Abstract. In this paper, we present an efficient attack against PROV, a recent variant of the popular Unbalanced Oil and Vinegar (UOV) multivariate signature scheme, that has been submitted to the ongoing NIST standardization process for additional post-quantum signature schemes. A notable feature of PROV is its proof of security, namely, existential unforgeability under a chosen-message attack (EUF-CMA), assuming the hardness of solving the system formed by the public-key non-linear equations. We present a polynomial-time key-recovery attack against the first specification of PROV (v1.0). To do so, we remark that a small fraction of the PROV secret-key is leaked during the signature process. Adapting and extending previous works on basic UOV, we show that the entire secret-key can be then recovered from such a small fraction in polynomial-time. This leads to an efficient attack against PROV that we validated in practice. For all the security parameters suggested by the authors of PROV, our attack recovers the secret-key in at most 8 seconds. We conclude the paper by discussing the apparent mismatch between such a practical attack and the theoretical security claimed by PROV designers. Our attack is not structural but exploits that the current specification of PROV differs from the required security model. A simple countermeasure makes PROV immune against our attack and led the designers to update the specification of PROV (v1.1).

Keywords: Post-quantum · NIST PQC · Cryptanalysis · Key-Recovery

1 Introduction

In 2022, the National Institute of Standards and Technology (NIST) selected the first post-quantum cryptographic standards after five years of competition. In particular, three digital signature schemes (DSS) relying either on structured lattices (Dilithium [16] and Falcon [13]) or hash functions (SPHINCS+ [10]) have been selected for standardization. NIST also decided to start a new standardization process for additional post-quantum DSS to increase the diversity of hardness assumptions. From a practical point of view, the new call was especially targeting schemes with “*short signature*” and “*fast verification*” [1].

Such practical features are typical of multivariate schemes. As such, UOV [11] appears today as the most appealing candidate such that round-1 candidates of the new NIST standardization process [1] includes about 8 UOV-based DSS¹. A promising candidate among these UOV-variants is the PRovable Unbalanced Oil and Vinegar (PROV) that includes a strong security argument with an EUF-CMA security proof under the hardness assumption of solving PROV public-key multivariate equations. Until now, no security weakness has been reported against PROV.

1.1 Organization of the Paper and Main Results

We organize the paper as follows. In Sect. 2, we introduce the necessary notations, mathematical objects, and the security framework used in PROV. In Sect. 3, we recall the PROV signature scheme as defined in the NIST-specification v1.0 [6]. Also, we extend the new Kipnis-Shamir attack on UOV of [14] to PROV, which recovers the secret-key in polynomial-time for small parameters. Section 4 describes our attack: Sects. 4.1 and 4.2 details a polynomial-time key-recovery attack against PROV specification v1.0 (Theorem 1). To do so, we exploit the fact that a small fraction of the secret-key is leaked during the signature generation. Then, we extend to the specific characteristics of PROV results from [2, 14] on UOV demonstrating that the entire secret-key can be then recovered from this small leakage. The attack has a polynomial-time complexity and is also very efficient in practice. In Sect. 4.3, we present experimental results and show that the secret key can be recovered in a few seconds for all security levels (Table 2). Section 4.4 discusses a simple tweak that prevents this attack and reestablishes the validity of the security model used in [6]. The vulnerability was reported to the designers of PROV who then updated the specification (v1.1, [7]) with this countermeasure.

2 Preliminaries

2.1 Notations

Let q be a prime or a prime power (for PROV, $q = 2^8$). We denote by bold lowercase (resp. capital) letter any column vector $\mathbf{v} \in \mathbb{F}_q^n$ of size n in \mathbb{F}_q or respectively any matrix $\mathbf{M} \in \mathbb{F}_q^{n \times m}$ of size $n \times m$ in \mathbb{F}_q . In particular, let $\mathbf{0}_n$ be the zero column vector of size n in \mathbb{F}_q , $\mathbf{0}_{n \times m}$ be the zero matrix of size $n \times m$ in \mathbb{F}_q and $\mathbf{1}_n$ be the n -by- n identity matrix in \mathbb{F}_q . For a set of vector $\mathbf{b} = (\mathbf{b}_1, \dots, \mathbf{b}_m) \in (\mathbb{F}_q^n)^m$, we denote by $\text{span}(\mathbf{b}) \subset \mathbb{F}_q^n$ the linear span of \mathbf{b} . Also, we express the kernel of a matrix $\mathbf{M} \in \mathbb{F}_q^{n \times m}$ or a linear map f respectively by $\text{Ker}(\mathbf{M})$ and $\text{Ker}(f)$. For the complexity analysis, we consider ω the exponent of matrix multiplication where $2 \leq \omega \leq 3$.

The function `Upper` takes as input a square matrix $\mathbf{A} = \{a_{i,j}\}_{1 \leq i,j \leq n}$ and outputs an upper triangular matrix $\text{Upper}(\mathbf{A}) = \{b_{i,j}\}_{1 \leq i,j \leq n}$ such that $b_{i,j} = a_{i,j} + a_{j,i}$ if $i < j$, $b_{i,j} = a_{i,j}$ if $i = j$ or $b_{i,j} = 0$ otherwise. We refer by the symbol

¹ <https://csrc.nist.gov/Projects/pqc-dig-sig/round-1-additional-signatures>.

|| either the concatenation of two bit-strings or the horizontal concatenation of two matrices depending on the context. Let \emptyset be the empty set, i.e. the set with no element.

Let $\mathbb{F}_q[x_1, \dots, x_n]$ be the ring of multivariate polynomials in n variables with coefficients over \mathbb{F}_q . In this work, every quadratic polynomial $p \in \mathbb{F}_q[x_1, \dots, x_n]$ will be homogeneous, i.e. $p(\lambda(x_1, \dots, x_n)) = \lambda^2 p(x_1, \dots, x_n)$, for all $\lambda \in \mathbb{F}_q^*$. The polar form $p^* : \mathbb{F}_q^n \times \mathbb{F}_q^n \rightarrow \mathbb{F}_q$ of a homogeneous quadratic polynomial $p \in \mathbb{F}_q[x_1, \dots, x_n]$ is a bi-linear and symmetric function defined as $p^*(\mathbf{x}, \mathbf{y}) := p(\mathbf{x} + \mathbf{y}) - p(\mathbf{x}) - p(\mathbf{y})$ for all $\mathbf{x}, \mathbf{y} \in \mathbb{F}_q^n$. Any homogeneous quadratic polynomial $p \in \mathbb{F}_q[x_1, \dots, x_n]$ can be uniquely represented as $p(\mathbf{x}) = \mathbf{x}^\top \mathbf{Q} \mathbf{x}$, where $\mathbf{Q} \in \mathbb{F}_q^{n \times n}$ is an upper triangular matrix, and the corresponding polar form as $p^*(\mathbf{x}, \mathbf{y}) = \mathbf{x}^\top (\mathbf{Q} + \mathbf{Q}^\top) \mathbf{y}$ with $\mathbf{x}, \mathbf{y} \in \mathbb{F}_q^n$. A multivariate quadratic map $\mathcal{P} : \mathbb{F}_q^n \rightarrow \mathbb{F}_q^m$ is defined by a set of multivariate quadratic polynomials $(p_1, \dots, p_m) \in \mathbb{F}_q[x_1, \dots, x_n]^m$.

2.2 Security Framework of PROV

Here, we recall the definition of a Weak Preimage-Sampleable Function (WPSF) used in the security analysis of PROV [6].

Definition 1 (WPSF [6]). *A WPSF \mathbf{T} consists of four probabilistic polynomial-time algorithms:*

- **Gen**: *this algorithm takes as input a security parameter 1^λ and outputs a function $\mathbf{F} : \mathcal{X} \rightarrow \mathcal{Y}$ with a trapdoor \mathbf{I} ;*
- **F**: *this algorithm takes as input a value $x \in \mathcal{X}$ and deterministically outputs $\mathbf{F}(x)$;*
- **I** = $(\mathbf{I}^1, \mathbf{I}^2)$: *the algorithm \mathbf{I}^1 takes no input and outputs a value $z \in \mathcal{Z}$; the algorithm \mathbf{I}^2 takes as input $z \in \mathcal{Z}$, $y \in \mathcal{Y}$, and outputs $x \in \mathcal{X}$ such that $\mathbf{F}(x) = y$, or outputs \perp if it failed;*
- **SampDom**: *this algorithm takes as input a function $\mathbf{F} : \mathcal{X} \rightarrow \mathcal{Y}$ and outputs a value $x \in \mathcal{X}$.*

The Preimage Sampling (PS) security of a WPSF is defined as:

Definition 2 (PS security [6]). *Let T be a WPSF. The advantage of an adversary \mathcal{A} against the PS security of \mathbf{T} is defined as:*

$$\text{Adv}_{\mathbf{T}}^{\text{PS}}(\mathcal{A}) = \left| \Pr \left[\text{PS}_0^{\mathcal{A}} = 1 \right] - \Pr \left[\text{PS}_1^{\mathcal{A}} = 1 \right] \right|$$

where PS_0 and PS_1 are the security games defined in Fig. 1.

3 Description of PROV

PROvable Unbalanced Oil and Vinegar (PROV) is a new signature scheme [6] submitted to the recent NIST standardization process for additional post-quantum signature schemes [1]. As several multivariate schemes submitted to this standardization process, PROV is a variant of the Unbalanced Oil and Vinegar (UOV) multivariate signature scheme [11].

PROV uses the the recent definition of UOV introduced by W. Beullens in [5] in combination with an efficient variant of the so-called salt-UOV [15], a provably secure variant of UOV. In [5], the traditional UOV trapdoor [11] is rephrased as the vanishing subspace of a multivariate quadratic map.

Definition 3. Let $\mathcal{P} : \mathbb{F}_q^n \rightarrow \mathbb{F}_q^m$ be a multivariate quadratic map and $\mathbf{O} \subset \mathbb{F}_q^n$ be a linear subspace. We shall say that \mathbf{O} is a vanishing subspace of \mathcal{P} if:

$$\forall \mathbf{o} \in \mathbf{O}, \mathcal{P}(\mathbf{o}) = \mathbf{0}_m.$$

From a high-level point of view, the public-key in PROV is given by the multivariate quadratic map $\mathcal{P} : \mathbb{F}_q^n \rightarrow \mathbb{F}_q^m$ and the corresponding secret-key is a vanishing subspace $\mathbf{O} \subset \mathbb{F}_q^n$ of dimension $m + \delta$ with $\delta \geq 1$. The main specificity of PROV is related to the parameter δ that allows a more efficient reduction than salt-UOV [15]. From now on, we set $v = n - m - \delta$.

3.1 Key-Generation in PROV

In order to generate a PROV key pair (Definition 3) $(\mathcal{P}, \mathbf{O})$ with $\mathcal{P} : \mathbb{F}_q^n \rightarrow \mathbb{F}_q^m$ and a vanishing subspace $\mathbf{O} \subset \mathbb{F}_q^n$ of dimension $m + \delta$ with $\delta \geq 1$, [6] suggests to first generate a random basis of \mathbf{O} in systematic form, i.e. namely a basis of the form:

$$(\mathbf{O}^\top \mathbf{1}_{m+\delta}) \in \mathbb{F}_q^{(m+\delta) \times n}, \text{ with } \mathbf{O} \in \mathbb{F}_q^{v \times (m+\delta)}. \quad (1)$$

Then, the components $p_1, \dots, p_m \in \mathbb{F}_q[x_1, \dots, x_n]$ of $\mathcal{P} : \mathbb{F}_q^n \rightarrow \mathbb{F}_q^m$ are constructed as follows:

$$p_i(\mathbf{x}) = \mathbf{x}^\top \mathbf{P}_i \mathbf{x}, \quad \mathbf{P}_i = \begin{pmatrix} \mathbf{P}_i^{(1)} & \mathbf{P}_i^{(2)} \\ \mathbf{0}_{(m+\delta) \times v} & \mathbf{P}_i^{(3)} \end{pmatrix} \in \mathbb{F}_q^{n \times n}, \forall i, 1 \leq i \leq m, \quad (2)$$

with $\mathbf{x} = (x_1, \dots, x_n) \in \mathbb{F}_q^n$, $\mathbf{P}_i^{(1)} \in \mathbb{F}_q^{v \times v}$ be an upper triangular matrix, $\mathbf{P}_i^{(2)} \in \mathbb{F}_q^{v \times (m+\delta)}$ be a matrix and $\mathbf{P}_i^{(3)} = \text{Upper} \left(-\mathbf{O}^\top \mathbf{P}_i^{(1)} \mathbf{O} - \mathbf{O}^\top \mathbf{P}_i^{(2)} \right) \in \mathbb{F}_q^{(m+\delta) \times (m+\delta)}$. The linear subspace \mathbf{O} generated as in (1) is a vanishing subspace of the map defined by the polynomials (2).

3.2 Signature Verification and Generation

The PROV signature for a message $\text{msg} \in \{0, 1\}^*$ is given by a vector $\mathbf{s} \in \mathbb{F}_q^n$ and a fixed-length bit string $\text{salt} \in \{0, 1\}^{\text{len}_{\text{salt}}}$ such that

$$\mathcal{P}(\mathbf{s}) = \mathcal{H}(\text{msg} \parallel \text{salt}),$$

where $\mathcal{H} : \{0, 1\}^* \rightarrow \mathbb{F}_q^m$ is a hash function².

The PROV trapdoor is based on the result below, demonstrating that the knowledge of the vanishing subspace allows one to compute a valid signature by solving a linear system.

Lemma 1. *Let $\mathbf{O} \in \mathbb{F}_q^{v \times (m+\delta)}$, $\mathcal{P} : \mathbb{F}_q^n \rightarrow \mathbb{F}_q^m$ be represented with matrices $(\mathbf{P}_1, \dots, \mathbf{P}_m) \in (\mathbb{F}_q^{n \times n})^m$ as defined in (2), $\bar{\mathbf{v}} = \begin{pmatrix} \mathbf{v} \\ \mathbf{0}_{m+\delta} \end{pmatrix}$, $\bar{\mathbf{o}} = \begin{pmatrix} \mathbf{O} \\ \mathbf{1}_{m+\delta} \end{pmatrix}$, $\mathbf{o} \in \mathbb{F}_q^n$, with $\mathbf{v} \in \mathbb{F}_q^v$ and $\mathbf{o} \in \mathbb{F}_q^{(m+\delta)}$. For all $\mathbf{h} = (h_1, \dots, h_m) \in \mathbb{F}_q^m$, it holds that:*

$$\mathcal{P}(\bar{\mathbf{v}} + \bar{\mathbf{o}}) = \mathbf{h} \iff \mathbf{v}^\top \mathbf{S}_i \mathbf{o} = h_i - \mathbf{v}^\top \mathbf{P}_i^{(1)} \mathbf{v}, \forall i, 1 \leq i \leq m,$$

with $\mathbf{S}_i = (\mathbf{P}_i^{(1)} + \mathbf{P}_i^{(1)\top}) \mathbf{O} + \mathbf{P}_i^{(2)} \in \mathbb{F}_q^{v \times (m+\delta)}$.

In order to generate a signature of $\text{msg} \in \{0, 1\}^*$, the signer generates a random pair $(\mathbf{v}, \text{salt}) \in \mathbb{F}_q^v \times \{0, 1\}^{\text{len}_{\text{salt}}}$ and solves the corresponding linear system of Lemma 1 with $\mathbf{h} = \mathcal{H}(\text{msg} \parallel \text{salt}) \in \mathbb{F}_q^m$. If the linear system has no solution, then the signer samples a new $\text{salt} \in \{0, 1\}^{\text{len}_{\text{salt}}}$ and solves the new system. The process is repeated until a solution exists. Finally, he recovers the signature $\mathbf{s} = \bar{\mathbf{v}} + \bar{\mathbf{o}} \in \mathbb{F}_q^n$, with $\bar{\mathbf{v}}, \bar{\mathbf{o}} \in \mathbb{F}_q^n$ as in Lemma 1. We detail the PROV signature generation in Algorithm 1.

Remark 1. Note that the vector $\bar{\mathbf{o}}$ belongs in the secret vanishing subspace \mathbf{O} of the public key.

Given a matrix $\mathbf{A} \in \mathbb{F}_q^{m \times n}$, and vector $\mathbf{b} \in \mathbb{F}_q^m$, the algorithm `LinSolve` outputs the set of all solutions $\mathbf{x} \in \mathbb{F}_q^n$ of the linear system $\mathbf{A}\mathbf{x} = \mathbf{b}$.

² Precisely, in [6], they generate \mathbf{h} as $\mathcal{H}(4 \parallel \text{hpk} \parallel \text{msg} \parallel \text{salt})$ where `hpk` is a hash of the public key and a secret seed. We omit this detail to simplify the presentation.

3.3 Security of PROV

An appealing feature of PROV lies in its security proof where existential forgery under chosen message attacks (EUF-CMA) can be reduced to the problem of inverting the public-key polynomials defined as follows:

Definition 4 (UOV⁻ problem). Let $\mathbf{p} = (p_1, \dots, p_m) \in \mathbb{F}_q[x_1, \dots, x_n]^m$ be quadratic polynomials corresponding to a PROV public-key and $\mathbf{d} = (d_1, \dots, d_m) \in \mathbb{F}_q^m$. The UOV⁻ problem asks to find a solution to the non-linear system of equations:

$$p_1 - d_1 = 0, \dots, p_m - d_m = 0.$$

As discussed in [6], the best approaches known for solving the UOV⁻ problem are generic techniques for solving non-linear equations and then exponential in the classical and quantum settings [3, 4, 8, 9].

15	$\mathbf{s} \leftarrow \begin{pmatrix} \mathbf{v} \\ \mathbf{0}_{m+\delta} \end{pmatrix} + \begin{pmatrix} \mathbf{O} \\ \mathbf{1}_{m+\delta} \end{pmatrix} \mathbf{o}$
16	Return $(\mathbf{s}, \text{salt})$

3.4 Kipnis-Shamir Attack When $n \leq 2m$ and $\delta \geq 1$

In [12], Kipnis and Shamir introduced a polynomial-time key-recovery attack on Oil and Vinegar signature scheme (when $n = 2m$ and $\delta = 0$). This attack has been improved in [14] when $n \leq 2m$ and $\delta = 0$. Here, we extend this attack to PROV when $n \leq 2m$ and $\delta \geq 1$. First, let recall a special property of the polar form of a PROV key pair.

Lemma 2 ([14]). Let $\mathcal{P} : \mathbb{F}_q^n \rightarrow \mathbb{F}_q^m$ be a multivariate quadratic map, $\mathbf{O} \subset \mathbb{F}_q^n$ be a vanishing subspace of \mathcal{P} and $\mathcal{P}^* : \mathbb{F}_q^n \times \mathbb{F}_q^n \rightarrow \mathbb{F}_q^m$ be the polar form of \mathcal{P} . Then, for all $(\mathbf{o}_1, \mathbf{o}_2) \in \mathbf{O}^2$, we have $\mathcal{P}^*(\mathbf{o}_1, \mathbf{o}_2) = \mathcal{P}^*(\mathbf{o}_2, \mathbf{o}_1) = \mathbf{0}_m$.

This characteristic restricts the rank of the matrices representing the polar form for large dimensional vanishing subspace.

Corollary 1. *Let $p \in \mathbb{F}_q[x_1, \dots, x_n]$ be a homogeneous polynomial represented as $p(\mathbf{x}) = \mathbf{x}^\top \mathbf{P} \mathbf{x}$ with $\mathbf{P} \in \mathbb{F}_q^{n \times n}$ and $\mathbf{x} \in \mathbb{F}_q^n$, $\mathcal{O} \subset \mathbb{F}_q^n$ be a vanishing subspace of p with $\dim(\mathcal{O}) = m + \delta$. Then, the rank of the matrix $\mathbf{P}' = (\mathbf{P} + \mathbf{P}^\top) \in \mathbb{F}_q^{n \times n}$ is at most $2n - 2(m + \delta)$.*

This proof combines ideas of [14] but is provided for the sake of correctness and completeness.

Proof. Let $\mathbf{B}_1 \in \mathbb{F}_q^{n \times (m+\delta)}$ be a basis of \mathcal{O} and $\hat{\mathbf{B}} \in \mathbb{F}_q^{n \times n}$ be a basis of \mathbb{F}_q^n such that $\hat{\mathbf{B}} = (\mathbf{B}_1 || \mathbf{B}_2)$ with $\mathbf{B}_2 \in \mathbb{F}_q^{n \times v}$. By Lemma 2, we obtain $\mathbf{B}_1^\top \mathbf{P}' \mathbf{B}_1 = \mathbf{0}_{m+\delta}$. Therefore, the matrix \mathbf{P}' in the basis $\hat{\mathbf{B}}$ has the following form

$$\hat{\mathbf{B}}^\top \mathbf{P}' \hat{\mathbf{B}} = \begin{pmatrix} \mathbf{0}_{(m+\delta) \times (m+\delta)} & \mathbf{C}_1 \\ \mathbf{C}_2 & \mathbf{C}_3 \end{pmatrix}$$

with $\mathbf{C}_1 \in \mathbb{F}_q^{(m+\delta) \times v}$, $\mathbf{C}_2 \in \mathbb{F}_q^{v \times (m+\delta)}$ and $\mathbf{C}_3 \in \mathbb{F}_q^{v \times v}$. Then, the rank of the matrix $\hat{\mathbf{B}}^\top \mathbf{P}' \hat{\mathbf{B}}$ is at most $2n - 2(m + \delta)$ because of the block of zero of size $m + \delta$ in the top left. Since the rank of a matrix is invariant by change of basis, this proves the rank of \mathbf{P}' is at most $2n - 2(m + \delta)$. \square

In [14], the author exploits this rank defect to recover a basis of the vanishing subspace by computing the kernel of the matrices $\mathbf{P}'_i \in \mathbb{F}_q^{n \times n}$ representing the polar form based on the assumption that $\text{Ker}(\mathbf{P}'_i) \subset \mathcal{O}$ with high probability for key pair obtained with PROV key-generation. In the next lemma, we precise the condition underlying this assumption.

Lemma 3. *Let $p \in \mathbb{F}_q[x_1, \dots, x_n]$ be a homogeneous polynomial represented as $p(\mathbf{x}) = \mathbf{x}^\top \mathbf{P} \mathbf{x}$ with $\mathbf{P} \in \mathbb{F}_q^{n \times n}$, $\mathcal{O} \subset \mathbb{F}_q^n$ be a vanishing subspace of p with $\dim(\mathcal{O}) = m + \delta$ and $p^* : \mathbb{F}_q^n \times \mathbb{F}_q^n \rightarrow \mathbb{F}_q$ be the polar form of p . If there exist no subspace $V \subset \mathbb{F}_q^n$ with dimension $m + \delta + r$ for any $1 \leq r \leq n - m - \delta$ where for all pairs $(\mathbf{v}_1, \mathbf{v}_2) \in V$, $p^*(\mathbf{v}_1, \mathbf{v}_2) = 0$ then $\text{Ker}(\mathbf{P}') \subset \mathcal{O}$ where $\mathbf{P}' = \mathbf{P} + \mathbf{P}^\top$.*

Proof. Let assume $\text{Ker}(\mathbf{P}') \not\subset \mathcal{O}$. Therefore, there exists a vector $\mathbf{x} \in \text{Ker}(\mathbf{P}')$ such that $\mathbf{x} \notin \mathcal{O}$. Since \mathcal{O} is a vector space in a finite field and $\mathbf{x} \notin \mathcal{O}$, then we have $\text{span}(\mathbf{x}) \not\subset \mathcal{O}$ and $\dim(\text{span}(\mathbf{x})) = 1$. Consider the vector space V defined by the closure of $\text{span}(\mathbf{x})$ and \mathcal{O} under the addition and the scalar multiplication. The linear subspace V is of dimension $m + \delta + 1$ because $\mathbf{x} \notin \mathcal{O}$. Also, let two vectors \mathbf{v}_1 and \mathbf{v}_2 of V that can be expressed as $\mathbf{v}_1 = \mathbf{o}_1 + \mathbf{x}_1$ and $\mathbf{v}_2 = \mathbf{o}_2 + \mathbf{x}_2$ with $\mathbf{o}_1, \mathbf{o}_2 \in \mathcal{O}$ and $\mathbf{x}_1, \mathbf{x}_2 \in \text{span}(\mathbf{x})$. If we evaluate the polar p^* on \mathbf{v}_1 and \mathbf{v}_2 , we obtain

$$p^*(\mathbf{v}_1, \mathbf{v}_2) = \mathbf{o}_1^\top \mathbf{P}' \mathbf{o}_2 + \mathbf{x}_1^\top \mathbf{P}' \mathbf{o}_2 + \mathbf{o}_1^\top \mathbf{P}' \mathbf{x}_2 + \mathbf{x}_1^\top \mathbf{P}' \mathbf{x}_2.$$

By Lemma 2, we deduce $\mathbf{o}_1^\top \mathbf{P}' \mathbf{o}_2 = 0$. Also, the matrix \mathbf{P}' is symmetric, therefore $\text{Ker}(\mathbf{P}') = \text{Ker}(\mathbf{P}'^\top)$. This implies $\mathbf{x}_1^\top \mathbf{P}' = \mathbf{0}_n^\top$ and $\mathbf{P}' \mathbf{x}_2 = \mathbf{0}_n$ because $\text{span}(\mathbf{x}) \subset$

$\text{Ker}(\mathbf{P}')$. We conclude $p^*(\mathbf{v}_1, \mathbf{v}_2) = 0$ for any vector \mathbf{v}_1 and \mathbf{v}_2 of V . This proves by contradiction that $\text{Ker}(\mathbf{P}') \subset \mathbf{O}$ because V is of dimension strictly larger than \mathbf{O} . \square

Now, we extend the polynomial-time key-recovery attack of [14] to PROV where $n \leq 2m$ and $\delta \geq 1$.

Lemma 4 (Kipnis-Shamir attack – Kernel Approach). *Let $\mathcal{P} : \mathbb{F}_q^n \rightarrow \mathbb{F}_q^m$ be a PROV public-key, $\mathbf{O} \subset \mathbb{F}_q^n$ be the vanishing subspace of \mathcal{P} with $\dim(\mathbf{O}) = m + \delta$ and $\delta \geq 1$ obtained with PROV key-generation (Subsect. 3.1). Then, there exists an algorithm that recovers a basis $\mathbf{B} \in \mathbb{F}_q^{n \times (m+\delta)}$ of \mathbf{O} in time $O(mn^\omega)$ with high probability when $n \leq 2m$.*

Proof. Let $(\mathbf{P}_1, \dots, \mathbf{P}_m) \in (\mathbb{F}_q^{n \times n})^m$ be the matrices representing the PROV public-key \mathcal{P} . By Corollary 1, we deduce the rank of the matrix $\mathbf{P}_i + \mathbf{P}_i^\top$ is at most $2n - 2(m + \delta)$ for $1 \leq i \leq m$. Since we clearly have $-2m \leq -n$, it follows that $2n - 2m - 2\delta \leq n - 2\delta$. Also, we know $-2\delta \leq -2$, therefore we obtain $2n - 2m - 2\delta \leq n - 2$. This implies the kernel of $\mathbf{P}_i + \mathbf{P}_i^\top$ is at least of dimension 2 because $\text{rank}(\mathbf{P}_i + \mathbf{P}_i^\top) \leq n - 2$ for $1 \leq i \leq m$. We assume the condition of Lemma 3 is satisfied with high probability, therefore we have $\text{Ker}(\mathbf{P}_i + \mathbf{P}_i^\top) \subset \mathbf{O}$ for $1 \leq i \leq m$. Since the m kernels of the polar form are at least of dimension 2 and $m + \delta \leq 2m$, an adversary recovers a basis of \mathbf{O} with high probability by computing the m random kernels for key pair obtained with PROV key generation. Finally, computing these kernels takes time $O(mn^\omega)$. This concludes the proof. \square

4 Polynomial-Time Attack Against PROV Specification

4.1 Overview

Our attack relies on the fact that the (vinegar) vector $\mathbf{v} \in \mathbb{F}_q^v$ is leaked and constant in the PROV specification v1.0 [6]. More precisely, the designers described a probabilistic signature generation, similar to Algorithm 1, only for “ease of exposition”. In practice, they deterministically generate \mathbf{v} as $\mathcal{H}(3||\text{msg})$ where \mathcal{H} is the hash function SHAKE256. We emphasize that the reference implementation generates the vinegar vector $\mathbf{v} \in \mathbb{F}_q^v$ similarly.

The vinegar vector (and the corresponding signature) leaks information about the secret-key, precisely it reveals one vector in the secret linear subspace $\mathbf{O} \subset \mathbb{F}_q^n$. Recently, [2] demonstrated an efficient attack allowing recovery of the entire secret-key from such a vector. Soon after in [14], it was proposed an even more efficient polynomial-time key-recovery attack on UOV using elementary linear algebra. In the next part, we adapt this key-recovery attack on PROV.

4.2 Description of the Attack

First, we explain why the PROV specification leaks one vector in the secret linear subspace.

Let $(\mathbf{v}, \mathbf{s}) \in \mathbb{F}_q^v \times \mathbb{F}_q^n$ be a pair of a vinegar vector and a signature³ for the message $\text{msg} \in \{0, 1\}^*$ and the PROV key pair $(\mathcal{P}, \mathbf{O})$ with $\mathcal{P} : \mathbb{F}_q^n \rightarrow \mathbb{F}_q^m$ and $\mathbf{O} \subset \mathbb{F}_q^n$. We recall that $\mathbf{s} = \bar{\mathbf{v}} + \bar{\mathbf{o}}$ where $\bar{\mathbf{v}}^\top = (\mathbf{v}^\top \parallel \mathbf{0}_{m+\delta}^\top) \in \mathbb{F}_q^n$ and $\bar{\mathbf{o}} \in \mathbb{F}_q^n$. As discussed above, the pair (\mathbf{v}, \mathbf{s}) is public. Therefore, any adversary can compute a vector in the secret linear subspace $\bar{\mathbf{o}} = \mathbf{s} - \bar{\mathbf{v}} \in \mathbf{O}$ (see Remark 1).

In the following, we focus on the key-recovery attack assuming the knowledge of one non-zero vector in the linear subspace. Also, we assume that $n \leq 3m$ (this statement holds for concrete parameters proposed in the PROV submission, see Table 1) and that the rank of the matrices $\mathbf{P}_1 + \mathbf{P}_1^\top, \dots, \mathbf{P}_m + \mathbf{P}_m^\top$ defined as in (2) is n . Now, we present an adaption of the attack from [14] to the PROV case (see Remark 2).

Lemma 5. *Let $\mathcal{P} : \mathbb{F}_q^n \rightarrow \mathbb{F}_q^m$ be a PROV public-key, $\mathbf{O} \subset \mathbb{F}_q^n$ be the vanishing subspace of \mathcal{P} where \mathcal{P} are represented with matrices $\mathbf{P}_1, \dots, \mathbf{P}_m \in \mathbb{F}_q^{n \times n}$ defined as in (2). Let $\mathbf{o} \in \mathbf{O} \setminus \{\mathbf{0}\}$ and $J_{\mathbf{o}}(\mathbf{z}) = (\mathbf{o}^\top(\mathbf{P}_1 + \mathbf{P}_1^\top)\mathbf{z}, \dots, \mathbf{o}^\top(\mathbf{P}_m + \mathbf{P}_m^\top)\mathbf{z})$ with $\mathbf{z} = (z_1, \dots, z_n)$ a vector of variables. Then, the subspace $\text{Ker}(J_{\mathbf{o}})$ is a $(n - m)$ -dimensional subspace with high probability and always satisfies*

$$\mathbf{O} \subset \text{Ker}(J_{\mathbf{o}}).$$

Proof. Let $\mathcal{P}^* : \mathbb{F}_q^n \times \mathbb{F}_q^n \rightarrow \mathbb{F}_q^m$ be the polar form of \mathcal{P} with components p_1^*, \dots, p_m^* where $p_i^*(\mathbf{y}, \mathbf{z}) = \mathbf{y}^\top(\mathbf{P}_i + \mathbf{P}_i^\top)\mathbf{z}$ for all $1 \leq i \leq m$. By Lemma 2, for all $\mathbf{x} \in \mathbf{O}$.

$$p_i^*(\mathbf{o}, \mathbf{x}) = 0, \forall 1 \leq i \leq m.$$

This implies that the kernel of the linear application $p_{i,\mathbf{o}}^*(\mathbf{z}) = \mathbf{o}^\top(\mathbf{P}_i + \mathbf{P}_i^\top)\mathbf{z}$ contains \mathbf{O} . By hypothesis, all the matrices $\mathbf{P}_1 + \mathbf{P}_1^\top, \dots, \mathbf{P}_m + \mathbf{P}_m^\top$ are of rank n and $\mathbf{o} \neq \mathbf{0}_n$, therefore $p_{i,\mathbf{o}}^*(\mathbf{z})$ is non-zero. Since the linear map is non-zero, its kernel is a hyperplane. We have shown that $\mathbf{O} \subset \text{Ker}(p_{i,\mathbf{o}}^*)$, for all $1 \leq i \leq m$. Therefore, we obtain:

$$\mathbf{O} \subset \bigcap_{1 \leq i \leq m} \text{Ker}(p_{i,\mathbf{o}}^*) = \text{Ker}(J_{\mathbf{o}})$$

Also, the hyperplanes are non-parallel, because we have $\mathbf{O} \subset \text{Ker}(p_{i,\mathbf{o}}^*)$ for all $1 \leq i \leq m$. Finally, the hyperplanes (i.e. the vectors $\mathbf{o}^\top(\mathbf{P}_1 + \mathbf{P}_1^\top), \dots, \mathbf{o}^\top(\mathbf{P}_m + \mathbf{P}_m^\top) \in \mathbb{F}_q^{1 \times n}$) are linearly independent with high probability for key pair obtained with PROV key-generation.⁴ Therefore, the intersection of the m hyperplanes has dimension $n - m$. This concludes the proof. \square

³ The salt is irrelevant for the attack, therefore we ignore it.

⁴ We verify in practice that this statement holds true.

Remark 2. In [14], the authors consider finite fields of odd characteristics and exploit the bijective relation $p = 2^{-1}p^*$ between any quadratic homogeneous polynomial $p \in \mathbb{F}_q[x_1, \dots, x_n]$ and its polar form $p^* : \mathbb{F}_q^n \times \mathbb{F}_q^n \rightarrow \mathbb{F}_q$. Therefore, any homogeneous quadratic polynomial $p \in \mathbb{F}_q[x_1, \dots, x_n]$ can be represented with a symmetric matrix $\mathbf{M} \in \mathbb{F}_q^{n \times n}$ such that $p(\mathbf{x}) = \mathbf{x}^\top \mathbf{M} \mathbf{x}$. However, a polynomial $p(\mathbf{x}) = \mathbf{x}^\top \mathbf{M} \mathbf{x}$ with a symmetric matrix \mathbf{M} is either linear or zero in a finite field of characteristic two (as with PROV). In other words, the bijective relation does not hold for finite fields of characteristic two (as discussed in [14, 17]). Therefore, we need to slightly adapt the approach from [14] by considering the polar form of the public-key and not by exploiting a symmetric representation of the public-key as in [14].

The next step is then essentially similar to [14, Theorem 7], namely we restrict the public-key polynomials on $\text{Ker}(J_{\mathbf{o}})$ and obtain new polynomial with fewer variables and the same secret vanishing subspace \mathbf{O} . The secret-key can be recovered in polynomial-time from these new polynomials.

Theorem 1. *Let $\mathcal{P} : \mathbb{F}_q^n \rightarrow \mathbb{F}_q^m$ be a PROV public-key, $\mathbf{O} \subset \mathbb{F}_q^n$ be the vanishing subspace of \mathcal{P} with $\dim(\mathbf{O}) = m + \delta$ where $\delta \geq 1$ and \mathcal{P} be represented by matrices $(\mathbf{P}_1, \dots, \mathbf{P}_m) \in (\mathbb{F}_q^{n \times n})^m$ defined as in (2). Then, there exists an adversary \mathcal{A} taking as input $((\mathbf{P}_1, \dots, \mathbf{P}_m), \mathbf{o}) \in (\mathbb{F}_q^{n \times n})^m \times \mathbf{O} \setminus \{\mathbf{0}\}$ that outputs a basis of \mathbf{O} in polynomial-time with high probability.*

The proof is similar to [14] but again provided for the sake of correctness and completeness.

Proof. Let $J_{\mathbf{o}}(\mathbf{z}) = (\mathbf{o}^\top(\mathbf{P}_1 + \mathbf{P}_1^\top)\mathbf{z}, \dots, \mathbf{o}^\top(\mathbf{P}_m + \mathbf{P}_m^\top)\mathbf{z})$ with $\mathbf{z} = (z_1, \dots, z_n)$ a vector of variables. By Lemma 5, $\mathbf{O} \subset \text{Ker}(J_{\mathbf{o}})$ for which a basis $\mathbf{B} \in \mathbb{F}_q^{n \times (n-m)}$ can be computed in $O(n^\omega)$, with $2 \leq \omega \leq 3$ the matrix multiplication exponent. Then, we restrict the public-key polynomials to $\text{Ker}(J_{\mathbf{o}})$. This yields:

$$\mathbf{P}_{i, \text{Ker}(J_{\mathbf{o}})} = \mathbf{B}^\top \mathbf{P}_i \mathbf{B}, \forall i, 1 \leq i \leq m.$$

The restricted public-key $\mathcal{P}_{\text{Ker}(J_{\mathbf{o}})} : \mathbb{F}_q^{(n-m)} \rightarrow \mathbb{F}_q^m$ can be computed in polynomial-time $O(mn^\omega)$ and be represented with matrices $\mathbf{P}_{1, \text{Ker}(J_{\mathbf{o}})}, \dots, \mathbf{P}_{m, \text{Ker}(J_{\mathbf{o}})} \in \mathbb{F}_q^{(n-m) \times (n-m)}$ is a PROV public key with parameters $(q, n - m, m, \delta)$ because $\mathbf{O} \subset \text{Ker}(J_{\mathbf{o}})$. Let $\bar{\mathbf{O}} \subset \mathbb{F}_q^{n-m}$ be the vanishing subspace of $\mathcal{P}_{\text{Ker}(J_{\mathbf{o}})}$ with $\dim(\bar{\mathbf{O}}) = m + \delta$. With our assumption $n \leq 3m$, we obtain $n - m \leq 2m$. The attack described in Lemma 4 recovers a basis $\mathbf{C} \in \mathbb{F}_q^{(n-m) \times (m+\delta)}$ of the secret subspace $\bar{\mathbf{O}}$ in time $O(mn^\omega)$. Then, for all i with $1 \leq i \leq m$, we have

$$(\mathbf{B}\mathbf{C})^\top \mathbf{P}_i \mathbf{B}\mathbf{C} = \mathbf{C}^\top (\mathbf{B}^\top \mathbf{P}_i \mathbf{B}) \mathbf{C} = \mathbf{C}^\top \mathbf{P}_{i, \text{Ker}(J_{\mathbf{o}})} \mathbf{C} = \mathbf{0}_{(m+\delta) \times (m+\delta)}.$$

Namely, the matrix $\mathbf{B}\mathbf{C} \in \mathbb{F}_q^{n \times (m+\delta)}$ is a basis of \mathbf{O} . Multiplying these matrices takes time $O(n^\omega)$ and concludes the proof that the secret-key can be recovered in $O(mn^\omega)$. \square

Remark 3. Our attack recovers the secret-key in polynomial-time with only one signature. However, an adversary can directly recover the secret-key with multiple signatures because we can view the PROV signature generation as an oracle of vectors in \mathcal{O} . Precisely, an adversary would recover uniformly distributed vectors in \mathcal{O} for signature requests on uniformly distributed messages (because the linear systems will be uniformly distributed, see Remark 1 of [6]). Therefore, an equivalent secret-key (i.e. $m + \delta$ linearly independent vectors of \mathcal{O}) can be recovered in a small amount of signature requests.

4.3 Experimental Results

In this part, we show that our attack is not only efficient from a theoretical point of view but also very practical. To do so, we implemented the attack (Theorem 1) in Sagemath⁵ [18] (taking as reference the code used in [14]) with the parameters of PROV suggested in [6] (Table 1). The non-zero vector of the vanishing subspace of the public key is generated with an oracle since such vector is leaked in PROV specification (Subsect. 4.2).

Table 1. Parameter sets of the PROV signature scheme.

Variant	λ	q	n	m	δ	v
PROV-I	128	256	136	46	8	82
PROV-III	192	256	200	70	8	122
PROV-V	256	256	264	96	8	160

We estimate the performance of the implementation on a single thread of a laptop with an Intel CPU i7-1365U at 5.2 GHz and with 32 GB of RAM. In Table 2, we report the experimental results obtained. To summarize, we recover the secret-key of PROV in a few seconds for every security level.

Table 2. Key-recovery attack of PROV.

Variant	PROV-I	PROV-III	PROV-V
Time	1.78.s	4.72.s	7.93s

4.4 Countermeasure

Before presenting the countermeasure, we briefly recall the security model used PROV. One idea of the proof is to model the PROV signature scheme as a weak preimage-sampleable function (WPSF) (Definition 1), denoted \mathbf{T}_{PROV} , such as:

⁵ Our implementation is available at <https://github.com/River-Moreira-Ferreira/prov-attack>.

- The algorithm $(pk, sk) \leftarrow \mathbf{Gen}$ is the PROV key-generation;
- The algorithm \mathbf{F} evaluates the PROV public-key;
- The algorithm $\mathbf{SampDom}$ uniformly generates a value in \mathbb{F}_q^n ;
- The pair of algorithms $\mathbf{I} = (\mathbf{I}^1, \mathbf{I}^2)$ are defined as follows:
 - The algorithm \mathbf{I}^1 outputs a uniformly distributed vector $\mathbf{v} \in \mathbb{F}_q^v$;
 - The algorithm \mathbf{I}^2 takes as input $(pk, sk, \mathbf{v}, \mathbf{y})$ with $\mathbf{v} \in \mathbb{F}_q^v$ and $\mathbf{y} \in \mathbb{F}_q^m$, performs one iteration of the while loop in the signature generation (see Algorithm 1) for the given vector \mathbf{v} and outputs a PROV signature $\mathbf{s} \in \mathbb{F}_q^n$ for $\mathbf{h} = \mathbf{y}$ or \perp if the iteration failed.

One can remark that the model assumes, in particular, that the vinegar vector should be uniform and kept secret to the adversary in PS security of \mathbf{T}_{PROV} (see Definition 2). Precisely, in the PS_0 game, the adversary has access to the oracle Sample_0 (both described in Fig. 1). The oracle Sample_0 keeps secret the value $z_i \leftarrow \mathbf{I}^1$ used for \mathbf{I}^2 from the adversary \mathcal{A} . Also, the algorithm \mathbf{I}^1 uniformly generates the vector $z_i \in \mathbb{F}_q^v$ for \mathbf{T}_{PROV} .

The specification of PROV v.1.0 differs from this model as the vinegar vector, which corresponds to a value $z_i \in \mathbb{F}_q^v$, is leaked during signature generation and constant.

The countermeasure appears evident when knowing this flaw in the security model: the vinegar vector should be uniformly generated and kept secret. This tweak will prevent an adversary from recovering easily a vector in the secret linear subspace with the previous strategy and makes PROV immune against our polynomial-time key-recovery attack.

For example, we can suggest generating the vector \mathbf{v} as $\mathcal{H}(3||s_{\text{sk}}||\text{msg})$ where s_{sk} is the secret seed uniformly generated during the key-generation (this was the strategy followed by others UOV candidates to the ongoing NIST standardization process). We will obtain a deterministic signature generation, as desired in the PROV specification.

Finally, we have reported this vulnerability to the designers of PROV and they updated the specification (v1.1, [7]) with such countermeasure.

Acknowledgement. We thank Pierre Pébereau, who helped us with some technical details of his attack and implementation [14]. Before publishing this work, we informed the authors of PROV that confirmed the flaw and released quickly a new specification (v.1.1). We would like to thank them for the constructive discussions. The second author would like to thank Google which partially supported this work thanks to a gift dedicated to post-quantum research. Also, we acknowledge the financial support of the French *Ministère des Armées - Agence de l'innovation de défense* on this research. Finally, the authors thanks the financial support on this research by QuanTEdu-France project (ANR-22-CMAS-0001) as part of France 2030.
