), \tag{1.10}
\end{align*}
$$

where $h^{-}(u)$ is some continuous function, which increases monotonically towards 1 as $u \rightarrow+\infty$ and $h^{-}(u)>0$ for $u>\beta_{2}=4.2664 \ldots$

Our main technical result, which we establish in Section 6, is the following.

Lemma 1.5. Let $0<\xi<1 / 2$. There exists $c>0$, which depends only on $\xi$, such that for any $n \geqslant 1$, we have

$$
\sum_{\substack{d<2^{\xi n} \\ d ~ o d d}} \mu^{2}(d) 4^{\omega(d)}\left|R_{n}(d)\right|<_{\xi} 2^{n} \exp (-c \sqrt{n})
$$

In order to prove Lemma 1.5, we define for any real numbers $\alpha$ and $\vartheta$, the exponential sum

$$
\begin{equation*}
F_{n}(\alpha, \vartheta)=\frac{1}{\left|\mathcal{B}_{n}\right|} \sum_{a \in \mathcal{B}_{n}} \mathrm{e}(\alpha \overleftarrow{a}-\vartheta a) \tag{1.11}
\end{equation*}
$$

and for any integer $d \geqslant 1$ and $\left(h_{1}, h_{2}\right) \in \mathbb{Z}^{2}$,

$$
\begin{equation*}
H\left(d, h_{1}, h_{2}\right)=\sum_{\substack{0 \leqslant u, v<d \\ d \mid u v}} \mathrm{e}\left(\frac{h_{1} u+h_{2} v}{d}\right) . \tag{1.12}
\end{equation*}
$$

We show in Section 5 that to prove Lemma 1.5, it is enough to evaluate the sum

$$
E=\sum_{\substack{d \leq D \\ \mu^{2}(d)=1 \\ \operatorname{gcd}(d, 6)=1}} \frac{4^{\omega(d)}}{d^{2}} \sum_{0<h_{1}, h_{2}<d}\left|H\left(d, h_{1}, h_{2}\right)\right|\left|F_{n}\left(\frac{h_{2}}{d},-\left(\frac{h_{1}}{d}+\frac{\ell}{3^{j}}\right)\right)\right|
$$

with $D=2^{\xi n}, 0<\xi<1 / 2, j \in\{0,1\}, \ell \in\left\{0, \ldots, 3^{j}-1\right\}$.
We study $F_{n}(\alpha, \vartheta)$ in detail in Section 2. We strongly make use of the fact that $\left|F_{n}(\alpha, \vartheta)\right|$ can be written as a product of cosines (which is very common for exponential sums involving digital functions in base 2). Also, we combine the large sieve inequality and an extension of the Sobolev-Gallagher inequality to evaluate some discrete averages of $F_{n}$. Here we make the trivial observations that

$$
\begin{equation*}
\overline{F_{n}(\alpha, \vartheta)}=F_{n}(-\alpha,-\vartheta)=F_{n}(\vartheta, \alpha) \tag{1.13}
\end{equation*}
$$

and

$$
\begin{equation*}
\left|F_{n}(\alpha, \vartheta)\right| \leqslant 1 . \tag{1.14}
\end{equation*}
$$

We note that for rational $\alpha$ and $\vartheta$, the exponential sums $F_{n}(\alpha, \vartheta)$ have also been estimated in [2] via a different approach. However the bounds of [2] are not sufficient for our purpose.

The quantity $H\left(d, h_{1}, h_{2}\right)$ is studied in Section 3.
In Section 6, we use our estimates on $F_{n}(\vartheta, \alpha)$ and $H\left(d, h_{1}, h_{2}\right)$ to obtain the bound $E<_{\xi} \exp \left(-c_{\xi} \sqrt{n}\right)$ for some constant $c_{\xi}>0$ which depends only on $\xi$. We complete the proof of the main results in Section 7.

## 2. Study of $F_{n}(\alpha, \vartheta)$

2.1. Generalized Sobolev-Gallagher inequality. We recall the following:

Definition 2.1. We say that a sequence $\left(x_{1}, \ldots, x_{N}\right) \in \mathbb{R}^{N}$ is $\delta$-spaced modulo 1 if $\left\|x_{i}-x_{j}\right\| \geqslant \delta$ for $1 \leqslant i<j \leqslant N$.

The Sobolev-Gallagher inequality (see [24, Section 3] for relevant references) is known for continuously differentiable functions. We extend it to functions of bounded variation (see for instance [33, p. 355]).

Lemma 2.2. Let $f: \mathbb{R} \rightarrow \mathbb{R}$ be a 1-periodic continuous function of bounded variation, with total variation $\mathrm{V}_{f}$ on $[0,1]$. For $\delta>0$ and any $\delta$-spaced sequence $\left(x_{1}, \ldots, x_{N}\right) \in \mathbb{R}^{N}$, we have

$$
\sum_{n=1}^{N}\left|f\left(x_{n}\right)\right| \leqslant \frac{1}{\delta} \int_{0}^{1}|f(u)| d u+\frac{1}{2} \mathrm{~V}_{f}
$$

Proof. We adapt the proof in [24] with Stieltjes integrals. If $\widetilde{x}_{n}$ is the fractional part of $x_{n}-x_{1}+\frac{\delta}{2}$ and $g(x)=f\left(x+x_{1}-\frac{\delta}{2}\right)$ then $\widetilde{x}_{n} \in\left[\frac{\delta}{2}, 1-\frac{\delta}{2}\right]$, $g\left(\widetilde{x}_{n}\right)=f\left(x_{n}\right)$, and $g$ is also a 1-periodic continuous function, with a bounded variation $\mathrm{V}_{g}$ on $[0,1]$, and $\mathrm{V}_{g}=\mathrm{V}_{f}$. It is sufficient to prove the result for $g\left(\widetilde{x}_{n}\right)$. Hence we may assume from now that $x_{n} \in\left[\frac{\delta}{2}, 1-\frac{\delta}{2}\right]$. For $x \in[0,1]$ we denote by $\mathrm{V}_{f}(x)$ the total variation of $f$ on $[0, x]$ (thus $\mathrm{V}_{f}(1)=\mathrm{V}_{f}$ ). Since $f$ is continuous, by partial summation, for $n \in\{1, \ldots, N\}$ we have

$$
\begin{aligned}
f\left(x_{n}\right)=\frac{1}{\delta} \int_{x_{n}-\frac{\delta}{2}}^{x_{n}+\frac{\delta}{2}} f(u) d u+\int_{x_{n}-\frac{\delta}{2}}^{x_{n}} & \left(\frac{u-x_{n}}{\delta}+\frac{1}{2}\right) d f(u) \\
& +\int_{x_{n}}^{x_{n}+\frac{\delta}{2}}\left(\frac{u-x_{n}}{\delta}-\frac{1}{2}\right) d f(u)
\end{aligned}
$$

For $x_{n}-\frac{\delta}{2} \leqslant u \leqslant x_{n}$ we have

$$
0 \leqslant \frac{u-x_{n}}{\delta}+\frac{1}{2} \leqslant \frac{1}{2}
$$

and for $x_{n} \leqslant u \leqslant x_{n}+\frac{\delta}{2}$ we have

$$
-\frac{1}{2} \leqslant \frac{u-x_{n}}{\delta}-\frac{1}{2} \leqslant 0
$$

Hence

$$
\left|f\left(x_{n}\right)\right| \leqslant \frac{1}{\delta} \int_{x_{n}-\frac{\delta}{2}}^{x_{n}+\frac{\delta}{2}}|f(u)| d u+\frac{1}{2} \int_{x_{n}-\frac{\delta}{2}}^{x_{n}} d \bigvee_{f}(u)+\frac{1}{2} \int_{x_{n}}^{x_{n}+\frac{\delta}{2}} d \bigvee_{f}(u)
$$

Since the intervals $\left(x_{n}-\frac{\delta}{2}, x_{n}+\frac{\delta}{2}\right)$ are non-overlapping modulo 1 , it follows that

$$
\begin{aligned}
\sum_{n=1}^{N}\left|f\left(x_{n}\right)\right| \leqslant & \frac{1}{\delta} \int_{0}^{1}|f(u)| d u+\frac{1}{2} \int_{0}^{1} d \mathrm{~V}_{f}(u) \\
& =\frac{1}{\delta} \int_{0}^{1}|f(u)| d u+\frac{1}{2} \bigvee_{f}
\end{aligned}
$$

as desired.
2.2. Product formula. We need the following useful identities for $F_{n}(\alpha, \vartheta)$ defined by (1.11).

Lemma 2.3. For $(\alpha, \vartheta) \in \mathbb{R}^{2}$ and $n \geqslant 3$, we have

$$
\left|F_{n}(\alpha, \vartheta)\right|=\left|F_{n}(\vartheta, \alpha)\right|=\prod_{j=1}^{n-2}\left|U\left(\alpha 2^{n-1-j}-\vartheta 2^{j}\right)\right|
$$

where

$$
U(x)=\frac{1+\mathrm{e}(x)}{2} .
$$

Proof. By writing

$$
\begin{aligned}
a & =2^{n-1}+a_{n-2} 2^{n-2}+\cdots+a_{1} 2+1 \\
\overleftarrow{a} & =1+a_{n-2} 2+\cdots+a_{1} 2^{n-2}+2^{n-1}
\end{aligned}
$$

we obtain

$$
F_{n}(\alpha, \vartheta)=\mathrm{e}\left((\alpha-\vartheta)\left(2^{n-1}+1\right)\right) \prod_{j=1}^{n-2} U\left(\alpha 2^{n-1-j}-\vartheta 2^{j}\right) .
$$

It is also obvious that $F_{n}(\alpha, \vartheta)=\overline{F_{n}(\vartheta, \alpha)}$.
Lemma 2.4. For $(\alpha, \vartheta) \in \mathbb{R}^{2}$ and $3 \leqslant m \leqslant n-1$, we have

$$
\left|F_{n}(\alpha, \vartheta)\right|=\left|F_{m}\left(\alpha 2^{n-m}, \vartheta\right)\right| \cdot\left|F_{n-m+2}\left(\alpha, \vartheta 2^{m-2}\right)\right| .
$$

Proof. For $3 \leqslant m \leqslant n$, by Lemma 2.3, with the help of $k=n-1-j$ we can write

$$
\left|F_{n}(\alpha, \vartheta)\right|=\left(\prod_{j=1}^{m-2}\left|U\left(\alpha 2^{n-1-j}-\vartheta 2^{j}\right)\right|\right)\left(\prod_{k=1}^{n-m}\left|U\left(\alpha 2^{k}-\vartheta 2^{n-1-k}\right)\right|\right),
$$

while

$$
\begin{aligned}
\left|F_{m}\left(\alpha 2^{n-m}, \vartheta\right)\right| & =\prod_{j=1}^{m-2}\left|U\left(\alpha 2^{n-m} 2^{m-1-j}-\vartheta 2^{j}\right)\right| \\
& =\prod_{j=1}^{m-2}\left|U\left(\alpha 2^{n-1-j}-\vartheta 2^{j}\right)\right|
\end{aligned}
$$

and

$$
\begin{aligned}
\left|F_{n-m+2}\left(\vartheta 2^{m-2}, \alpha\right)\right| & =\prod_{k=1}^{n-m+2-2}\left|U\left(\vartheta 2^{m-2} 2^{n-m+2-1-k}-\alpha 2^{k}\right)\right| \\
& =\prod_{k=1}^{n-m}\left|U\left(\vartheta 2^{n-1-k}-\alpha 2^{k}\right)\right|
\end{aligned}
$$

Since

$$
\left|F_{n-m+2}\left(\alpha, \vartheta 2^{m-2}\right)\right|=\left|F_{n-m+2}\left(\vartheta 2^{m-2}, \alpha\right)\right|
$$

and $|U(\cdot)|$ is even, the result follows.
2.3. Pointwise bounds for $F_{n}$. We use an idea of Col [9, Proof of Lemme 2] and sharpen the arguments of [9, Section 4.2] to get an upper bound for $\left|F_{n}(\alpha, \vartheta)\right|$.
Lemma 2.5. For $(x, y, z) \in \mathbb{R}^{3}$ we have

$$
|U(x) U(y) U(z)| \leqslant \frac{1}{4}|U(x+y+z)|+\frac{3}{4}
$$

Proof. For $(x, y, z) \in \mathbb{R}^{3}$ we have

$$
\begin{aligned}
|U(x) U(y) U(z)| & \left.=\frac{1}{8} \right\rvert\, 1+\mathrm{e}(x)+\mathrm{e}(y)+\mathrm{e}(z)+\mathrm{e}(x+y) \\
& +\mathrm{e}(x+z)+\mathrm{e}(y+z)+\mathrm{e}(x+y+z) \mid \\
& \leqslant \frac{|1+\mathrm{e}(x+y+z)|+6}{8}=\frac{1}{4}|U(x+y+z)|+\frac{3}{4}
\end{aligned}
$$

which concludes the proof.
For any integer $N \geqslant 1$ and any $\vartheta \in \mathbb{R}$, we define

$$
\begin{equation*}
G_{N}(\vartheta)=\prod_{j=0}^{N-1}\left(\frac{1}{4}\left|U\left(\vartheta 2^{j}\right)\right|+\frac{3}{4}\right) . \tag{2.1}
\end{equation*}
$$

Lemma 2.6. For any integer $n \geqslant 4$ and any $(\alpha, \vartheta) \in \mathbb{R}^{2}$, we have

$$
\begin{equation*}
\left|F_{n}(\alpha, \vartheta)\right| \leqslant \prod_{j=1}^{n-3}\left(\frac{1}{4}\left|U\left(3 \vartheta 2^{j}\right)\right|+\frac{3}{4}\right)^{1 / 3}=G_{n-3}^{1 / 3}(6 \vartheta) \tag{2.2}
\end{equation*}
$$

Proof. Applying Lemma 2.3 and writing

$$
\begin{aligned}
\left|F_{n}(\alpha, \vartheta)\right| & =\prod_{j=1}^{n-2}\left|U\left(\alpha 2^{n-1-j}-\vartheta 2^{j}\right)\right| \\
& \leqslant \prod_{j=1}^{n-3}\left|U\left(\alpha 2^{n-1-j}-\vartheta 2^{j}\right)\right|^{1 / 3} \prod_{j=2}^{n-2}\left|\overline{U\left(\alpha 2^{n-1-j}-\vartheta 2^{j}\right)}\right|^{2 / 3}
\end{aligned}
$$

we get

$$
\left|F_{n}(\alpha, \vartheta)\right| \leqslant \prod_{j=1}^{n-3}\left|U\left(\alpha 2^{n-1-j}-\vartheta 2^{j}\right) U^{2}\left(-\alpha 2^{n-2-j}+\vartheta 2^{j+1}\right)\right|^{1 / 3}
$$

Taking

$$
x=\alpha 2^{n-1-j}-\vartheta 2^{j} \quad \text { and } \quad y=z=-\alpha 2^{n-2-j}+\vartheta 2^{j+1}
$$

in Lemma 2.5 we obtain the desired estimate.
Lemma 2.7. For $q \in \mathbb{Z}, q \geqslant 2$ and $\vartheta \in \mathbb{R} \backslash \mathbb{Z}$, the integer

$$
j=\left\lfloor\frac{\log \frac{q}{(q+1)\|\vartheta\|}}{\log q}\right\rfloor
$$

satisfies

$$
\left\|q^{j} \vartheta\right\| \geqslant \frac{1}{q+1} .
$$

Proof. Since $\|\vartheta\| \leqslant 1 / 2$, we have $j \geqslant 0$. Therefore $q^{j} \in \mathbb{Z}$ and we have $\left\|q^{j} \vartheta\right\|=\left\|q^{j}\right\| \vartheta\| \|$ by parity and periodicity. By definition of $j$, we have

$$
\frac{1}{q+1}<q^{j}\|\vartheta\| \leqslant \frac{q}{q+1}=1-\frac{1}{q+1}
$$

which gives the result.
We are now ready to establish one of our main technical tools.
Lemma 2.8. For $\alpha \in \mathbb{R}$ and $n, \ell, h, d \in \mathbb{Z}$ such that $n \geqslant 4, d \geqslant 5$, $d$ is odd and $d \nmid 3 h$, we have

$$
\left|F_{n}\left(\alpha, \frac{h}{d}+\frac{\ell}{3}\right)\right| \ll \exp \left(\frac{-c_{0} n}{\log \left(\frac{4 d}{3}\right)}\right),
$$

where

$$
c_{0}=\frac{1}{3} \log \left(\frac{8}{7}\right) \log 2=0.0308 \ldots
$$

Proof. Since $|U(x)|=\cos \pi\|x\|$ for any $x \in \mathbb{R}$, we have by Lemma 2.6,

$$
\begin{aligned}
\left|F_{n}\left(\alpha, \frac{h}{d}+\frac{\ell}{3}\right)\right| \leqslant & \prod_{j=1}^{n-3}\left(\frac{1}{4} \cos \pi\left\|3\left(\frac{h}{d}+\frac{\ell}{3}\right) 2^{j}\right\|+\frac{3}{4}\right)^{1 / 3} \\
& =\prod_{j=1}^{n-3}\left(\frac{1}{4} \cos \pi\left\|\frac{3 h 2^{j}}{d}\right\|+\frac{3}{4}\right)^{1 / 3}
\end{aligned}
$$

Thus, defining

$$
J=1+\left\lfloor\frac{\log \left(\frac{2 d}{3}\right)}{\log 2}\right\rfloor \geqslant 1, \quad K=\left\lfloor\frac{n-3}{J}\right\rfloor, \quad \vartheta_{k}=\frac{3 h 2^{k J+1}}{d}
$$

for any integer $k$, we may write

$$
\left|F_{n}\left(\alpha, \frac{h}{d}+\frac{\ell}{3}\right)\right| \leqslant \prod_{0 \leqslant k<K} \prod_{0 \leqslant j<J}\left(\frac{1}{4} \cos \pi\left\|2^{j} \vartheta_{k}\right\|+\frac{3}{4}\right)^{1 / 3} .
$$

We fix $k \in\{0, \ldots, K-1\}$. Since $d$ is odd and $d \nmid 3 h$, we have $\left\|\vartheta_{k}\right\| \geqslant \frac{1}{d}$. Thus, denoting

$$
j_{k}=\left\lfloor\frac{\log \frac{2}{3\left\|\vartheta_{k}\right\|}}{\log 2}\right\rfloor,
$$

we have

$$
0 \leqslant j_{k} \leqslant J-1
$$

and by Lemma 2.7,

$$
\left\|2^{j_{k}} \vartheta_{k}\right\| \geqslant \frac{1}{3} .
$$

It follows that

$$
\left|F_{n}\left(\alpha, \frac{h}{d}+\frac{\ell}{3}\right)\right| \leqslant \prod_{0 \leqslant k<K}\left(\frac{1}{4} \cos \pi\left\|2^{j_{k}} \vartheta_{k}\right\|+\frac{3}{4}\right)^{1 / 3} \leqslant\left(\frac{7}{8}\right)^{K / 3} .
$$

Since $J \leqslant \frac{\log \left(\frac{4 d}{3}\right)}{\log 2}$, we have

$$
K>\frac{n-3}{J}-1 \geqslant \frac{(n-3) \log 2}{\log \left(\frac{4 d}{3}\right)}-1=\frac{n \log 2}{\log \left(\frac{4 d}{3}\right)}+O(1),
$$

we get

$$
\left|F_{n}\left(\alpha, \frac{h}{d}+\frac{\ell}{3}\right)\right| \leqslant\left(\frac{7}{8}\right)^{\frac{K}{3}} \ll \exp \left(\frac{-n \log \left(\frac{8}{7}\right) \log 2}{3 \log \left(\frac{4 d}{3}\right)}\right)
$$

which completes the proof.
2.4. Bounds on some continuous averages. To fix the ideas, it is interesting to note that by orthogonality we have

$$
\begin{aligned}
& \int_{0}^{1}\left|F_{n}(\alpha, \vartheta)\right|^{2} d \vartheta=\frac{1}{\left|\mathcal{B}_{n}\right|^{2}} \int_{0}^{1}\left|\sum_{a \in \mathcal{B}_{n}} \mathrm{e}(\alpha \overleftarrow{a}-\vartheta a)\right|^{2} d \vartheta \\
& \quad=\frac{1}{\left|\mathcal{B}_{n}\right|^{2}} \sum_{a_{1} \in \mathcal{B}_{n}} \sum_{a_{2} \in \mathcal{B}_{n}} \mathrm{e}\left(\alpha\left(\overleftarrow{a_{1}}-\overleftarrow{a_{2}}\right)\right) \int_{0}^{1} \mathrm{e}\left(\vartheta\left(a_{2}-a_{1}\right)\right) d \vartheta=\frac{1}{\left|\mathcal{B}_{n}\right|},
\end{aligned}
$$

and by the Cauchy-Schwarz inequality this gives the trivial upper bound

$$
\int_{0}^{1}\left|F_{n}(\alpha, \vartheta)\right| d \vartheta \leqslant\left(\int_{0}^{1}\left|F_{n}(\alpha, \vartheta)\right|^{2} d \vartheta\right)^{1 / 2}=\frac{1}{\left|\mathcal{B}_{n}\right|^{1 / 2}}
$$

The following estimate of $G_{N}$ (defined by (2.1)) is a key argument in the sequel.

Lemma 2.9. For any integer $N \geqslant 1$ and any real number $\kappa \in[0,1]$, we have

$$
\int_{0}^{1} G_{N}^{\kappa}(\vartheta) d \vartheta \leqslant C(\kappa)^{N}
$$

where

$$
C(\kappa)=\left(\frac{\sqrt{2}}{8}+\frac{3}{4}\right)^{\kappa} .
$$

Proof. For any $N \geqslant 1$, we have

$$
\begin{aligned}
\int_{0}^{1} G_{N}^{\kappa}(\vartheta) d \vartheta= & \int_{0}^{1}\left(\frac{1}{4}|U(\vartheta)|+\frac{3}{4}\right)^{\kappa} G_{N-1}^{\kappa}(2 \vartheta) d \vartheta \\
= & \int_{0}^{1 / 2}\left(\frac{1}{4}|U(\vartheta)|+\frac{3}{4}\right)^{\kappa} G_{N-1}^{\kappa}(2 \vartheta) d \vartheta \\
& \quad+\int_{0}^{1 / 2}\left(\frac{1}{4}\left|U\left(\vartheta+\frac{1}{2}\right)\right|+\frac{3}{4}\right)^{\kappa} G_{N-1}^{\kappa}(2 \vartheta) d \vartheta \\
= & \int_{0}^{1}\left(\frac{1}{4}\left|U\left(\frac{\vartheta}{2}\right)\right|+\frac{3}{4}\right)^{\kappa} G_{N-1}^{\kappa}(\vartheta) \frac{d \vartheta}{2} \\
& \quad+\int_{0}^{1}\left(\frac{1}{4}\left|U\left(\frac{\vartheta+1}{2}\right)\right|+\frac{3}{4}\right)^{\kappa} G_{N-1}^{\kappa}(\vartheta) \frac{d \vartheta}{2} \\
= & \int_{0}^{1} \Phi_{\kappa}(\vartheta) G_{N-1}^{\kappa}(\vartheta) d \vartheta
\end{aligned}
$$

where

$$
\Phi_{\kappa}(\vartheta)=\frac{1}{2}\left(\frac{1}{4}\left|U\left(\frac{\vartheta}{2}\right)\right|+\frac{3}{4}\right)^{\kappa}+\frac{1}{2}\left(\frac{1}{4}\left|U\left(\frac{\vartheta+1}{2}\right)\right|+\frac{3}{4}\right)^{\kappa} .
$$

Since $x \mapsto x^{\kappa}$ is concave for $0 \leqslant \kappa \leqslant 1$ and $|\cos x|+|\sin x| \leqslant \sqrt{2}$, we have

$$
\begin{aligned}
\Phi_{\kappa}(\vartheta) & \leqslant\left(\frac{1}{2}\left(\frac{1}{4}\left|U\left(\frac{\vartheta}{2}\right)\right|+\frac{3}{4}\right)+\frac{1}{2}\left(\frac{1}{4}\left|U\left(\frac{\vartheta+1}{2}\right)\right|+\frac{3}{4}\right)\right)^{\kappa} \\
& =\left(\frac{1}{8}\left(\left|U\left(\frac{\vartheta}{2}\right)\right|+\left|U\left(\frac{\vartheta+1}{2}\right)\right|\right)+\frac{3}{4}\right)^{\kappa} \\
& =\left(\frac{1}{8}\left(\left|\cos \frac{\pi \vartheta}{2}\right|+\left|\sin \frac{\pi \vartheta}{2}\right|\right)+\frac{3}{4}\right)^{\kappa} \\
& \leqslant\left(\frac{\sqrt{2}}{8}+\frac{3}{4}\right)^{\kappa}=C(\kappa)
\end{aligned}
$$

We have proved that

$$
\int_{0}^{1} G_{N}^{\kappa}(\vartheta) d \vartheta \leqslant C(\kappa) \int_{0}^{1} G_{N-1}^{\kappa}(\vartheta) d \vartheta
$$

By induction, it follows that

$$
\int_{0}^{1} G_{N}^{\kappa}(\vartheta) d \vartheta \leqslant C(\kappa)^{N} \int_{0}^{1} G_{0}^{\kappa}(\vartheta) d \vartheta=C(\kappa)^{N}
$$

which completes the proof.
Lemma 2.10. For any integer $N \geqslant 1$ and any real number $\kappa>0, G_{N}^{\kappa}$ admits almost everywhere a derivative $\left(G_{N}^{\kappa}\right)^{\prime}$ which satisfies

$$
\left\|\left(G_{N}^{\kappa}\right)^{\prime}\right\|_{1} \leqslant \frac{\kappa \pi}{3} 2^{N}\left\|G_{N}^{\kappa}\right\|_{1} .
$$

Proof. Since

$$
G_{N}(\vartheta)=\prod_{j=0}^{N-1}\left(\frac{1}{4}\left|\cos \left(\pi \vartheta 2^{j}\right)\right|+\frac{3}{4}\right)
$$

we have for almost all $\vartheta \in \mathbb{R}$,

$$
\left|\left(G_{N}^{\kappa}\right)^{\prime}(\vartheta)\right| \leqslant\left|G_{N}^{\kappa}(\vartheta)\right| \sum_{j=0}^{N-1} \frac{\kappa \frac{\pi 2^{j}}{4}\left|\sin \left(\pi \vartheta 2^{j}\right)\right|}{\frac{1}{4}\left|\cos \left(\pi \vartheta 2^{j}\right)\right|+\frac{3}{4}} \leqslant \frac{\kappa \pi}{3} 2^{N}\left|G_{N}^{\kappa}(\vartheta)\right|
$$

and the result follows.
2.5. Bounds on some discrete averages of $F_{n}$. For a triple $\mathcal{D}=$ $\left(D_{1}, D_{2}, D_{3}\right)$ we define the set

$$
\begin{aligned}
& \mathfrak{D}(\mathcal{D})=\left\{\left(d_{1}, d_{2}, d_{3}\right) \in \mathbb{N}^{3}: d_{1} \sim D_{1}, d_{2} \sim D_{2}, d_{3} \sim D_{3}\right. \\
&\left.\operatorname{gcd}\left(d_{1} d_{2} d_{3}, 6\right)=1\right\}
\end{aligned}
$$

and for

$$
\mathbf{d}=\left(d_{1}, d_{2}, d_{3}\right) \in \mathfrak{D}(\mathcal{D})
$$

we define

$$
\begin{aligned}
& \mathfrak{H}(\mathbf{d})=\left\{\left(h_{1}, h_{2}\right) \in \mathbb{N}^{2}: 0<h_{1}<d_{2} d_{3}, 0<h_{2}<d_{1} d_{3}\right. \\
& \operatorname{gcd}\left(h_{1}, d_{2} d_{3}\right)= \\
&\left.\operatorname{gcd}\left(h_{2}, d_{1} d_{3}\right)=1\right\} .
\end{aligned}
$$

Finally, for $\mathcal{D}=\left(D_{1}, D_{2}, D_{3}\right), \ell=\left(\ell_{1}, \ell_{2}\right) \in \mathbb{Z}^{2}$ and $r \in\{1,2\}$, we define

$$
\begin{align*}
& M_{r}(n ; \mathcal{D}, \ell) \\
& \quad=\sum_{\mathbf{d} \in \mathfrak{D}(\mathcal{D})} \sum_{\left(h_{1}, h_{2}\right) \in \mathfrak{H}(\mathbf{d})}\left|F_{n}\left(\frac{h_{2}}{d_{1} d_{3}}+\frac{\ell_{1}}{3},-\frac{h_{1}}{d_{2} d_{3}}-\frac{\ell_{2}}{3}\right)\right|^{r} . \tag{2.3}
\end{align*}
$$

Let us introduce the non-decreasing function $\widetilde{\tau}$ defined by

$$
\widetilde{\tau}(t)=\max _{d \leqslant t} \tau(d), \quad t \in[1,+\infty)
$$

and observe that, for any positive integer $d$,

$$
\begin{equation*}
2^{\omega(d)} \leqslant \tau(d) \leqslant \widetilde{\tau}(d) . \tag{2.4}
\end{equation*}
$$

Recalling the definition of $C(\kappa)$ from Lemma 2.9, we define

$$
\eta_{0}=-\frac{\log C(2 / 3)}{\log 2} \approx 0.073 \ldots
$$

In order to bound $M_{1}(n ; \mathcal{D}, \ell)$, we first establish the following bound on $M_{2}(n ; \mathcal{D}, \ell)$.

Lemma 2.11. For any $n \geqslant 10$, any $\mathcal{D}=\left(D_{1}, D_{2}, D_{3}\right) \in[1,+\infty)^{3}$ and any $\varepsilon \in(0,1]$ such that

$$
\begin{equation*}
D_{1}^{2} D_{2}^{2 \varepsilon} D_{3}^{1+\varepsilon} \leqslant 2^{n-10} \tag{2.5}
\end{equation*}
$$

we have for any $\ell=\left(\ell_{1}, \ell_{2}\right) \in \mathbb{Z}^{2}$,

$$
\frac{M_{2}(n ; \mathcal{D}, \ell)}{D_{1} D_{2} D_{3}^{2}} \ll \widetilde{\tau}\left(4 D_{2} D_{3}\right) \frac{D_{2}}{D_{1}}\left(D_{2}^{2} D_{3}\right)^{-\varepsilon \eta_{0}}
$$

where the implicit constant is absolute.
Proof. We introduce two integer parameters $n_{1}, n_{2} \geqslant 4$ such that $n_{1}+$ $n_{2} \leqslant n$. Applying Lemma 2.4 twice and recalling (1.14), we derive that there exists $(u, v) \in \mathbb{N}^{2}$ such that for any $(\alpha, \vartheta) \in \mathbb{R}^{2}$,

$$
\begin{equation*}
\left|F_{n}(\alpha, \vartheta)\right| \leqslant\left|F_{n_{1}}\left(\alpha 2^{u}, \vartheta\right)\right| \cdot\left|F_{n_{2}}\left(\alpha, \vartheta 2^{v}\right)\right| . \tag{2.6}
\end{equation*}
$$

Furthermore, by (2.2), we have

$$
\left|F_{n}(\alpha, \vartheta)\right| \leqslant G_{n_{1}-3}^{1 / 3}(6 \vartheta) \cdot\left|F_{n_{2}}\left(\alpha, \vartheta 2^{v}\right)\right| .
$$

Moreover, since $G_{n_{1}-3}$ is 1-periodic and even, we have

$$
G_{n_{1}-3}\left(6\left(-\frac{h_{1}}{d_{2} d_{3}}-\frac{\ell_{2}}{3}\right)\right)=G_{n_{1}-3}\left(\frac{6 h_{1}}{d_{2} d_{3}}\right) .
$$

Hence,

$$
\begin{aligned}
M_{2}(n ; \mathcal{D}, \ell) \leqslant & \sum_{\mathbf{d} \in \mathfrak{D}(\mathcal{D})\left(h_{1}, h_{2}\right) \in \mathfrak{H}(\mathbf{d})} G_{n_{1}-3}^{2 / 3}\left(\frac{6 h_{1}}{d_{2} d_{3}}\right) \times \\
& \left|F_{n_{2}}\left(\frac{h_{2}}{d_{1} d_{3}}+\frac{\ell_{1}}{3},-\frac{h_{1} 2^{v}}{d_{2} d_{3}}-\frac{\ell_{2} 2^{v}}{3}\right)\right|^{2}
\end{aligned}
$$

For given $d_{3}$ and $\ell_{1}$, the points

$$
\frac{h_{2}}{d_{1} d_{3}}+\frac{\ell_{1}}{3}, \quad d_{1} \sim D_{1}, 0<h_{2}<d_{1} d_{3}, \operatorname{gcd}\left(h_{2}, d_{1} d_{3}\right)=1
$$

are $\left(8 D_{1}^{2} D_{3}\right)^{-1}$-spaced modulo 1 . By summing over $d_{1}$ and $h_{2}$, we obtain by the large sieve inequality (see for instance [24]),

$$
M_{2}(n ; \mathcal{D}, \ell) \ll \sum_{\substack{d_{2} \sim D_{2} \\ d_{3} \sim D_{3} \\ \operatorname{gcd}\left(d_{2} d_{3}, 6\right)=1}} \sum_{\substack{0<h_{1}<d_{2} d_{3} \\ \operatorname{gcd}\left(h_{1}, d_{2} d_{3}\right)=1}} G_{n_{1}-3}^{2 / 3}\left(\frac{6 h_{1}}{d_{2} d_{3}}\right)\left(D_{1}^{2} D_{3} 2^{-n_{2}}+1\right) .
$$

Since $\operatorname{gcd}\left(d_{2} d_{3}, 6\right)=1$, we have by a change of variable,

$$
M_{2}(n ; \mathcal{D}, \ell) \ll\left(D_{1}^{2} D_{3} 2^{-n_{2}}+1\right) \sum_{\substack{d_{2} \sim D_{2} \\ d_{3} \sim D_{3} \\ \operatorname{gcd}\left(d_{2} d_{3}, 6\right)=1}} \sum_{\substack{0<h_{1}<d_{2} d_{3} \\ \operatorname{gcd}\left(h_{1}, d_{2} d_{3}\right)=1}} G_{n_{1}-3}^{2 / 3}\left(\frac{h_{1}}{d_{2} d_{3}}\right) .
$$

Writing

$$
\tau\left(d ; D_{2}, D_{3}\right)=\left|\left\{\left(d_{2}, d_{3}\right): d_{2} \sim D_{2}, d_{3} \sim D_{3}, d=d_{2} d_{3}\right\}\right|
$$

we have

$$
\begin{aligned}
& M_{2}(n ; \mathcal{D}, \ell) \\
& \quad \ll\left(D_{1}^{2} D_{3} 2^{-n_{2}}+1\right) \sum_{d \in\left[D_{2} D_{3}, 4 D_{2} D_{3}\right)} \tau\left(d ; D_{2}, D_{3}\right) \\
& \quad \sum_{\substack{0<h_{1}<d \\
\operatorname{gcd}\left(h_{1}, d\right)=1}} G_{n_{1}-3}^{2 / 3}\left(\frac{h_{1}}{d}\right),
\end{aligned}
$$

and observing that by (2.4) we have

$$
\tau\left(d ; D_{2}, D_{3}\right) \leqslant \tau(d) \leqslant \widetilde{\tau}(d) \leqslant \widetilde{\tau}\left(4 D_{2} D_{3}\right)
$$

we immediately derive

$$
\begin{aligned}
& M_{2}(n ; \mathcal{D}, \ell) \\
& \quad \ll \widetilde{\tau}\left(4 D_{2} D_{3}\right)\left(D_{1}^{2} D_{3} 2^{-n_{2}}+1\right) \sum_{d \in\left[D_{2} D_{3}, 4 D_{2} D_{3}\right)} \sum_{\substack{0<h_{1}<d \\
\operatorname{gcd}\left(h_{1}, d\right)=1}} G_{n_{1}-3}^{2 / 3}\left(\frac{h_{1}}{d}\right) .
\end{aligned}
$$

By Lemma 2.9, we have

$$
\left\|G_{n_{1}-3}^{2 / 3}\right\|_{1} \ll C(2 / 3)^{n_{1}}=2^{-n_{1} \eta_{0}}
$$

and by Lemma 2.10, the variation of $G_{n_{1}-3}^{2 / 3}$ on $[0,1]$ is

$$
\mathrm{V}_{G_{n_{1}-3}^{2 / 3}} \ll 2^{n_{1}}\left\|G_{n_{1}-3}^{2 / 3}\right\|_{1} .
$$

Since the points $h_{1} / d$ are $\left(16 D_{2}^{2} D_{3}^{2}\right)^{-1}$-spaced modulo 1, it follows from Lemma 2.2 that

$$
M_{2}(n ; \mathcal{D}, \ell) \ll \widetilde{\tau}\left(4 D_{2} D_{3}\right)\left(D_{1}^{2} D_{3} 2^{-n_{2}}+1\right)\left(D_{2}^{2} D_{3}^{2}+2^{n_{1}}\right) 2^{-n_{1} \eta_{0}}
$$

We choose for $n_{1}$ and $n_{2}$ the unique integers such that

$$
2^{n_{1}-5}<\left(D_{2}^{2} D_{3}\right)^{\varepsilon} \leqslant 2^{n_{1}-4}, \quad 2^{n_{2}-5}<D_{1}^{2} D_{3} \leqslant 2^{n_{2}-4}
$$

Since $D_{1}, D_{2}, D_{3} \geqslant 1$ we have $n_{1} \geqslant 4, n_{2} \geqslant 4$ and by (2.5) we have $n_{1}+n_{2} \leqslant n$. Since $\varepsilon \in(0,1]$, this leads to

$$
M_{2}(n ; \mathcal{D}, \ell) \ll \widetilde{\tau}\left(4 D_{2} D_{3}\right) D_{2}^{2} D_{3}^{2}\left(D_{2}^{2} D_{3}\right)^{-\varepsilon \eta_{0}}
$$

and completes the proof.
We are now able to bound $M_{1}(n ; \mathcal{D}, \ell)$.
Lemma 2.12. For any $n \geqslant 22$, any $\mathcal{D}=\left(D_{1}, D_{2}, D_{3}\right) \in[1,+\infty)^{3}$ and any $\varepsilon \in(0,1]$ such that

$$
\begin{equation*}
\left(D_{1} D_{2} D_{3}\right)^{2(1+\varepsilon)} \leqslant 2^{n-22} \tag{2.7}
\end{equation*}
$$

we have for any $\ell=\left(\ell_{1}, \ell_{2}\right) \in \mathbb{Z}^{2}$,

$$
\frac{M_{1}(n ; \mathcal{D}, \ell)}{D_{1} D_{2} D_{3}^{2}} \ll \widetilde{\tau}\left(4 D_{1} D_{3}\right)^{1 / 2} \widetilde{\tau}\left(4 D_{2} D_{3}\right)^{1 / 2}\left(D_{1} D_{2} D_{3}\right)^{-\varepsilon \eta_{0}}
$$

where the implicit constant is absolute.
Proof. Let $n_{1}, n_{2} \geqslant 10$ such that $n_{1}+n_{2} \leqslant n$. Similarly to (2.6), we see that there exists $(u, v) \in \mathbb{N}^{2}$ such that for any $(\alpha, \vartheta) \in \mathbb{R}^{2}$,

$$
\left|F_{n}(\alpha, \vartheta)\right| \leqslant\left|F_{n_{1}}\left(\alpha 2^{u}, \vartheta\right)\right| \cdot\left|F_{n_{2}}\left(\alpha, \vartheta 2^{v}\right)\right| .
$$

It is convenient to define

$$
\left(u_{1}, v_{1}\right)=(u, 0) \quad \text { and } \quad\left(u_{2}, v_{2}\right)=(0, v)
$$

Applying the Cauchy-Schwarz inequality, we get

$$
\begin{aligned}
& M_{1}(n ; \mathcal{D}, \ell)^{2} \\
& \quad \leqslant \prod_{k=1}^{2} \sum_{\mathbf{d} \in \mathfrak{Q}(\mathcal{D})} \sum_{\left(h_{1}, h_{2}\right) \in \mathfrak{H}(\mathbf{d})}\left|F_{n_{k}}\left(\frac{h_{2} 2^{u_{k}}}{d_{1} d_{3}}+\frac{\ell_{1} 2^{u_{k}}}{3},-\frac{h_{1} 2^{v_{k}}}{d_{2} d_{3}}-\frac{\ell_{2} 2^{v_{k}}}{3}\right)\right|^{2} .
\end{aligned}
$$

The maps $\alpha \mapsto F_{n_{k}}(\alpha, \vartheta)$ and $\vartheta \mapsto F_{n_{k}}(\alpha, \vartheta)$ are 1-periodic, and since

$$
\operatorname{gcd}\left(2^{u_{k}}, d_{1} d_{3}\right)=\operatorname{gcd}\left(2^{v_{k}}, d_{2} d_{3}\right)=1,
$$

the integer $h_{1} 2^{v_{k}}$ runs over all residue classes modulo $d_{2} d_{3}$ coprime with $d_{2} d_{3}$ and $h_{2} 2^{u_{k}}$ runs over all residue classes modulo $d_{1} d_{3}$ coprime with $d_{1} d_{3}$. Therefore, by a change of variables we obtain

$$
\begin{aligned}
& M_{1}(n ; \mathcal{D}, \ell)^{2} \\
& \qquad \leqslant \prod_{k=1}^{2} \sum_{\mathbf{d} \in \mathfrak{D}(\mathcal{D})} \sum_{\left(h_{1}, h_{2}\right) \in \mathfrak{H}(\mathbf{d})}\left|F_{n_{k}}\left(\frac{h_{2}}{d_{1} d_{3}}+\frac{\ell_{1} 2^{u_{k}}}{3},-\frac{h_{1}}{d_{2} d_{3}}-\frac{\ell_{2} 2^{v_{k}}}{3}\right)\right|^{2} \\
& \quad=\prod_{k=1}^{2} M_{2}\left(n_{k} ; \mathcal{D}, \ell_{k}\right),
\end{aligned}
$$

where $\boldsymbol{\ell}_{k}=\left(\ell_{1} 2^{u_{k}}, \ell_{2} 2^{v_{k}}\right)$. We choose for $n_{1}$ and $n_{2}$ the unique integers such that

$$
2^{n_{1}-11}<D_{1}^{2} D_{2}^{2 \varepsilon} D_{3}^{1+\varepsilon} \leqslant 2^{n_{1}-10}, \quad 2^{n_{2}-10}<D_{1}^{2 \varepsilon} D_{2}^{2} D_{3}^{1+\varepsilon} \leqslant 2^{n_{2}-10}
$$

Since $D_{1}, D_{2}, D_{3} \geqslant 1$ we have $n_{1} \geqslant 10, n_{2} \geqslant 10$ and by (2.7) we have $n_{1}+n_{2} \leqslant n$. By applying Lemma 2.11 with $n$ replaced by $n_{1}$, we obtain

$$
\frac{M_{2}\left(n_{1} ; \mathcal{D}, \ell_{1}\right)}{D_{1} D_{2} D_{3}^{2}} \ll \widetilde{\tau}\left(4 D_{2} D_{3}\right) \frac{D_{2}}{D_{1}}\left(D_{2}^{2} D_{3}\right)^{-\varepsilon \eta_{0}} .
$$

To bound $M_{2}\left(n_{2} ; \mathcal{D}, \ell_{2}\right)$, we first note that by (1.13), we have

$$
M_{2}\left(n_{2} ; \mathcal{D}, \ell_{2}\right)=M_{2}\left(n_{2} ; \widetilde{\mathcal{D}}, \tilde{\ell}_{2}\right)
$$

where $\widetilde{\mathcal{D}}=\left(D_{2}, D_{1}, D_{3}\right)$ and $\widetilde{\ell}_{2}=\left(\ell_{2} 2^{v_{2}}, \ell_{1} 2^{u_{2}}\right)$. Next, by applying Lemma 2.11 with $n, \mathcal{D}$ and $\boldsymbol{\ell}$ replaced by $n_{2}, \widetilde{\mathcal{D}}$ and $\widetilde{\ell}_{2}$, we get

$$
\frac{M_{2}\left(n_{2} ; \mathcal{D}, \ell_{2}\right)}{D_{1} D_{2} D_{3}^{2}} \ll \widetilde{\tau}\left(4 D_{1} D_{3}\right) \frac{D_{1}}{D_{2}}\left(D_{1}^{2} D_{3}\right)^{-\varepsilon \eta_{0}} .
$$

It follows that

$$
\frac{M_{1}(n ; \mathcal{D}, \ell)^{2}}{\left(D_{1} D_{2} D_{3}^{2}\right)^{2}} \ll \widetilde{\tau}\left(4 D_{1} D_{3}\right) \widetilde{\tau}\left(4 D_{2} D_{3}\right)\left(D_{1} D_{2} D_{3}\right)^{-2 \varepsilon \eta_{0}}
$$

as desired.

## 3. Study of $H\left(d, h_{1}, h_{2}\right)$

We recall that, by (1.12), for any integer $d \geqslant 1$ and $\left(h_{1}, h_{2}\right) \in \mathbb{Z}^{2}$,

$$
H\left(d, h_{1}, h_{2}\right)=\sum_{\substack{0 \leqslant u, v<d \\ d \mid u v}} \mathrm{e}\left(\frac{h_{1} u+h_{2} v}{d}\right) .
$$

Lemma 3.1. For any $\left(h_{1}, h_{2}\right) \in \mathbb{Z}^{2}$ the function $d \mapsto H\left(d, h_{1}, h_{2}\right)$ is multiplicative and for any prime number $p$, we have

$$
H\left(p, h_{1}, h_{2}\right)=p \mathbf{1}_{p \mid h_{1}}+p \mathbf{1}_{p \mid h_{2}}-1
$$

Proof. For $d_{1} \geqslant 1$ and $d_{2} \geqslant 1$ with $\operatorname{gcd}\left(d_{1}, d_{2}\right)=1$ the summation over $u$ with $0 \leqslant u<d=d_{1} d_{2}$ may be replaced by $d_{2} u_{1}+d_{1} u_{2}$ with $0 \leqslant u_{1}<d_{1}, 0 \leqslant u_{2}<d_{2}$ and similarly for $v$. We have

$$
\begin{aligned}
& \frac{h_{1} u}{d} \equiv \frac{h_{1}\left(d_{2} u_{1}+d_{1} u_{2}\right)}{d_{1} d_{2}} \equiv \frac{h_{1} u_{1}}{d_{1}}+\frac{h_{1} u_{2}}{d_{2}} \bmod 1, \\
& \frac{h_{2} v}{d} \equiv \frac{h_{2}\left(d_{2} v_{1}+d_{1} v_{2}\right)}{d_{1} d_{2}} \equiv \frac{h_{2} v_{1}}{d_{1}}+\frac{h_{2} v_{2}}{d_{2}} \bmod 1,
\end{aligned}
$$

and also

$$
\begin{aligned}
& u v \equiv\left(d_{2} u_{1}+d_{1} u_{2}\right)\left(d_{2} v_{1}+d_{1} v_{2}\right) \equiv d_{2}^{2} u_{1} v_{1} \bmod d_{1} \\
& u v \equiv\left(d_{2} u_{1}+d_{1} u_{2}\right)\left(d_{2} v_{1}+d_{1} v_{2}\right) \equiv d_{1}^{2} u_{2} v_{2} \bmod d_{2}
\end{aligned}
$$

Since $\operatorname{gcd}\left(d_{1}, d_{2}\right)=1$, the condition $d_{1} d_{2} \mid u v$, may be replaced by $d_{1} \mid u_{1} v_{1}$ and $d_{2} \mid u_{2} v_{2}$. This leads to

$$
\begin{aligned}
& H\left(d_{1} d_{2}, h_{1}, h_{2}\right) \\
& \qquad=\sum_{\substack{0 \leqslant u_{1}, v_{1}<d_{1} \\
d_{1} \mid u_{1} v_{1}}} \mathrm{e}\left(\frac{h_{1} u_{1}+h_{2} v_{1}}{d_{1}}\right) \sum_{\substack{0 \leqslant u_{2}, v_{2}<d_{2} \\
d_{2} \mid u_{2} v_{2}}} \mathrm{e}\left(\frac{h_{1} u_{2}+h_{2} v_{2}}{d_{2}}\right), \\
& \quad=H\left(d_{1}, h_{1}, h_{2}\right) H\left(d_{2}, h_{1}, h_{2}\right)
\end{aligned}
$$

which shows that $d \mapsto H\left(d, h_{1}, h_{2}\right)$ is multiplicative.
If $d=p$ is a prime number then $p \mid u v$ means $p \mid u$ or $p \mid v$, namely $u=0$ or $v=0$, hence

$$
\begin{aligned}
H\left(p, h_{1}, h_{2}\right) & =\sum_{0 \leqslant v<p} \mathrm{e}\left(\frac{h_{2} v}{p}\right)+\sum_{0 \leqslant u<p} \mathrm{e}\left(\frac{h_{1} u}{p}\right)-1 \\
& =p \mathbf{1}_{p \mid h_{1}}+p \mathbf{1}_{p \mid h_{2}}-1
\end{aligned}
$$

as claimed.
We now recall the definition (1.8) of the multiplicative function $f(d)$.

Lemma 3.2. For any squarefree integer $d \geqslant 1$ such that $\operatorname{gcd}(d, 6)=1$, we have

$$
H(d, 0,0)=d f(d)
$$

Proof. For any prime number $p \geqslant 5$, we have

$$
H(p, 0,0)=2 p-1=p f(p)
$$

and the result now follows from the multiplicativity of the functions $H(d, 0,0)$ and $f(d)$.

## 4. Average order of useful multiplicative functions

We use the following upper bounds in the proof of Lemma 1.5.
Lemma 4.1. For any real numbers $z>0$ and $x \geqslant 2$, we have

$$
\begin{equation*}
\sum_{n \leqslant x} \frac{\mu^{2}(n) z^{\omega(n)}}{n} \ll z_{z}(\log x)^{z} \tag{4.1}
\end{equation*}
$$

and

$$
\begin{equation*}
\sum_{n \leqslant x} \mu^{2}(n) z^{\omega(n)}<_{z} x(\log x)^{z-1} \tag{4.2}
\end{equation*}
$$

Stronger results may be obtained by [25, Corollary 2.15] and [32, Chapter II, Theorem 6.1].

Proof. Since $n \mapsto \mu^{2}(n) z^{\omega(n)}$ is multiplicative with non negative values, we have

$$
\sum_{n \leqslant x} \frac{\mu^{2}(n) z^{\omega(n)}}{n} \leqslant \prod_{p \leqslant x}\left(1+\frac{\mu^{2}(p) z^{\omega(p)}}{p}\right)=\prod_{p \leqslant x}\left(1+\frac{z}{p}\right)
$$

and by Mertens formula,

$$
\sum_{p \leqslant x} \log \left(1+\frac{z}{p}\right) \leqslant z \sum_{p \leqslant x} \frac{1}{p}=z(\log \log x+O(1)) .
$$

This shows (4.1). In order to prove (4.2), we first write

$$
(\log x) \sum_{n \leqslant x} \mu^{2}(n) z^{\omega(n)}=S_{1}(x)+S_{2}(x)
$$

where

$$
S_{1}(x)=\sum_{n \leqslant x} \mu^{2}(n) z^{\omega(n)} \log n \quad \text { and } \quad S_{2}(x)=\sum_{n \leqslant x} \mu^{2}(n) z^{\omega(n)} \log \frac{x}{n}
$$

Since $\mu^{2}(n) \log n=\mu^{2}(n) \sum_{p \mid n} \log p$ and $\sum_{p \leqslant X} \log p \ll X$, we obtain

$$
\begin{aligned}
S_{1}(x) & =\sum_{p \leqslant x} \log p \sum_{m \leqslant x / p} \mu^{2}(m p) z^{\omega(m p)}=\sum_{p \leqslant x} \log p \sum_{\substack{m \leqslant x / p \\
p \nmid m}} \mu^{2}(m) z^{1+\omega(m)} \\
& \leqslant \sum_{m \leqslant x} \mu^{2}(m) z^{1+\omega(m)} \sum_{p \leqslant x / m} \log p<_{z} x \sum_{m \leqslant x} \frac{\mu^{2}(m) z^{\omega(m)}}{m}
\end{aligned}
$$

Moreover since $\log \frac{x}{n} \leqslant \frac{x}{n}$, the same bound also holds for $S_{2}(x)$. By (4.1), it follows that

$$
\sum_{n \leqslant x} \mu^{2}(n) z^{\omega(n)}<_{z} \frac{x}{\log x} \sum_{n \leqslant x} \frac{\mu^{2}(n) z^{\omega(n)}}{n}<_{z} x(\log x)^{z-1}
$$

which establishes (4.2).

## 5. Preliminary study of $R_{n}(d)$

We recall that $R_{n}(d)$ is defined by (1.7) together with (1.6). It is convenient to define for $j \in\{0,1\}$ and $d \geqslant 1$ :

$$
\begin{align*}
& \widetilde{R}_{n}(d, j)=\frac{\left|\mathcal{B}_{n}\right|}{3^{j} d^{2}} \sum_{0<h_{1}, h_{2}<d} \overline{H\left(d, h_{1}, h_{2}\right)} \\
& \sum_{0 \leqslant \ell<3^{j}} F_{n}\left(\frac{h_{2}}{d},-\left(\frac{h_{1}}{d}+\frac{\ell}{3^{j}}\right)\right) . \tag{5.1}
\end{align*}
$$

We note that for $j \in\{0,1\}, \widetilde{R}_{n}(1, j)=0$.
Lemma 5.1. For any squarefree integer $d \geqslant 1$ such that $\operatorname{gcd}(d, 6)=1$ and any $j \in\{0,1\}$, we have

$$
R_{n}\left(3^{j} d\right)=\widetilde{R}_{n}(d, j)+O(f(d))
$$

Proof. Let $j \in\{0,1\}$. By multiplicativity, we have

$$
\frac{f\left(3^{j} d\right)}{3^{j} d}=\frac{f\left(3^{j}\right) f(d)}{3^{j} d}=\frac{f(d)}{3^{j} d},
$$

hence, recalling (1.7), we obtain

$$
R_{n}\left(3^{j} d\right)=T_{n}\left(3^{j} d\right)-\frac{f\left(3^{j} d\right)}{3^{j} d}\left|\mathcal{B}_{n}\right|=T_{n}\left(3^{j} d\right)-\frac{f(d)}{3^{j} d}\left|\mathcal{B}_{n}\right|
$$

Since $\overleftarrow{a} \equiv(-1)^{n-1} a \bmod 3$, recalling the definition (1.6) we may also write

$$
T_{n}\left(3^{j} d\right)=\mid\left\{a \in \mathcal{B}_{n}: d \mid a \overleftarrow{a} \text { and } 3^{j} \mid a\right\} \mid
$$

We now filter the integers $a \in \mathcal{B}_{n}$ according to the residue classes of $a$ and $\overleftarrow{a}$ modulo $d$ :

$$
T_{n}\left(3^{j} d\right)=\sum_{\substack{0 \leqslant u, v<d \\ u v \equiv 0 \bmod d}} \sum_{\substack{a \in \mathcal{B}_{n} \\ a \equiv 0 \bmod 3^{j}}} \mathbf{1}_{a \equiv u \bmod d} \mathbf{1}_{\overleftarrow{a} \equiv v \bmod d},
$$

and using the orthogonality of exponential functions to control the conditions $a \equiv u \bmod d$ and $\overleftarrow{a} \equiv v \bmod d$, we obtain

$$
\begin{aligned}
T_{n}\left(3^{j} d\right) & =\sum_{\substack{0 \leqslant u, v<d \\
d \mid u v}} \sum_{\substack{a \in \mathcal{B}_{n} \\
a \equiv 0 \bmod 3^{j}}} \frac{1}{d^{2}} \sum_{0 \leqslant h_{1}, h_{2}<d} \mathrm{e}\left(\frac{h_{1}(a-u)+h_{2}(\overleftarrow{a}-v)}{d}\right) \\
& =T_{n, 0}\left(3^{j} d\right)+T_{n, 1}\left(3^{j} d\right)+T_{n, 2}\left(3^{j} d\right)-T_{n, 3}\left(3^{j} d\right)
\end{aligned}
$$

with

$$
\begin{aligned}
& T_{n, 0}\left(3^{j} d\right)=\sum_{\substack{0 \leqslant u, v<d \\
d \mid u v}} \sum_{\substack{a \in \mathcal{B}_{n} \\
a \equiv 0 \bmod 3^{j}}} \frac{1}{d^{2}} \sum_{0<h_{1}, h_{2}<d} \mathrm{e}\left(\frac{h_{1}(a-u)+h_{2}(\overleftarrow{a}-v)}{d}\right), \\
& T_{n, 1}\left(3^{j} d\right)=\sum_{\substack{0 \leqslant u, v<d \\
d \mid u v}} \sum_{\substack{a \in \mathcal{B}_{n} \\
a \equiv 0 \bmod 3^{j}}} \frac{1}{d^{2}} \sum_{0 \leqslant h_{2}<d} \mathrm{e}\left(\frac{h_{2}(\overleftarrow{a}-v)}{d}\right), \\
& T_{n, 2}\left(3^{j} d\right)=\sum_{\substack{0 \leqslant u, v<d \\
d \mid u v}} \sum_{\substack{a \in \mathcal{B}_{n} \\
a \equiv 0 \bmod 3^{j}}} \frac{1}{d^{2}} \sum_{0 \leqslant h_{1}<d} \mathrm{e}\left(\frac{h_{1}(a-u)}{d}\right), \\
& T_{n, 3}\left(3^{j} d\right)=\sum_{\substack{0 \leqslant u, v<d \\
d \mid u v}} \sum_{\substack{a \in \mathcal{B}_{n} \\
a \equiv 0 \bmod 3^{j}}} \frac{1}{d^{2}} .
\end{aligned}
$$

Note that $T_{n, 3}\left(3^{j} d\right)$ compensates for double counting of the term corresponding to $h_{1}=h_{2}=0$, which is counted in both $T_{n, 1}\left(3^{j} d\right)$ and $T_{n, 2}\left(3^{j} d\right)$. By Lemma 3.2, we have

$$
\sum_{\substack{0 \leqslant u, v<d \\ d \mid u v}} 1=H(d, 0,0)=d f(d) .
$$

It follows that

$$
T_{n, 3}\left(3^{j} d\right)=\frac{f(d)}{d} \sum_{\substack{a \in \mathcal{B}_{n} \\ a \equiv 0 \bmod 3^{j}}} 1=\frac{f(d)}{d} \frac{\left|\mathcal{B}_{n}\right|}{3^{j}}+O\left(\frac{f(d)}{d}\right) .
$$

Moreover, since $a \equiv 0 \bmod 3^{j}$ is equivalent to $\overleftarrow{a} \equiv 0 \bmod 3^{j}$, we have

$$
\begin{aligned}
T_{n, 1}\left(3^{j} d\right) & =\sum_{\substack{0 \leqslant u, v<d \\
d \mid u v}} \frac{1}{d} \sum_{\substack{a \in \mathcal{B}_{n} \\
a \equiv 0 \bmod 3^{j}}} \mathbf{1}_{\overleftarrow{a} \equiv v \bmod d}=\sum_{\substack{0 \leqslant u, v<d \\
d \mid u v}} \frac{1}{d}\left(\frac{\left|\mathcal{B}_{n}\right|}{3^{j} d}+O(1)\right) \\
& =\frac{f(d)}{d} \frac{\left|\mathcal{B}_{n}\right|}{3^{j}}+O(f(d)) .
\end{aligned}
$$

Similarly, we obtain

$$
T_{n, 2}\left(3^{j} d\right)=\frac{f(d)}{d} \frac{\left|\mathcal{B}_{n}\right|}{3^{j}}+O(f(d)) .
$$

For $T_{n, 0}\left(3^{j} d\right)$, we write

$$
\begin{aligned}
& T_{n, 0}\left(3^{j} d\right) \\
& \quad=\frac{1}{d^{2}} \sum_{0<h_{1}, h_{2}<d<d u, v<d} \sum_{\substack{d \mid u v}} \mathrm{e}\left(\frac{-h_{1} u-h_{2} v}{d}\right) \sum_{\substack{a \in \mathcal{B}_{n} \\
a \equiv 0 \bmod 3^{j}}} \mathrm{e}\left(\frac{h_{1} a+h_{2} \overleftarrow{a}}{d}\right) \\
& \quad=\frac{1}{d^{2}} \sum_{0<h_{1}, h_{2}<d} \overline{H\left(d, h_{1}, h_{2}\right)} \sum_{\substack{a \in \mathcal{B}_{n} \\
a \equiv 0 \bmod 3^{j}}} \mathrm{e}\left(\frac{h_{1} a+h_{2} \overleftarrow{a}}{d}\right),
\end{aligned}
$$

where for any $h_{1}, h_{2}$,

$$
\begin{aligned}
\sum_{\substack{a \in \mathcal{B}_{n} \\
a \equiv 0 \bmod 3^{j}}} \mathrm{e}\left(\frac{h_{1} a+h_{2} \overleftarrow{a}}{d}\right) & =\frac{1}{3^{j}} \sum_{0 \leqslant \ell<3^{j}} \sum_{a \in \mathcal{B}_{n}} \mathrm{e}\left(\frac{h_{1} a+h_{2} \overleftarrow{a}}{d}+\frac{\ell a}{3^{j}}\right) \\
& =\frac{\left|\mathcal{B}_{n}\right|}{3^{j}} \sum_{0 \leqslant \ell<3^{j}} F_{n}\left(\frac{h_{2}}{d},-\left(\frac{h_{1}}{d}+\frac{\ell}{3^{j}}\right)\right)
\end{aligned}
$$

so that

$$
T_{n, 0}\left(3^{j} d\right)=\widetilde{R}_{n}(d, j)
$$

This completes the proof.
Lemma 5.2. For any real number $D \geqslant 2$, we have

$$
\begin{aligned}
& \sum_{\substack{d<D \\
d \text { odd }}} \mu^{2}(d) 4^{\omega(d)}\left|R_{n}(d)\right| \\
& \\
& \ll D(\log D)^{7}+\max _{j \in\{0,1\}} \sum_{\substack{d<D \\
\operatorname{gcd}(d, 6)=1}} \mu^{2}(d) 4^{\omega(d)}\left|\widetilde{R}_{n}(d, j)\right| .
\end{aligned}
$$

Proof. By splitting the sum over $d$ according to $\operatorname{gcd}(d, 3)$, we obtain

$$
\begin{aligned}
\sum_{\substack{d<D \\
\mu^{2}(d)=1 \\
d \text { odd }}} 4^{\omega(d)}\left|R_{n}(d)\right| & =\sum_{\substack{d<D \\
\mu^{2}(d)=1 \\
\operatorname{gcd}(d, 6)=1}} 4^{\omega(d)}\left|R_{n}(d)\right|+\sum_{\begin{array}{c}
d<D / 3 \\
\mu^{2}(d)=1 \\
\operatorname{gcd}(d, 6)=1
\end{array}} 4^{\omega(3 d)}\left|R_{n}(3 d)\right| \\
& \leqslant 5 \max _{j \in\{0,1\}} \sum_{\begin{array}{c}
d<D \\
\mu^{2}(d)=1 \\
\operatorname{gcd}(d, 6)=1
\end{array}} 4^{\omega(d)}\left|R_{n}\left(3^{j} d\right)\right| .
\end{aligned}
$$

It follows from Lemma 5.1 that for $j \in\{0,1\}$,

$$
\sum_{\substack{d<D \\ \mu^{2}(d)=1 \\ \operatorname{gcd}(d, 6)=1}} 4^{\omega(d)}\left|R_{n}\left(3^{j} d\right)\right| \ll \sum_{\substack{d<D \\ \mu^{2}(d)=1 \\ \operatorname{gcd}(d, 6)=1}} 4^{\omega(d)}\left|\widetilde{R}_{n}(d, j)\right|+\sum_{\substack{d<D \\ \mu^{2}(d)=1}} 4^{\omega(d)} f(d)
$$

Since $f(d)<2^{\omega(d)}$ for any squarefree integer $d$ (this follows from the multiplicativity of $f$ and $f(p)<2$ ), we have by (4.2),

$$
\sum_{\substack{d<D \\ \mu^{2}(d)=1}} 4^{\omega(d)} f(d) \leqslant \sum_{\substack{d<D \\ \mu^{2}(d)=1}} 8^{\omega(d)} \ll D(\log D)^{7} .
$$

Combining the previous estimates, we get

$$
\sum_{\substack{d<D \\ \mu^{2}(d)=1 \\ d \text { odd }}} 4^{\omega(d)}\left|R_{n}(d)\right| \ll D(\log D)^{7}+\max _{j \in\{0,1\}} \sum_{\substack{d<D \\ \mu^{2}(d)=1 \\ \operatorname{gcd}(d, 6)=1}} 4^{\omega(d)}\left|\widetilde{R}_{n}(d, j)\right|,
$$

as desired.

## 6. Proof of Lemma 1.5

Let $0<\xi<1 / 2$ and $D=2^{\xi n}$. Let $j \in\{0,1\}$ and $0 \leqslant \ell<3^{j}$. By Lemma 5.2 and (5.1), it suffices to show that there exists $c>0$, which depends only on $\xi$, such that

$$
E(n, D, j, \ell)<_{\xi} \exp (-c \sqrt{n})
$$

where

$$
\begin{aligned}
& E(n, D, j, \ell) \\
& \quad=\sum_{\substack{d \leqslant D \\
\mu^{2}(d)=1 \\
\operatorname{gcd}(d, 6)=1}} \frac{4^{\omega(d)}}{d^{2}} \sum_{0<h_{1}, h_{2}<d}\left|H\left(d, h_{1}, h_{2}\right)\right|\left|F_{n}\left(\frac{h_{2}}{d},-\left(\frac{h_{1}}{d}+\frac{\ell}{3^{j}}\right)\right)\right| .
\end{aligned}
$$

In order to handle the common factors of $d, h_{1}$ and $h_{2}$, we write $d=$ $d_{0} d_{1} d_{2} d_{3}$ with suitable $d_{i}$. More precisely, we show that the set of summation $\mathcal{E}(D)$ of all $\left(d, h_{1}, h_{2}\right) \in \mathbb{N}^{3}$ satisfying

$$
\begin{gathered}
1 \leqslant d \leqslant D, \mu^{2}(d)=1, \operatorname{gcd}(d, 6)=1, \\
0<h_{1}<d, 0<h_{2}<d
\end{gathered}
$$

may be replaced by the set $\mathcal{F}(D)$ of all $\left(d_{0}, d_{1}, d_{2}, d_{3}, h_{1}^{*}, h_{2}^{*}\right) \in \mathbb{N}^{6}$ satisfying

$$
\begin{gathered}
1 \leqslant d_{0} d_{1} d_{2} d_{3} \leqslant D, \mu^{2}\left(d_{0} d_{1} d_{2} d_{3}\right)=1, \operatorname{gcd}\left(d_{0} d_{1} d_{2} d_{3}, 6\right)=1 \\
0<h_{1}^{*}<d_{2} d_{3}, 0<h_{2}^{*}<d_{1} d_{3}, \operatorname{gcd}\left(h_{1}^{*}, d_{2} d_{3}\right)=1, \operatorname{gcd}\left(h_{2}^{*}, d_{1} d_{3}\right)=1 .
\end{gathered}
$$

We easily check that the map

$$
\begin{array}{ccc}
\mathcal{E}(D) & \rightarrow & \mathcal{F}(D) \\
\left(d, h_{1}, h_{2}\right) & \mapsto & \left(d_{0}, d_{1}, d_{2}, d_{3}, h_{1}^{*}, h_{2}^{*}\right)
\end{array}
$$

where $d_{0}, d_{1}, d_{2}, d_{3}, h_{1}^{*}, h_{2}^{*}$ are defined by

$$
\begin{gathered}
d_{0}=\operatorname{gcd}\left(d, h_{1}, h_{2}\right), d_{0} d_{1}=\operatorname{gcd}\left(d, h_{1}\right), d_{0} d_{2}=\operatorname{gcd}\left(d, h_{2}\right), \\
d_{0} d_{1} d_{2} d_{3}=d, h_{1}^{*} d_{0} d_{1}=h_{1}, h_{2}^{*} d_{0} d_{2}=h_{2},
\end{gathered}
$$

is well defined and bijective with inverse

$$
\begin{array}{ccc}
\mathcal{F}(D) & \rightarrow & \mathcal{E}(D) \\
\left(d_{0}, d_{1}, d_{2}, d_{3}, h_{1}^{*}, h_{2}^{*}\right) & \mapsto & \left.\mapsto d_{0} d_{1} d_{2} d_{3}, h_{1}^{*} d_{0} d_{1}, h_{2}^{*} d_{0} d_{2}\right) .
\end{array}
$$

It follows that

$$
\begin{aligned}
E(n, D, j, \ell)=\sum_{\left(d_{0}, d_{1}, d_{2}, d_{3}, h_{1}^{*}, h_{2}^{*}\right) \in \mathcal{F}(D)} & \frac{4^{\omega\left(d_{0} d_{1} d_{2} d_{3}\right)}}{\left(d_{0} d_{1} d_{2} d_{3}\right)^{2}} \\
& \times\left|H\left(d_{0} d_{1} d_{2} d_{3}, h_{1}^{*} d_{0} d_{1}, h_{2}^{*} d_{0} d_{2}\right)\right| \\
& \quad \times\left|F_{n}\left(\frac{h_{2}^{*}}{d_{1} d_{3}},-\left(\frac{h_{1}^{*}}{d_{2} d_{3}}+\frac{\ell}{3^{j}}\right)\right)\right| .
\end{aligned}
$$

Moreover, Lemma 3.1 implies that for $\left(d_{0}, d_{1}, d_{2}, d_{3}, h_{1}^{*}, h_{2}^{*}\right) \in \mathcal{F}(D)$,

$$
\left|H\left(d_{0} d_{1} d_{2} d_{3}, h_{1}^{*} d_{0} d_{1}, h_{2}^{*} d_{0} d_{2}\right)\right| \leqslant 2^{\omega\left(d_{0}\right)} d_{0} d_{1} d_{2} .
$$

Hence

$$
E(n, D, j, \ell) \leqslant E_{1}(n, D, j, \ell)
$$

where

$$
\begin{aligned}
& E_{1}(n, D, j, \ell) \\
& \quad=\sum_{\left(d_{0}, d_{1}, d_{2}, d_{3}, h_{1}^{*}, h_{2}^{*}\right) \in \mathcal{F}(D)} \frac{8^{\omega\left(d_{0}\right)} 4^{\omega\left(d_{1} d_{2} d_{3}\right)}}{d_{0} d_{1} d_{2} d_{3}^{2}}\left|F_{n}\left(\frac{h_{2}^{*}}{d_{1} d_{3}},-\left(\frac{h_{1}^{*}}{d_{2} d_{3}}+\frac{\ell}{3^{j}}\right)\right)\right| .
\end{aligned}
$$

We now write $E_{1}(n, D, j, \ell)=E_{2}(n, D, j, \ell)+E_{3}(n, D, j, \ell)$, where in the sum $E_{2}(n, D, j, \ell)$ we have $d_{1} d_{2} d_{3} \leqslant W$ and in the sum $E_{3}(n, D, j, \ell)$, we have $d_{1} d_{2} d_{3}>W$, where $W$ is a parameter to be precised such that

$$
2 \leqslant W \leqslant D
$$

For $\left(d_{0}, d_{1}, d_{2}, d_{3}, h_{1}^{*}, h_{2}^{*}\right) \in \mathcal{F}(D)$ with $d_{1} d_{2} d_{3} \leqslant W$, by Lemma 2.8 , we have

$$
\left|F_{n}\left(\frac{h_{2}^{*}}{d_{1} d_{3}},-\left(\frac{h_{1}^{*}}{d_{2} d_{3}}+\frac{\ell}{3^{j}}\right)\right)\right| \ll \exp \left(\frac{-c_{0} n}{\log \left(\frac{4 W}{3}\right)}\right) .
$$

It follows that

$$
E_{2}(n, D, j, \ell) \ll \exp \left(\frac{-c_{0} n}{\log \left(\frac{4 W}{3}\right)}\right) \sum_{\substack{1 \leqslant d_{0} d_{1} d_{2} d_{3} \leqslant D \\ d_{1} d_{3} d_{3} \leqslant W \\ \mu^{2}\left(d_{0} d_{1} d_{2} d_{3}\right)=1}} \frac{8^{\omega\left(d_{0}\right)} 4^{\omega\left(d_{1} d_{2} d_{3}\right)}}{d_{0}},
$$

where, by Lemma 4.1, the sum in the right-hand side is at most

$$
\begin{aligned}
& \sum_{\substack{d_{1} \leqslant W \\
\mu^{2}\left(d_{1}\right)=1}} 4^{\omega\left(d_{1}\right)} \sum_{\substack{d_{2} \leqslant W / d_{1} \\
\mu^{2}\left(d_{2}\right)=1}} 4^{\omega\left(d_{2}\right)} \sum_{\substack{d_{3} \leqslant W /\left(d_{1} d_{2}\right) \\
\mu^{2}\left(d_{3}\right)=1}} 4^{\omega\left(d_{3}\right)} \sum_{\substack{d_{0} \leqslant D \\
\mu^{2}\left(d_{0}\right)=1}} \frac{8^{\omega\left(d_{0}\right)}}{d_{0}} \\
& \ll W(\log W)^{3}(\log D)^{8} \sum_{\substack{d_{1} \leqslant W \\
\mu^{2}\left(d_{1}\right)=1}} \frac{4^{\omega\left(d_{1}\right)}}{d_{1}} \sum_{\substack{d_{2} \leqslant W \\
\mu^{2}\left(d_{2}\right)=1}} \frac{4^{\omega\left(d_{2}\right)}}{d_{2}} \\
& \ll W(\log W)^{11}(\log D)^{8} \ll W(\log D)^{19} .
\end{aligned}
$$

Therefore,

$$
E_{2}(n, D, j, \ell) \ll W(\log D)^{19} \exp \left(\frac{-c_{0} n}{\log \left(\frac{4 W}{3}\right)}\right) .
$$

In order to bound $E_{3}(n, D, j, \ell)$, we first proceed to some dyadic splitting in $d_{1}, d_{2}, d_{3}$ so that $d_{i} \in\left[D_{i}, 2 D_{i}\right)$ for $i=1,2,3$ with

$$
W / 8<D_{1} D_{2} D_{3} \leqslant D
$$

and we relax the conditions $\mu^{2}\left(d_{0} d_{1} d_{2} d_{3}\right)=1$ and $\operatorname{gcd}\left(d_{0} d_{1} d_{2} d_{3}, 6\right)=1$ to keep only $\mu^{2}\left(d_{0}\right)=1$ and $\operatorname{gcd}\left(d_{1} d_{2} d_{3}, 6\right)=1$ :

$$
\begin{aligned}
& E_{3}(n, D, j, \ell) \\
& \qquad<(\log D)^{3} \sum_{\substack{d_{0} \leqslant D \\
\mu^{2}\left(d_{0}\right)=1}} \frac{8^{\omega\left(d_{0}\right)}}{d_{0}} \max _{\substack{\left(D_{1}, D_{2}, D_{3}\right) \in \mathbb{N}^{3} \\
W / 8<D_{1} D_{2} D_{3} \leqslant D}} \sum_{\substack{d_{1}, d_{2}, d_{3} \\
d_{i} \sim D_{i} i, 1,2,3 \\
\operatorname{gcd}\left(d_{1} d_{2} d_{3}, 6\right)=1}} \frac{4^{\omega\left(d_{1} d_{2} d_{3}\right)}}{d_{1} d_{2} d_{3}^{2}} \\
& \quad \times \sum_{\begin{array}{c}
0<h_{1}^{*}<d_{2} d_{3} \\
\operatorname{gcd}\left(h_{1}^{*}, d_{2} d_{3}\right)=1 \\
\operatorname{gcd}\left(h_{2}^{*}, d_{1} d_{3}\right)=1
\end{array}} \sum_{\substack{0 h_{1}^{*}<d_{1} d_{3}}}\left|F_{n}\left(\frac{h_{2}^{*}}{d_{1} d_{3}},-\left(\frac{h_{1}^{*}}{d_{2} d_{3}}+\frac{\ell}{3^{j}}\right)\right)\right| .
\end{aligned}
$$

It follows from (4.1) and (2.4) that

$$
\begin{aligned}
& E_{3}(n, D, j, \ell) \\
& \quad \ll(\log D)^{11} \max _{\substack{\mathcal{D}=\left(D_{1}, D_{2}, D_{3}\right) \in \mathbb{N}^{3} \\
W / 8<D_{1} D_{2} D_{3} \leqslant D}} \widetilde{\tau}\left(8 D_{1} D_{2} D_{3}\right)^{2} \frac{M_{1}\left(n ; \mathcal{D},\left(0,3^{1-j} \ell\right)\right)}{D_{1} D_{2} D_{3}^{2}},
\end{aligned}
$$

where $M_{1}\left(n ; \mathcal{D},\left(0,3^{1-j} \ell\right)\right)$ is defined by (2.3). If $D_{1} D_{2} D_{3} \leqslant D$ then, since $D=2^{\xi n}$, the condition (2.7) is satisfied for $n \geqslant n_{0}(\xi)$ with the choice

$$
\varepsilon=\varepsilon(\xi)=\frac{1}{2} \min \left\{2, \frac{1}{2 \xi}-1\right\} \in(0,1] .
$$

Thus by Lemma 2.12,

$$
\frac{M_{1}\left(n ; \mathcal{D},\left(0,3^{1-j} \ell\right)\right)}{D_{1} D_{2} D_{3}^{2}} \ll \widetilde{\tau}\left(4 D_{1} D_{3}\right)^{1 / 2} \widetilde{\tau}\left(4 D_{2} D_{3}\right)^{1 / 2}\left(D_{1} D_{2} D_{3}\right)^{-\varepsilon \eta_{0}}
$$

Since $\widetilde{\tau}(d)<_{\xi} d^{\varepsilon \eta_{0} / 6}$ for any positive integer $d$ (see for instance [17, Theorem 315]) and recalling that $D_{1} D_{2} D_{3}>W / 8$, we obtain

$$
E_{3}(n, D, j, \ell)<_{\xi}(\log D)^{11} W^{-\varepsilon \eta_{0} / 2} .
$$

Combining the previous estimates, we get

$$
E(n, D, j, \ell)<_{\xi} W(\log D)^{19} \exp \left(\frac{-c_{0} n}{\log \left(\frac{4 W}{3}\right)}\right)+(\log D)^{11} W^{-\varepsilon \eta_{0} / 2}
$$

By choosing

$$
W=\exp \left(\delta n^{1 / 2}\right) \quad \text { with } \quad \delta=\delta(\xi)=c_{0}^{1 / 2}\left(\frac{\varepsilon(\xi) \eta_{0}}{2}+1\right)^{-1 / 2}>0
$$

we obtain

$$
\begin{gathered}
E(n, D, j, \ell)<_{\xi} n^{19} \exp \left(-\left(\frac{c_{0}}{\delta}-\delta\right) n^{1 / 2}\right)+n^{11} \exp \left(-\frac{\delta \varepsilon \eta_{0}}{2} n^{1 / 2}\right) \\
=\left(n^{19}+n^{11}\right) \exp \left(-\widetilde{\delta} n^{1 / 2}\right),
\end{gathered}
$$

where $\widetilde{\delta}=\delta \varepsilon \eta_{0} / 2>0$ depends only on $\xi$. It follows that

$$
E(n, D, j, \ell)<_{\xi} \exp \left(-\frac{\widetilde{\delta}}{2} n^{1 / 2}\right)
$$

which completes the proof of Lemma 1.5.

## 7. Proofs of main results

7.1. Proof of Theorem 1.1. We recall the notations introduced in Section 1.3.

Let $0<\gamma<1 /\left(2 \beta_{2}\right)$. We define $\xi=\frac{1}{2}\left(\beta_{2} \gamma+\frac{1}{2}\right)$ so that $\beta_{2} \gamma<\xi<1 / 2$ and let $z=2^{\gamma n}$ and $y=2^{\xi n} \geqslant z$.

By Lemma 1.5, there exists $c>0$, which depends only on $\gamma$, such that

$$
\sum_{\substack{d \mid P(z) \\ d<y}} 4^{\omega(d)}\left|R_{n}(d)\right| \leqslant \sum_{\substack{d<y \\ d \text { odd }}} \mu^{2}(d) 4^{\omega(d)}\left|R_{n}(d)\right| \ll{ }_{\gamma} 2^{n} \exp (-c \sqrt{n}) .
$$

Since $h^{+}\left(\frac{\log y}{\log z}\right)=h^{+}\left(\frac{\xi}{\gamma}\right)>0$, it follows from (1.9) that

$$
\Theta(n, z) \ll_{\gamma} \frac{2^{n}}{n^{2}}
$$

Moreover, since $\beta_{2} \gamma<\xi$, we have $h^{-}\left(\frac{\log y}{\log z}\right)=h^{-}\left(\frac{\xi}{\gamma}\right)>0$ and it follows from (1.10) that there exists $n_{0}=n_{0}(\gamma)$ such that for $n \geqslant n_{0}$, we have

$$
\Theta(n, z) \gg_{\gamma} \frac{2^{n}}{n^{2}} .
$$

This completes the proof of Theorem 1.1.
7.2. Proof of Theorem 1.4. We first detect the condition that $\overleftarrow{a}$ is squarefree:

$$
Q(n)=\sum_{a \in \mathcal{B}_{n}} \mu^{2}(a) \sum_{d_{1}^{2} \mid \overleftarrow{a}} \mu\left(d_{1}\right) .
$$

Let $D_{1} \leqslant 2^{n / 2}$ be a parameter to be precised. We split the sum in $Q(n)=S_{11}+S_{12}$, where $d_{1} \leqslant D_{1}$ in $S_{11}$ and $d_{1}>D_{1}$ in $S_{12}$. For the
sum $S_{12}$, we forget the condition " $a$ is squarefree", and reverse the roles between $a$ and $\overleftarrow{a}$ :

$$
\begin{aligned}
\left|S_{12}\right| & =\left|\sum_{D_{1}<d_{1}<2^{n / 2}} \mu\left(d_{1}\right) \sum_{\substack{a \in \mathcal{B}_{n} \\
d_{1}^{2} \left\lvert\, \frac{\mathfrak{a}}{a}\right.}} \mu^{2}(a)\right| \\
& \leqslant \sum_{D_{1}<d_{1}<2^{n / 2}} \sum_{a \in \mathcal{B}_{n}} 1 \ll \sum_{d_{1}>D_{1}} \frac{\left|\mathcal{B}_{n}\right|}{d_{1}^{2} \mid a} \ll \frac{\left|\mathcal{B}_{n}\right|}{D_{1}} .
\end{aligned}
$$

We now detect in $S_{11}$ the condition $\mu^{2}(a)=1$ :

$$
S_{11}=\sum_{d_{1} \leqslant D_{1}} \mu\left(d_{1}\right) \sum_{\substack{a \in \mathcal{B}_{n} \\ d_{1}^{2} \mid \bar{a}}} \mu^{2}(a)=\sum_{d_{1} \leqslant D_{1}} \mu\left(d_{1}\right) \sum_{\substack{a \in \mathcal{B}_{n} \\ d_{1}^{2} \mid \bar{a}}} \sum_{\substack{2 \\ 2}} \mu\left(d_{2}\right) .
$$

We introduce a parameter $D_{2}$ such that $D_{1} \leqslant D_{2} \leqslant 2^{n / 2}$ and split $S_{11}$ in $S_{11}=S_{21}+S_{22}$, where $d_{2} \leqslant D_{2}$ in $S_{21}$ and $d_{2}>D_{2}$ in $S_{22}$. We bound trivially $S_{22}$ :

$$
\left|S_{22}\right| \leqslant D_{1} \sum_{d_{2}>D_{2}} \sum_{\substack{a \in \mathcal{B}_{n} \\ d_{2}^{2} \mid a}} 1 \ll\left|\mathcal{B}_{n}\right| \frac{D_{1}}{D_{2}} .
$$

It remains to estimate

$$
S_{21}=\sum_{\substack{d_{1} \leqslant D_{1} \\ d_{2} \leqslant D_{2} \\ \operatorname{gcd}\left(d_{1} d_{2}, 2\right)=1}} \mu\left(d_{1}\right) \mu\left(d_{2}\right) \sum_{\substack{a \in \mathcal{B}_{n} \\ d_{1}^{2}\left|, \ldots \\ d_{2}^{2}\right| a}} 1 .
$$

Since the inner sum above is for $a \in \mathcal{B}_{n}$, it is licit to add the condition $\operatorname{gcd}\left(d_{1} d_{2}, 2\right)=1$. We detect the conditions $d_{1}^{2} \mid \overleftarrow{a}$ and $d_{2}^{2} \mid a$ via exponential sums. The sum $S_{21}$ becomes:

$$
\begin{aligned}
S_{21} & =\sum_{\substack{d_{1} \leqslant D_{1} \\
d_{2} \leqslant D_{2} \\
\operatorname{gcd}\left(d_{1} d_{2}, 2\right)=1}} \frac{\mu\left(d_{1}\right) \mu\left(d_{2}\right)}{d_{1}^{2} d_{2}^{2}} \sum_{a \in \mathcal{B}_{n}} \sum_{0 \leqslant h_{1}<d_{1}^{2}} \sum_{0 \leqslant h_{2}<d_{2}^{2}} \mathrm{e}\left(\frac{h_{1} \overleftarrow{a}}{d_{1}^{2}}+\frac{h_{2} a}{d_{2}^{2}}\right) \\
& =\left|\mathcal{B}_{n}\right| \sum_{\substack{d_{1} \leqslant D_{1} \\
d_{2} \leqslant D_{2} \\
\operatorname{gcd}\left(d_{1} d_{2}, 2\right)=1}} \frac{\mu\left(d_{1}\right) \mu\left(d_{2}\right)}{d_{1}^{2} d_{2}^{2}} \sum_{0 \leqslant h_{1}<d_{1}^{2}} \sum_{0 \leqslant h_{2}<d_{2}^{2}} F_{n}\left(\frac{h_{1}}{d_{1}^{2}}, \frac{-h_{2}}{d_{2}^{2}}\right) .
\end{aligned}
$$

We now split this sum in $S_{21}=S_{31}+S_{32}$, where, in $S_{31}$ we have $d_{1}^{2} \nmid 3 h_{1}$ or $d_{2}^{2} \nmid 3 h_{2}$ and in $S_{32}, d_{1}^{2} \mid 3 h_{1}$ and $d_{2}^{2} \mid 3 h_{2}$. By Lemma 2.8, we have

$$
\begin{aligned}
\left|S_{31}\right| & \leqslant\left|\mathcal{B}_{n}\right| D_{1} D_{2} \max _{\substack{\left(d_{1}, d_{2}, h_{1}, h_{2}\right) \\
d_{i} \leqslant D_{i}, 0 h_{i}<d_{2}^{2}, i=1,2 \\
\text { gcd }\left(d_{1} d_{2}, 2\right)=1 \\
d_{1}^{2} 33 h_{1} \text { or } d_{2}^{2}+3 h_{2}}}\left|F_{n}\left(\frac{h_{1}}{d_{1}^{2}}, \frac{-h_{2}}{d_{2}^{2}}\right)\right| \\
& \ll\left|\mathcal{B}_{n}\right| D_{1} D_{2} \exp \left(\frac{-c_{0} n}{\log \left(\frac{4 D_{2}^{2}}{3}\right)}\right) .
\end{aligned}
$$

It remains to estimate $S_{32}$. We split the sum according to the value of $\left(\frac{3 h_{1}}{d_{1}^{2}}, \frac{3 h_{2}}{d_{2}^{2}}\right) \in\{0,1,2\}^{2}$ :

$$
S_{32}=\left|\mathcal{B}_{n}\right| \sum_{0 \leqslant u_{1}, u_{2} \leqslant 2} F_{n}\left(\frac{u_{1}}{3}, \frac{-u_{2}}{3}\right) \prod_{i=1}^{2}\left(\sum_{\substack{d_{i} \leqslant D_{i} \\ \operatorname{gcd}\left(d_{i}, 2\right)=1,3 \mid u_{i} d_{i}^{2}}} \frac{\mu\left(d_{i}\right)}{d_{i}^{2}}\right) .
$$

For $i \in\{1,2\}$ and $u_{i} \in\{0,1,2\}$, we easily check that

$$
\sum_{\substack{d_{i} \leqslant D_{i} \\ \operatorname{gcd}\left(d_{i}, 2\right)=1,3 \mid u_{i} d_{i}^{2}}} \frac{\mu\left(d_{i}\right)}{d_{i}^{2}}=\frac{c\left(u_{i}\right)}{\zeta(2)}+O\left(\frac{1}{D_{i}}\right),
$$

where $c\left(u_{i}\right)$ is defined by $c(0)=4 / 3$ and $c(1)=c(2)=-1 / 6$. It follows that

$$
\begin{aligned}
S_{32} & =\left|\mathcal{B}_{n}\right| \sum_{0 \leqslant u_{1}, u_{2} \leqslant 2} F_{n}\left(\frac{u_{1}}{3}, \frac{-u_{2}}{3}\right)\left(\frac{c\left(u_{1}\right) c\left(u_{2}\right)}{\zeta(2)^{2}}+O\left(\frac{1}{D_{1}}\right)\right) \\
& =\frac{S_{41}}{\zeta(2)^{2}}+O\left(\frac{\left|\mathcal{B}_{n}\right|}{D_{1}}\right),
\end{aligned}
$$

where $S_{41}$ is defined by

$$
S_{41}=\left|\mathcal{B}_{n}\right| \sum_{0 \leqslant u_{1}, u_{2} \leqslant 2} F_{n}\left(\frac{u_{1}}{3}, \frac{-u_{2}}{3}\right) c\left(u_{1}\right) c\left(u_{2}\right) .
$$

To estimate the sum over $\left(u_{1}, u_{2}\right)$, we use again exponential sums:

$$
\begin{aligned}
S_{41} & =\sum_{0 \leqslant u_{1}, u_{2} \leqslant 2} c\left(u_{1}\right) c\left(u_{2}\right) \sum_{a \in \mathcal{B}_{n}} \mathrm{e}\left(\frac{u_{1} \overleftarrow{a}}{3}+\frac{u_{2} a}{3}\right) \\
& =\sum_{a \in \mathcal{B}_{n}}\left(\sum_{0 \leqslant u_{1} \leqslant 2} c\left(u_{1}\right) \mathrm{e}\left(\frac{u_{1} \overleftarrow{a}}{3}\right)\right)\left(\sum_{0 \leqslant u_{2} \leqslant 2} c\left(u_{2}\right) \mathrm{e}\left(\frac{u_{2} a}{3}\right)\right) .
\end{aligned}
$$

For the inner sum over $u_{1}$, we write

$$
\begin{aligned}
\sum_{0 \leqslant u_{1} \leqslant 2} c\left(u_{1}\right) \mathrm{e}\left(\frac{u_{1} \overleftarrow{a}}{3}\right) & =c(0)+c(1)\left(\mathrm{e}\left(\frac{\overleftarrow{a}}{3}\right)+\mathrm{e}\left(\frac{2 \overleftarrow{a}}{3}\right)\right) \\
& =c(0)+c(1)\left(3 \cdot \mathbf{1}_{3 \mid \overleftarrow{a}}-1\right) \\
& =\frac{1}{2}\left(3-\mathbf{1}_{3 \mid \overleftarrow{a}}\right)
\end{aligned}
$$

and similarly for the sum over $u_{2}$. Since

$$
\overleftarrow{a} \equiv(-1)^{n-1} a \bmod 3
$$

it follows that

$$
S_{41}=\frac{1}{4} \sum_{a \in \mathcal{B}_{n}}\left(3-\mathbf{1}_{3 \mid a}\right)^{2}=\frac{1}{4}\left(9\left|\mathcal{B}_{n}\right|-5 \sum_{\substack{a \in \mathcal{B}_{n} \\ 3 \mid a}} 1\right)=\frac{11}{6}\left|\mathcal{B}_{n}\right|+O(1) .
$$

Combining the previous estimates, we finally obtain

$$
Q(n)=\left|\mathcal{B}_{n}\right|\left(\frac{11}{6 \zeta(2)^{2}}+O\left(\frac{D_{1}}{D_{2}}+\frac{1}{D_{1}}+D_{1} D_{2} \exp \left(\frac{-c_{0} n}{\log \left(\frac{4 D_{2}^{2}}{3}\right)}\right)\right)\right)
$$

By choosing $D_{2}=D_{1}^{2}=\exp \left(\frac{1}{2} c_{0}^{1 / 2} n^{1 / 2}\right)$, we get

$$
Q(n)=\left|\mathcal{B}_{n}\right|\left(\frac{11}{6 \zeta(2)^{2}}+O\left(\exp \left(-c n^{1 / 2}\right)\right)\right)
$$

with $c=\frac{1}{4} c_{0}^{1 / 2}=0.0439 \ldots$, which proves (1.4).
If $b$ is an $(n-1)$-bit integer then $2 b$ is an $n$-bit integer and $\overleftarrow{2 b}=\overleftarrow{b}$ It follows that the number of even integers $a$ such that $2^{n-1} \leqslant a<2^{n}$ and $\mu^{2}(a)=\mu^{2}(\overleftarrow{a})=1$ is

$$
\left|\left\{2^{n-2} \leqslant b<2^{n-1}: \mu^{2}(2 b)=\mu^{2}(\overleftarrow{b})=1\right\}\right|=Q(n-1)
$$

Since $\left|\mathcal{B}_{n}\right|=2^{n-2}$, this implies that

$$
\widetilde{Q}(n)=Q(n)+Q(n-1)=2^{n-1}\left(\frac{11}{8 \zeta(2)^{2}}+O\left(\exp \left(-c n^{1 / 2}\right)\right)\right)
$$

which proves (1.5).

## 8. Numerical investigations on the number of Reversible PRIMES

8.1. Preambule. In this section, we provide numerical investigations on reversible primes. In fact, we do not restrict ourselves to base 2 and provide also some numerical data in base 10 .
8.2. Base 2. We recall that [27, A074831] provides a table of the number of binary reversible primes less than $10^{m}$ for $m \leqslant 12$. We think more useful to provide a table of the number $\Theta(n)$ of binary reversible primes with exactly $n$ binary digits and we do so for $n \leqslant 50$ in Table 1, see also [27, A366910].

We have written a program that combines a classical Eratosthenes sieve (optimized using the library primesieve) with a variant of Eratosthenes sieve in residue classes. This permits to organize the computations by blocks so that the tables fit into the computer memory and produce a considerable speedup due to a strong use of the L1 memory cache.

| $n$ | $\Theta(n)$ | $n$ | $\Theta(n)$ | $n$ | $\Theta(n)$ | $n$ | $\Theta(n)$ | $n$ | $\Theta(n)$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | 0 | 11 | 69 | 21 | 16732 | 31 | 7377931 | 41 | 4222570054 |
| 2 | 1 | 12 | 94 | 22 | 29392 | 32 | 13878622 | 42 | 8056984176 |
| 3 | 2 | 13 | 178 | 23 | 55109 | 33 | 25958590 | 43 | 15315267089 |

| 5 | 4 | 15 | 589 | 25 | 179654 | 35 | 92163237 | 45 | 55976669028 |
| 6 | 6 | 16 | 908 | 26 | 332130 | 36 | 173672988 | 46 | 106505783902 |
| 7 | 9 | 17 | 1540 | 27 | 625928 | 37 | 325098134 | 47 | 204628057694 |
| 8 | 14 | 18 | 2814 | 28 | 1136814 | 38 | 617741968 | 48 | 392422557460 |
| 9 | 27 | 19 | 5158 | 29 | 2120399 | 39 | 1177573074 | 49 | 749026893680 |
| 10 | 36 | 20 | 9210 | 30 | 3963166 | 40 | 2221353224 | 50 | 1440435348050 |

Table 1. Base 2: values of $\Theta(n)$ for $n \leqslant 50$.

A table of the number of binary prime palindromes with $n$ binary digits is given in [27, A117773]. Our calculations give us the opportunity to confirm these values for all $n \leqslant 50$.

Let us describe a heuristic argument that leads us to a conjecture on the asymptotic behaviour of $\Theta(n)$.

Let $a$ be a randomly chosen integer in $\mathcal{B}_{n}$. If $a$ is prime then $3 \nmid a$, which is equivalent to $3 \nmid \overleftarrow{a}$ by (1.1). Therefore the events " $a$ is prime" and " $\overleftarrow{a}$ is prime" are not expected to be "independent" but it is natural to expect that they are "conditionally independent" given
that $3 \nmid a$. This would imply that
$\mathbb{P}(a$ and $\overleftarrow{a}$ are prime $)$

$$
\begin{aligned}
& =\mathbb{P}(a \text { and } \overleftarrow{a} \text { are prime } \mid 3 \nmid a) \mathbb{P}(3 \nmid a) \\
& \approx \mathbb{P}(a \text { is prime } \mid 3 \nmid a) \mathbb{P}(\overleftarrow{a} \text { is prime } \mid 3 \nmid a) \mathbb{P}(3 \nmid a) \\
& =\frac{\mathbb{P}(a \text { is prime }) \mathbb{P}(\overleftarrow{a} \text { is prime })}{\mathbb{P}(3 \nmid a)} .
\end{aligned}
$$

Moreover $\mathbb{P}(a$ is prime $)=\mathbb{P}(\overleftarrow{a}$ is prime $)$ and since $a \in \mathcal{B}_{n}$, by the Prime Number Theorem, we have

$$
\mathbb{P}(a \text { is prime })=\frac{\operatorname{Li}\left(2^{n}\right)-\operatorname{Li}\left(2^{n-1}\right)}{\left|\mathcal{B}_{n}\right|}(1+o(1)) \quad(n \rightarrow \infty),
$$

where

$$
\operatorname{Li}(x)=\int_{2}^{x} \frac{d t}{\log t}
$$

Thus we may expect that

$$
\Theta(n)=\left|\mathcal{B}_{n}\right| \mathbb{P}(a \text { and } \overleftarrow{a} \text { are prime }) \approx \Theta_{\exp }(n)
$$

where

$$
\Theta_{\exp }(n)=\frac{3\left(\operatorname{Li}\left(2^{n}\right)-\operatorname{Li}\left(2^{n-1}\right)\right)^{2}}{2^{n-1}}=(3+o(1)) \frac{2^{n-1}}{\left(\log 2^{n}\right)^{2}} \quad(n \rightarrow \infty)
$$

This agrees with the values of $\Theta(n)$ provided in Table 1, as illustrated graphically by Figure 1.

Figure 1. Base 2: graph of $\Theta(n) / \Theta_{\exp }(n)$ for $n \leqslant 50$.
This leads us to formulate the following.

## Conjecture 8.1.

$$
\Theta(n)=(3+o(1)) \frac{2^{n-1}}{\left(\log 2^{n}\right)^{2}} \quad(n \rightarrow \infty)
$$

8.3. Base 10. In this section, we consider $n$-digits integers $k$ in base 10 such that

$$
k=\sum_{j=0}^{n-1} \varepsilon_{j}(k) 10^{j}, \quad \overleftarrow{k}=\sum_{j=0}^{n-1} \varepsilon_{j}(k) 10^{n-1-j}
$$

where $\varepsilon_{j}(k) \in\{0,1, \ldots, 10\}, j \in\{0, \ldots, n-1\}, \varepsilon_{n-1}(k) \neq 0$. We define

$$
\Theta_{10}(n)=\mid\left\{10^{n-1} \leqslant p<10^{n}: p \text { and } \overleftarrow{p} \text { are prime }\right\} \mid
$$

We note that [27, A048054] provides a table of the number $\Theta_{10}(n)$ of base 10 reversible primes with exactly $n$ digits in base 10 for $n \leqslant 13$. We extend this to $n \leqslant 15$ in Table 2.

| $n$ | $\Theta_{10}(n)$ | $n$ | $\Theta_{10}(n)$ | $n$ | $\Theta_{10}(n)$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | 4 | 6 | 9538 | 11 | 274932272 |
| 2 | 9 | 7 | 71142 | 12 | 2294771254 |
| 3 | 43 | 8 | 535578 | 13 | 19489886063 |
| 4 | 204 | 9 | 4197196 | 14 | 167630912672 |
| 5 | 1499 | 10 | 33619380 | 15 | 1456476399463 |

Table 2. Base 10: values of $\Theta_{10}(n)$ for $n \leqslant 15$.

Furthermore, [27, A016115] provides a table of the number of base 10 prime palindromes with $n$ digits. Our calculations give us the opportunity to confirm these values for all $n \leqslant 15$.

## Acknowledgement

This work was motivated by conversations with Pieter Moree, who we would like to thank. The authors also express their gratitude to their late colleague and friend Christian Mauduit with who several possible approaches to this project were discussed in 2014 in Luminy.

During the preparation of this work C.D., B.M. and J.R. were supported by ANR-FWF Grant 4945-N and ANR Grant 20-CE91-0006 and I.S. by the ARC Grants DP230100530 and DP230100534.

Declarations of interest: none.
