**Abstract:** Revised measurements of hominoid teeth from Berg Aukas, Namibia, indicate that the two species previously reported from the site were of similar body size, raising the possibility that there might be only a single species present. However comparisons of dental morphology confirm the hypothesis of two species, *Otavipithecus namibiensis* and cf *Kenyapithecus* sp. closer in dimensions to *K. africanus* than to *K. wickeri*.

**Key words:** Late Middle Miocene, Hominoidea, Africa, Measurements, Dentition

### INTRODUCTION

The sample of late Middle Miocene hominoids from Namibia was recently augmented by the description of several dentognathic and postcranial specimens collected at Berg Aukas during the 1960's (Mocke et al. 2022). In that study, the material was interpreted to belong to a genus close to *Kenyapithecus*, because the morphology of the cheek teeth is closer to the situation in *Kenyapithecus wickeri* Leakey, 1962, from Kenya, than it was to the type material of *Otavipithecus namibiensis* Conroy et al. 1992. Restudy of all the Berg Aukas fossils in 2022 led to the realisation that the published measurements were taken in slightly different ways from the usual method. We herein publish revised measurements of the dental remains (Table 1).

### MATERIAL AND METHODS

The fossils are curated at the Earth Science Museum, Geological Survey of Namibia, Windhoek, under the register numbers GSN BA 11'21, mandible and GSN BA 12'21, upper molar. The mesio-distal length and buccolingual breadth of the fossil teeth were measured using metal sliding calipers to the nearest tenth of a mm.

### RESULTS

The new measurements of all the Berg Aukas hominoid teeth indicate that the recently described material (Mocke et al. 2022) agrees in metric details with the previously described hypodigm of *Otavipithecus namibiensis* (Conroy et al. 1992) (Table 1, Fig. 6). As a result, the length/breadth ratios of the teeth are slightly different from what was previously published, and now accord more closely in length/breadth proportions to the original hypodigm of *Otavipithecus namibiensis*. However, the morphology of the teeth indicate that there are indeed two taxa of hominoids in the Berg Aukas sample, *Otavipithecus namibiensis* and a *Kenyapithecus*-like form (Figs 1-4). 35 Comparison of the upper molar from Berg Aukas (GSN

BA 12'21) with East African hominoids, reveals similarities to the species *Kenyapithecus africanus* (Le Gros Clark & Leakey, 1950) (Fig. 5).

## CONCLUSION

Revised measurements and reexamination of the dental sample of hominoid fossils from Berg Aukas, Namibia (late Middle Miocene) indicate that the two species of apelike creature that have been reported from there were of similar body size, but that the differences in dental morphology indicate that they belong to distinct genera, as was concluded in previous studies.

## ACKNOWLEDGEMENTS

We thank Mr Faan Van der Merwe for providing access to the fossils for detailed study. The National Commission on Research, Science and Technology authorised the Namibia Palaeontology Expedition to carry out research in the country. The NPE is a collaborative project undertaken by the Geological Survey of Namibia and the French National Museum of Natural History/Sorbonne University (CR2P). Funding was provided by the ATM project PalPrim Namibie (Paléobiodiversité des Primates du Néogène et du Quaternaire en Namibie) and by the Simone and Cimo Del Duca Foundation (Institut de France).
