HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

Paraxial quantum fluids light in hot atomic vapors

Abstract. Hot atomic vapors are widely used in non-linear and quantum optics due to their large Kerr non-linearity. This non-linearity induces effective photon-photon interactions allowing light to behave as a fluid displaying quantum properties such as superfluidity. In this presentation, I will show that we have full control over the Hamiltonian that drives the system and that we can engineer an analogue simulator with light.

Quantum fluids of light rely on the analogy between the non-linear Schrodinger equation (NLSE) describing the propagation of light in non-linear media and the Gross-Pitaevskii equation (GPE) describing a weakly interacting Bose gas [1]. :

$$i\hbar \frac{\partial}{\partial t} \psi = \left(-\frac{\hbar^2}{2m} \nabla^2 + V + g|\psi|^2 \right) \psi \quad (\text{GPE})$$

$$i \frac{\partial}{\partial z} E = \left(\underbrace{-\frac{1}{2k_0} \nabla_{\perp}^2}_{\text{Kinetic}} - \underbrace{\frac{\delta n(\mathbf{r}) k_0}{2}}_{\text{Potential}} + i \frac{\alpha}{2} - \underbrace{n_2 k_0 |E|^2}_{\text{Interaction}} \right) E \quad (\text{NLSE})$$

In this presentation, I will show that we have full control over the three terms and we can engineer an analogue simulator with light.

By studying the effect of interaction quenches in the fluid [2], we evidence the dynamical Casimir effect i.e the spontaneous emission of correlated pairs of phonons. Employing Bragg spectroscopy, we measure the static structure factor of our fluid of light [3],

confirming the similarity between our photon-photon interactions and interatomic interactions in a BEC.

We merge novel characterization tools [4] and all optical potential in our latest experimental setup. Using beam shaping techniques, we realize arbitrary potential shapes and sign, allowing to explore new effects arising from confinement (see Fig. 1).

Finally, we control the initial kinetic energy distribution by sending intensity fluctuations on top of a gaussian background fluid, and measure the coherence of these fluctuations. We report on the observation of a pre-thermal state in a non-equilibrium, two-dimensional fluid of light. Direct measurements of the

first order coherence function of the fluid reveal the dynamical emergence of algebraic correlations, a quasi steady-state with properties close to those of thermal superfluids. We observe the emergence of a prethermal state [5] with long range order, with a topological phase transition precursor. With increasing fluctuation intensity, the coherence function switches from an algebraic to an exponential decay, strongly reminiscent of a BKT transition (see Fig. 2).
