

THEIA

Microarcsecond Astrometric Observatory

Exploration des architectures des systèmes exoplanétaires proches par astrométrie spatiale à haute précision

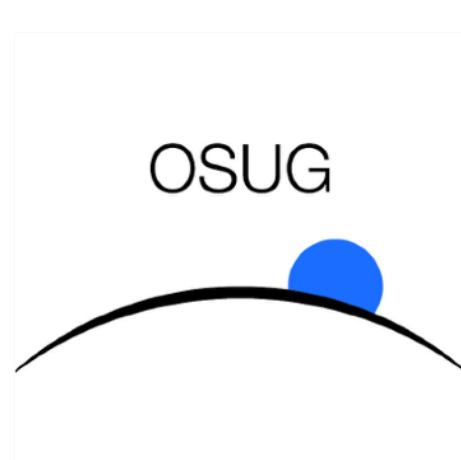

Fabien MALBET

*IPAG / Univ. Grenoble Alpes / CNRS
and trie Theia collaboration*

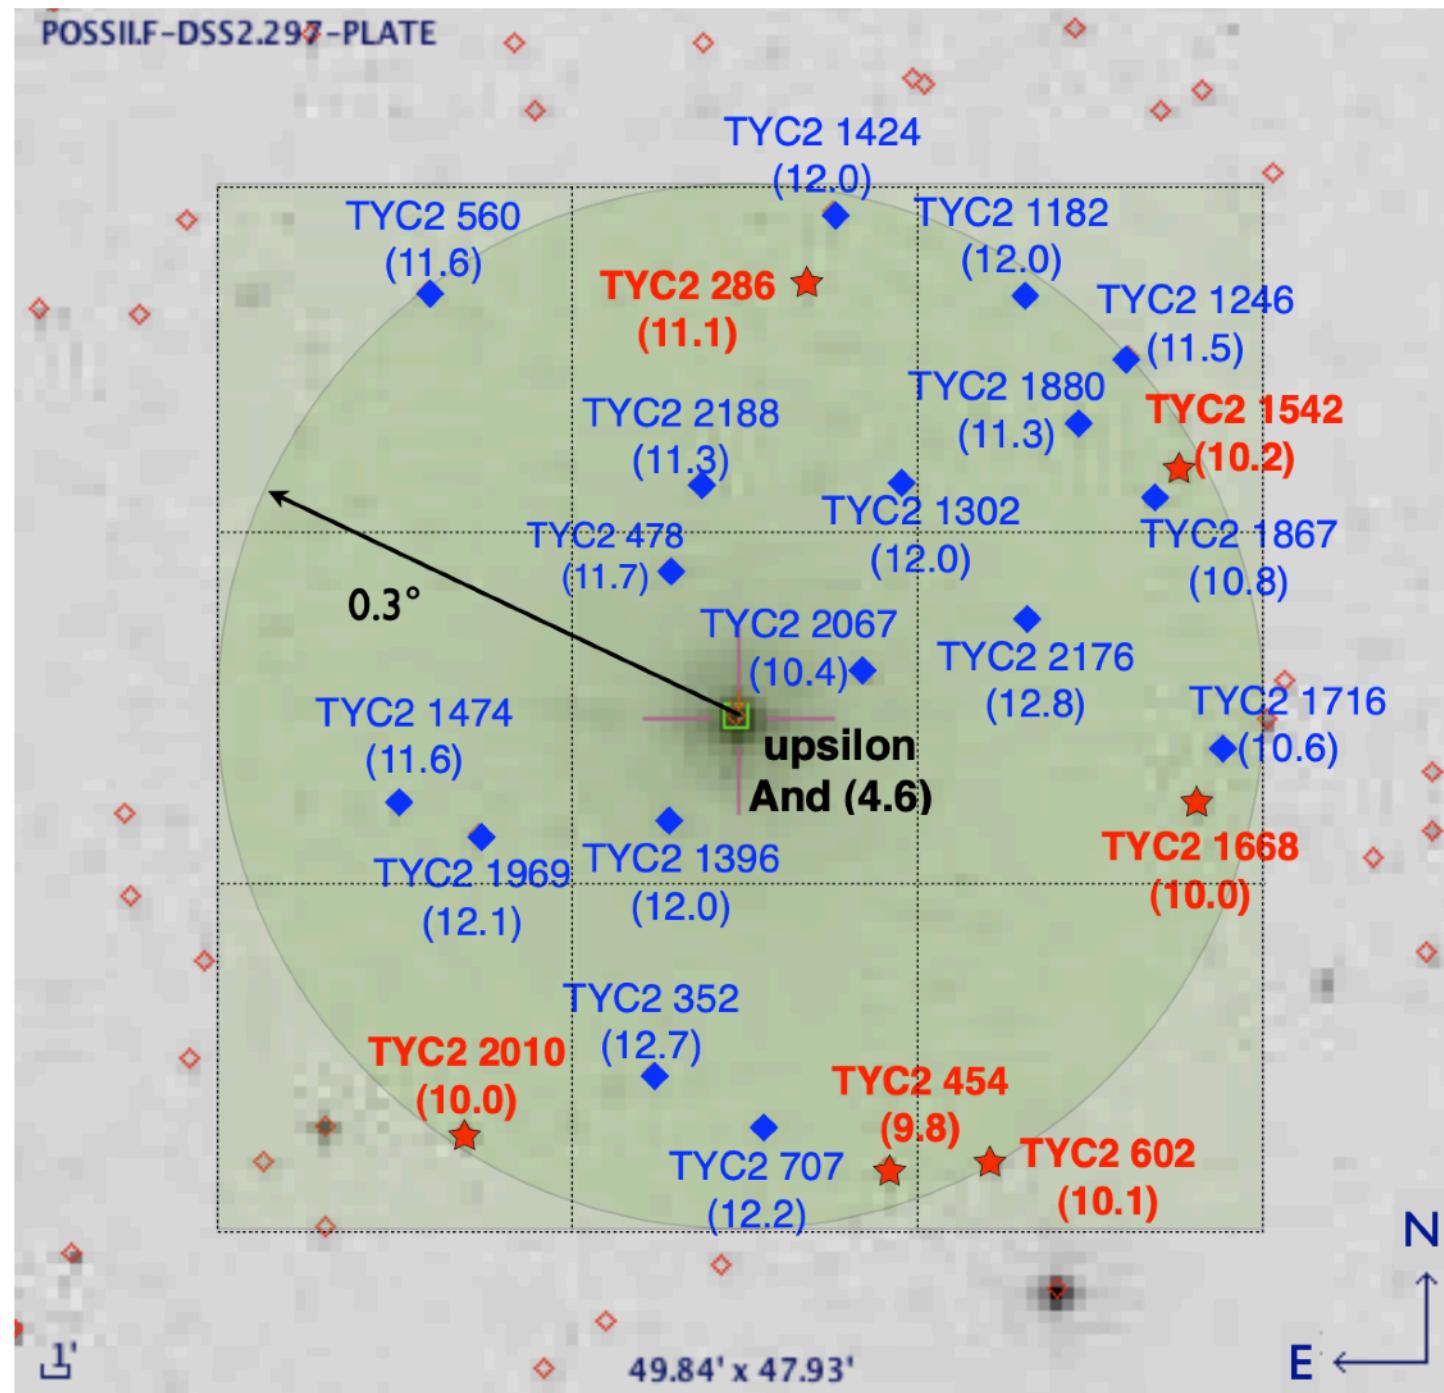

+ *Manon Lizzana, Fabrice Pancher, Thierry Lépine, Alain Léger, Gary Mamon and Theia collaboration*

Atelier Exosystèmes IV - Lyon 31 janvier - 1 février 2024

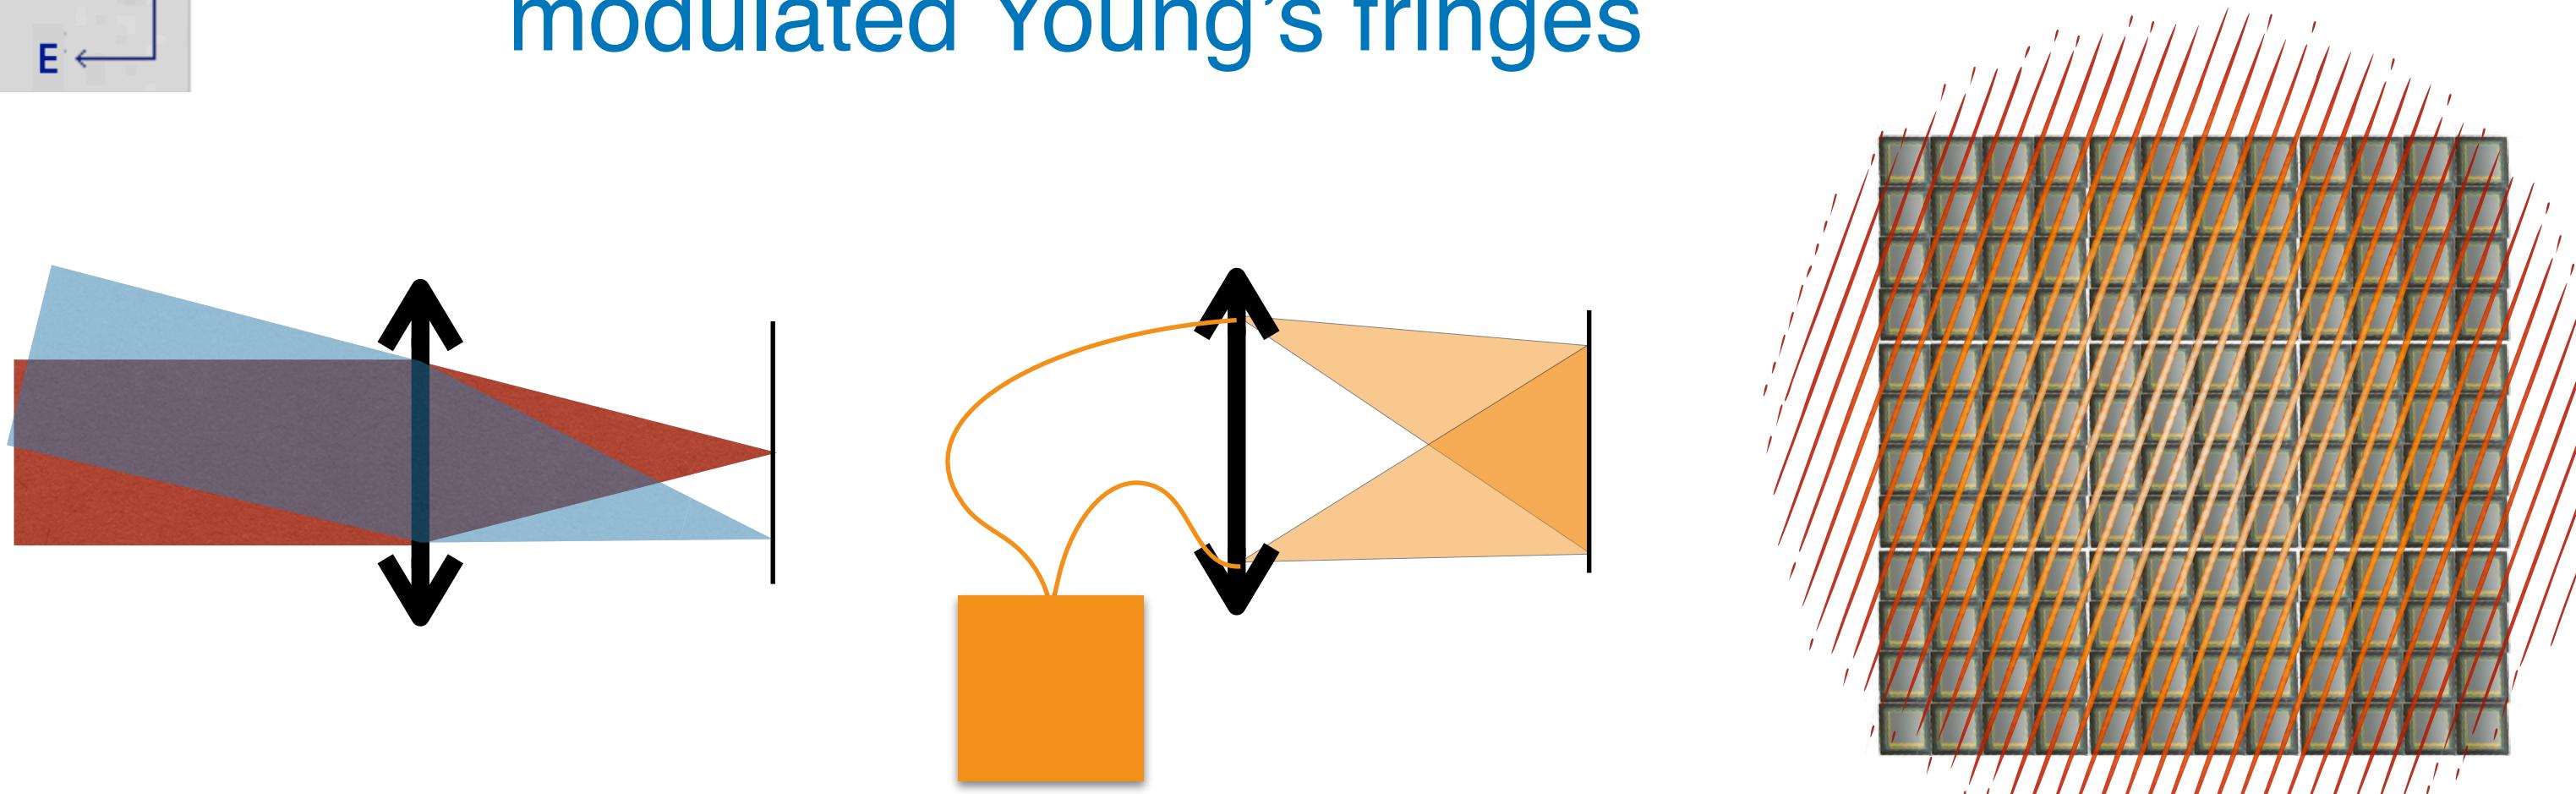

**TERRE &
UNIVERS**

Principle of Theia : relative and precise differential astrometry

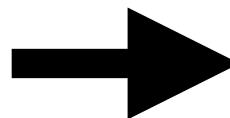

- ✓ The science target is at the center of the FOV
- ✓ We measure the offset angles between the target object (in **black**) and the reference stars (other stars in **red** and **blue**)
- ✓ The single measurement is repeated several times over the mission lifetime to reach the required accuracy on the target motion
- ✓ The detector calibration is done using interferometric modulated Young's fringes

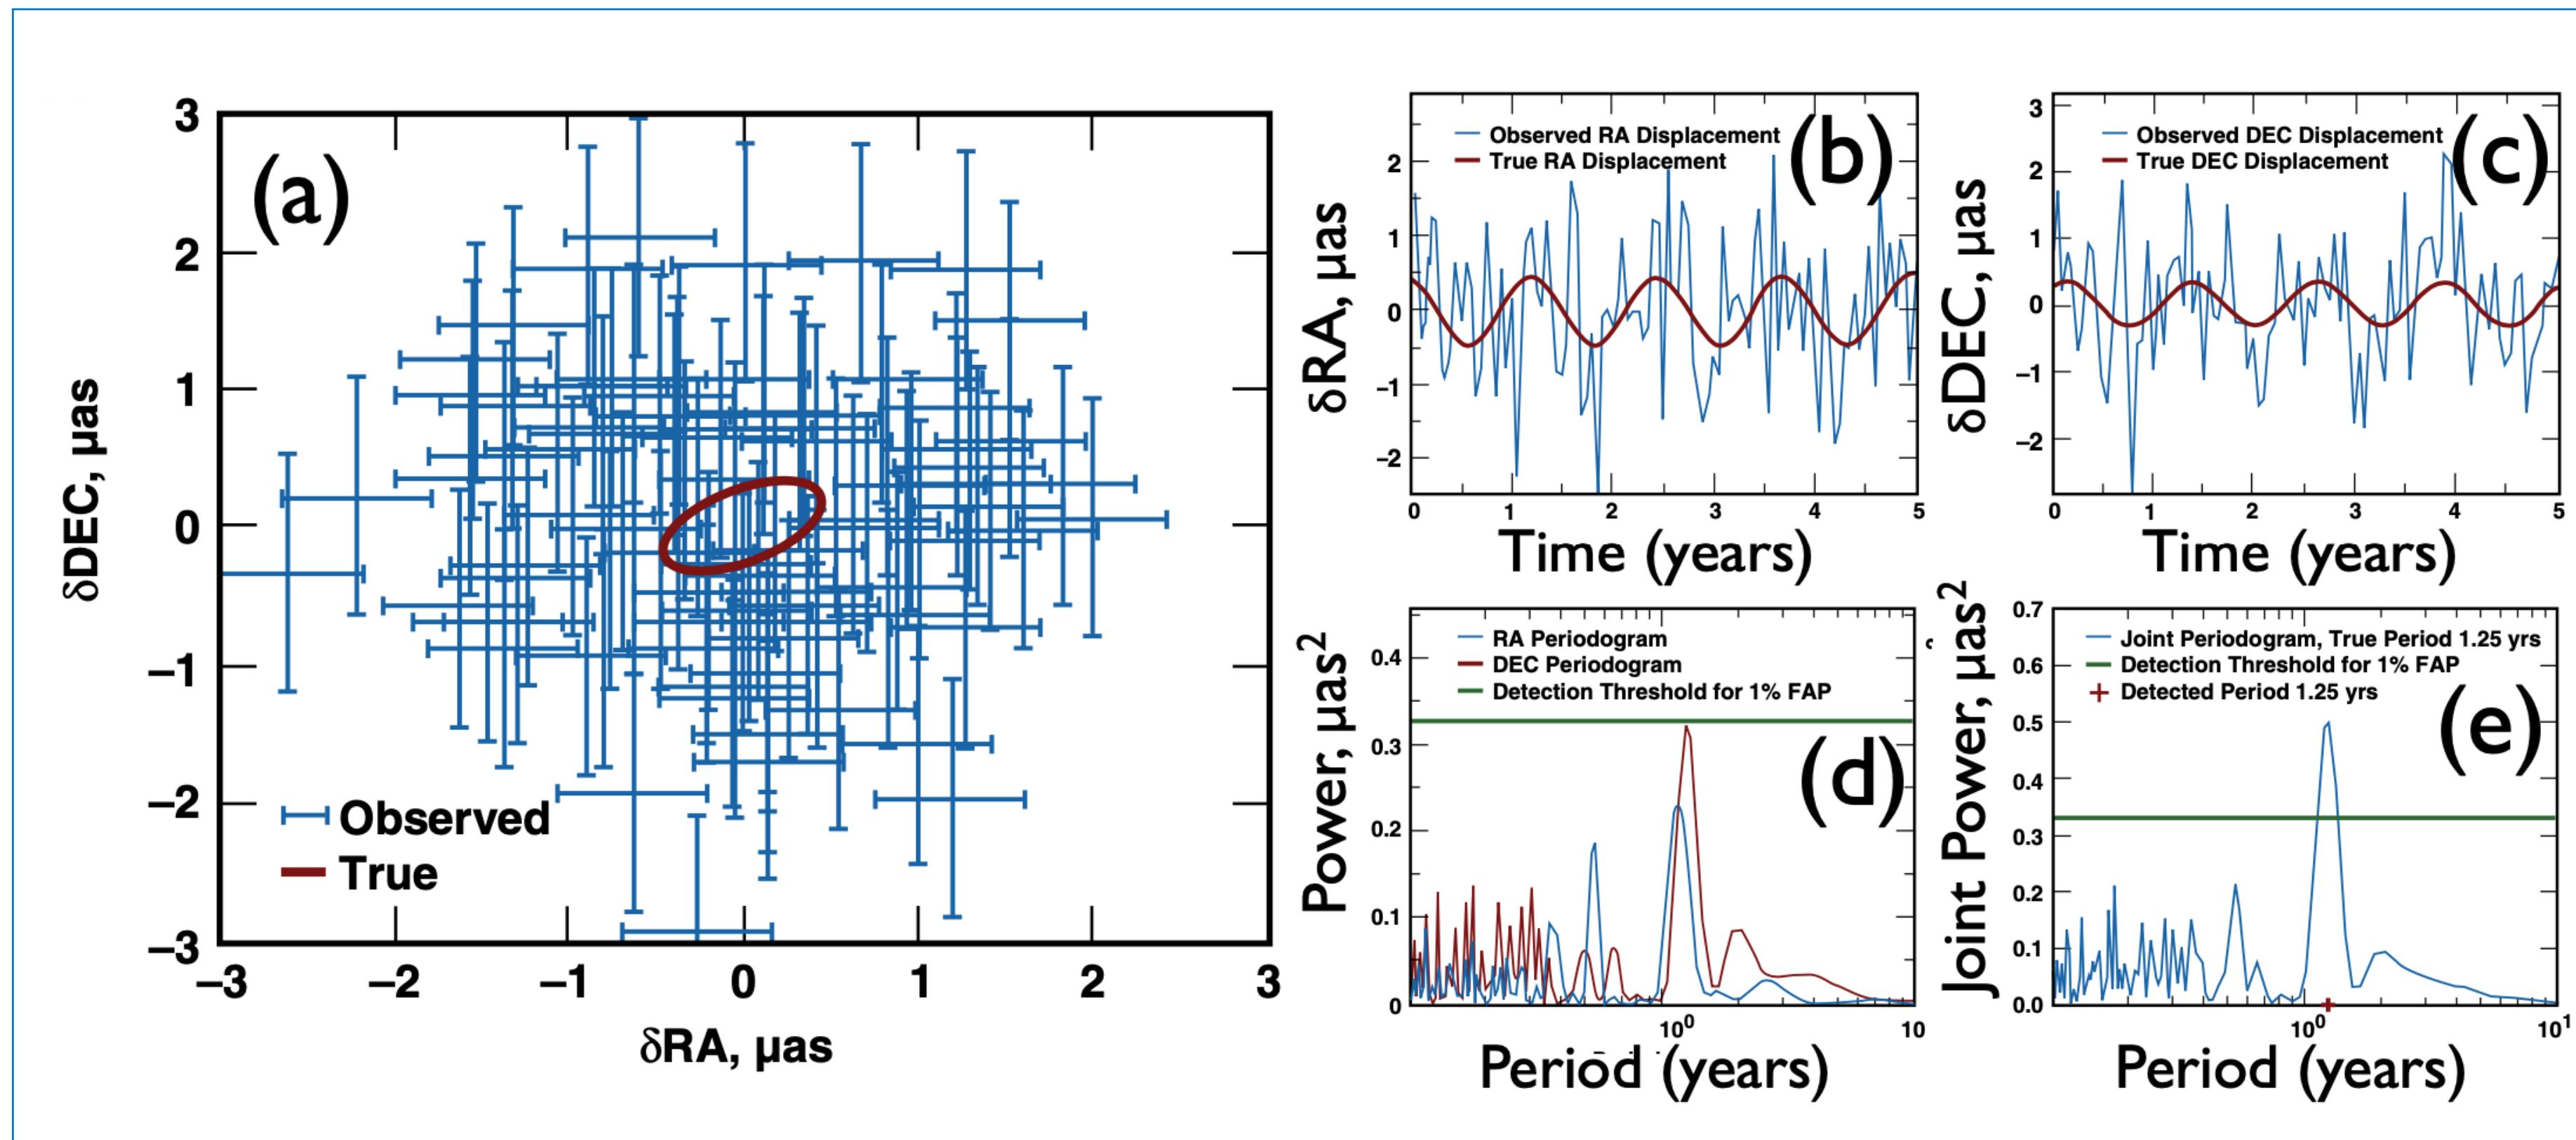

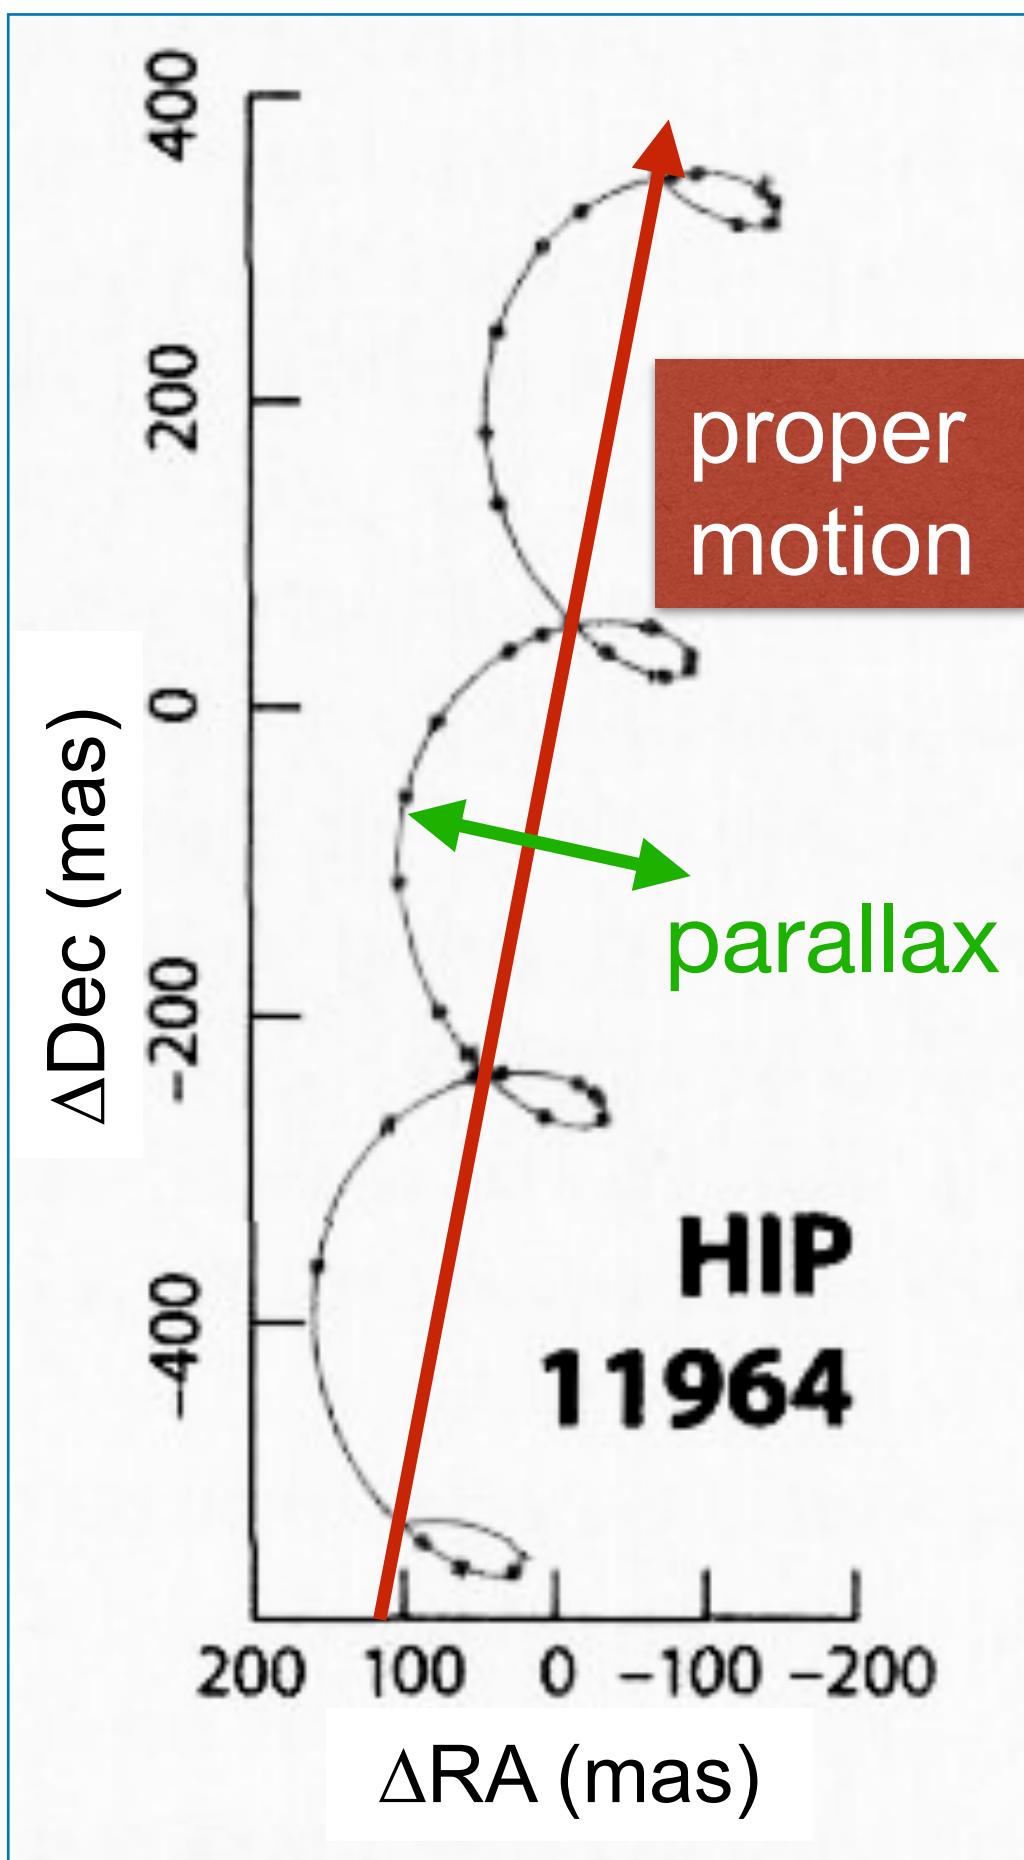

Astrometry: parallax, proper motion and reflex motion

Proper Motion + Parallax

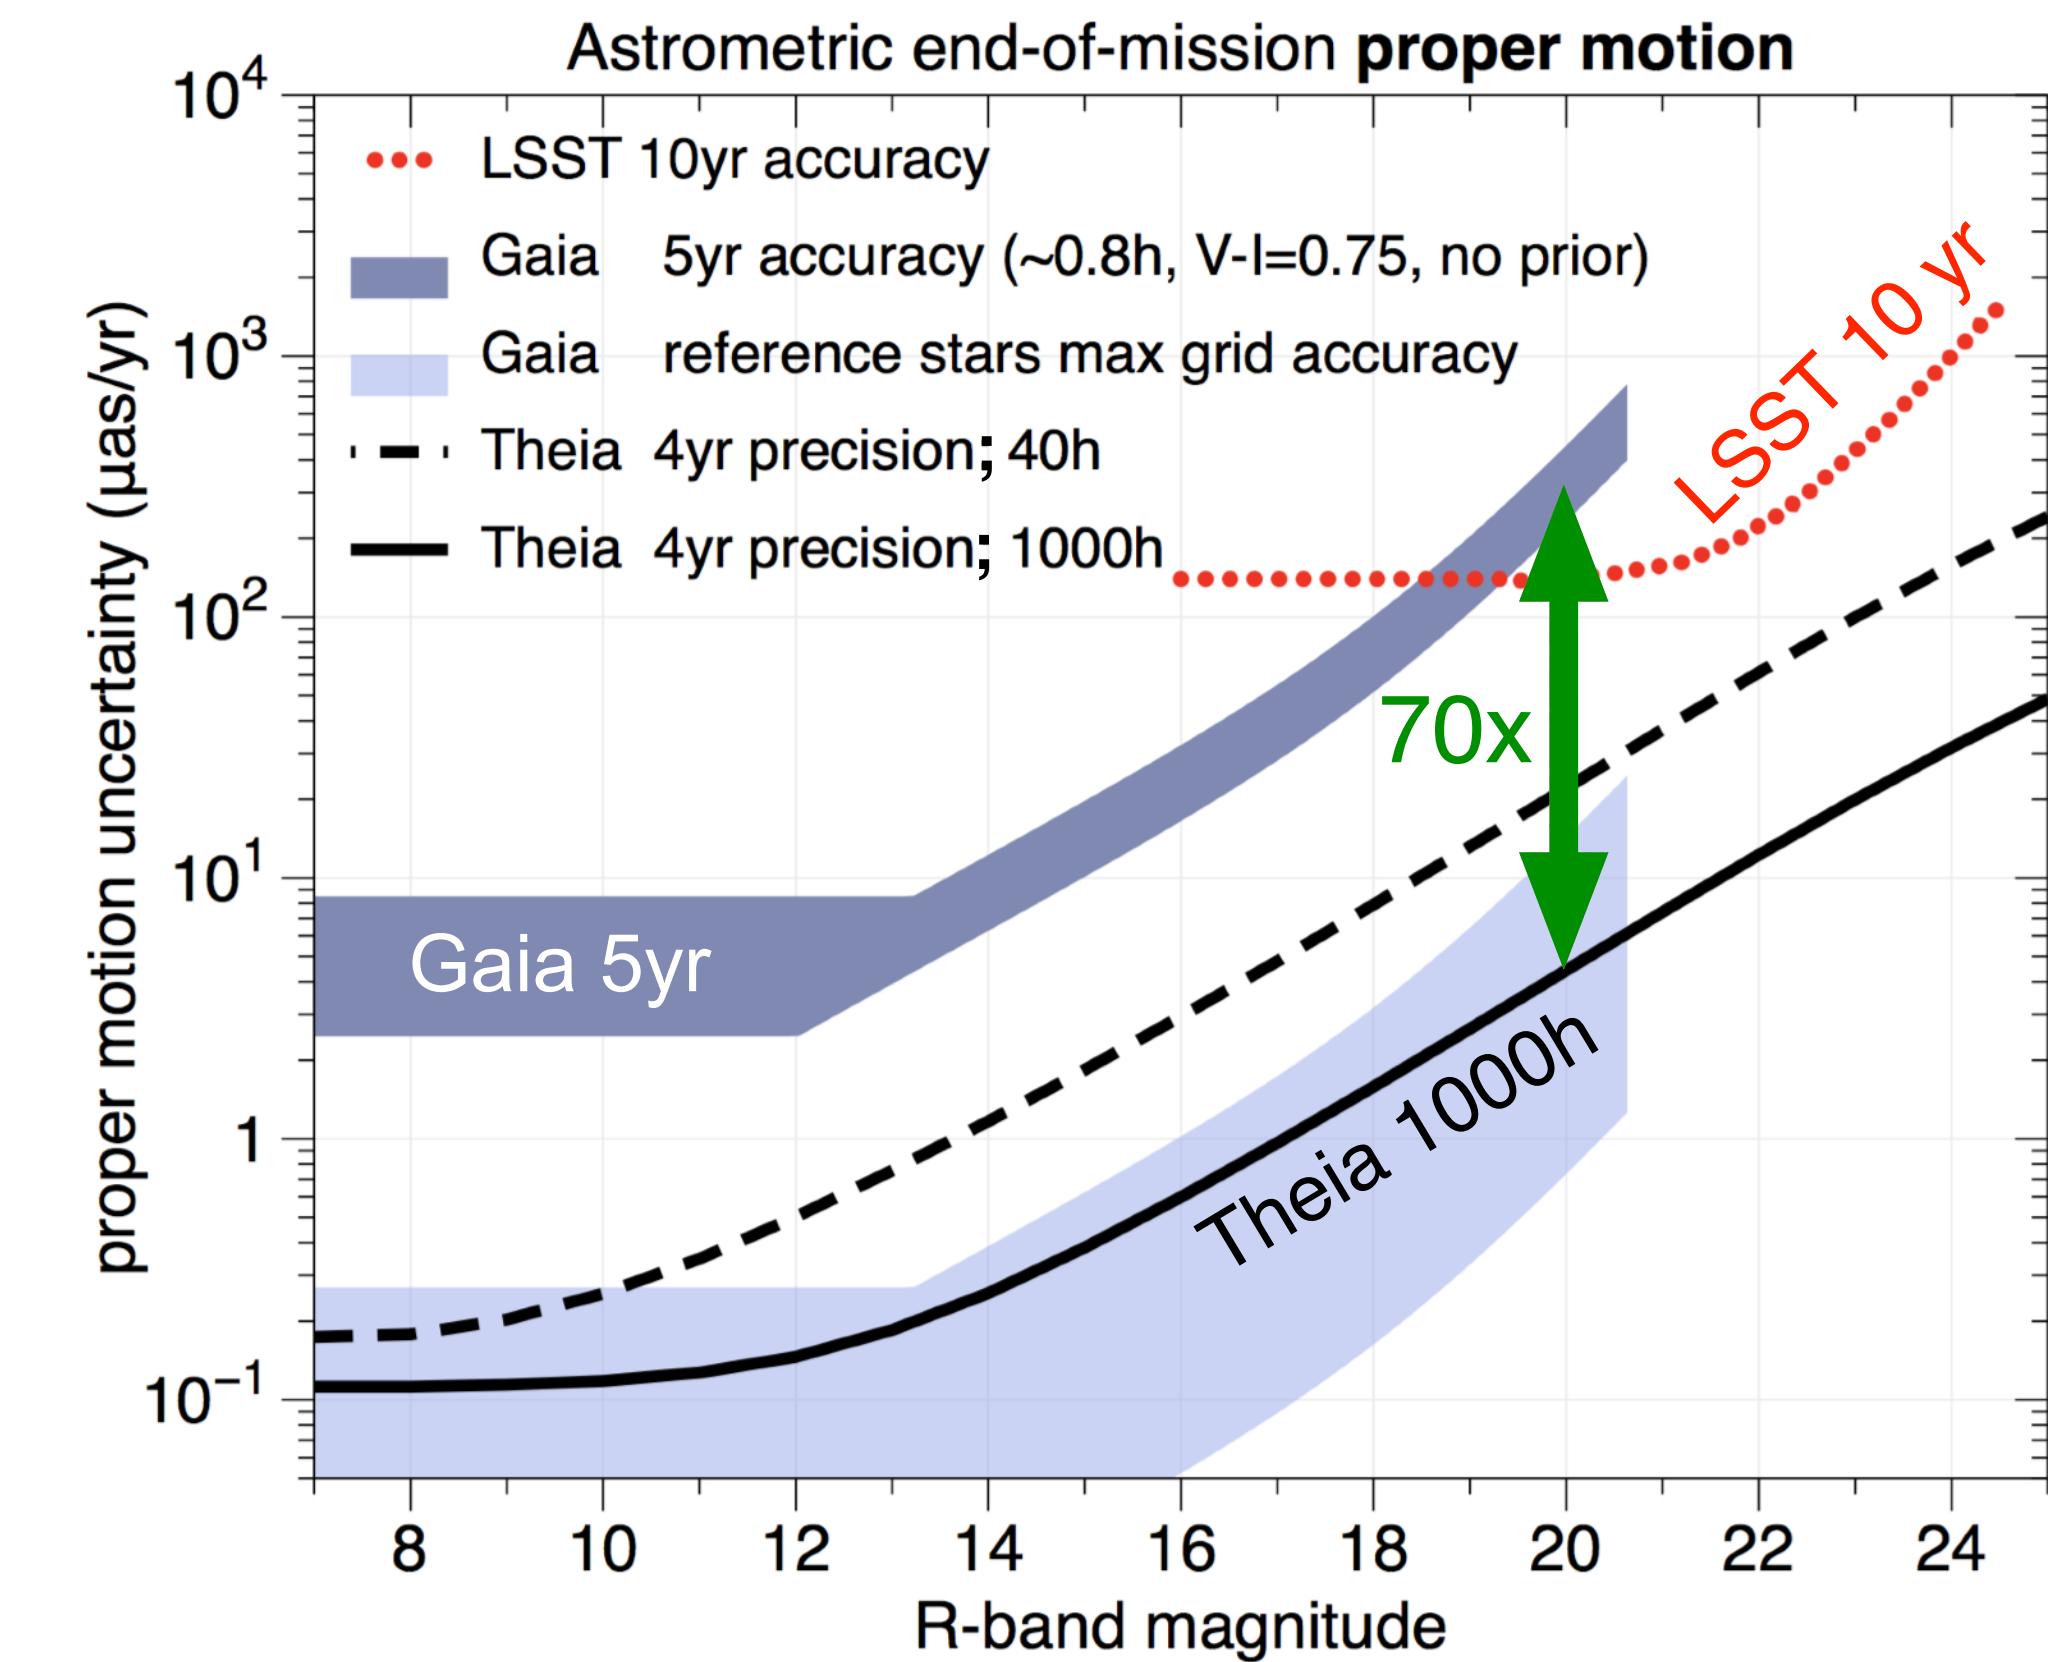

Residuals where (a) plots RA and DEC positions while (b,c) are positions with time and (d, e) are period-gram for each direction

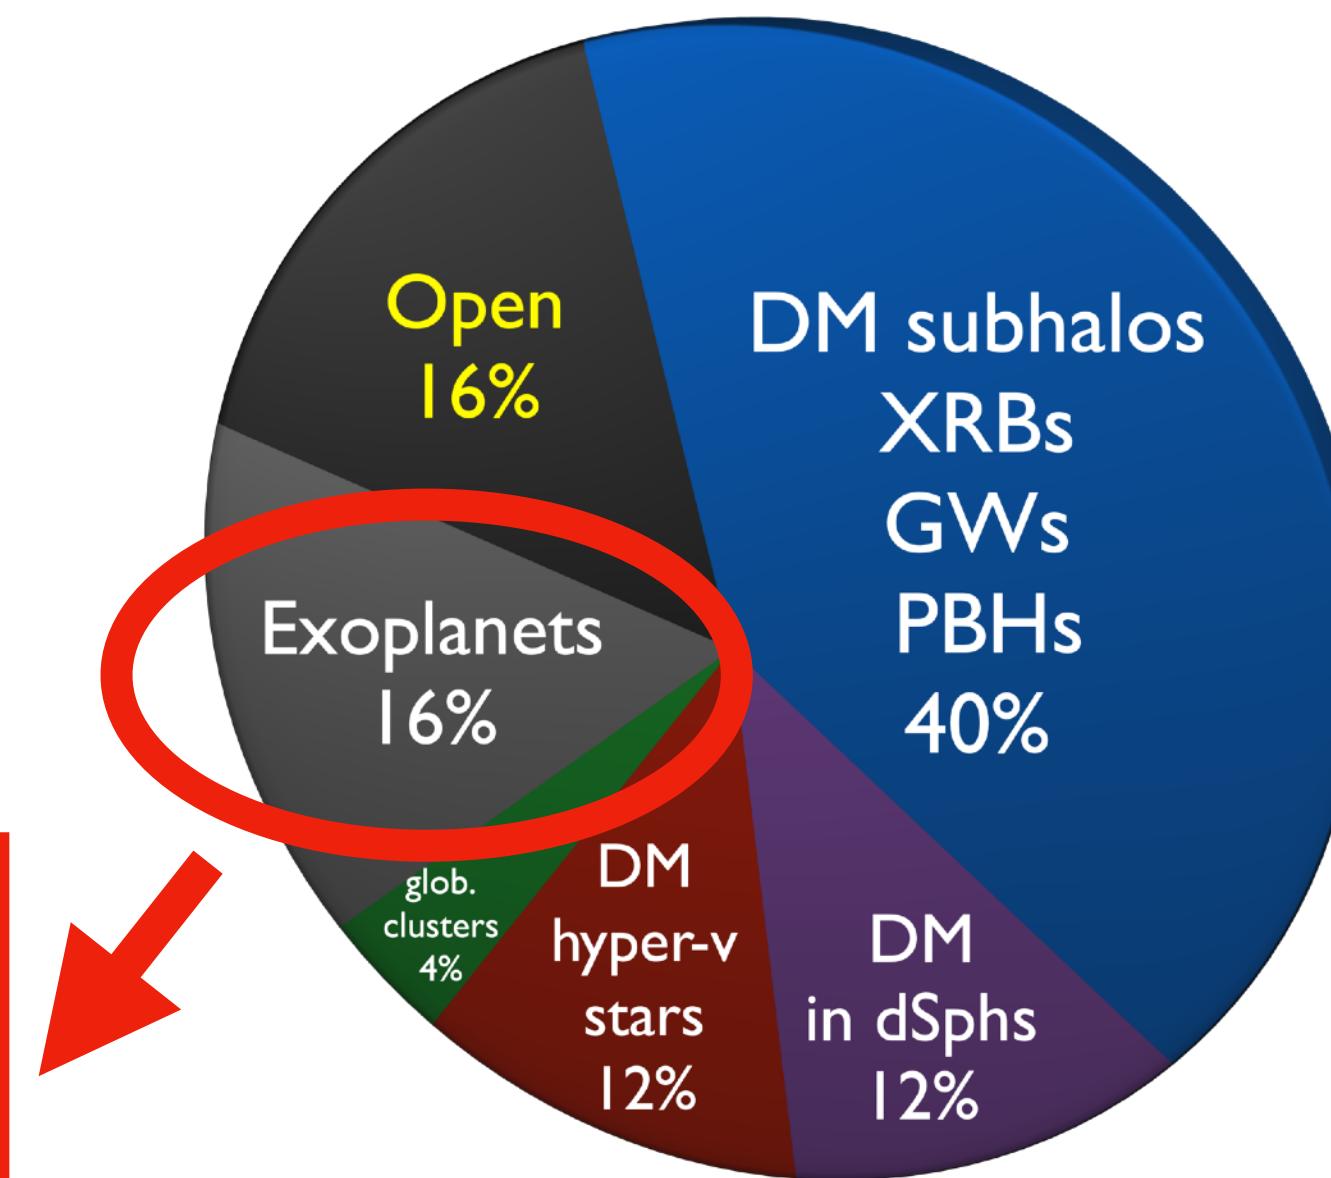

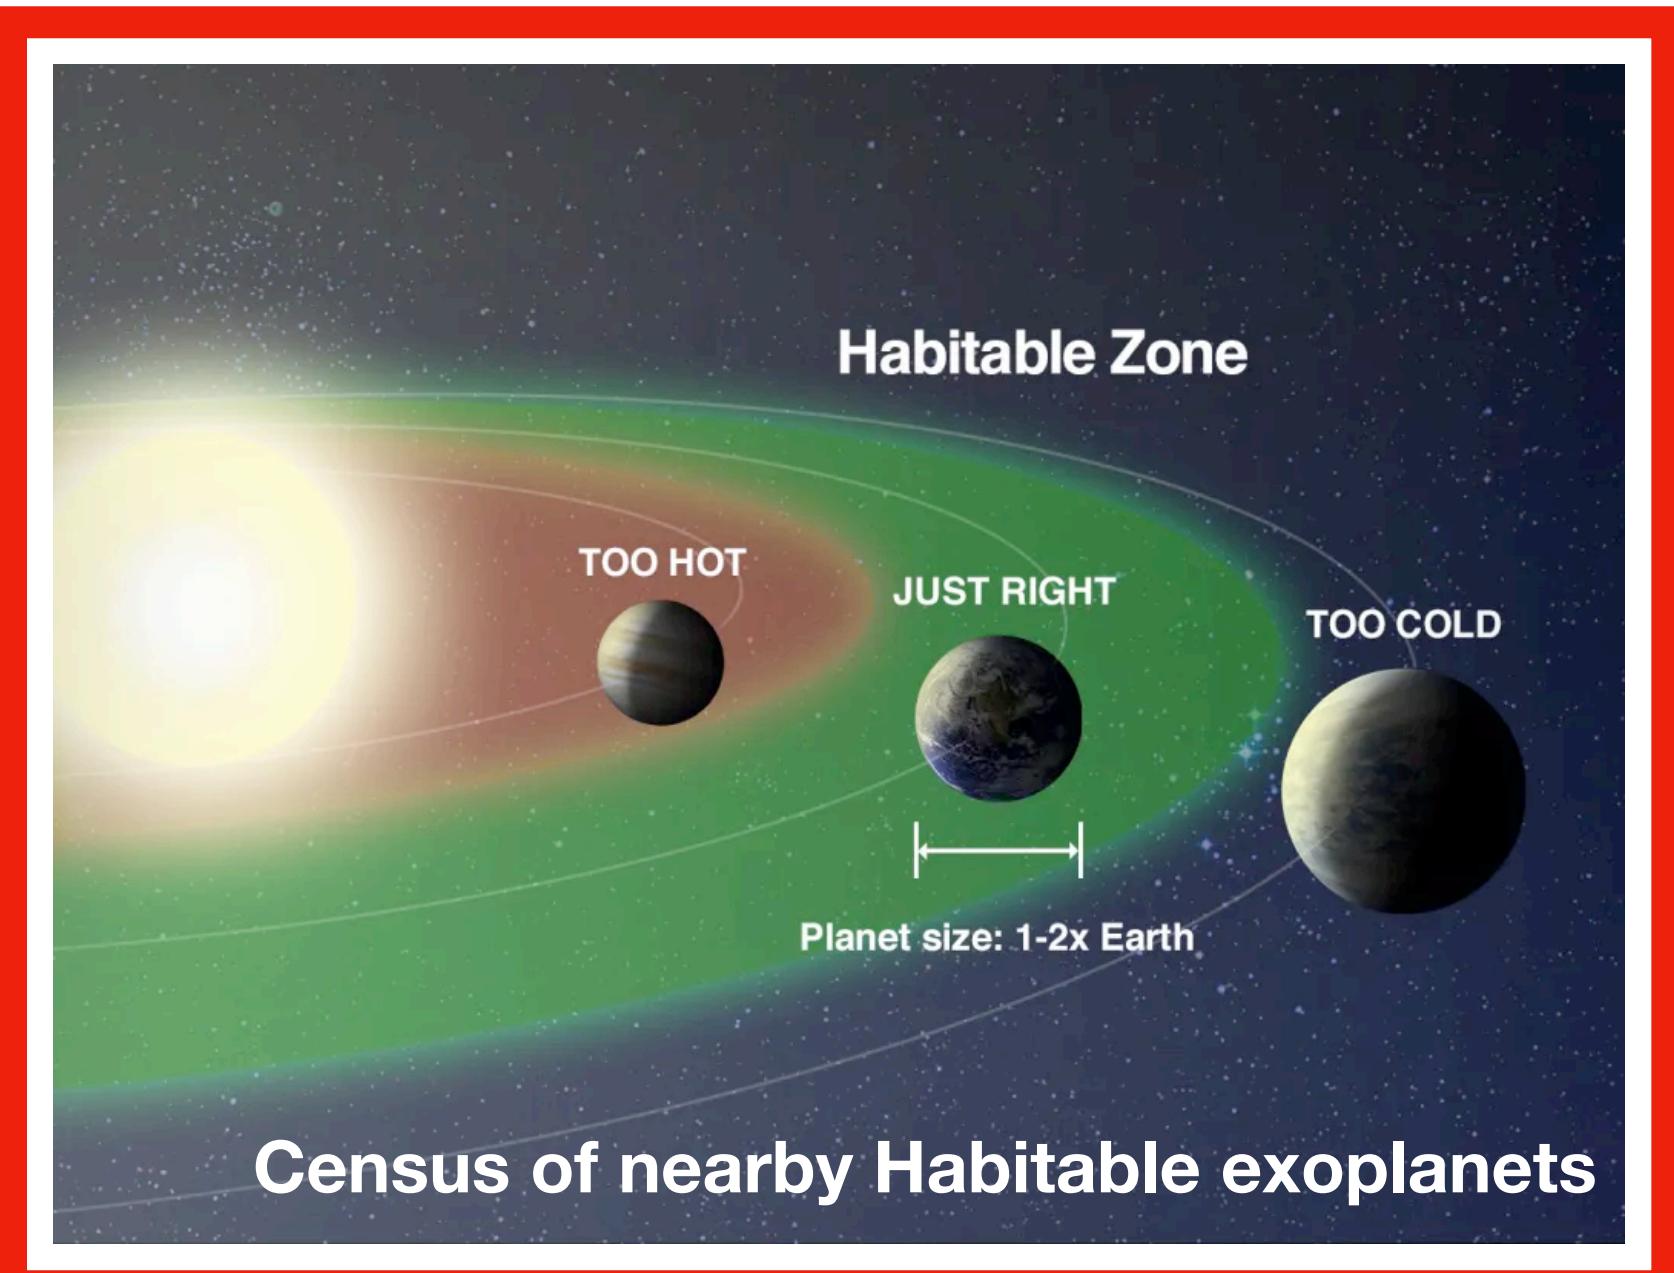

Unwin et al. (2008) ; Malbet et al. (2012)

Improvement compared to Gaia

	Gaia post-launch	Theia	improvement
Telescope Aperture	$1.49 \times 0.54 = 0.80 \text{ m}^2$	$0.8 \rightarrow 0.50 \text{ m}^2$	0.62
Field of view		0.5 deg	
Coverage	Survey	<i>Pointed</i>	
Astrometry	Global	<i>Differential</i>	
Exposure time per field	$76 \times 9 \text{ (CCD)} \times 4.4 \text{ sec} = 0.84 \text{ hr}$	$25 \times 40 \text{ hr} = 1000 \text{ hr}$	1200
Additional factors	2D vs 1D astrometry: 1.4, Gaia Stray light: 1.9		
Proper motion accuracy G=10 star	3.5 $\mu\text{as}/\text{yr}$	0.11 $\mu\text{as}/\text{yr}$	30
Proper motion accuracy G=15 star	14 $\mu\text{as}/\text{yr}$	0.4 $\mu\text{as}/\text{yr}$	35
Proper motion accuracy G=20 star	330 $\mu\text{as}/\text{yr}$	5 $\mu\text{as}/\text{yr}$	66

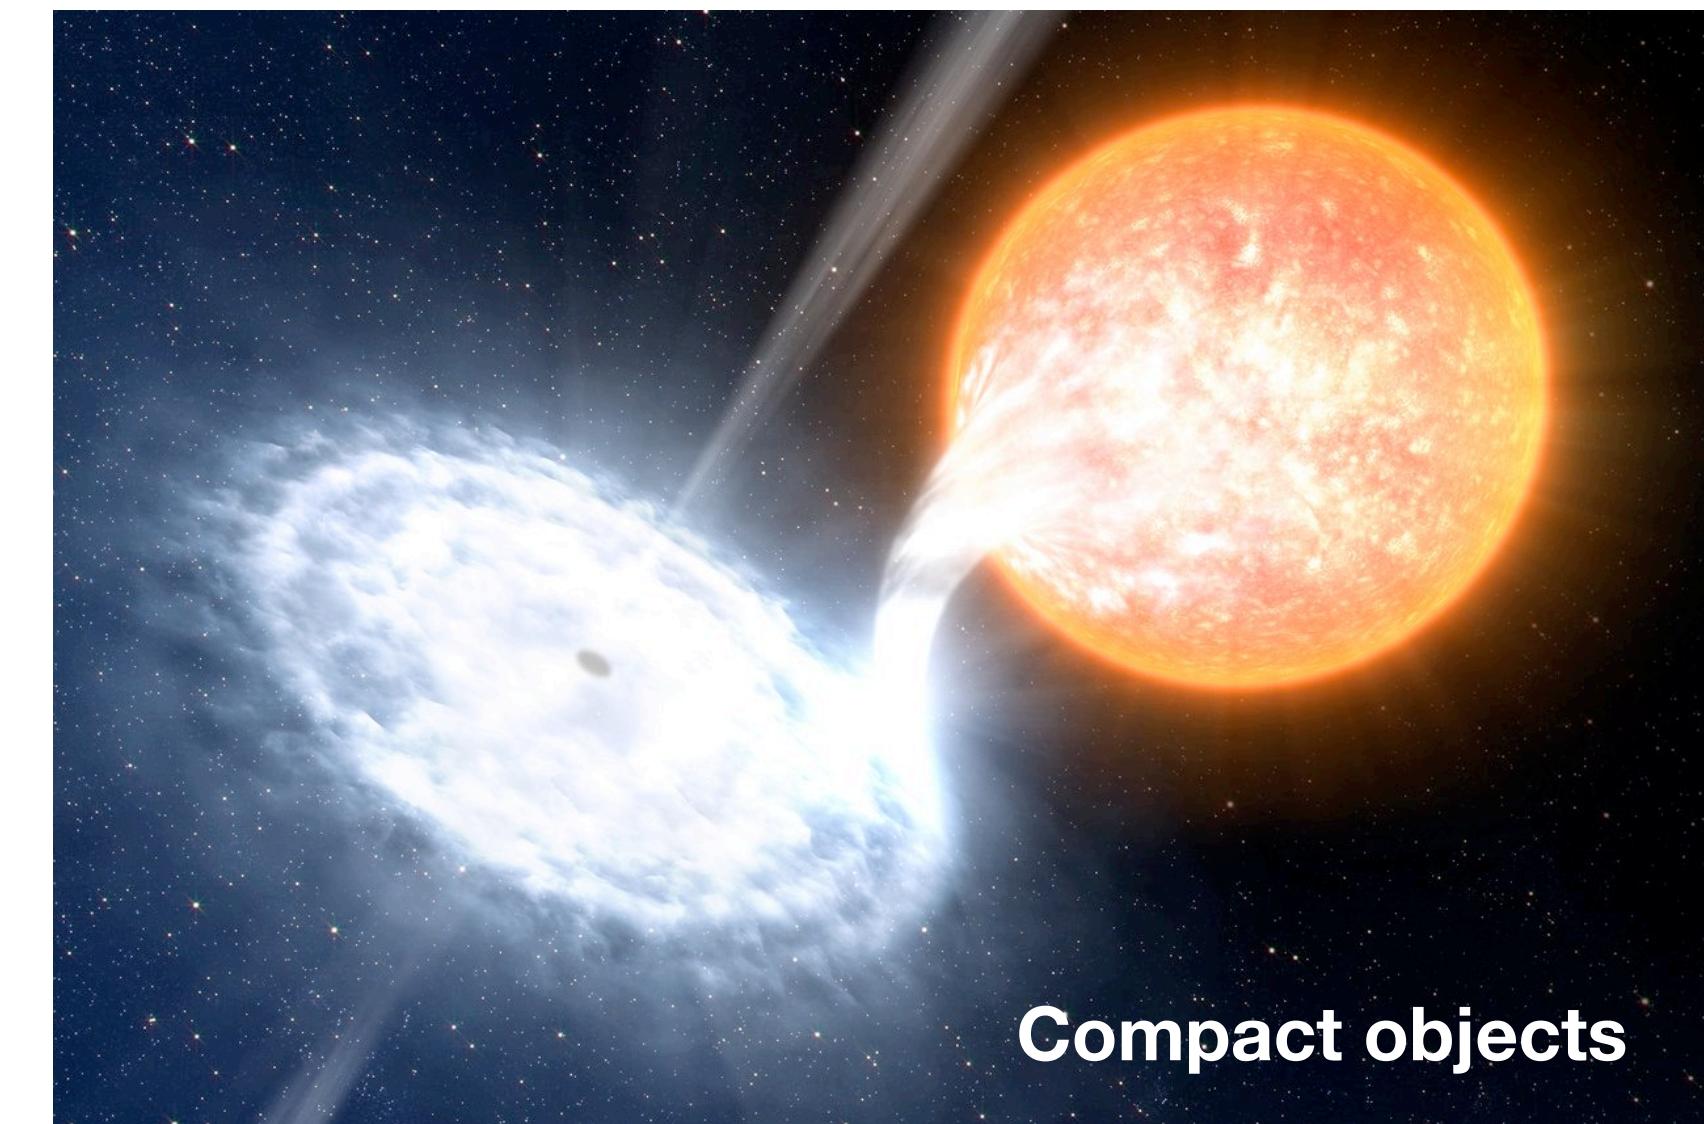

Theia's main science based on high precision astrometry

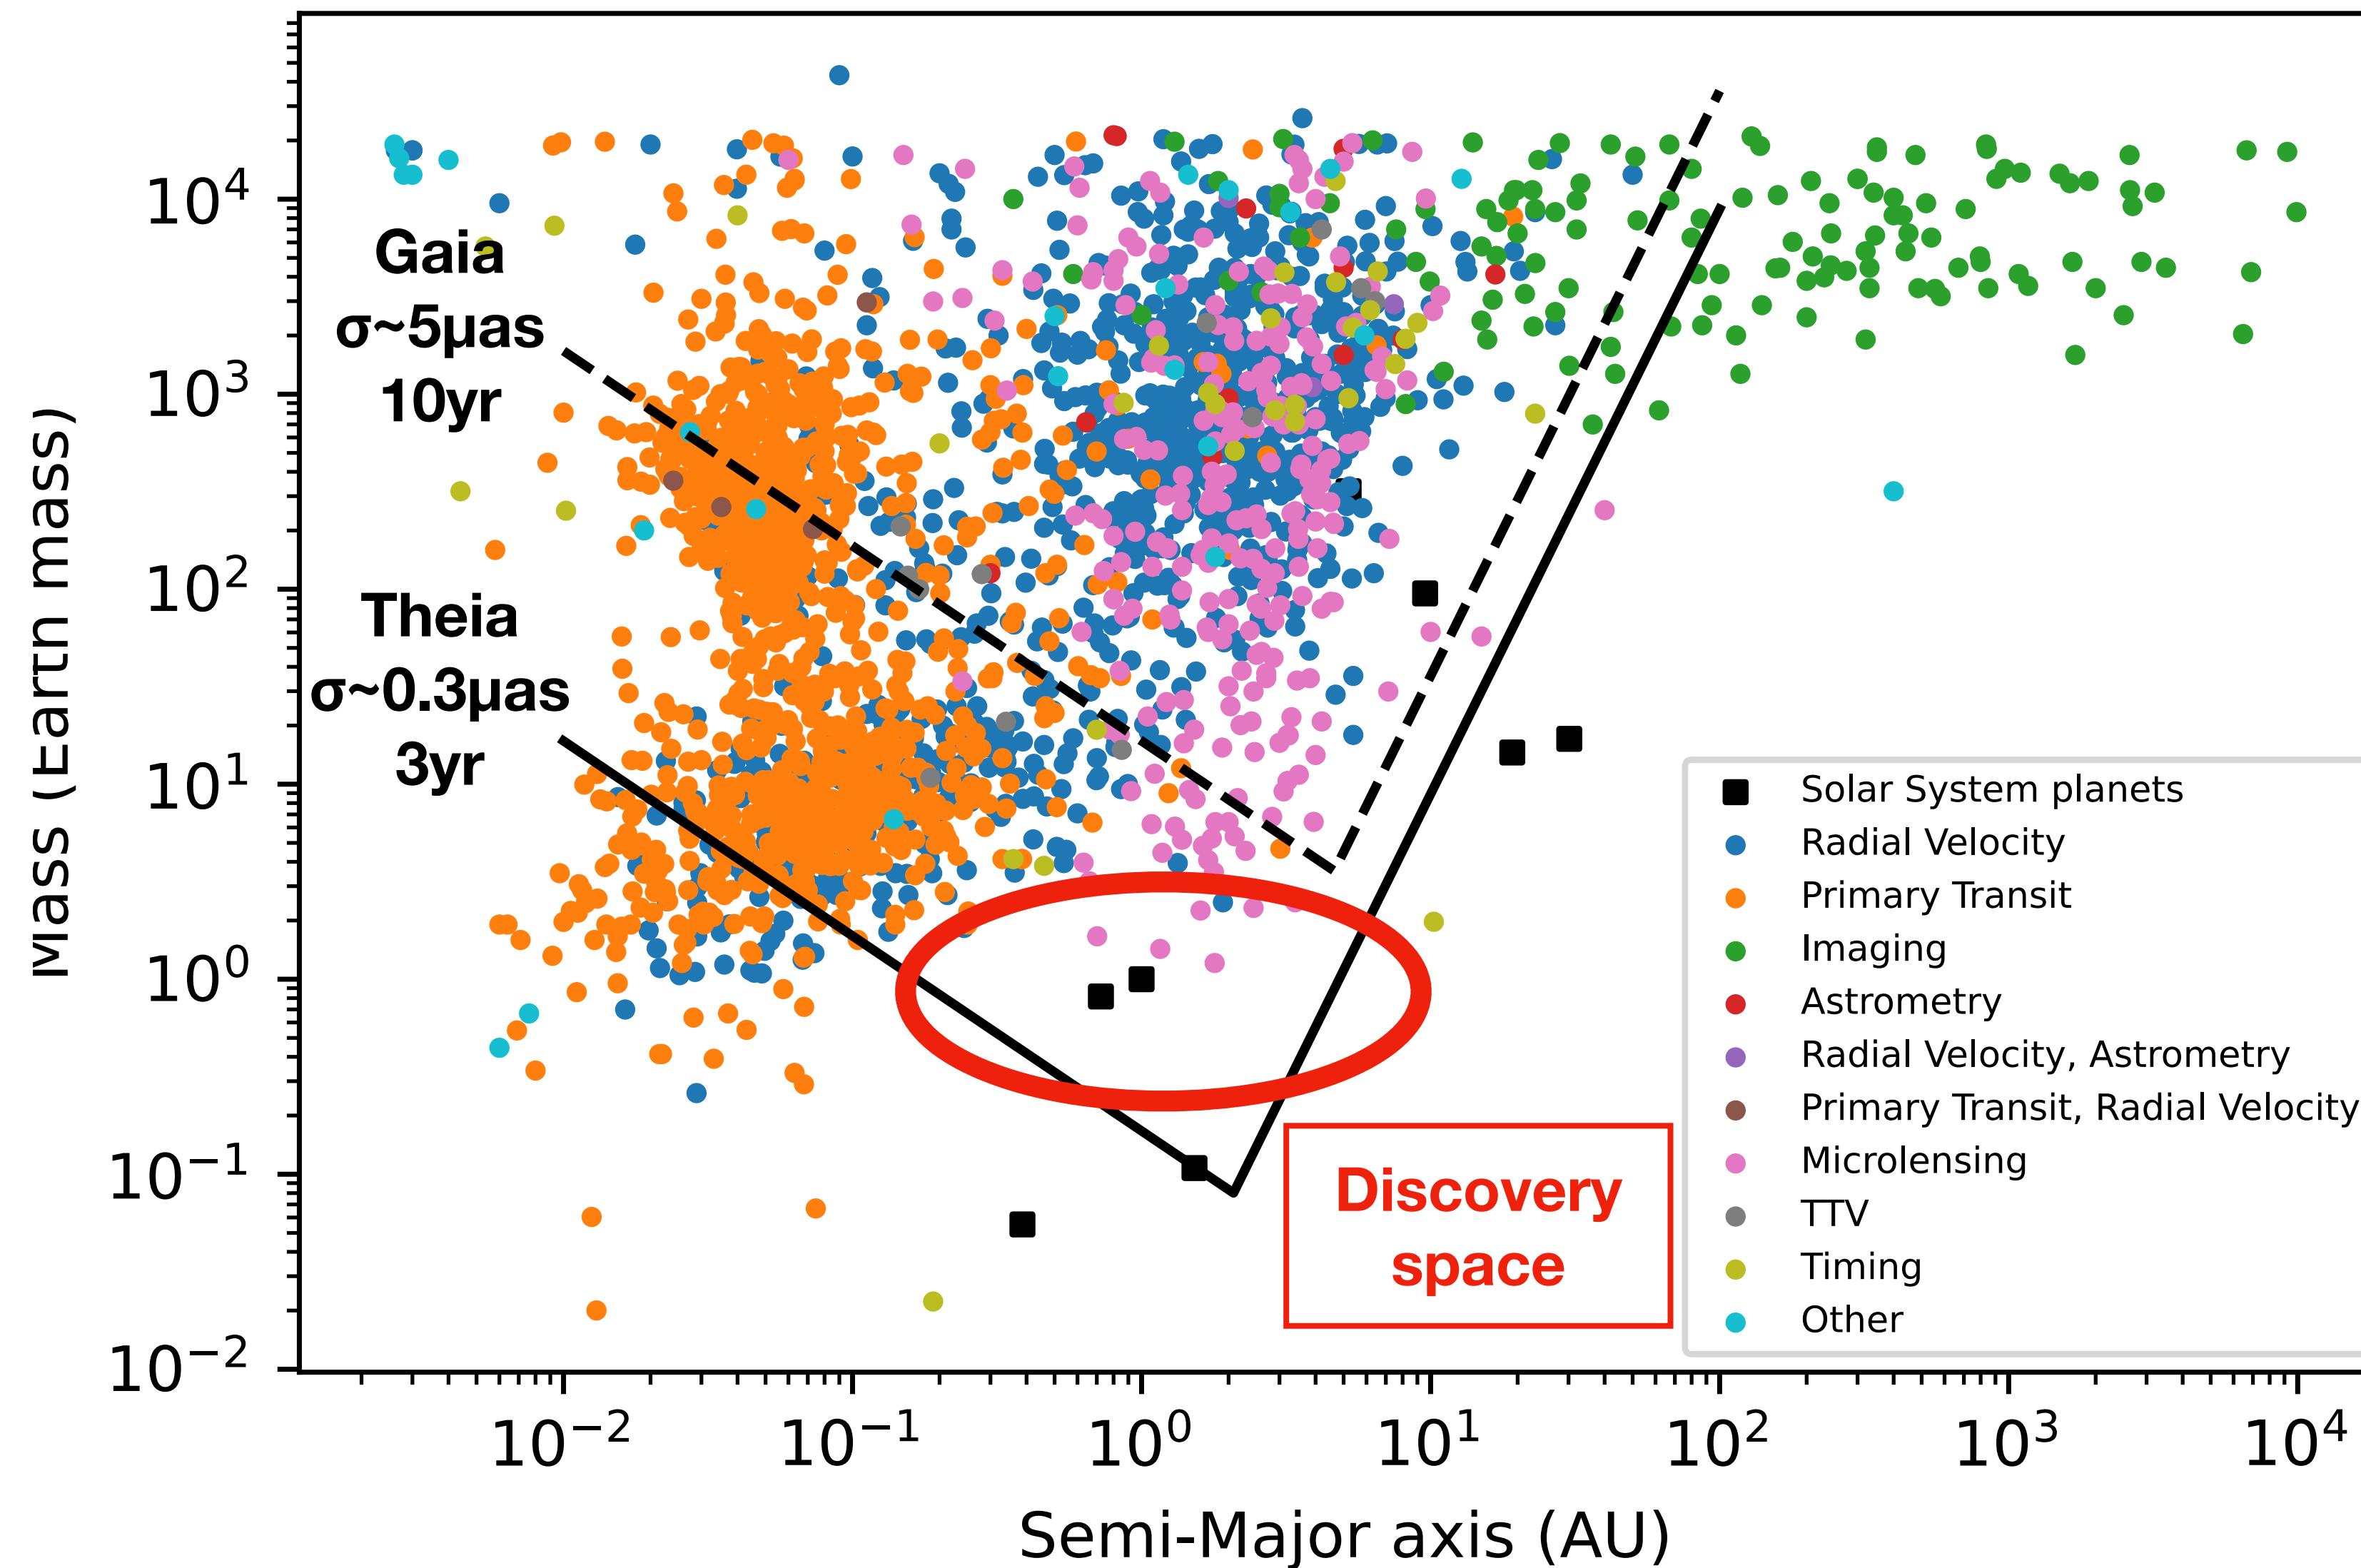

Two main observing modes:

- Faint star mode
- Bright star mode

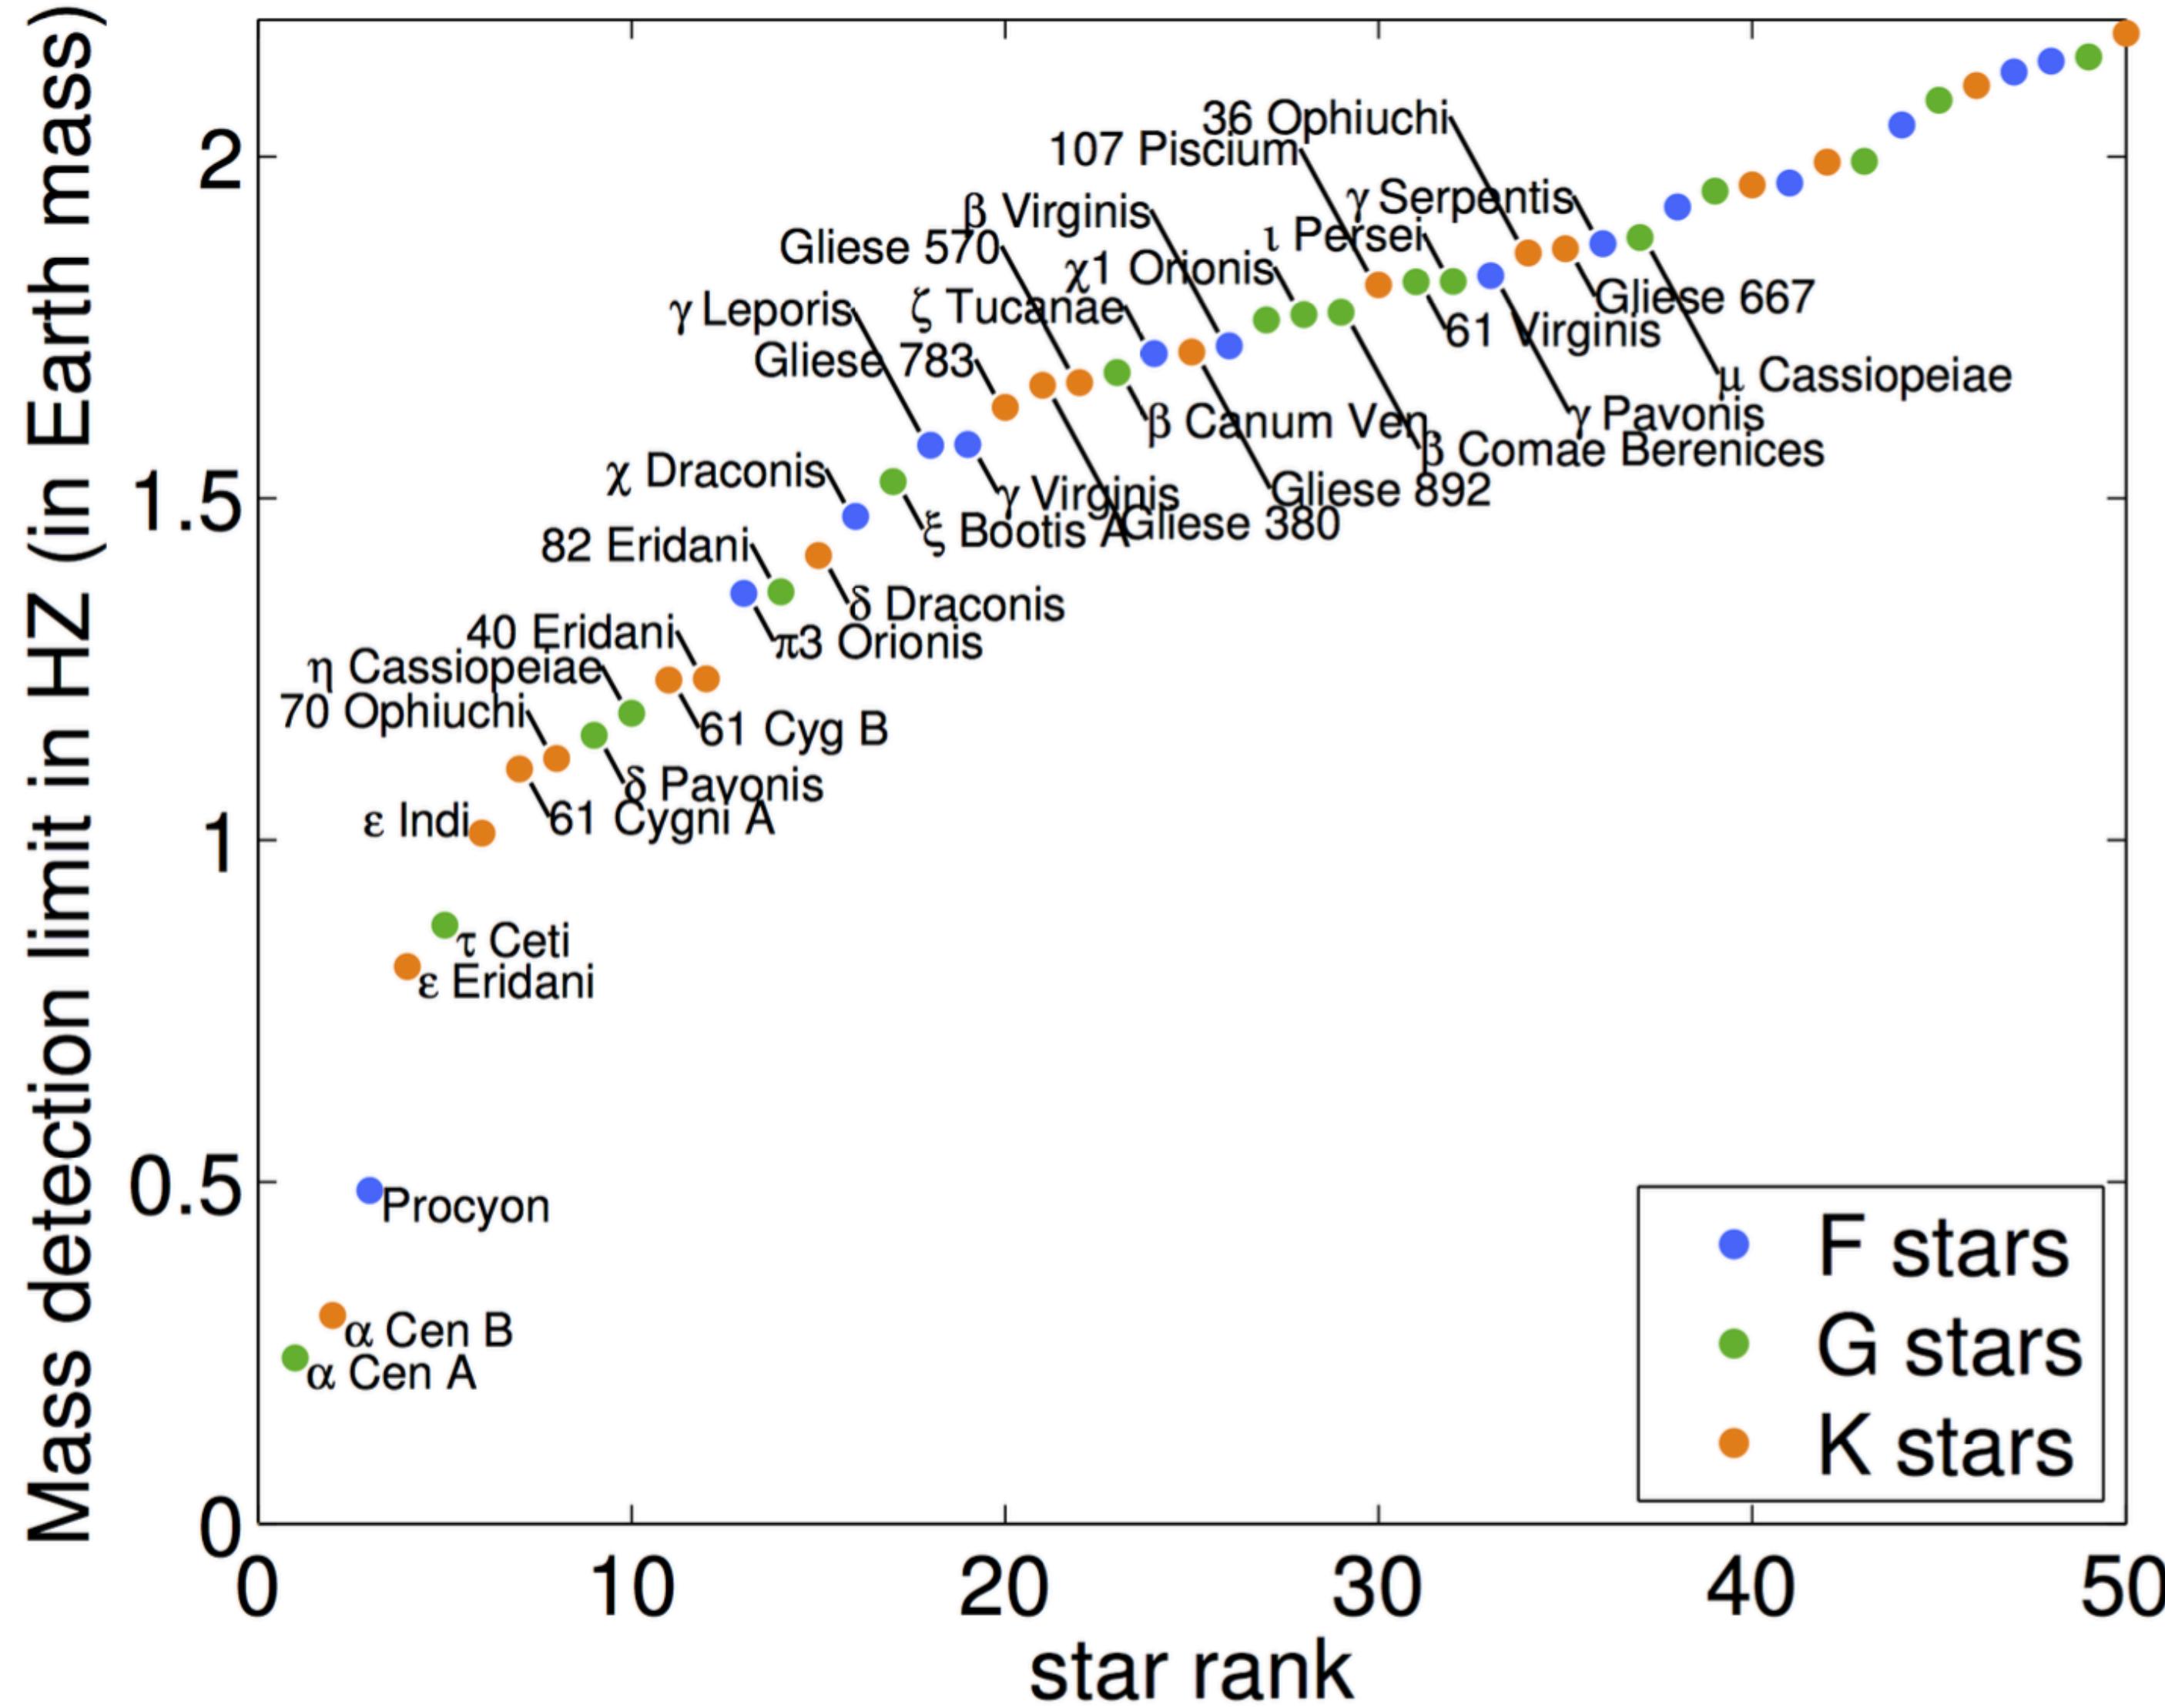

Exoplanets discovery space

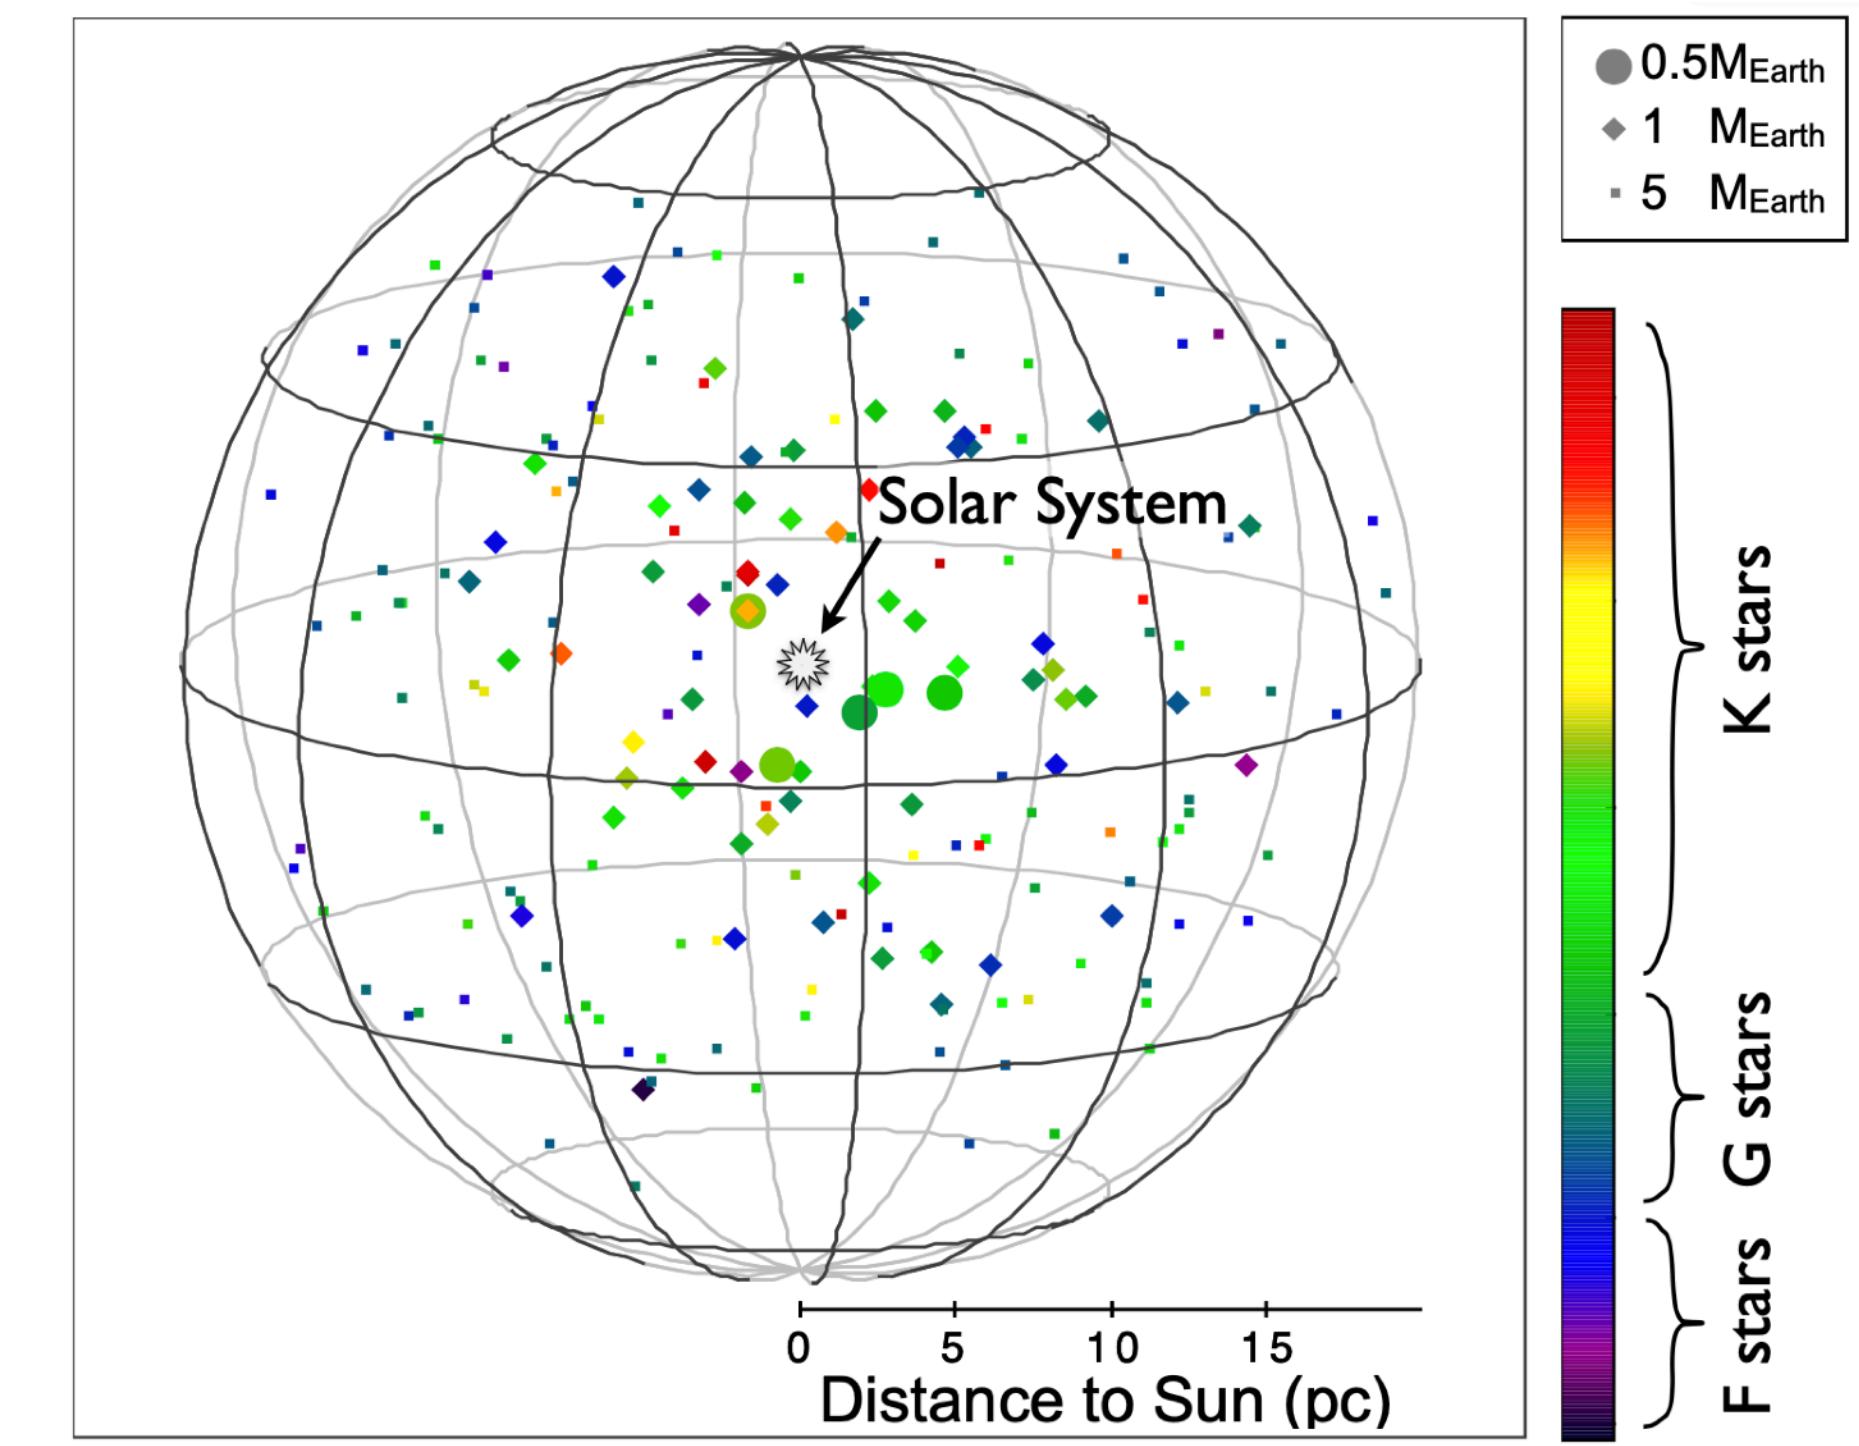

Mass vs Semi-Major Axis Diagram (from exoplanet.eu)

Exoplanets primary goal : Earth-mass planets in HZ in the vicinity of the Sun

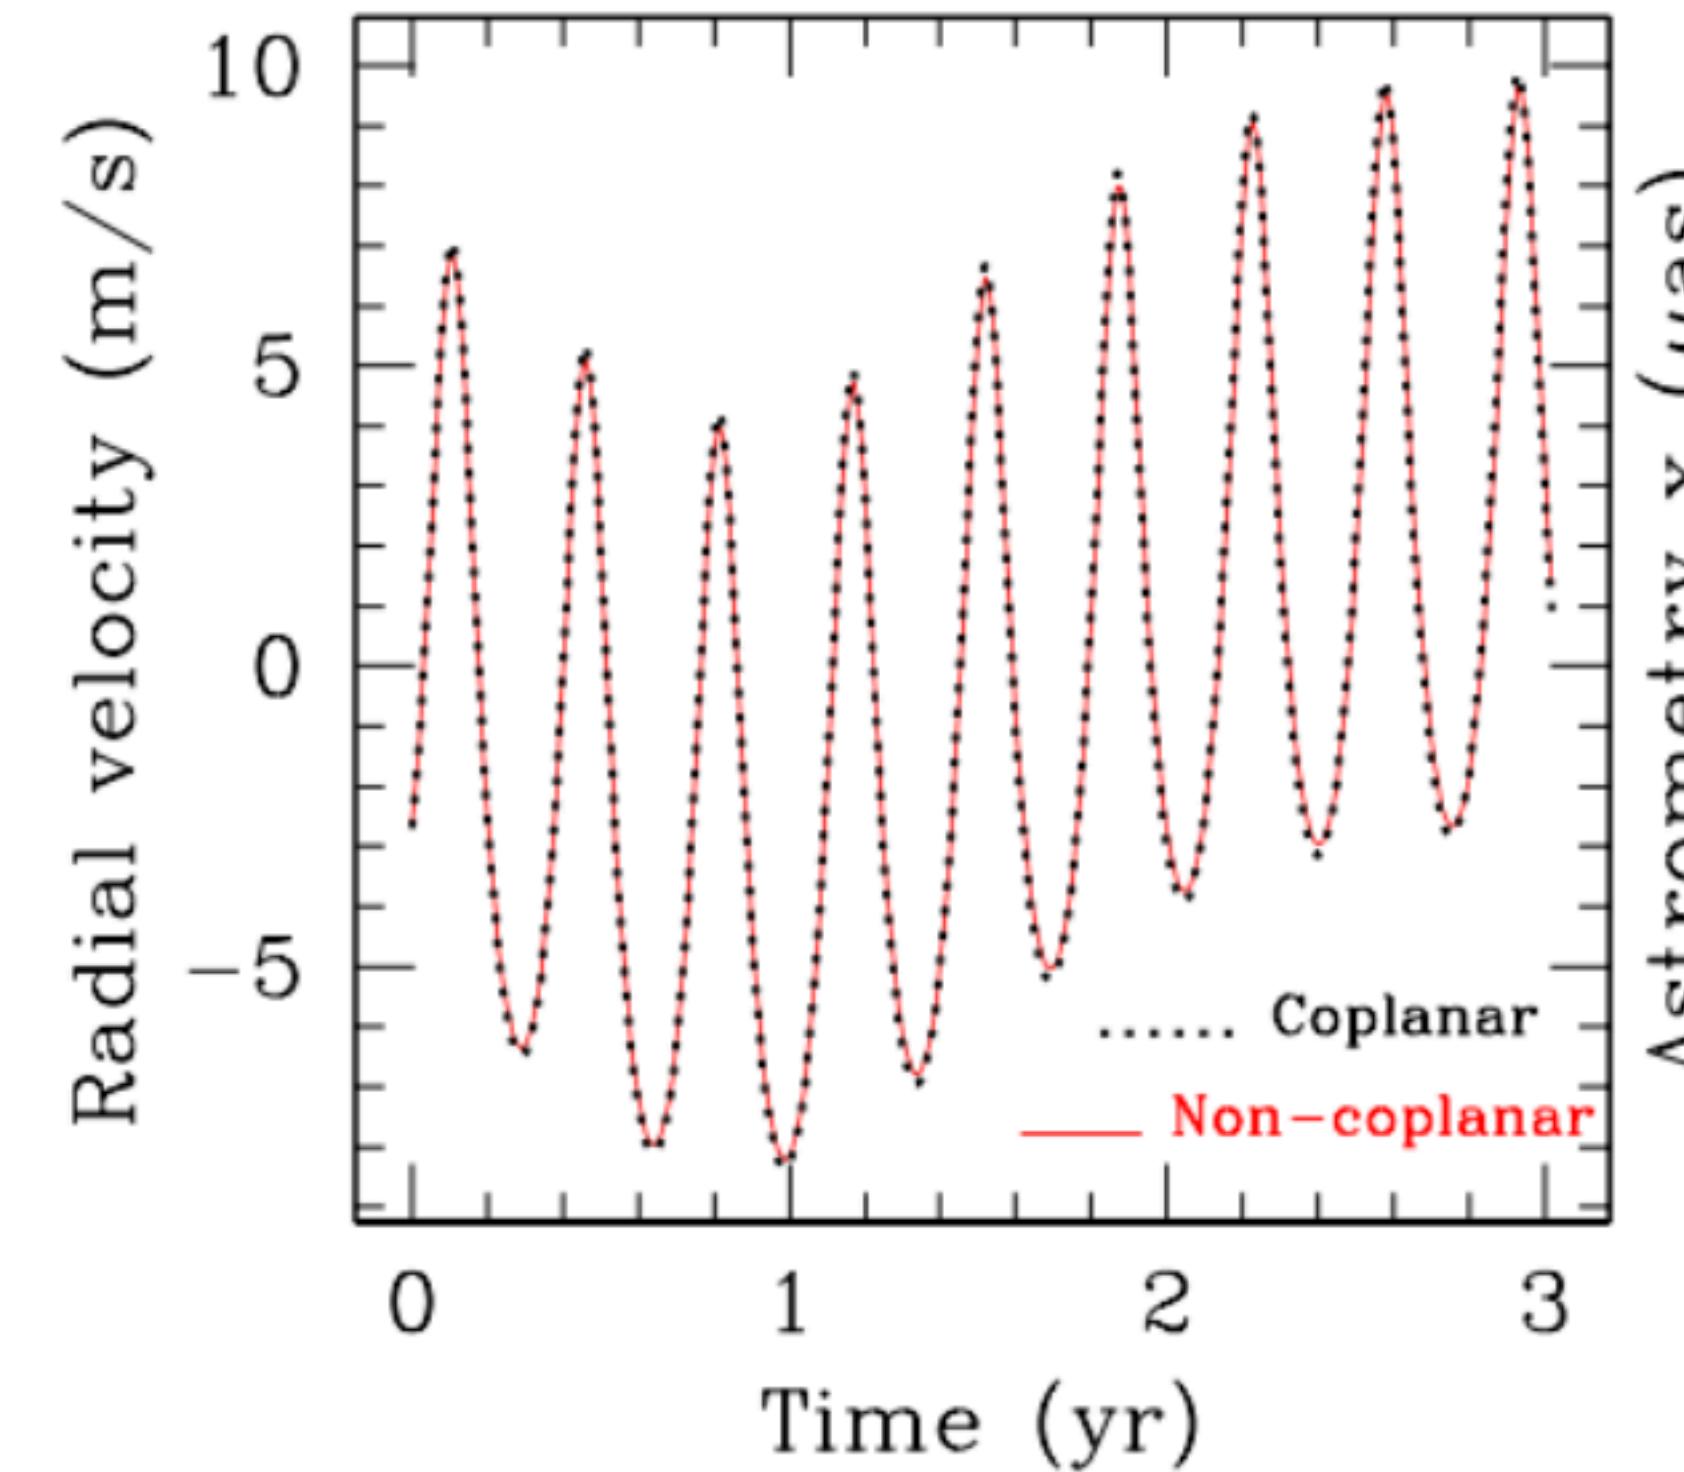

Complete census of exo-Earths,
superEarths and mini-Neptune
($M < 5 M_{\text{Earth}}$) orbiting our 50
nearest Solar-type stars

Astrometry breaks some orbit degeneracy: an example

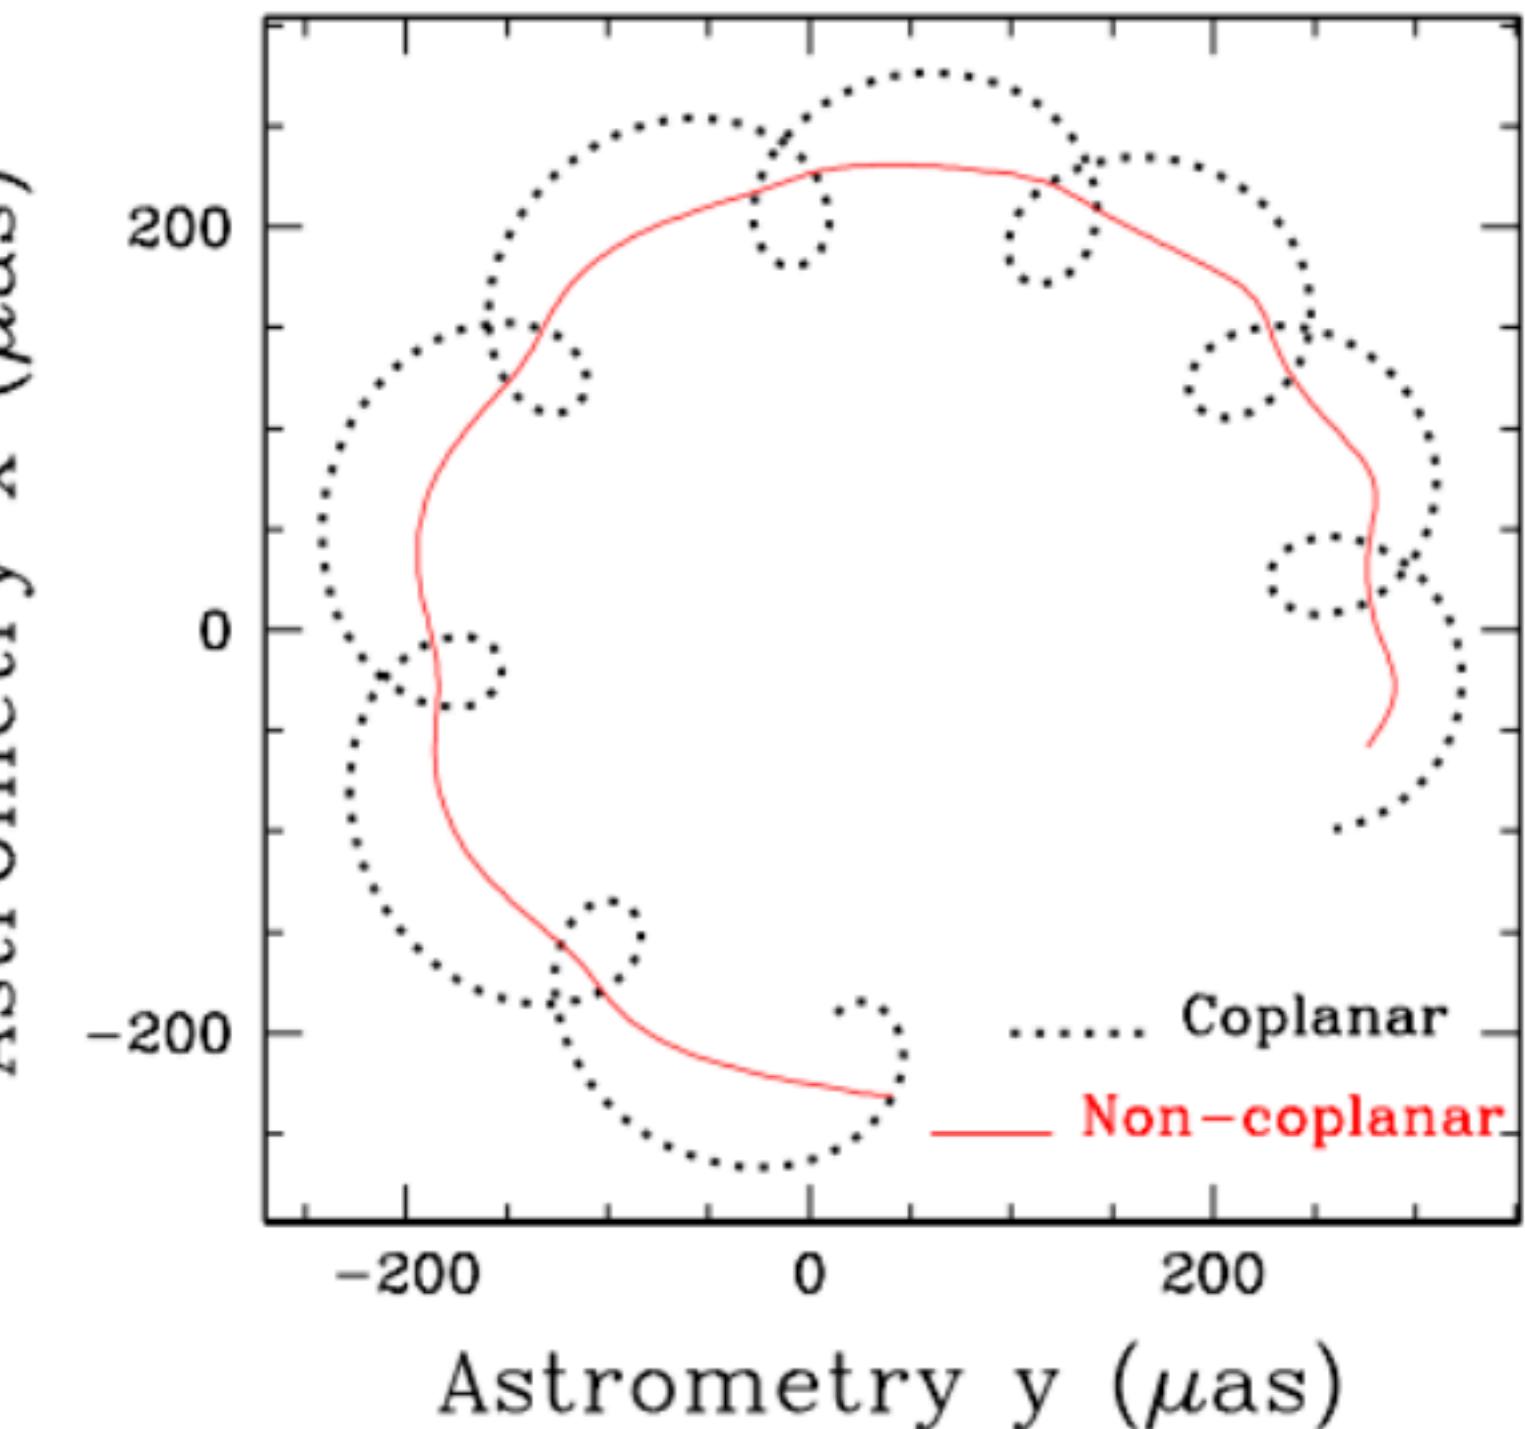

Coplanar planetary system

Non-coplanar planetary system

Two simulated planetary systems around
a solar-type star at 10 pc, with two
Jupiter-like planets at 0.5 and 2.5 AU

Radial velocity

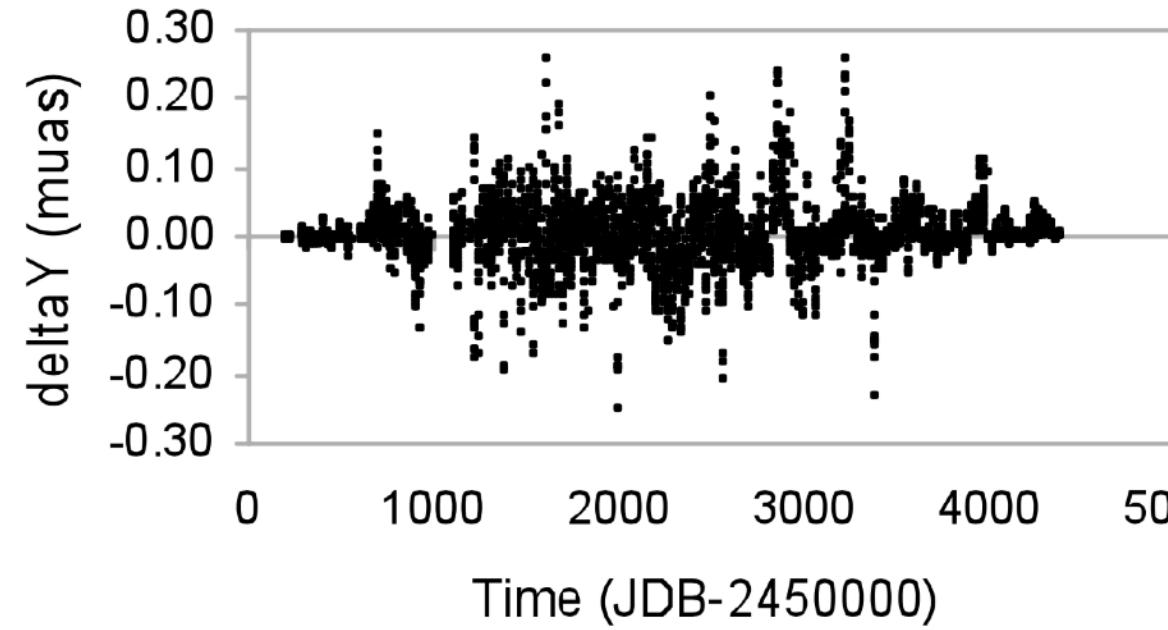

Astrometry

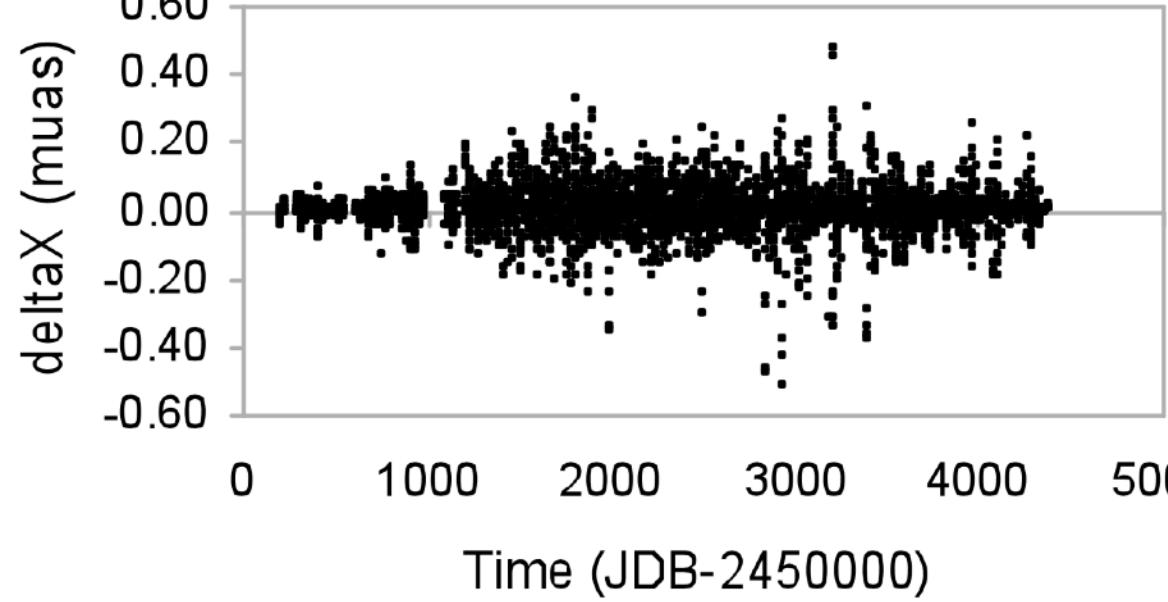

Malbet et al. (2021)

Astrometry less sensitive to stellar activity than RV

Sun's astrometric position
due to activity (1996-2007)

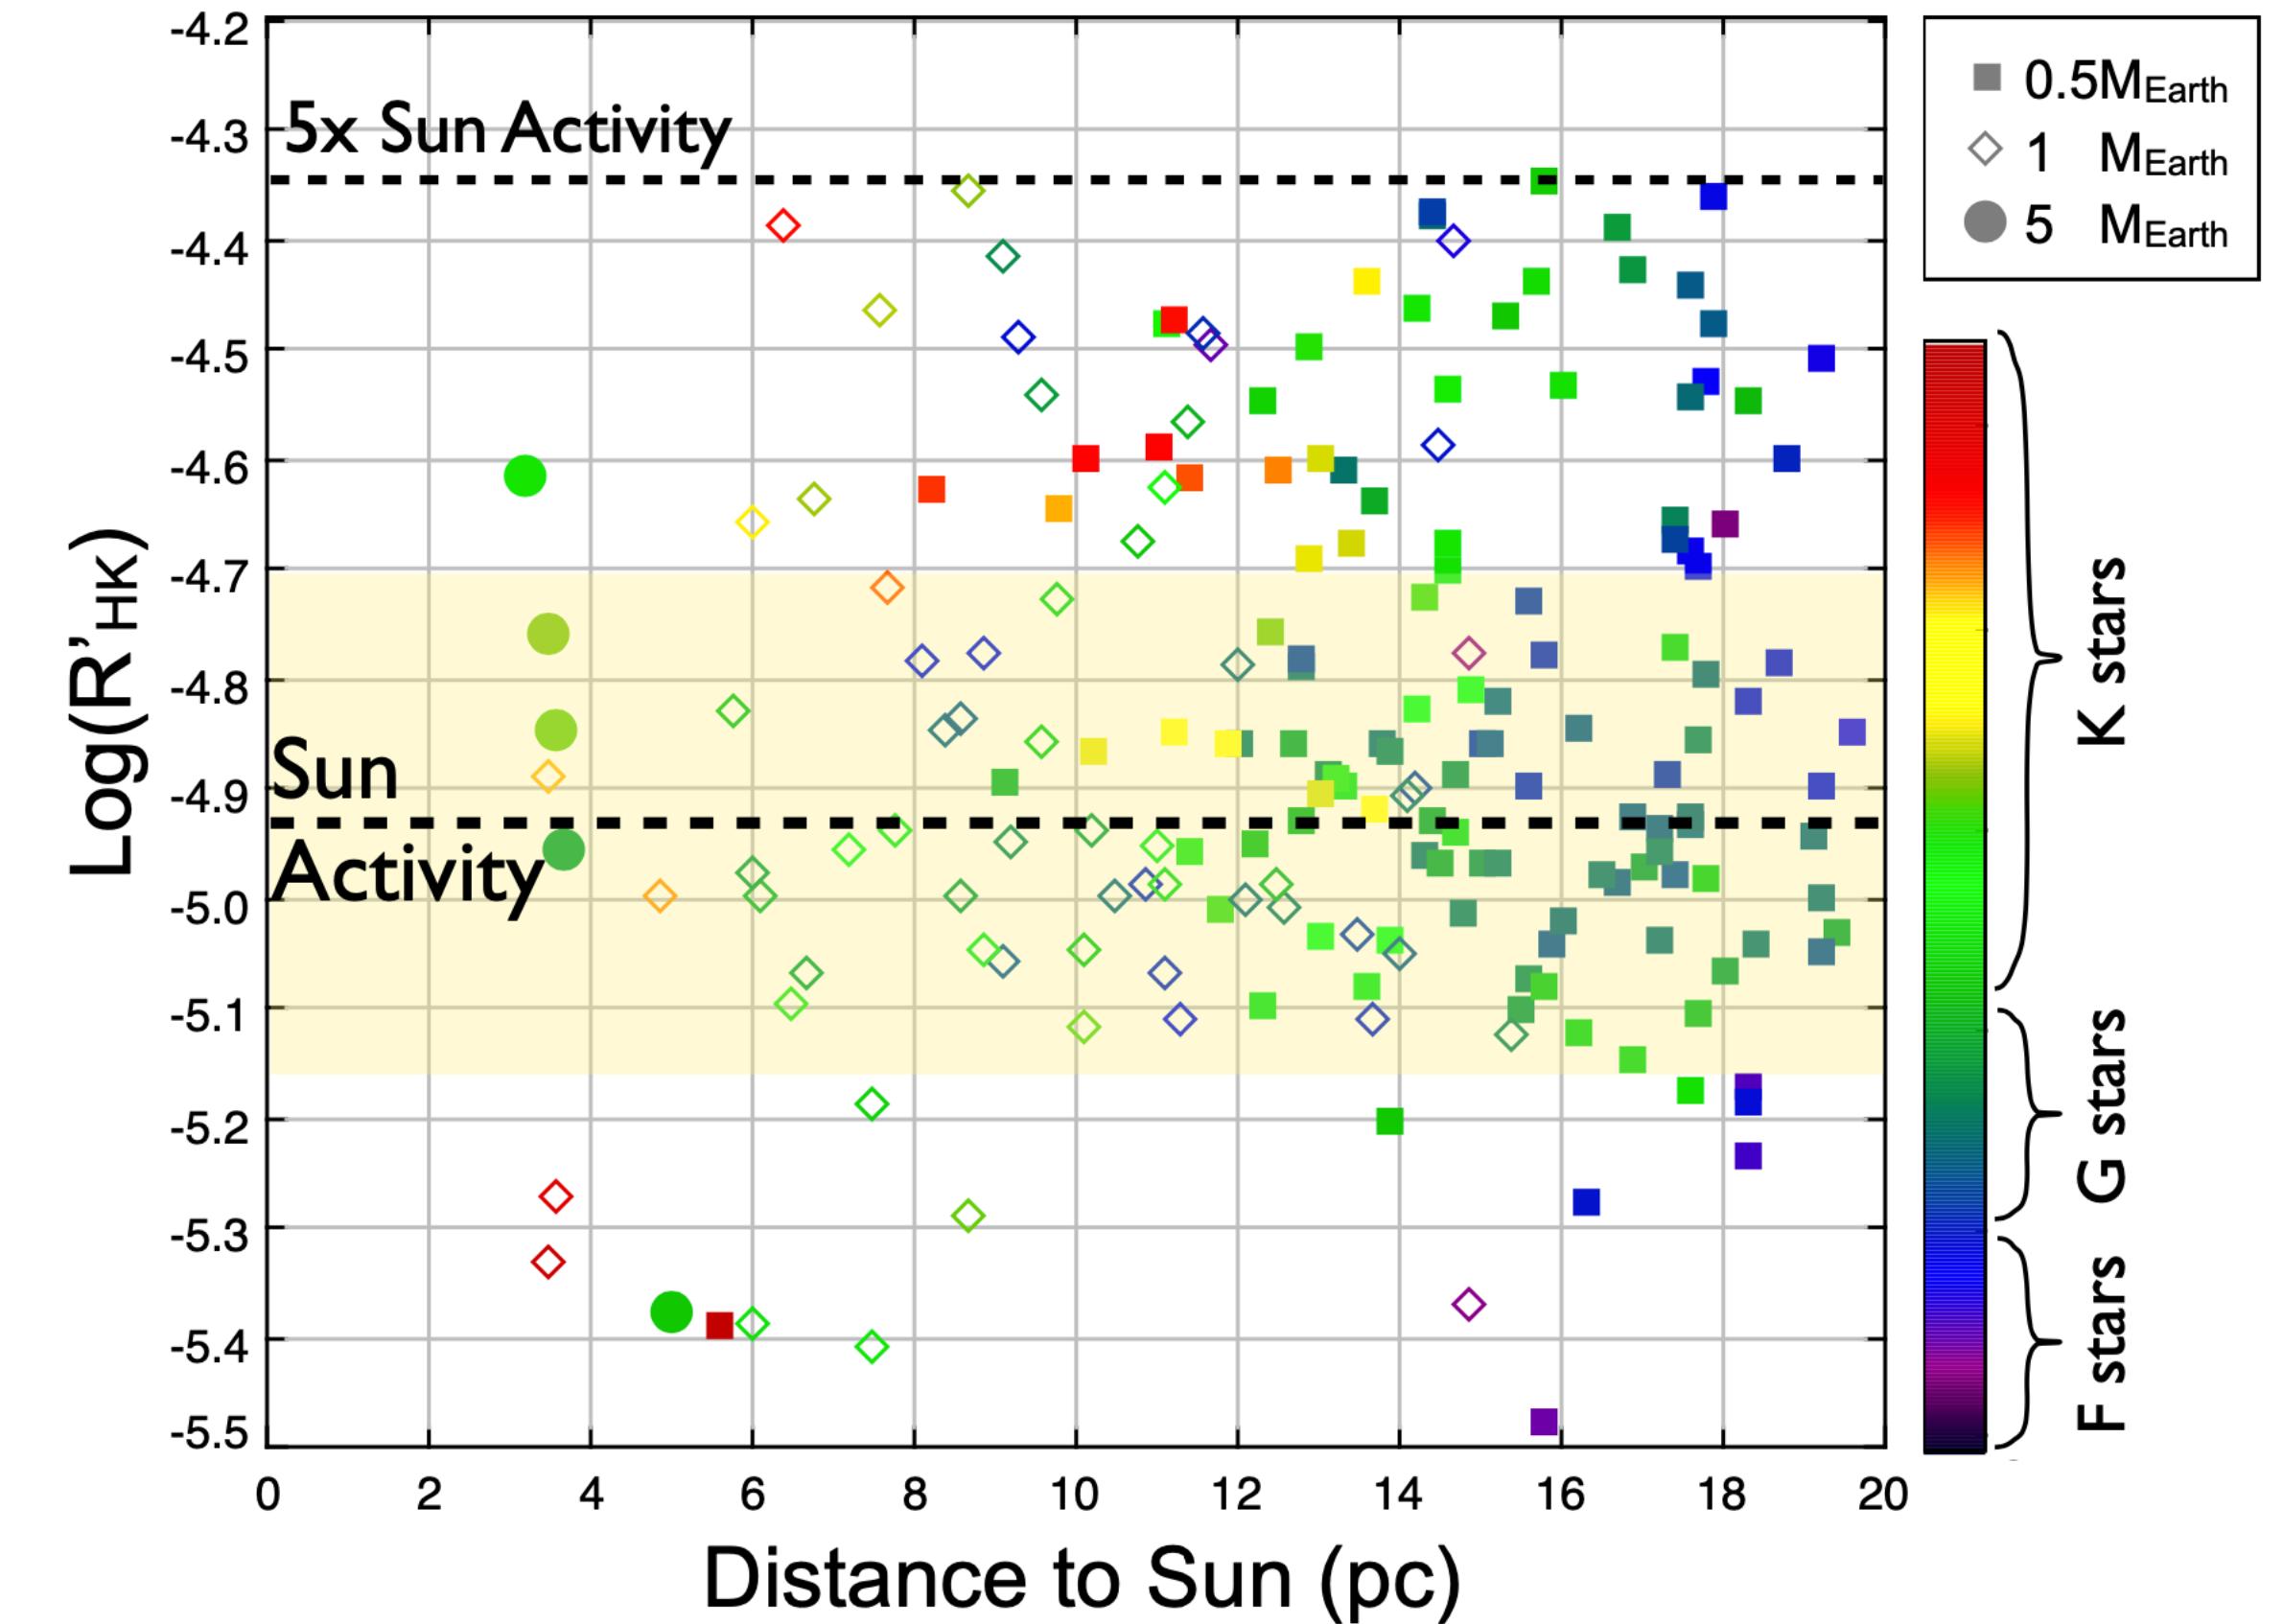

Earth astrometric
signature @10pc

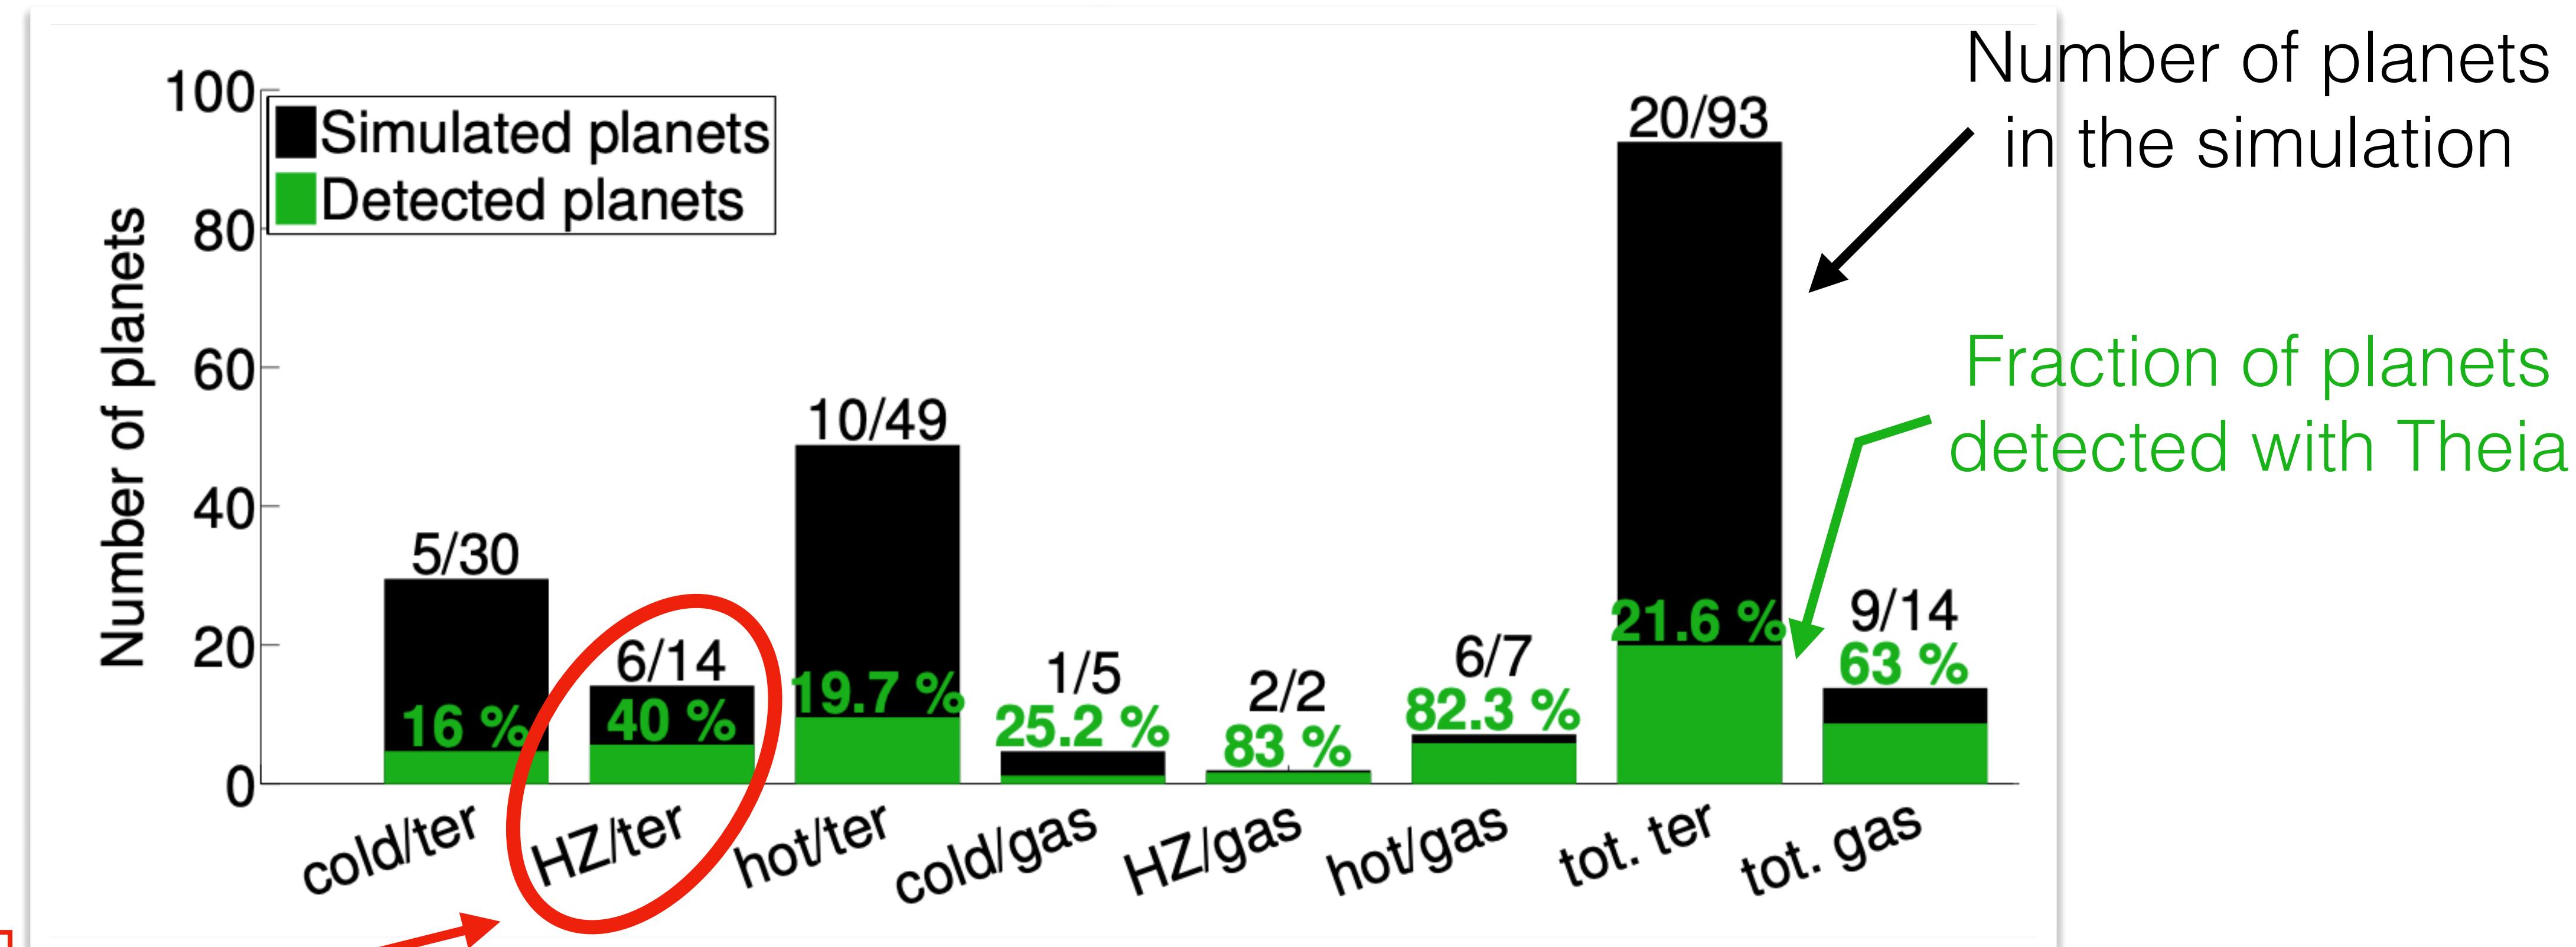

Earth astrometric
signature @10pc

Detection limits have been revisited by Meunier & Lagrange (2023) through a blind test method and found lower detection limits, except for a handful of stars, **showing that it is probably possible to reach lower masses.**

Activity index $\log(R'_{HK})$ of the Theia targets as a function of the distance. The symbols represent the different detection threshold.

Expected detection rate from Kepler exoplanet population

Theia main objective

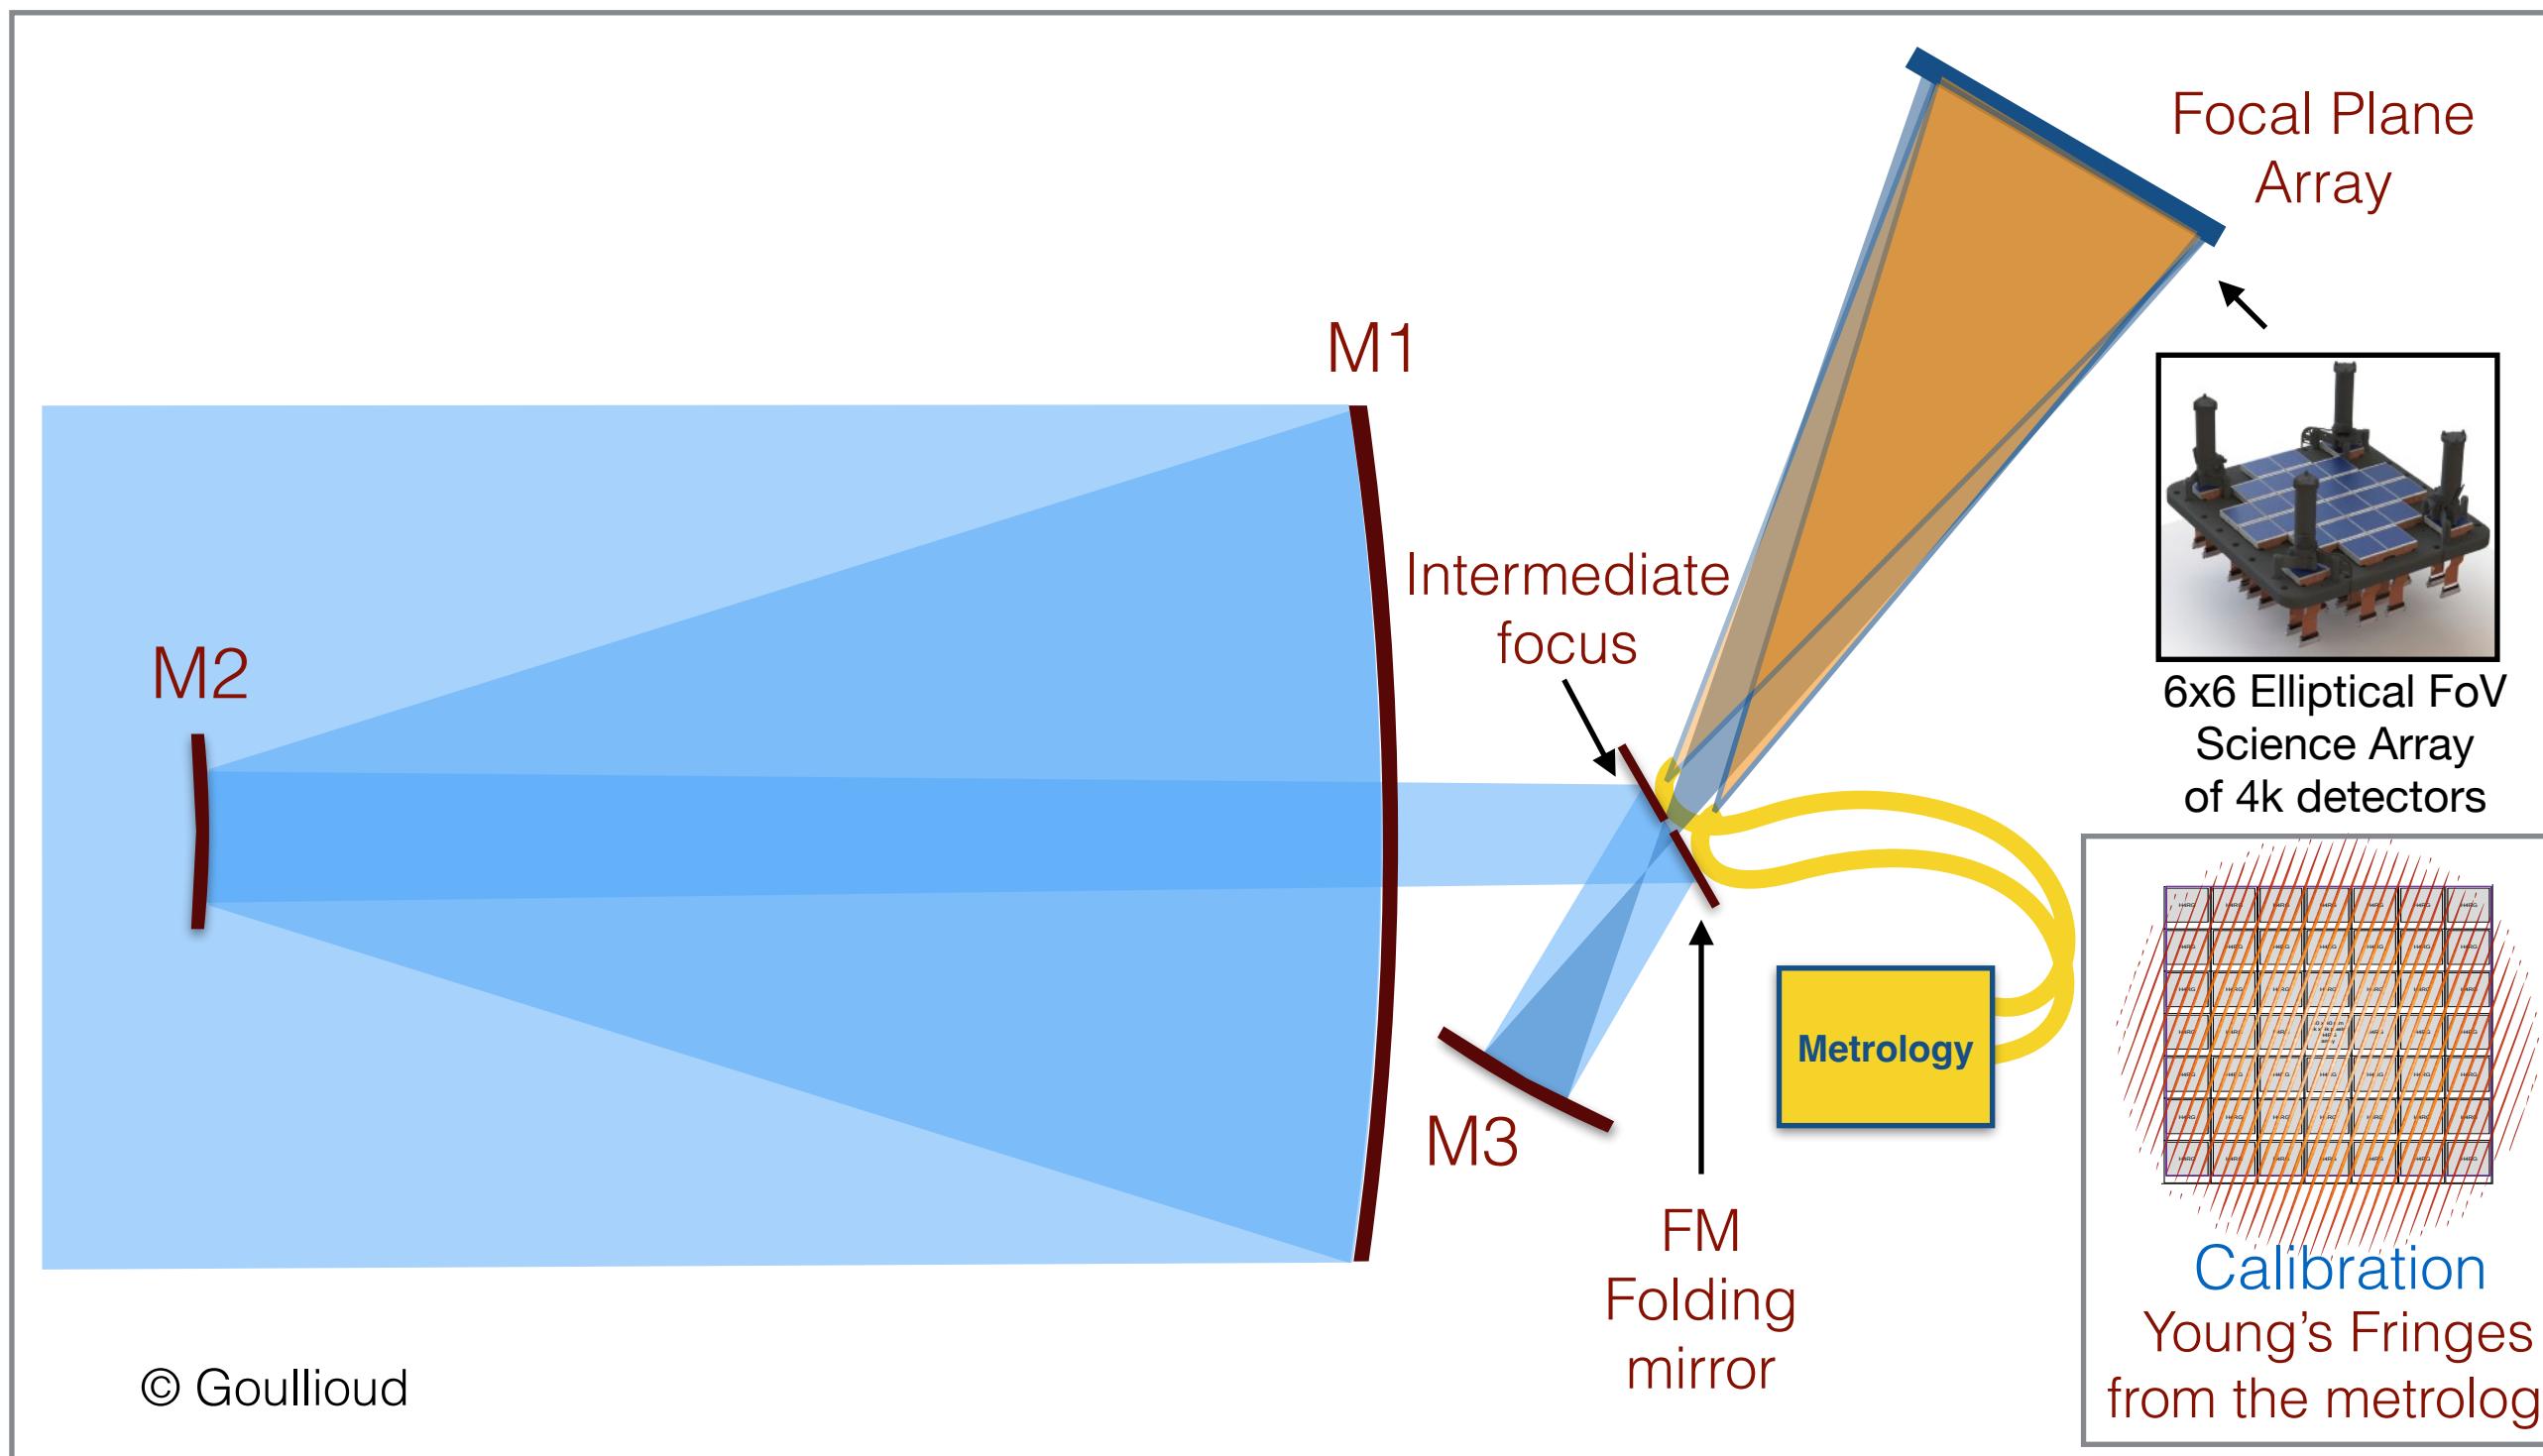

Averaging 10000 random exoplanets distributions around the 50 target stars (Crouzier 2014).

Theia instrumental concept

Specifications:

Diffraction-limited 0.5° FOV
 $\sim 30,000 \times 30,000$ pixels
 ≤ 1 billion pixels

Proposed implementation (M7)

© Goullioud

But new large CMOS detectors with smaller pixels !

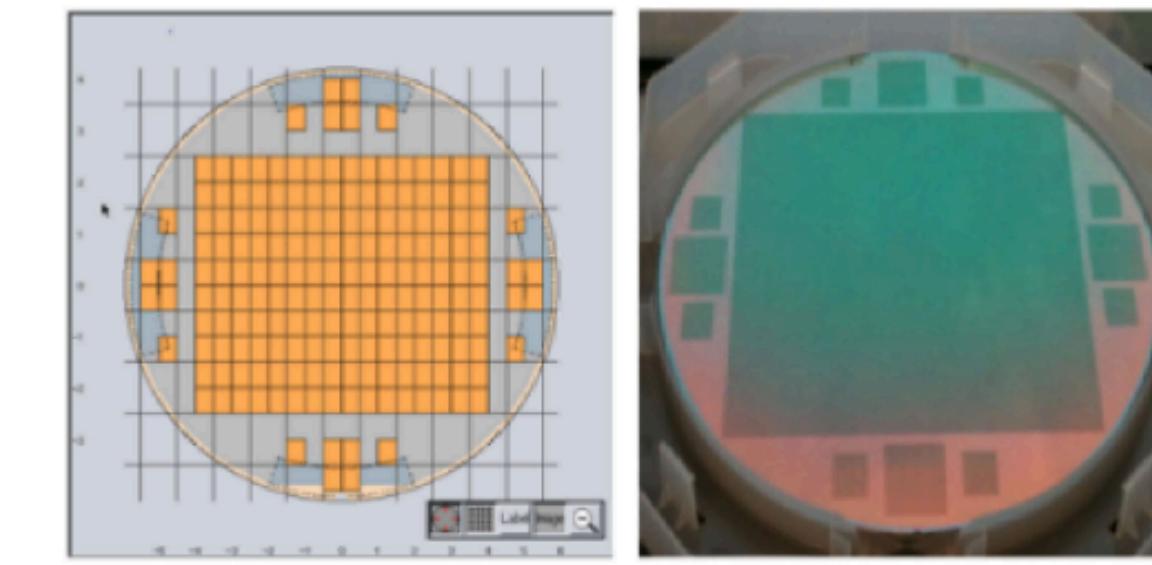

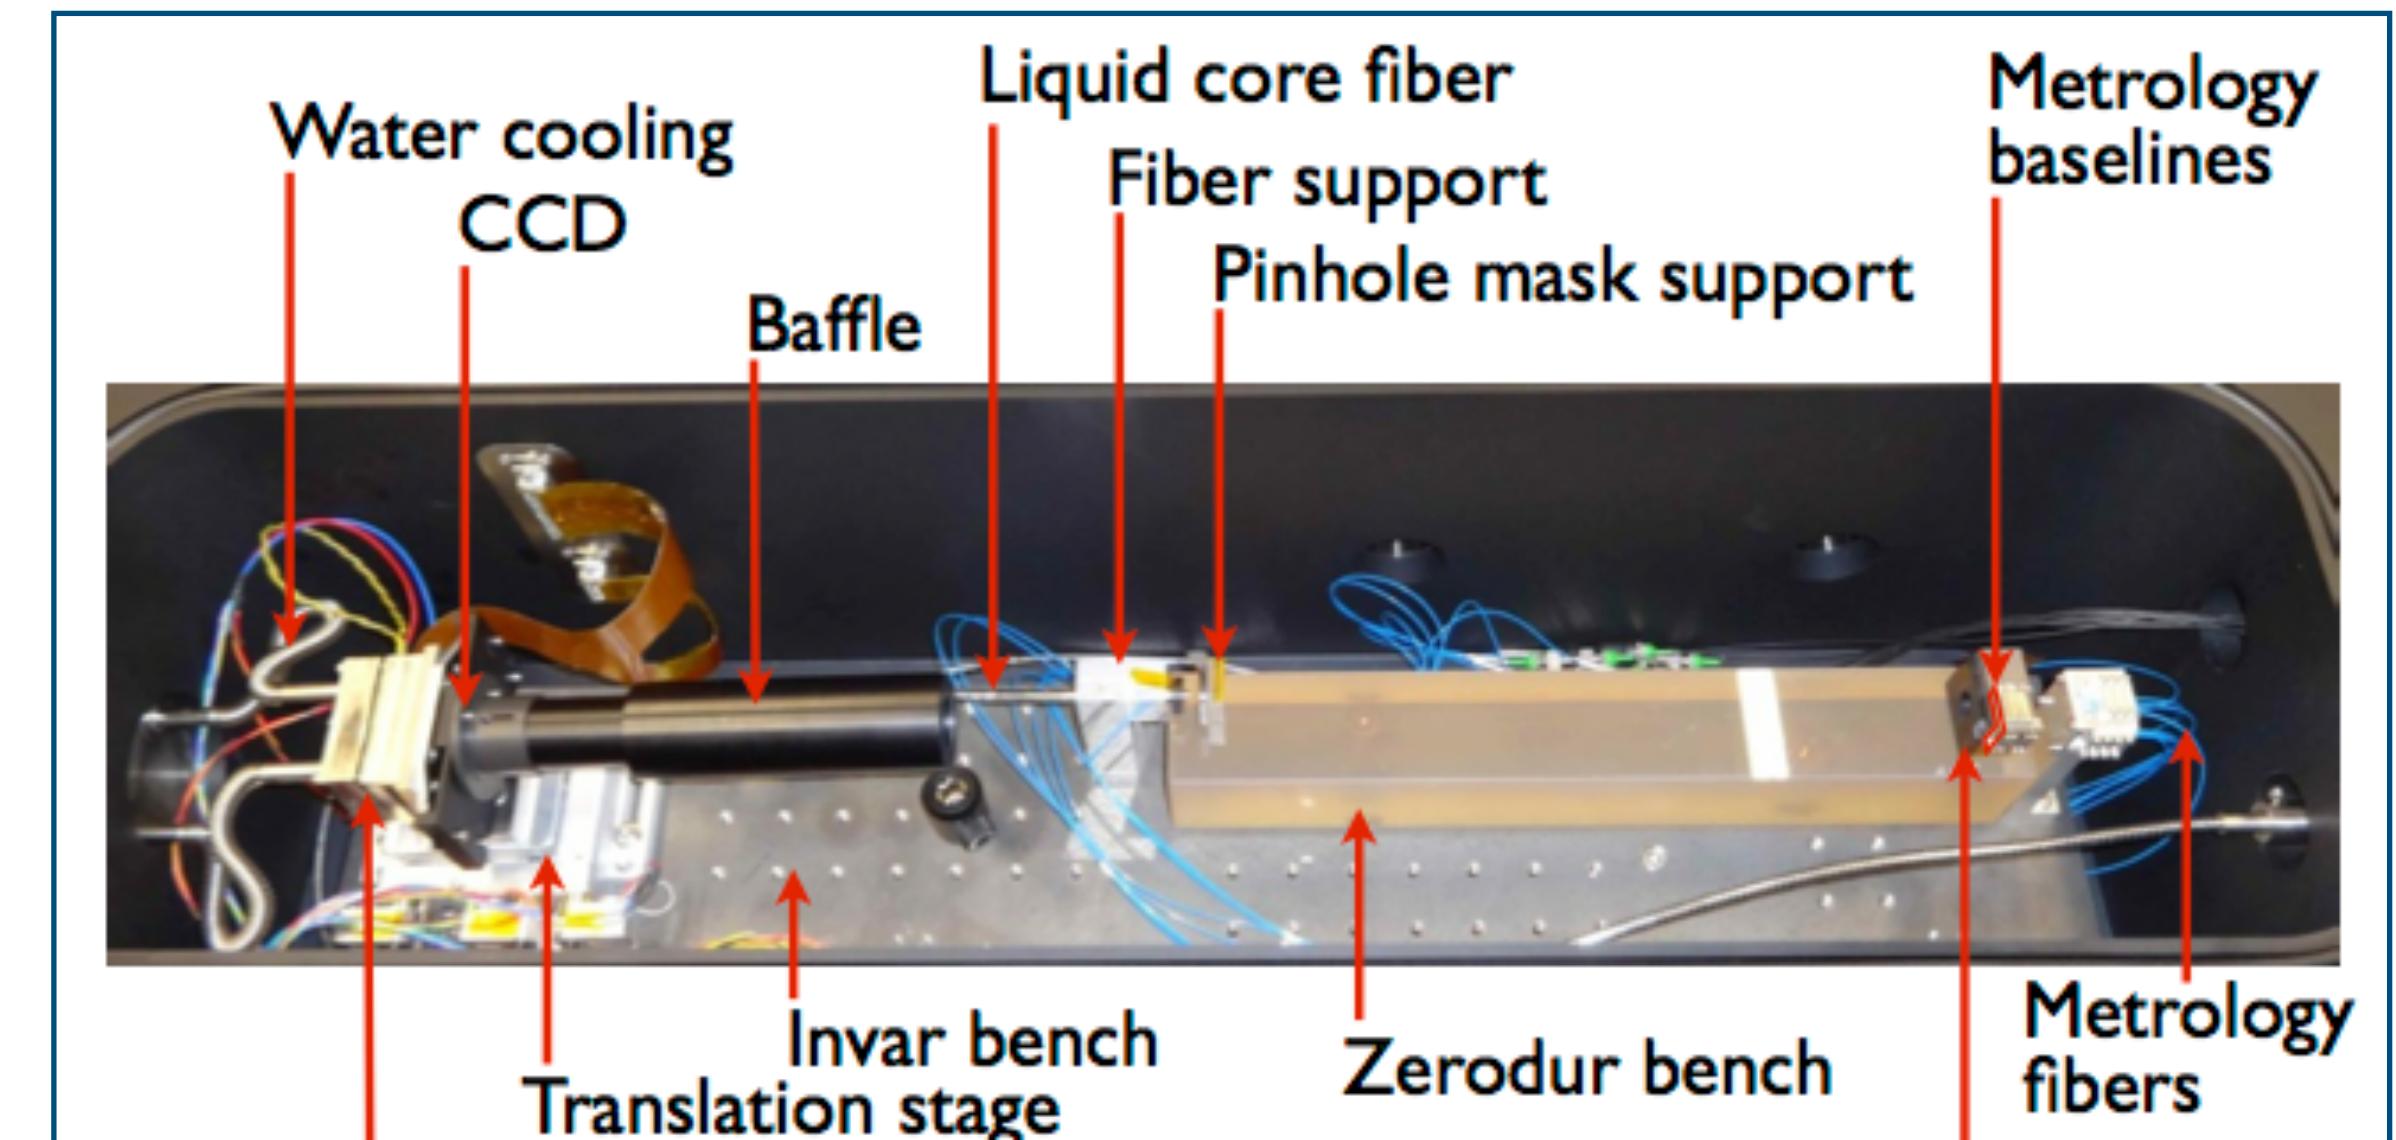

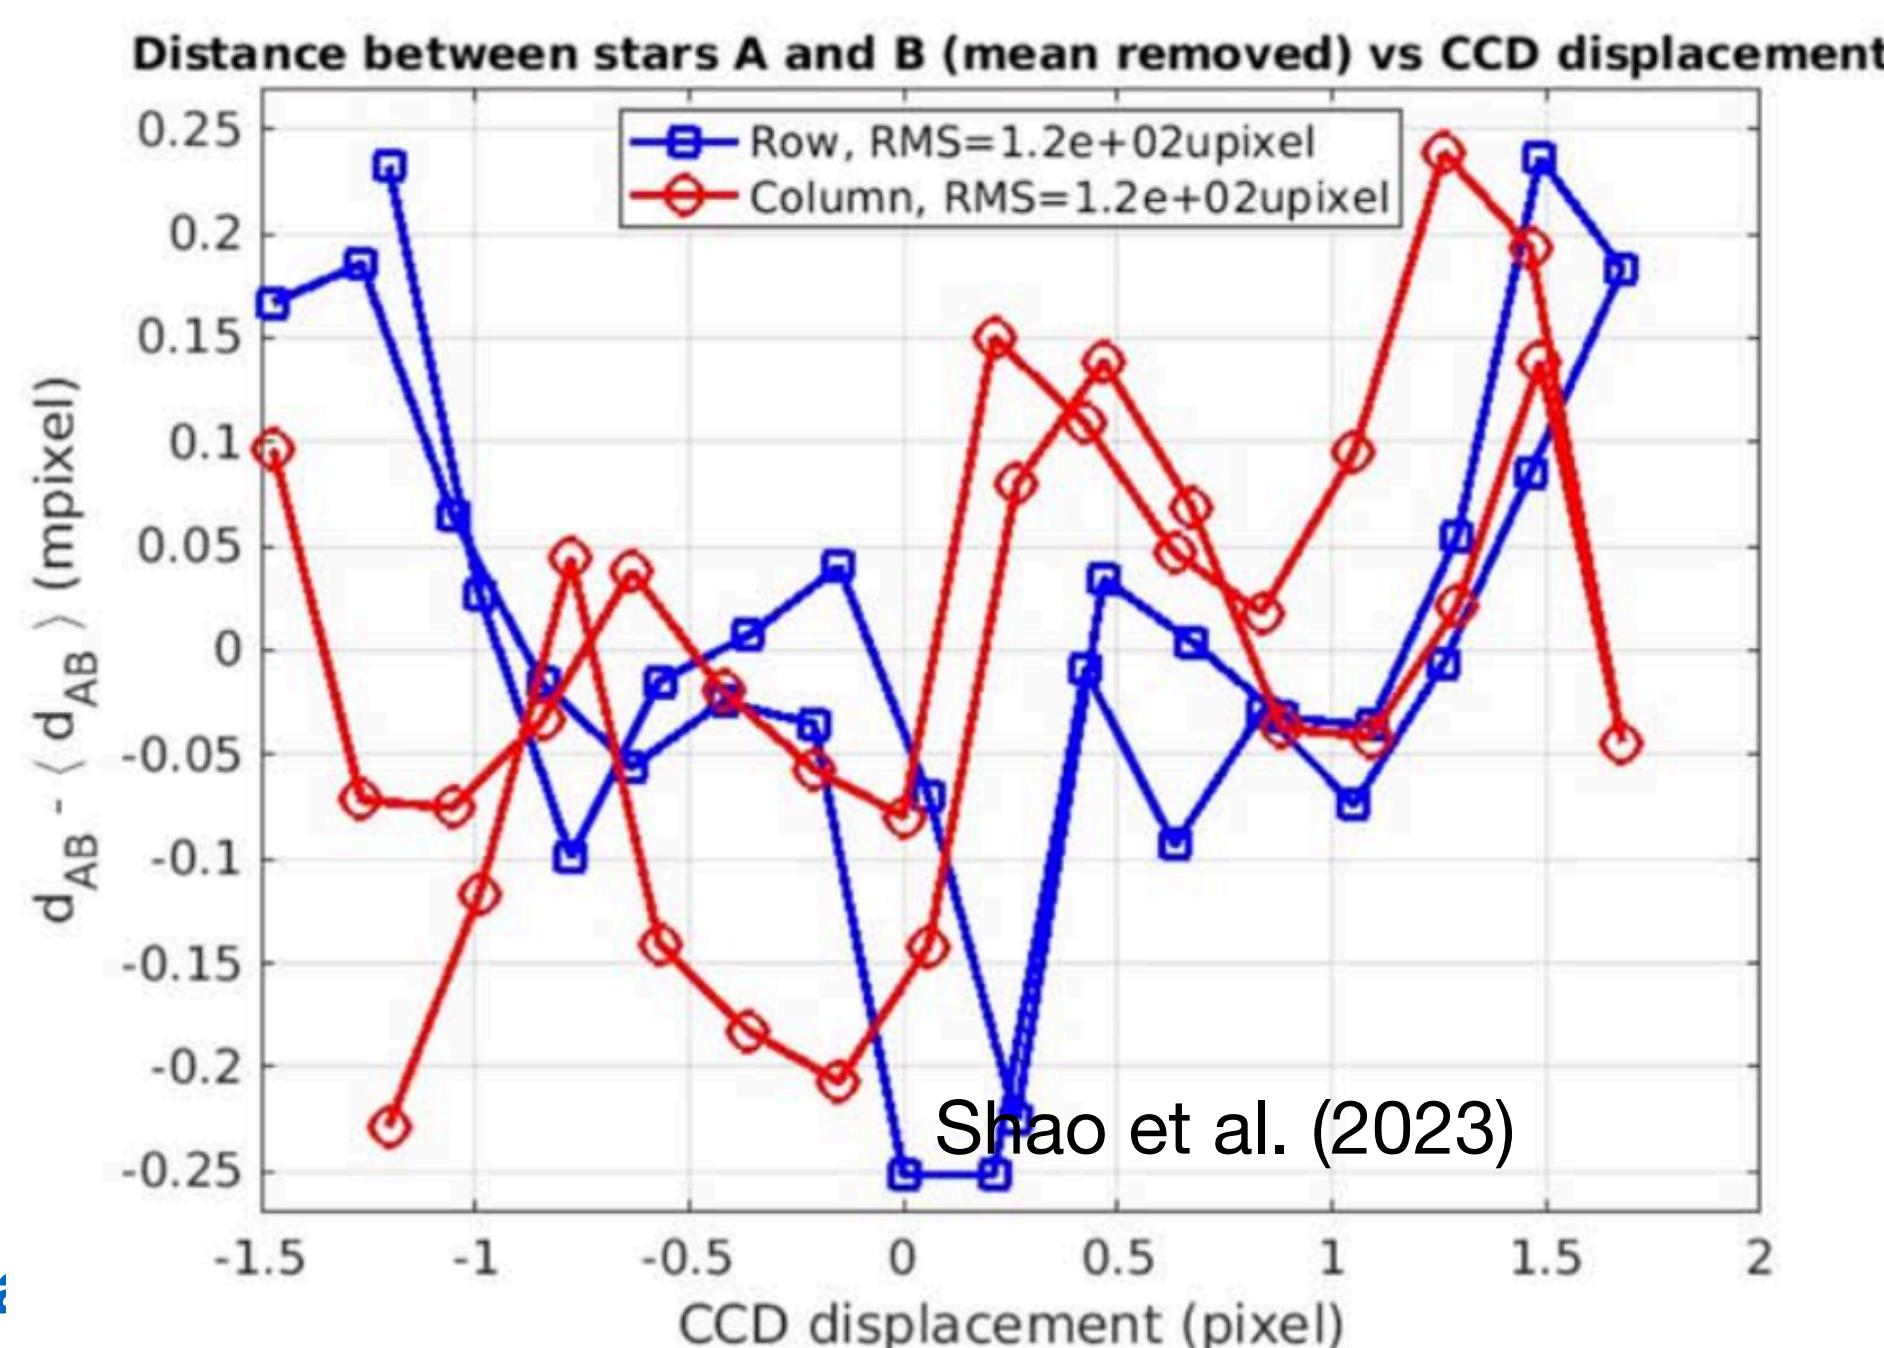

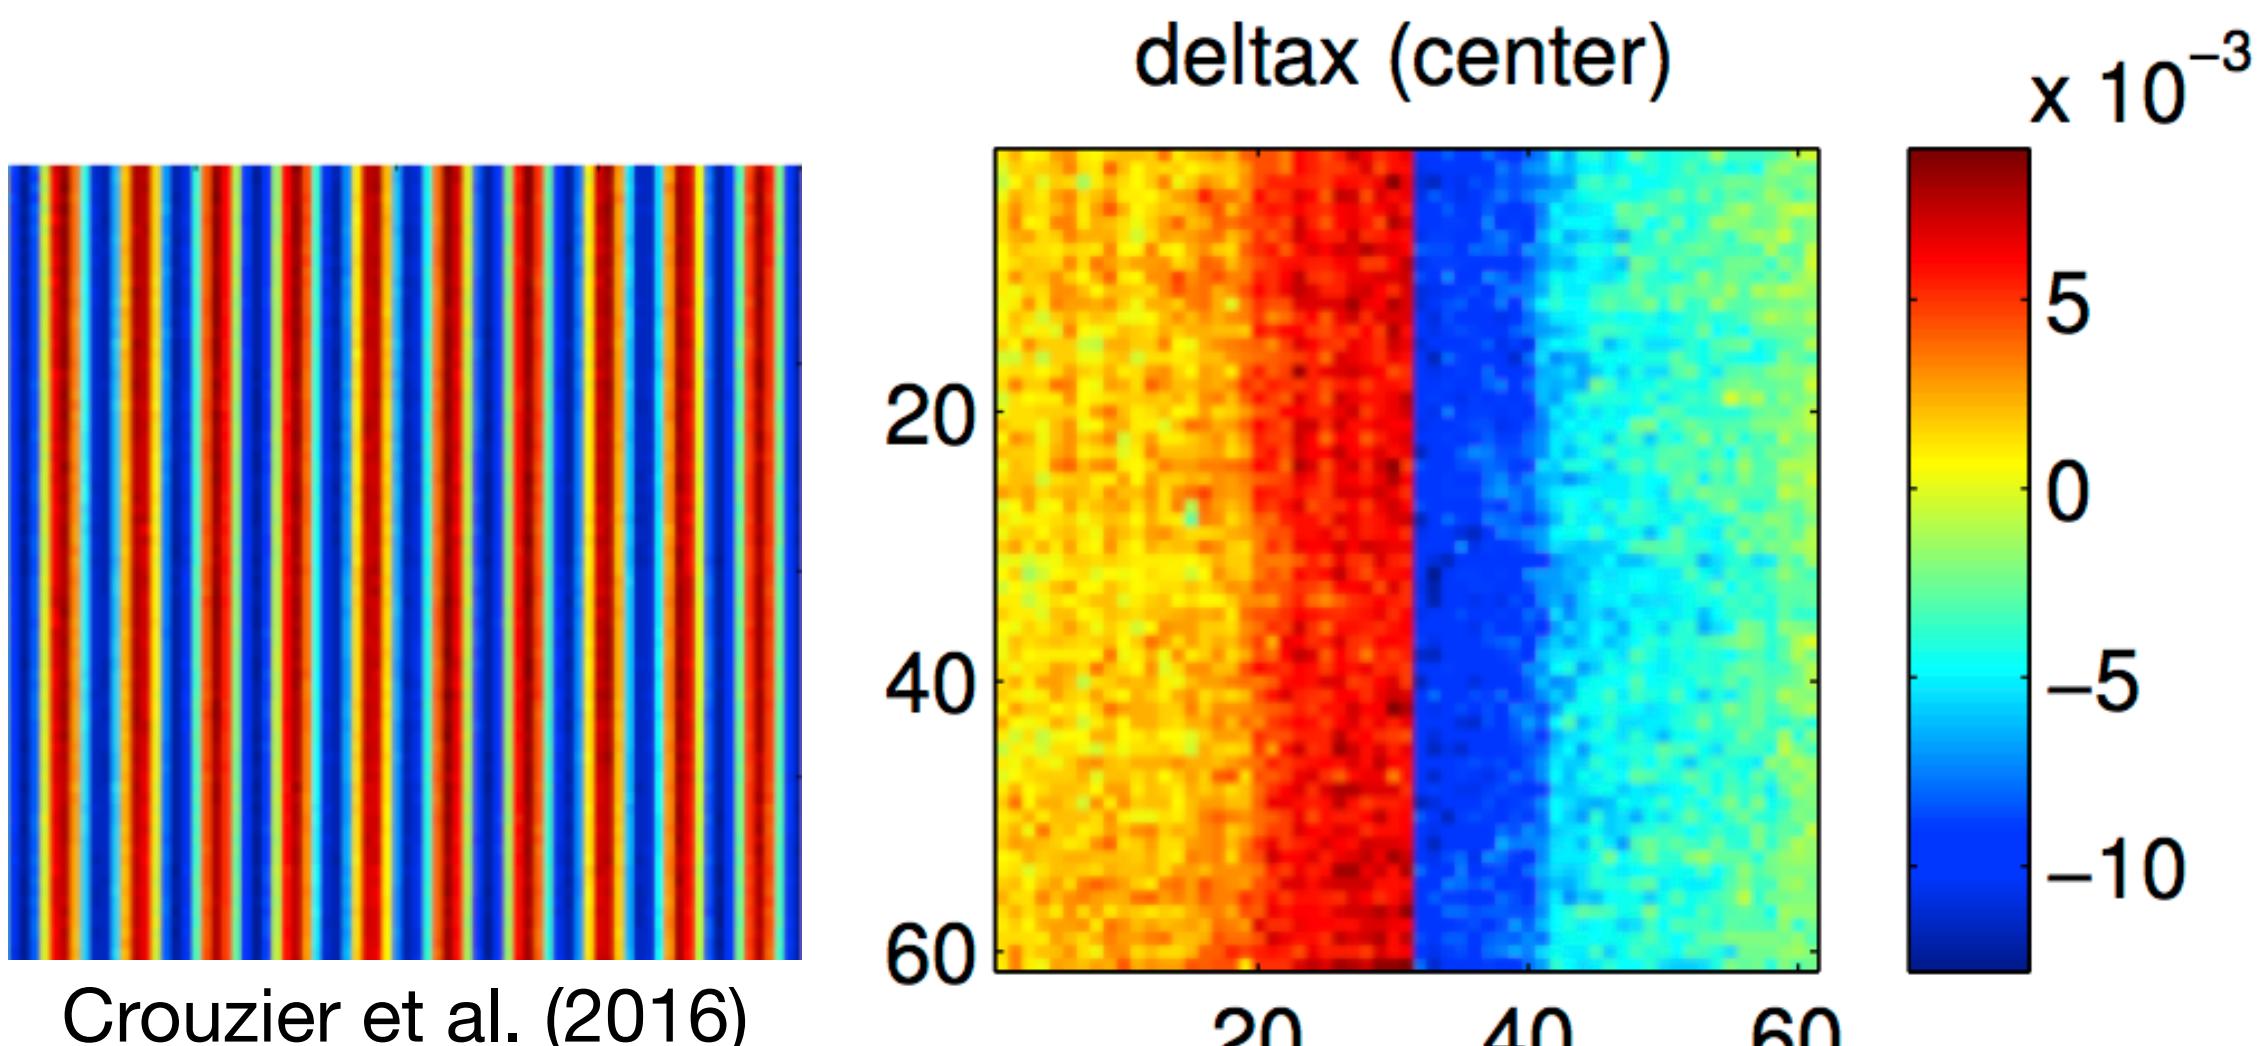

Fig. 14. A huge area, $203\text{ mm} \times 179\text{ mm}$, 1.8 Billion pixels CIS (Left: A photograph of the exposure shot map placement and the sensor fabricated on 12 inch; Right: the corresponding wafer image.)
Zhu et al. (2016)

Pixels of $\sim 4\mu\text{m}$
 \Rightarrow array of $12\text{ cm} \times 12\text{ cm}$,
(i.e. $30\text{k} \times 30\text{k}$ detector)
can be manufactured on a wafer of
 $12"$ (300mm)

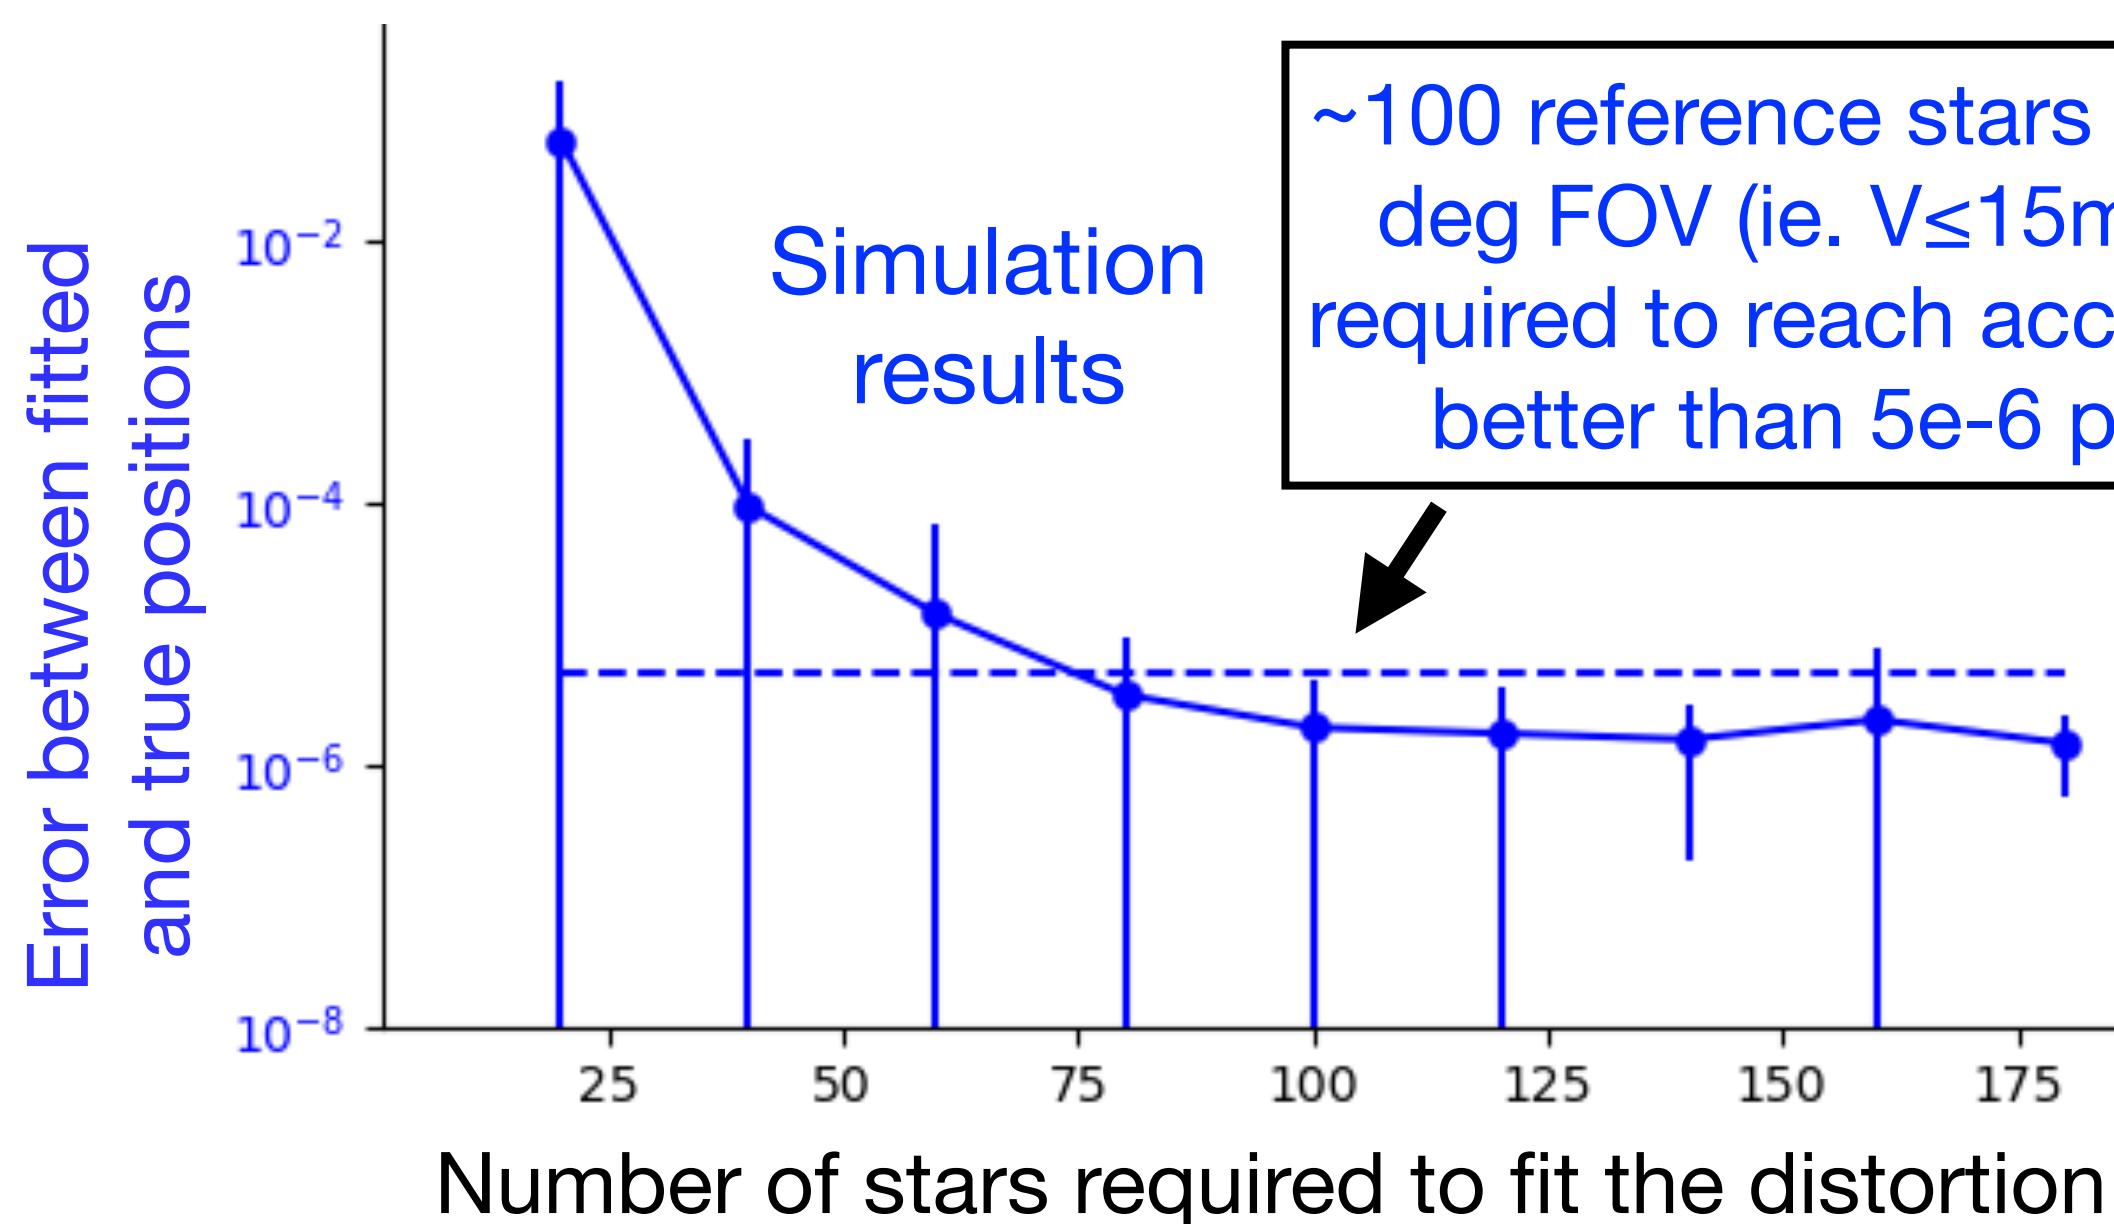

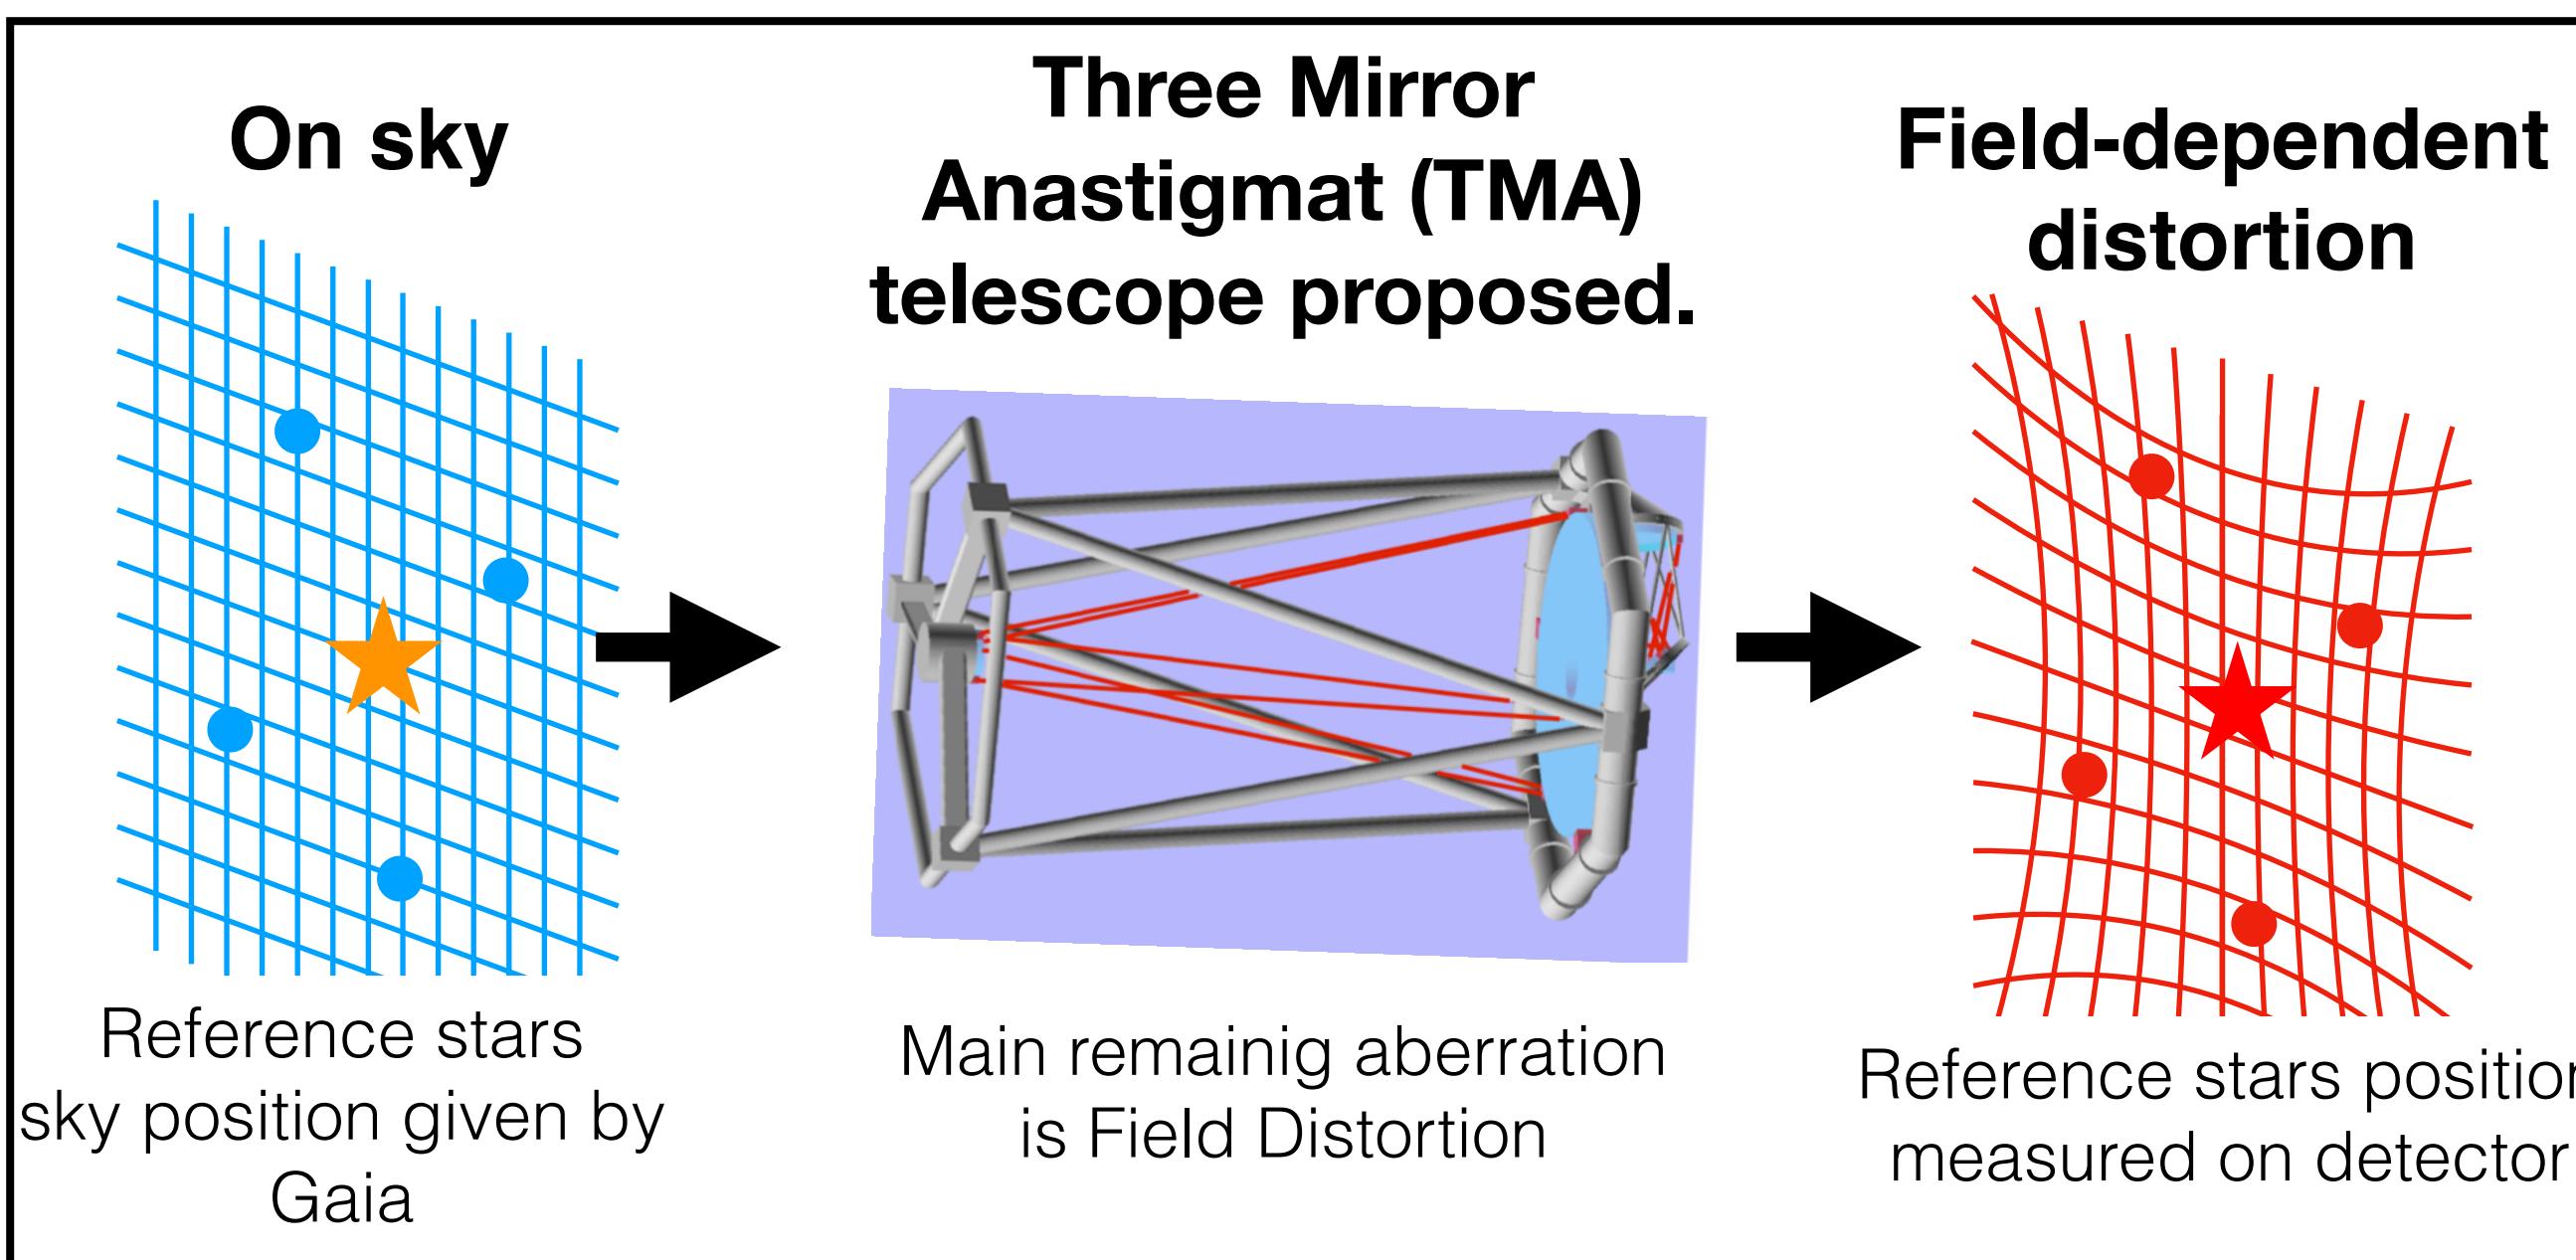

Detector calibration: laboratory results

Best results so far:

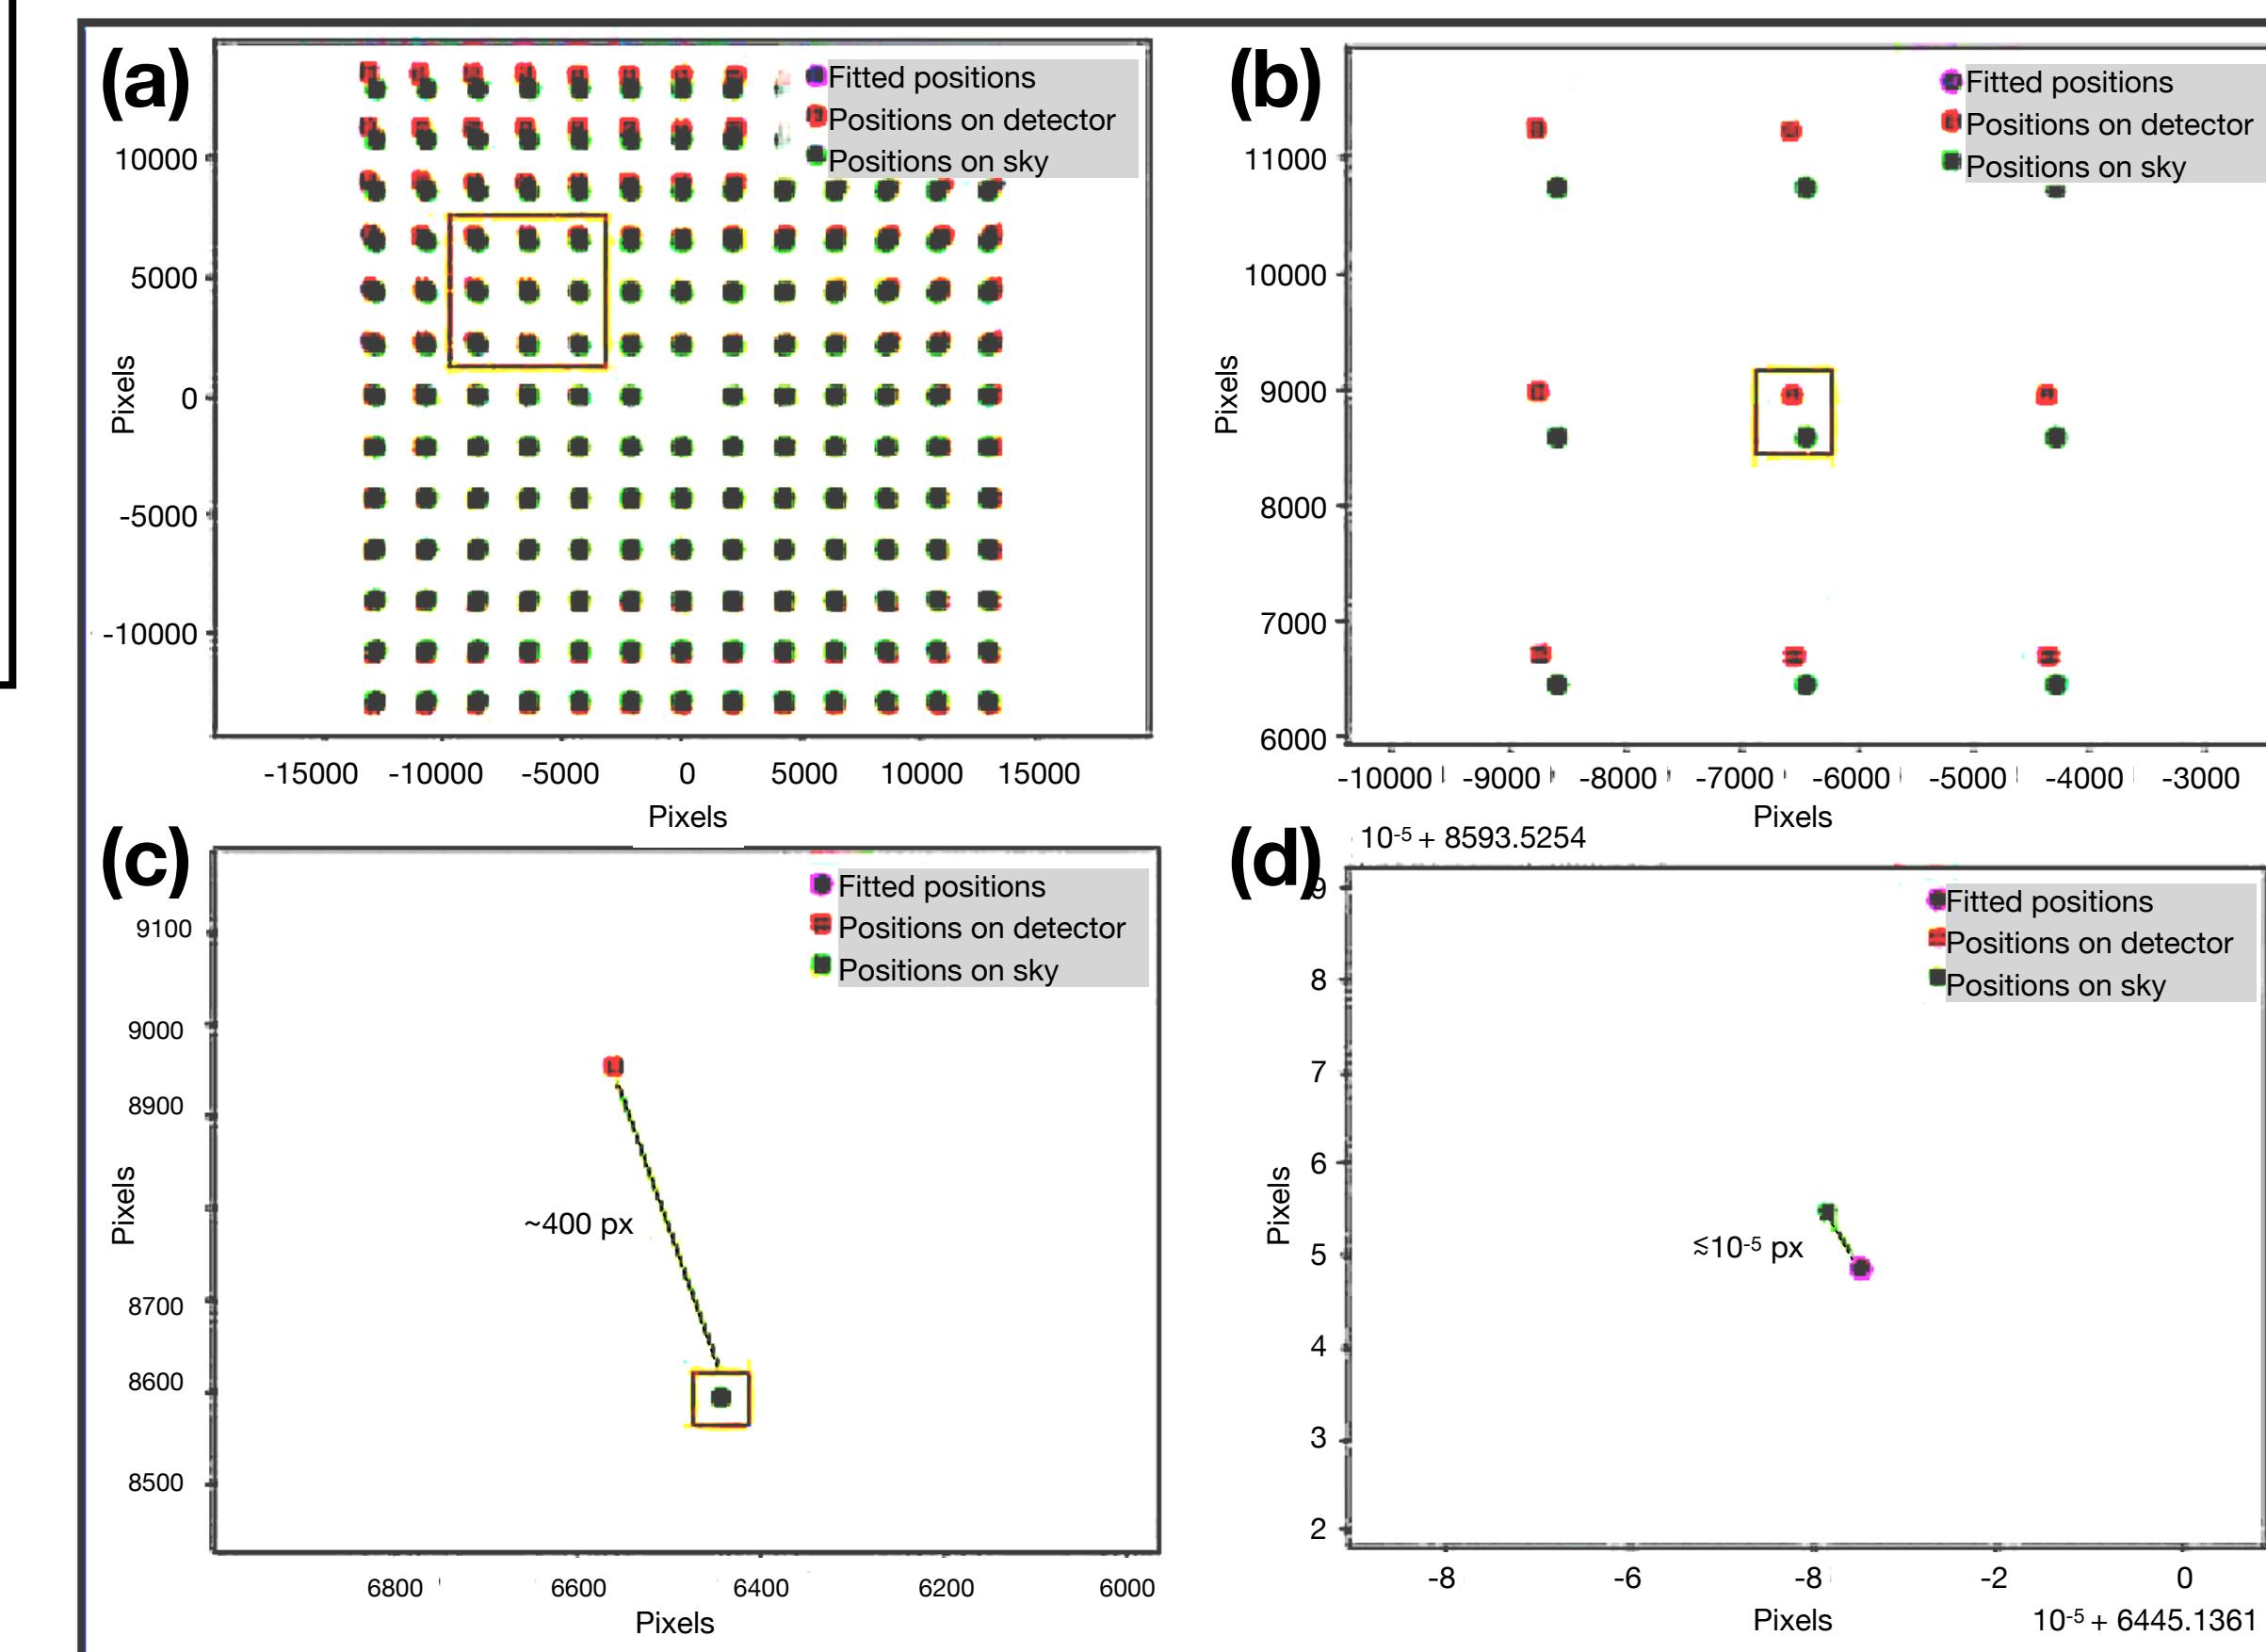

- IPAG/CNES: 6×10^{-5} pixels (Crouzier et al. 2016)
- JPL/VESTA: 3×10^{-5} pixels (Shao et al. 2023)

Telescope calibration : using reference stars to monitor the distortion

See Manon Lizzana's poster

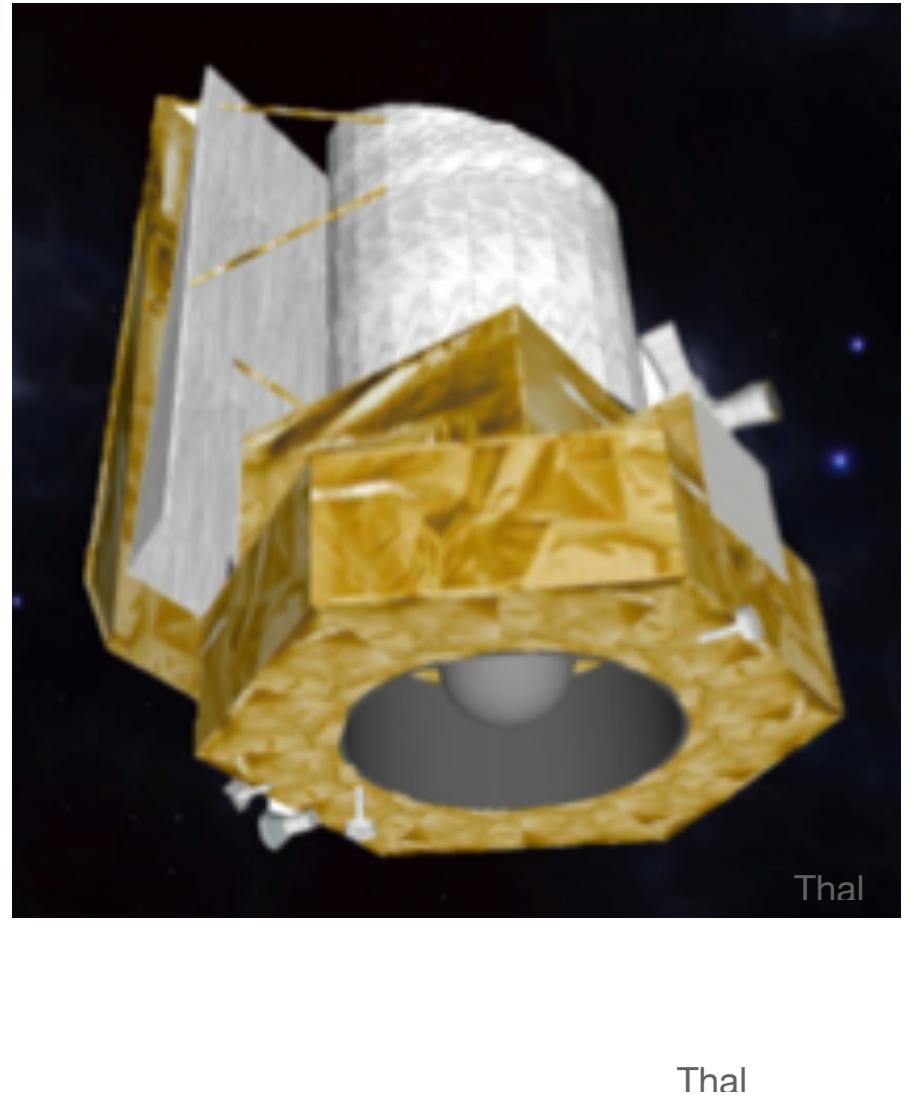

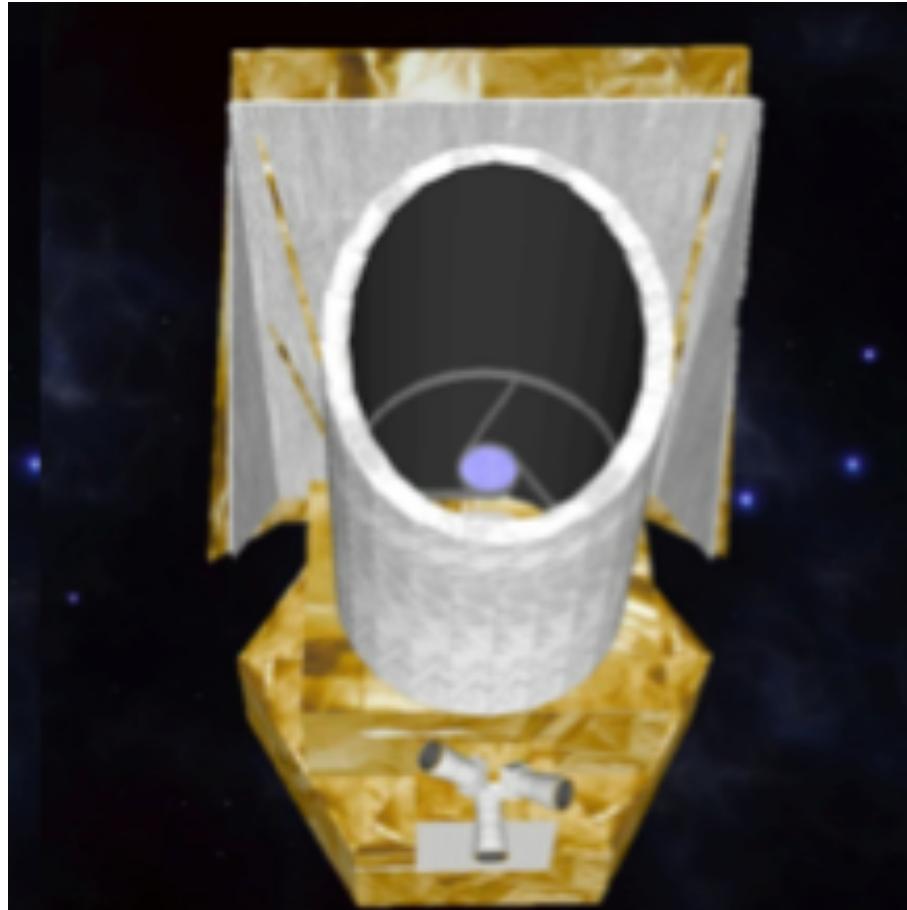

Distortion can be corrected by fitting the transformation (Sky \rightarrow Detector) as calculated by Ray-tracing (Zemax) by a 2D polynomial

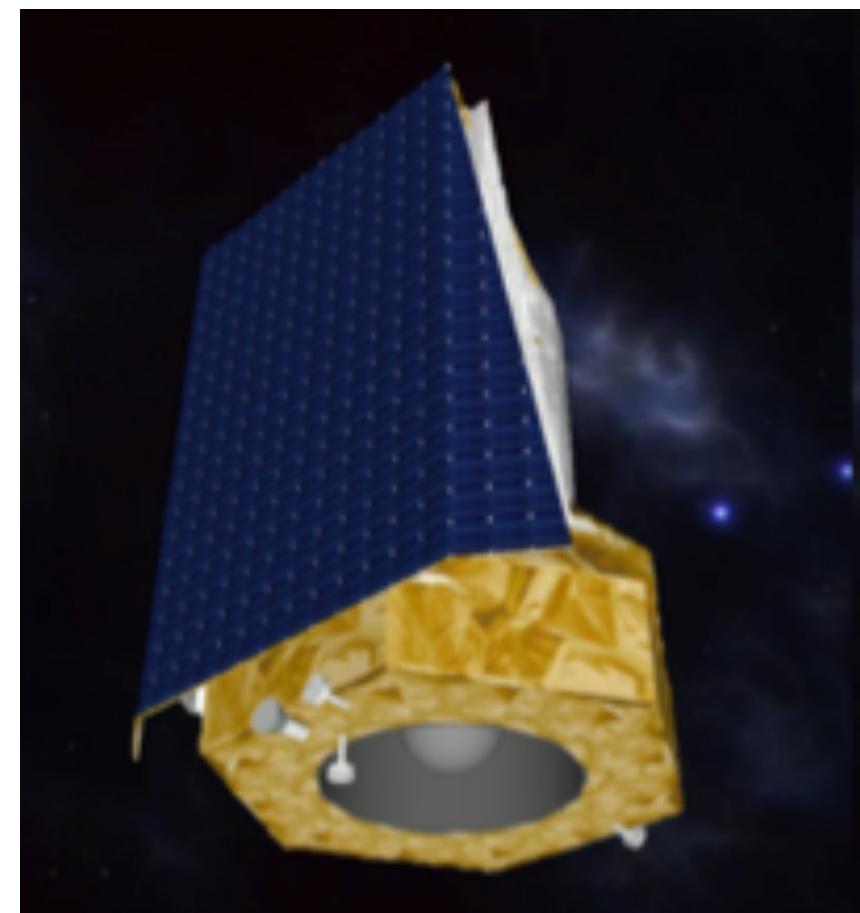

Simulated field-dependent distortion and fitted position

Theia mission profile

- **ESA-led, ESA-operated mission with consortium funded payload** (this is the normal type of ESA mission)
- Submitted for the **ESA M7 call** as an Ariane 6.02 launch
- Spacecraft dry mass with margin: 1063 kg. Total launch Mass: 1325 kg

Launch date	No constraints, allowing launch date in 2037
Orbit	Large Lissajous in L2
Lifetime	<ul style="list-style-type: none"> • 4 years of nominal science operations • Technical operations: 6 months orbit transfer plus instrument commissioning and 1 month decommissioning
Concept	Single spacecraft, single telescope in the PLM, single camera in the focal plane, metrological monitoring of PLM
Communication architecture	75 Mbps, 4h/day

Conclusion and perspectives

- One of Theia main science objectives is to identify planets down to the Earth mass ($M \leq 5 M_{\text{Earth}}$) exoplanets in the habitable zone of Solar-type stars in the vicinity of the Sun ($d \leq 30$ pc)
- Astrometry allows planet masses to be measured even for stars with stellar activity
- Pointed differential astrometry allows the number of exposures to be increased compared to global astrometry allowing to reach sub-microarcsecond accuracy
- Synergy with RV for long period and massive planets should allow us to identify Solar-type exo planetary systems
- Technical challenges are the focal plane array and mitigation of the optical distortion of the telescope: new detectors and new calibration strategy are under investigation with lab test benches.
- **Science Theia workshop planned for mid 2024** (stay tuned!)
