HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

Numerical modelling the reaction propagation in Al based thermites

Reactive materials or nanothermites are composites or physical mixtures that demonstrate self-sustaining exothermic reactions upon receiving an initial energy input. This category of materials is distinctive within the realm of energetic materials, differing from explosives in the manner in which reaction fronts propagate subsonically and rely on atomic diffusion or other physical transport mechanisms. A range of studies have explored the numerical modeling of reaction propagation in Al-based thermites. Kim [1] and Tichtchenko [2] both focused on the self-propagation of combustion waves in nanoscale thermite composites, with Kim's model predicting wave speed and Tichtchenko's model analyzing the reaction front progression rate. Lahiner [3] proposed a diffusion-reaction scheme for predicting ignition and reaction dynamics in Al/CuO multilayered thin films, considering the decomposition of CuO and the diffusion of released oxygen. Tichtchenko [4] developed a model for predicting gas generation during the reaction of aluminum-based thermites, with a focus on pressure generation and its components. These studies contributed to the understanding of combustion of Al-based thermites, but do not consider coupled gas-condensed phased processes. In nano-sized materials especially, the combustion processes include thermal conduction, phase change, mass diffusion etc., which happen simultaneously and play an important role [5]. However, models considering coupling of thermo-mechanical-chemical physics are still absent. In this talk, I will present a novel one-dimensional deflagration model that describes the dynamics of the reaction front propagation in Al/CuO powdered thermite considering the reacting flow combined with heat transfer, chemistry and fluid flow. Separate mass, momentum and energy transport equations for the three phases, namely Al, CuO particles and gas mixture, are written in the frame of N-Euler approach for multiphase reactive flows. These equations are coupled by modeled interphase transfer terms.
