Arbitrary order expansions for the automatic reduction and solutions of nonlinear vibratory systems have been developed successfully within the realm of the direct parametrisation of invariant manifolds. Whereas the method has been used with high-order expansions and large dimensional systems, this article proposes to look at the same problem from the opposite view angle. By using low-dimensional systems, symbolic computations, analytical developments and numerical verifications, this contribution analyzes the reduced dynamics appearing in cases where a single master mode is involved, reviewing typical scenarios in nonlinear vibrations: primary resonance, sub- and superharmonic resonances and parametric excitation. To achieve this task, the normal form style is preferentially used. A symbolic open-source package is also provided to generalize the presented results to other styles, higher orders, and different scenarios. It is shown how the low-order terms allow recovering the classical solutions given by perturbation methods, and how the automated expansions allow one to generalize the analysis to arbitrary orders. When analytical solutions are not tractable anymore, numerical solutions are employed to underline how converged solutions are at hand when the validity limit of the expansions is not reached. All the results presented in this paper can thus be used to better understand the nonlinear dynamical solutions occurring in nonlinear vibrations, as well as from a system identification perspective, since the normal form is the simplest dynamical system displaying a given resonance scenario.

Keywords nonlinear oscillations, normal form, parametrisation method, geometric nonlinearity, nonlinear resonance, asymptotic expansion, symbolic calculation

1 Introduction

Since its introduction in an abstract framework in [Cabr e et al. \(2003\)](#); [Cabr e et al. \(2003\)](#); [Cabr e et al. \(2005\)](#); [Haro et al. \(2016\)](#), the parametrisation method for invariant manifolds has been extensively used in order to produce arbitrary order expansions for model order reduction of systems with smooth nonlinearities. It has been used in the field of nonlinear vibrations in [Haller et al. \(2016\)](#), allowing demonstration of the existence and uniqueness of spectral submanifolds (SSMs). Since then, it has then been successfully used for the reduced order modelling of large dimensional problems discretized by the finite element (FE) procedure, see *e.g.* [Jain et al. \(2022\)](#); [Li et al. \(2022\)](#); [Vizzaccaro et al. \(2022\)](#); [Opreni et al. \(2023\)](#); [Martin et al. \(2023\)](#); [Vizzaccaro et al. \(2023\)](#).

Another powerful result given by the method is also to unify the two main approaches that have been used in the past to compute nonlinear normal modes (NNMs). The center manifold technique has been used in the works by Shaw and Pierre to derive reduced-order models based on invariant manifold theory ([Shaw et al. 1991](#); [Shaw et al. 1993](#); [Shaw et al. 1999](#)), whereas the normal form approach has been proposed in [J ez eque et al. \(1991\)](#); [Touz e et al. \(2004\)](#); [Touz e et al. \(2006\)](#) in order to arrive to close results. The exact link between the two approaches has been only recently uncovered by using the parametrisation method for invariant manifolds, which highlights that the two techniques are in fact two different styles of parametrisation that can be used to solve for the invariance equation.

Whereas previous works on the subject focus on direct applications to large dimensional FE problems to underline the impressive gains in computing time that can be expected from the application of the method, this contribution aims to give more insights into the results that can be awaited from a broad use of the method to derive accurate, high-order analytical results obtained thanks to symbolic computations on low-dimensional systems. To that purpose, a symbolic

package which relies on the previous developments of the MORFE project (MORFE stands for Model Order Reduction for Finite Element problems) is released with the present article in order to help the analyst in producing automated solutions up to arbitrary order. This paper illustrates how such outputs can be used to analyze the high-order reduced dynamics in different scenarios and using *ad hoc* assumptions. In particular, it will be clearly shown how the first-order solutions are completely equivalent to standard perturbative solutions. When the solutions are analytically tractable, they will be symbolically analyzed to show how one can easily get more accurate approximations that take into account the next orders. Finally, when the analytical solutions are too lengthy, it will be illustrated how one can then easily use numerical solutions to reach convergence to a reference solution, once the validity limit of the local expansions is not hit. The purpose of all these developments is thus to show the continuity that exists between low-order perturbative techniques and high-order numerical solutions, showing to the analyst how the method can be used in an integrated manner since providing both analytical approximations for the design and system understanding phase, and accurate numerical solution.

The development and release of symbolic softwares for computing high-order normal form solutions, center manifold approximations or automated perturbative techniques, is not new and has been largely documented in the past, see for example [Elphick et al. \(1987\)](#); [Roberts \(1997\)](#); [Leung et al. \(1998\)](#); [Yagasaki \(1998\)](#); [Yagasaki \(1999\)](#); [Yagasaki et al. \(1999\)](#); [Huseyin et al. \(2000\)](#); [Zhang et al. \(2000\)](#); [Leung et al. \(2003\)](#) for different proposals. However, we believe that, by replacing the normal form development in the more general framework of the parametrisation method, and proposing a symbolic software in order to automatically derive such high-order solutions, including also the graph style parametrisation, is a needed development in order to give more physical insights into the powerful results obtained when using large dimensional systems. Moreover, we will show in the course of the article that the results analyzed are general and can be used to better understand the reduced dynamics of large-scale problems, as well as to propose arbitrary order analytical solutions for nonlinear vibration problems. Moreover, thanks to the original treatment of the non-autonomous forcing term recently proposed in [Vizzaccaro et al. \(2023\)](#), the analysis can be enlarged to a high level of forcing and can treat any type of classical resonance scenario occurring in nonlinear vibrations: primary resonance, subharmonic and superharmonic resonance, parametric resonance, ...

Another target of the analytical developments presented in this contribution is to give a detailed explanation of the different variants of normal forms that have been used in the literature on nonlinear vibration, by proposing a unified presentation that also explains their advantages and drawbacks. Indeed, while complex normal form (CNF) is generally in use in the mathematical literature, see e.g. [Haragus et al. \(2009\)](#); [Iooss et al. \(1998\)](#); [Jézéquel et al. \(1991\)](#); [Gabale et al. \(2009\)](#); [Haller et al. \(2016\)](#); [Waswa et al. \(2020\)](#), a real normal form has been introduced in [Neild et al. \(2011\)](#); [Neild et al. \(2015\)](#) and analyzed in [Vizzaccaro et al. \(2022\)](#); [Opreni et al. \(2023\)](#) in the context of the parametrisation method. Furthermore, another variant of the normal form has been used in [Touzé et al. \(2004\)](#); [Touzé et al. \(2006\)](#); [Touzé \(2014\)](#) in order to keep real oscillator-like equations throughout the process. This third variant is called the *oscillator normal form* (ONF) and has been fruitful in order to make a direct link with the calculations of invariant manifolds using the center manifold technique as proposed by Shaw and Pierre, see e.g. [Touzé et al. \(2021\)](#).

The software used to produce automatically the outputs of the high-order expansions presented in this paper is called MORFE_Symbolic. It is based on the implementation of the parametrisation method for nonlinear vibrating systems used in the MORFE project ([Opreni et al. 2022](#)). A key feature is also the treatment of the forcing term and the time dependence of the invariant manifolds, when harmonic excitation is considered. This automatic treatment proposed in [Vizzaccaro et al. \(2023\)](#), allows very general results that are not limited to a first-order expansion in the forcing amplitude as proposed in [Breunung et al. \(2018\)](#); [Ponsioen et al. \(2018\)](#); [Jain et al. \(2022\)](#); [Opreni et al. \(2023\)](#). In particular, the nonlinear dependence upon the forcing amplitude can be taken into account with the method proposed in [Vizzaccaro et al. \(2023\)](#), such that all types of resonance scenarios including the superharmonic can be analyzed. The code MORFE_Symbolic also allows one to start from a differential algebraic equation (DAE), extending again the range of dynamical scenarios that can be analyzed. This feature will be illustrated here in the case of the parametric excitation. A repository containing different versions of the

symbolic code is provided in link with the paper, where both julia and Mathematica versions are released. The julia version has the advantage of not using a proprietary software. However, today's symbolic computation capacities of the julia package are not as efficient as those of Mathematica. Because of that, the more involved examples studied in this paper were treated with the Mathematica version, or using a mix of both codes, due to processing time.

As a final introductory remark, most of the results presented in the paper aim to analyze reduced-order dynamics by systematically understanding the effects of the terms produced by asymptotic expansions. The code `MORFE_Symbolic` can also be used in a very general manner to produce many more different cases than the ones analyzed here. We think that such a tool is a key feature allowing reinterpretation of the grammar of nonlinear oscillations. Another interesting feature of the results produced by the normal form approach is the creation of a dictionary of the simplest dynamical systems containing a typical feature in nonlinear vibration. Such a dictionary can be very efficiently used in the realm of system identification with data-driven techniques. Thanks to the automated symbolic calculation, the method can be used to derive the dynamical systems that will produce the feature of *e.g.* a superharmonic resonance or a 1:2 internal resonance with the minimal number of monomials.

The outline of the paper is as follows. [Section 2](#) is a pedagogical introduction to the different variants of normal form styles, which underlines some key features of the different techniques. [Section 3](#) contains most of the analysis by focusing on cases where the reduced dynamics contains a single master mode. Typical scenarios in nonlinear vibrations are analyzed: primary resonance, super and sub-harmonic resonance and parametric excitation. [Section 4](#) extends some of these results by accurately quantifying the effect that a slave mode can have on the reduced dynamics with a single master mode. In order to restrict the length of the paper, this section is deliberately shorter than the previous one and closes with an illustrative example.

2 Variants of normal form styles

This pedagogical introductory section aims to explain the different possible styles of normal forms that have been proposed in the literature for nonlinear vibratory systems. To that purpose and to make the presentation as simple as possible, the case of the unforced and undamped Duffing oscillator equation is considered, as it is sufficient to understand the different variants. Obviously, the findings extend naturally to coupled nonlinear oscillators, which will be studied in the next sections.

The starting point is thus a conservative unforced cubic Duffing oscillator, reading

$$\ddot{u} + \omega^2 u + hu^3 = 0. \quad (1)$$

The three main variants that will be emphasized in this presentation are: the complex normal form (CNF), the real normal form (RNF) and the oscillator normal form (ONF). The complex normal form is recommended by mathematical textbooks ([Iooss et al. 1998](#)), and has been used for example in [Jézéquel et al. \(1991\)](#); [Haller et al. \(2016\)](#); [Waswa et al. \(2020\)](#). The starting point is to write [Equation \(1\)](#) at first-order, with a diagonalized linear part containing the eigenvalues $\{\pm i\omega\}$. By doing so, complexification is enforced and the link to an oscillator-like equation is lost. This is the main reason why alternative procedures have been proposed in the vibration literature (namely RNF and ONF), in order to ease the realification and keep the link with oscillator equations. Let us explain this in extensive detail on the Duffing equation.

To rewrite the system with a first-order diagonal linear part, the following linear change of coordinate can be applied

$$\begin{bmatrix} u \\ v \end{bmatrix} = \begin{bmatrix} 1 & 1 \\ i\omega & -i\omega \end{bmatrix} \begin{bmatrix} y_1 \\ y_2 \end{bmatrix}, \quad (2)$$

where $v = \dot{u}$ has been introduced. Note that other linear transforms with different normalizations can be applied here. [Equation \(1\)](#) then reads

$$\dot{y}_1 = i\omega y_1 + i \frac{h}{2\omega} (y_1^3 + 3y_1^2 y_2 + 3y_1 y_2^2 + y_2^3), \quad (3a)$$

$$\dot{y}_2 = -i\omega y_1 - i\frac{h}{2\omega} (y_1^3 + 3y_1^2 y_2 + 3y_1 y_2^2 + y_2^3). \quad (3b)$$

In particular, one can see that, whereas only one monomial u^3 is present in Equation (1), eight monomials are in Equation (3). One can also remark that Equation (3b) is the complex conjugate of Equation (3a). This is the direct consequence of the fact that the initial problem, Equation (1) is second-order in time such that, when rewriting it as a first-order dynamical system, one of the two equations, namely $v = \dot{u}$, is tautological.

The normal form procedure can be unfolded on Equation (3). It starts with introducing a nonlinear change of coordinates between modal coordinates (y_1, y_2) and normal coordinates (z_1, z_2) as

$$y_1 = z_1 + a_{11}z_1^3 + a_{12}z_1^2 z_2 + a_{13}z_1 z_2^2 + a_{14}z_2^3 \quad (4a)$$

$$y_2 = z_2 + a_{21}z_1^3 + a_{22}z_1^2 z_2 + a_{23}z_1 z_2^2 + a_{24}z_2^3. \quad (4b)$$

The normal dynamics is also introduced as

$$\dot{z}_1 = i\omega z_1 + f_{11}z_1^3 + f_{12}z_1^2 z_2 + f_{13}z_1 z_2^2 + f_{14}z_2^3, \quad (5a)$$

$$\dot{z}_2 = -i\omega z_2 + f_{21}z_1^3 + f_{22}z_1^2 z_2 + f_{23}z_1 z_2^2 + f_{24}z_2^3, \quad (5b)$$

where the linear part is preserved because the nonlinear change of coordinates Equation (4) is identity-tangent.

The sixteen unknown coefficients $\{a_{ij}\}$ and $\{f_{ij}\}$, $i = \{1, 2\}$ and $j = \{1, \dots, 4\}$, are found by plugging Equations (4) and (5) into Equation (3), and identifying coefficients for each monomial of the normal coordinates. This leads to the four following equations, related to Equation (3a)

$$\text{For } z_1^3: \quad (i\omega + i\omega + i\omega) a_{11} + f_{11} = i\omega a_{11} + i\frac{h}{2\omega}, \quad (6a)$$

$$\text{For } z_1^2 z_2: \quad (i\omega + i\omega - i\omega) a_{12} + f_{12} = i\omega a_{12} + i\frac{3h}{2\omega}, \quad (6b)$$

$$\text{For } z_1 z_2^2: \quad (i\omega - i\omega - i\omega) a_{13} + f_{13} = i\omega a_{13} + i\frac{3h}{2\omega}, \quad (6c)$$

$$\text{For } z_2^3: \quad (-i\omega - i\omega - i\omega) a_{14} + f_{14} = i\omega a_{14} + i\frac{h}{2\omega}, \quad (6d)$$

while four other ones, not reported here for the sake of brevity, are derived from Equation (3b).

Equation (6) is an underdetermined system of four equations for eight unknowns, admitting an infinity of possible solutions. Equations (6a), (6c) and (6d) can be solved easily for a_{11} , a_{13} and a_{14} , by imposing $f_{11} = f_{13} = f_{14} = 0$. This choice is the classical one to derive the normal form of the system, with the idea of simplifying as much as possible the normal dynamics Equation (5). A *trivial* resonance relationship occurs in Equation (6b), as a direct consequence of the eigenspectrum composed of a purely complex conjugate pair $\{\pm i\omega\}$. The three variants of normal form styles discussed herein depart on the choices made in order to solve Equation (6), which can also be viewed as a more or less stringent interpretation of the resonance relationship. This is detailed now for each of the three normal form styles.

2.1 The complex normal form style

The complex normal form (CNF) style is the classical treatment proposed in mathematical textbooks to deal with purely imaginary complex eigenspectrum, see *e.g.* Iooss (1988); Haragus et al. (2009); Wiggins (2003); Jézéquel et al. (1991). Referring to the simple case of the Duffing equation, it amounts to cancel the three non-resonant monomials z_1^3 , $z_1 z_2^2$ and z_2^3 in Equations (6a), (6b) and (6d) with the choice $f_{11} = f_{13} = f_{14} = 0$. For the only resonant monomial $z_1^2 z_2$, then one imposes $a_{12} = 0$ and $f_{12} = 3ih/2\omega$. This follows from a strict interpretation of the resonance relationship stemming from the homological equations at each order. The generalisation of the resonance relationship to arbitrary order can be found in many classical books, see *e.g.* Poincaré (1892); Iooss (1988); Guckenheimer et al. (1983); Manneville (1990); Murdock (2003), and reads, for

a dynamical systems of dimension n with $\{\lambda_1, \dots, \lambda_n\}$ the eigenvalues, and for an order p of nonlinearity:

$$\lambda_k = \sum_{i=1}^n m_i \lambda_i, \quad \text{with } m_i \geq 0 \quad \text{and} \quad \sum_{i=1}^n m_i = p. \quad (7)$$

For conservative mechanical systems with an eigenspectrum composed of pairs of purely imaginary numbers, trivial resonance relationships appear at each odd order in the normal form computation. Focusing on the simple case of the Duffing equation with cubic nonlinearity, an interesting feature of the CNF is that, for each odd order, only one resonant monomial stays in the normal form, as a consequence of these trivial resonances. Symbolic calculation of the normal form up to arbitrary order is possible thanks to the code `MORFE_Symbolic`, which has been used to develop the calculations shown in this paper. As an illustration, we give below the CNF for the Duffing equation up to order 11, which reads:

$$\dot{z}_1 = i\omega z_1 + i\frac{3h}{2\omega} z_1^2 z_2 - i\frac{51h^2}{2^4 \omega^3} z_1^3 z_2^2 + i\frac{1419h^3}{2^7 \omega^5} z_1^4 z_2^3 - i\frac{47505h^4}{2^{10} \omega^7} z_1^5 z_2^4 + i\frac{438825h^5}{2^{11} \omega^9} z_1^6 z_2^5, \quad (8a)$$

$$\dot{z}_2 = -i\omega z_2 - i\frac{3h}{2\omega} z_1 z_2^2 + i\frac{51h^2}{2^4 \omega^3} z_1^2 z_2^3 - i\frac{1419h^3}{2^7 \omega^5} z_1^3 z_2^4 + i\frac{47505h^4}{2^{10} \omega^7} z_1^4 z_2^5 - i\frac{438825h^5}{2^{11} \omega^9} z_1^5 z_2^6. \quad (8b)$$

As announced, one can observe that only one resonant monomial of the form $z_1^{p+1} z_2^p$ stays in the normal dynamics for each odd order $2p + 1$. Equation (8b) is the complex conjugate of Equation (8a), and one can also observe the change of sign in each successive odd order coefficients. For the sake of completeness, the nonlinear change of coordinates is reported in Appendix A.

An essential property of the CNF solution for conservative systems is that an analytic backbone curve is easily computed for any order. This property is known and has been for example already used in Breunung et al. (2018). Let us recall why this property is essentially linked to the CNF style. In order to derive physical characteristics of the original system, or even just to compute numerical continuation solution on the reduced dynamics, a realification procedure needs to be applied to the complex normal form as given e.g. in Equation (8), see for example Haro et al. (2016); Vizzaccaro et al. (2022); Opreni et al. (2023) for general discussions. Different realification procedures can be used, choosing for instance cartesian or polar coordinates. A key feature of the CNF is to provide very simple expressions when realification with polar coordinates is employed. Let us introduce the polar form of the normal coordinates as

$$z_1 = \frac{1}{2} \rho e^{i\alpha}, \quad (9a)$$

$$z_2 = \frac{1}{2} \rho e^{-i\alpha}. \quad (9b)$$

Since only one resonant monomial ($z_1^{p+1} z_2^p$ for the first equation and $z_1^p z_2^{p+1}$ for the second equation), is present for each odd order, a simple calculation shows that, whatever the order of the expansion used for the normal form, the dynamical equation for the amplitude ρ simply reads $\dot{\rho} = 0$. This is a direct consequence of the existence of the Lyapunov subcenter manifold (LSM) densely filled with a family of periodic orbits that are parametrised by their amplitude ρ . The equation for the phase then contains all the important dynamical terms, and reads, for example, up to order 11:

$$\dot{\alpha} = \omega + \frac{3h}{2^3 \omega} \rho^2 - \frac{51h^2}{2^8 \omega^3} \rho^4 + \frac{1419h^3}{2^{13} \omega^5} \rho^6 - \frac{47505h^4}{2^{18} \omega^7} \rho^8 + \frac{438825h^5}{2^{21} \omega^9} \rho^{10}. \quad (10)$$

Note in this case that a simplification by ρ is made in this last equation, this explains why an odd order $2p + 1$ in the normal form gives rise to a power ρ^{2p} in the resulting equation for the phase. Since ρ is constant then this equation can be directly integrated and makes appear the frequency-amplitude relationship of the conservative problem, also known as the backbone curve.

With the help of the symbolic processor MORFE_Symbolic, high-order backbone curves can be easily derived, an example is given below up to order 11:

$$\omega_{NL} = \omega \left(1 + \frac{3h}{2^3\omega^2}\rho^2 - \frac{51h^2}{2^8\omega^4}\rho^4 + \frac{1419h^3}{2^{13}\omega^6}\rho^6 - \frac{47505h^4}{2^{18}\omega^8}\rho^8 + \frac{438825h^5}{2^{21}\omega^{10}}\rho^{10} \right). \quad (11)$$

Note that this property is particularly important and meaningful since it applies to the solutions derived by the parametrisation method using CNF. Consequently, even when dealing with FE problems involving a very large number of degrees-of-freedom (dofs), an analytical backbone curve can be derived when reducing the problem to a single NNM with CNF, meaning that no extra calculation (like a continuation procedure) is needed to obtain the amplitude-frequency relationship for the conservative problem (Breunung et al. 2018).

It is important to highlight, however, that the above backbone curve is written as a function of the amplitude ρ of the normal variables z_1 and z_2 , and not that of the maximum value of the physical displacement, which will be denoted u_{\max} in what follows. In order to obtain the physical displacement amplitude, the normal coordinates polar representation can be inserted into the nonlinear mapping displacement equation. Replacing for Equation (9) into Equation (A.1a), limited here at order 3 for the sake of brevity, one easily obtains:

$$u = \rho \cos \alpha + \frac{h}{32\omega^2}\rho^3 \cos 3\alpha - \frac{3h}{16\omega^2}\rho^3 \cos \alpha. \quad (12)$$

Since all cosines are in phase, the displacement amplitude is simply given by the sum of their coefficients obtained for $\alpha = 0$. This procedure is easily extendable to any order and is automated in MORFE_Symbolic. Up to order 11, the relationship between the maximum physical displacement amplitude u_{\max} and the amplitude of the normal coordinate ρ finally reads:

$$u_{\max} = \rho \left(1 - \frac{5h}{2^5\omega^2}\rho^2 + \frac{25h^2}{2^8\omega^4}\rho^4 - \frac{2781h^3}{2^{15}\omega^6}\rho^6 + \frac{90493h^4}{2^{20}\omega^8}\rho^8 - \frac{3234957h^5}{2^{25}\omega^{10}}\rho^{10} \right). \quad (13)$$

With Equations (11) and (13) it is possible to find coordinate pairs (ω_{NL}, u_{\max}) that yield the backbone of the systems parametrized by ρ . Despite the distinction between u_{\max} and ρ , it is interesting to note, nevertheless, that these two quantities coincide up to the second order, which implies that Equation (11) can be used as an approximation for the backbone for small displacement amplitudes.

As an illustration, let us show, for this simple example of the conservative cubic Duffing oscillator, the convergence of the backbone curve for different orders o of normal form expansion. Figure 1 shows backbone curves obtained with CNF in the way described above up to order $o = 25$. They are compared with the backbone in terms of u_{\max} found using an exact solution based on Jacobi elliptic functions, available for example in Salas et al. (2014).

From Figure 1(a) it can be seen that there exists a maximum validity range for the approximations given by the normal form expansion, corresponding in this case to a displacement amplitude of approximately $u_{\max} = 0.8$. This is in line with the fact that the normal form relies on a local theory, and this upper bound for validity limit has been explored for example in Lamarque et al. (2012). Figure 1(b) shows the same backbone as a function of the amplitude ρ of the normal variable. Since Equation (13) gives u_{\max} as a function of ρ , and since the analytical solution with Jacobi elliptic functions is given for the amplitude u_{\max} , Equation (13) needs to be inverted to plot the reference solution. This has been done in Figure 1(b) together with a first-order approximation $u_{\max} = \rho$ which is frequently used in perturbation methods. This highlights the difference between u_{\max} and ρ as amplitudes are increasing. In this case, the first-order approximation $u_{\max} = \rho$ can be used for amplitudes up to $\rho = 0.5$, but higher orders cannot be neglected after. It should be noted that Equation (13) is no longer valid once a certain level of amplitude is reached, as can be seen by the sudden deviation of the black curve on Figure 1(b) from where it is graphically expected to go. This deviation occurs at approximately $\rho = 0.9$, corresponding to $u_{\max} = 0.85$, and is clearly beyond the validity limit of the approximation.

As a last point of discussion, the effect of a viscous damping term in the Duffing equation is investigated. The damping is appended to Equation (1) with a modal damping factor ξ , thus

Figure 1: Backbone curves for the Duffing oscillator up to order $o = 25$ with a complex normal form style and parameter values set as $\omega = 1$, $h = 1$. The backbone curves are compared with an analytical solution based on Jacobi elliptic functions (Salas et al. 2014). (a) Comparison in terms of the maximum displacement u_{max} . (b) Comparison as a function of the amplitude ρ of the normal variable.

reading $2\xi\omega\dot{u}$. The damping affects the eigenvalues which now read

$$\lambda_{1,2} = -\xi\omega \pm i\omega\sqrt{1 - \xi^2} = \omega(-\xi \pm i\delta), \quad (14)$$

where $\delta = \sqrt{1 - \xi^2}$ has been introduced in order to ease the analytical expressions. A small damping assumption is made such that (i) underdamped oscillations are considered ($\xi < 1$), and (ii) the resonance check in the normal form procedure is done on the imaginary (oscillatory) parts only, as proposed in Touzé et al. (2006); Haller et al. (2016); Vizzaccaro et al. (2022) for nonlinear vibratory systems. Then the CNF up to order seven becomes:

$$\begin{aligned} \dot{z}_1 = & (i\delta\omega - \xi\omega) z_1 + i\frac{3h}{2\delta\omega} z_1^2 z_2 - i\frac{3h^2 (17 - 14\xi^2 + 4i\xi\delta)}{8\omega^3 \delta^2 (-2i\delta + \xi)} z_1^3 z_2^2 \\ & - i\frac{3h^3 (378\xi^6 - 48\xi^4 - 1420\xi^2 - 531i\delta\xi + 378i\delta\xi^5 - 207i\delta\xi^3 + 946)}{64\omega^5 \delta^3 (9\xi^4 - 9\xi^2 - 4)} z_1^4 z_2^3, \end{aligned} \quad (15)$$

the second equation for z_2 being the complex conjugate of this one. As one can see, taking the damping into account leads to a direct and easy interpretation. The linear term follows the change in the eigenvalue. The same resonant monomials are present in the normal form since the resonance relationships are verified based on the assumption of small damping. Only the coefficients are slightly modified by the damping ratio ξ . Proceeding with realification, as done in the undamped case, it is possible to find the following two equations, by considering the real and imaginary parts of Equation (15) once z_1 and z_2 are substituted by their polar representation:

$$\dot{\rho} = -\xi\omega\rho + \frac{3^2\xi h^2 (2\xi^2 - 3)}{2^7\delta^2\omega^3 (1 + 3\delta^2)}\rho^5 - \frac{3^3\xi h^3 (42\xi^4 - 23\xi^2 - 59)}{2^{12}\delta^2\omega^5 (1 + 3\delta^2) (1 + 3\xi^2)}\rho^7 \quad (16a)$$

$$\dot{\alpha} = \delta\omega + \frac{3h}{2^3\delta\omega}\rho^2 + \frac{3h^2 (12\xi^2 - 17)}{2^6\delta\omega^3 (1 + 3\delta^2)}\rho^4 + \frac{3h^3 (189\xi^6 - 24\xi^4 - 710\xi^2 + 473)}{2^{11}\delta\omega^5 (1 + 3\delta^2) (1 + 3\xi^2)}\rho^6. \quad (16b)$$

Equation (16a) gives the decay rate of the oscillation amplitude. It should be noted that up to the first order, the equation can be integrated to give the usual exponential decay predicted by

the linear theory. A nonlinear damping ratio ξ_{NL} can thus be defined by dividing Equation (16a) by $-\rho\omega$. A nonlinear instantaneous frequency ω_{NL} can also be derived from Equation (16b) through $\dot{\alpha} = \omega_{NL}$, yielding the two equations

$$\xi_{NL} = \xi \left(1 - \frac{3^2 h^2 (2\xi^2 - 3)}{2^7 \delta^2 \omega^4 (1 + 3\delta^2)} \rho^4 - \frac{3^3 h^3 (42\xi^4 - 23\xi^2 - 59)}{2^{12} \delta^2 \omega^6 (1 + 3\delta^2) (1 + 3\xi^2)} \rho^6 \right) \quad (17a)$$

$$\omega_{NL} = \delta\omega \left(1 + \frac{3h}{2^3 \delta^2 \omega^2} \rho^2 + \frac{3h^2 (12\xi^2 - 17)}{2^6 \delta^2 \omega^4 (1 + 3\delta^2)} \rho^4 + \frac{3h^3 (189\xi^6 - 24\xi^4 - 710\xi^2 + 473)}{2^{11} \delta^2 \omega^6 (1 + 3\delta^2) (1 + 3\xi^2)} \rho^6 \right). \quad (17b)$$

Equation (17b) can be viewed as a damped backbone curve, that smoothly perturbs from the undamped case when $\xi \neq 0$ (Touzé et al. 2006a; Llave et al. 2019). It gives an analytical formula for taking the damping into account in the backbone curve and quantitatively compares conservative and damped cases. Equation (17a) underlines that the linear viscous damping creates a nonlinear decay rate. Its effect will however appear at large amplitudes since the first order in ρ is a power 4.

In order to better understand the evolution of the above quantities, the terms inside the brackets in Equations (17a) and (17b) are plotted as a function of ρ for $\omega = 1$ and $h = 1$ in Figure 2(a) and Figure 2(b). From the figures, it is possible to notice that the inclusion of damping does not alter significantly the shape of the backbones up to $\rho = 0.8$, which corresponds to the validity limit of the asymptotic expansion.

It is also worth mentioning that, as opposed to the undamped case, obtaining the maximum physical displacement u_{\max} as a function of amplitude ρ is not feasible analytically. This is so because the coefficients of the nonlinear mappings become complex. Both cosines and sines appear in the equation for $u(\rho)$ (analogous to Equation (12)), hence no simple analytical solution exists for u_{\max} .

Figure 2: (a) Damped backbone curve and (b) nonlinear damping ratio for the Duffing oscillator with increasing values of the damping ratio ξ . The results are obtained using a complex normal form style, and parameter values were set as $\omega = 1$ and $h = 1$.

As a summary, the CNF shares a number of advantageous characteristics. It has a lot of symmetries, leads to the most parsimonious representation of the normal dynamics, and analytical backbone curves are directly attainable with polar realification. The only drawback is that the normal dynamics is expressed with complex coordinates. In order to propose normal form calculations that stay in a real formulation, different variants have thus been proposed in the past.

2.2 The real normal form

The real normal form (RNF) has been first introduced by Neild and Wagg (Neild et al. 2011; Neild et al. 2015; Liu et al. 2019; Nasir et al. 2021; Wagg 2022), and reformulated in the context of the parametrisation method in Vizzaccaro et al. (2022); Opreni et al. (2023). Note that the denomination RNF is not used by Neild and Wagg who called the method DNF for direct normal form, see e.g. Elliott et al. (2018). In their case, the adjective *direct* was used to mean that the normal form technique is directly applied to second-order problems in time that are under study for mechanical vibration. Also in their approach, the developments were slightly different from the one presented herein since the target was to obtain time-domain approximations of the solutions. On the other hand, the method has been named RNF in Vizzaccaro et al. (2022) in order to keep the adjective *direct* to specify calculations that can be operated from the physical space and not the modal space.

The main idea of the RNF consists of keeping two monomials as resonant in Equation (3a). In addition to the term $z_1^2 z_2$, which is trivially resonant and kept in the CNF, the monomial $z_1 z_2^2$ is also defined as a resonant one. The origin of this choice lies in the fact that the goal of the calculation proposed in Neild et al. (2011); Neild et al. (2015) was to apply the normal form computation to second-order problem, which gives additional constraint to the developments. Since the second derivative of the mapping with respect to time needs to be computed, the homological equations need to be written with these terms, thus making naturally appear squares of the eigenfrequencies in the resonance relationships. This can also be seen in the homological equations derived in Vizzaccaro et al. (2022) that have been rewritten only for the displacement mapping, by using the relationship that exists at any order between the displacement and the velocity mappings. In this case, the ill-conditioning of the term in front of the mapping, which is due to resonance relationships, appears with squared values. Rewriting the resonance relationships Equation (7) with squares leads to:

$$(\lambda_k)^2 = \left(\sum_{i=1}^n m_i \lambda_i \right)^2, \quad \text{with } m_i \geq 0 \quad \text{and} \quad \sum_{i=1}^n m_i = p, \quad (18)$$

which is indeed the resonance relationship used to derive the RNF. For the sake of illustration, the RNF of the Duffing equation is here given up to order 7, it reads

$$\dot{z}_1 = i\omega z_1 + i\frac{3h}{2\omega} z_1^2 z_2 + i\frac{3h}{2\omega} z_1 z_2^2 - i\frac{15h^2}{2^4 \omega^3} z_1^3 z_2^2 - i\frac{3h^2}{2^3 \omega^3} z_1^2 z_2^3 + i\frac{267h^3}{2^7 \omega^5} z_1^4 z_2^3 - i\frac{3h^3}{2^7 \omega^5} z_1^3 z_2^4, \quad (19a)$$

$$\dot{z}_2 = -i\omega z_2 - i\frac{3h}{2\omega} z_1^2 z_2 - i\frac{3h}{2\omega} z_1 z_2^2 + i\frac{3h^2}{2^3 \omega^3} z_1^3 z_2^2 + i\frac{15h^2}{2^4 \omega^3} z_1^2 z_2^3 + i\frac{3h^3}{2^7 \omega^5} z_1^4 z_2^3 - i\frac{267h^3}{2^7 \omega^5} z_1^3 z_2^4, \quad (19b)$$

while the nonlinear mapping is given in Appendix B. As a consequence of the choice retained for fulfilling the resonance relationship, the same monomials now appear on the two lines of the normal dynamics. Interestingly, the cubic order terms share the same coefficients. This property is useful in order to retrieve an oscillator equation when coming back to real coordinates using a cartesian representation. Let us define the cartesian real coordinates (a_1, a_2) as

$$a_1 = z_1 + z_2, \quad (20a)$$

$$a_2 = \frac{z_1 - z_2}{i}. \quad (20b)$$

By stopping the RNF developments in Equation (19) at order three, one can see that the dynamics for a_1 is simple and reads $\dot{a}_1 = -\omega a_2$. Consequently, an oscillator equation can be written for the cartesian coordinates (a_1, a_2) as

$$\ddot{a}_1 + \omega^2 a_1 + \frac{3h}{4} (a_1^3 + a_1 \frac{\dot{a}_1^2}{\omega^2}) = 0. \quad (21)$$

Whereas the CNF was conveniently realified with polar coordinates, the RNF is better suited for realification using cartesian coordinates, thanks to the symmetry properties appearing in the coefficients of Equation (19). Unfortunately the nice property $\dot{a}_1 = -\omega a_2$ is completely linked to the fact that cubic coefficients are all equal. From order 5, this property is lost, but realification is

still easy to manage since the two different coefficients sum up and hence can be factorized. At order 7, one obtains:

$$\begin{aligned} \dot{a}_1 = & -\omega a_2 + \frac{9h^2}{256\omega^3} a_1^4 a_2 + \frac{9h^2}{128\omega^3} a_1^2 a_2^3 + \frac{9h^2}{256\omega^3} a_2^5 \\ & - \frac{135h^3}{4096\omega^5} a_1^6 a_2 - \frac{405h^3}{4096\omega^5} a_1^4 a_2^3 - \frac{405h^3}{4096\omega^5} a_1^2 a_2^5 - \frac{135h^3}{4096\omega^5} a_2^7, \end{aligned} \quad (22a)$$

$$\begin{aligned} \dot{a}_2 = & \omega a_1 + \frac{3h}{4\omega} a_1^3 + \frac{3h}{4\omega} a_1 a_2^2 - \frac{21h^2}{256\omega^3} a_1^5 - \frac{21h^2}{128\omega^3} a_1^3 a_2^2 - \frac{21h^2}{256\omega^3} a_1 a_2^4 \\ & + \frac{33h^3}{1024\omega^5} a_1^7 + \frac{99h^3}{1024\omega^5} a_1^5 a_2^2 + \frac{99h^3}{1024\omega^5} a_1^3 a_2^4 + \frac{33h^3}{1024\omega^5} a_1 a_2^6. \end{aligned} \quad (22b)$$

From these two equations, one can try to recover an oscillator-like equation. Deriving the first equation with respect to time, replacing \dot{a}_2 by the second expression, and stopping the developments at order 5, one obtains:

$$\ddot{a}_1 + \omega^2 a_1 + \frac{3h}{4} (a_1^3 + a_1 a_2^2) - \frac{15h^2}{128\omega^2} (a_1^5 + 2a_1^3 a_2^2 + a_1 a_2^4) = 0. \quad (23)$$

This underlines that, from order 5, a closed-form expression involving only a_1 is not possible anymore such that two equations need to be kept with both a_1 and a_2 . Equation (22) or Equation (23) can then be solved with a perturbative approach or a numerical continuation method to derive the backbone curve.

All these results show that the RNF can be advantageously used with cartesian coordinates for realification. It can be easily automatized since the choice of resonant monomials derives from a broader interpretation of the resonance relationship. Arbitrary order solutions are at hand and can be computed thanks to `MORFE_Symbolic`. However, the resulting equations are not oscillator-like from order 5. Besides, it seems that no simple and exact solution allows giving an analytical backbone curve at arbitrary order, as was the case for the CNF. To draw out such a solution a few more assumptions need to be made, following for example the approximations used in Neild et al. (2011); Neild et al. (2015). This is illustrated in Appendix B.

2.3 The oscillator normal form

The oscillator normal form (ONF) has been first introduced in Touzé (2003); Touzé et al. (2004); Touzé et al. (2006); Touzé (2014), with the main idea of keeping oscillator equations without using any complex formulation. To that purpose, the linear part is not made diagonal with complex entries, but stays under its anti-diagonal formulation, see Touzé et al. (2004). To better understand how the ONF can be interpreted from the previous example where complexification is used, the key point is to understand that all complex monomials appearing due to the complexification of a real one, need to be kept in the analysis, in order to make possible the come back to oscillator-like equations. For the Duffing equation, the real monomial u^3 in Equation (1) gives rise to 8 monomials for y_1 and y_2 as shown in Equation (3). Since all these are mandatorily needed to be able to reconstruct u^3 , it means that no terms in Equation (6) will be cancelled. The choice $a_{11} = a_{12} = a_{13} = a_{14} = 0$ is selected. As a consequence, the Duffing equation Equation (1) is under its oscillator normal form. In ONF, the trivially resonant monomial is u^3 and cannot be cancelled, but many other terms, which are not linked to trivial resonances, can be cancelled in the process. In particular, all quadratic terms are not resonant and can be eliminated thanks to a nonlinear change of coordinate, see Touzé et al. (2004) for general discussions and Touzé (2014) for examples and classification of nonlinear terms thanks to this interpretation of the resonance relationship.

One of the main advantages of the ONF is thus to keep oscillator-like equations throughout the process. The nonlinear change of coordinate is given between two real coordinates that are homogeneous to a displacement and a velocity, whereas this interpretation is lost when using complex formulations. This choice came along with other advantages. For example, only the ONF allows drawing out a term-by-term comparison of the NNM calculation using either the center manifold technique as proposed by Shaw and Pierre, or the normal form approach, see e.g. Touzé et al. (2004); Touzé et al. (2021) for such discussions. Thanks to the ONF, a direct comparison with

the quadratic manifold method with modal derivatives has also been made possible. Indeed, since real coordinates are used in the two approaches, term-by-term comparisons are at hand, which allows understanding that the quadratic manifold is a simplification of the general formula given by ONF, see [Vizzaccaro et al. \(2021\)](#); [Shen et al. \(2021\)](#); [Touzé et al. \(2021\)](#) for more details. A final advantage of the ONF is that it can be rewritten from physical coordinates, which allows deriving a non-intrusive version of the reduction technique using the normal form, which has been named DNF for direct normal form, see [Vizzaccaro et al. \(2021\)](#); [Opreni et al. \(2021\)](#).

However, numerous drawbacks are linked to this formulation. First, it is difficult to translate the choice on the resonant monomial as a broader algebraic interpretation of the resonance relationships, as it has been possible for the RNF with [Equation \(18\)](#). As a consequence, it appears very difficult (and maybe not possible) to generalize the ONF to arbitrary order and automate its computation. As an illustration of these complications, one can refer to [Shami et al. \(2022\)](#) to see how the ONF with resonant quadratic terms can be computed up to order three. As a consequence, the ONF will not be much commented on in the rest of this paper, and is not included in `MORFE_Symbolic`.

3 High-order solutions for single-degree-of-freedom systems with forcing and damping

This section extends the analysis using normal form expansions to illustrate how this formalism allows an understanding of the main features of nonlinear oscillations. Primary and secondary resonances will be analyzed. The first case under study is a Duffing oscillator with quadratic and cubic nonlinearities, derived to explain how the even order nonlinear terms can be cancelled and how the high-order terms on the backbone can be analyzed in terms of hardening/softening behaviour.

3.1 Duffing oscillator with quadratic and cubic nonlinearities

In this section, the results of the previous section are generalized to a Duffing equation with quadratic and cubic nonlinearities:

$$\ddot{u} + \omega^2 u + gu^2 + hu^3 = 0. \quad (24)$$

Using the automated symbolic development provided by `MORFE_Symbolic`, the complex normal form (CNF) can be written up to arbitrary order. The first step consists in diagonalizing the linear part using [Equation \(2\)](#), then the nonlinear mappings and the reduced dynamics are computed. For the sake of illustration, the normal dynamics up to order 7 is shown here:

$$\begin{aligned} \dot{z}_1 = & i\omega z_1 + i \frac{-10g^2 + 9h\omega^2}{6\omega^3} z_1^2 z_2 + i \frac{-3140g^4 + 8388g^2 h\omega^2 - 1377h^2\omega^4}{432\omega^7} z_1^3 z_2^2 \\ & + i \frac{-523960g^6 + 2186724g^4 h\omega^2 - 1913274g^2 h^2\omega^4 + 114939h^3\omega^6}{10368\omega^{11}} z_1^4 z_2^3. \end{aligned} \quad (25)$$

while the associated nonlinear mapping is reported in [Appendix C](#). For the sake of brevity, only the equation for z_1 is shown in [Equation \(25\)](#), the second equation for z_2 being simply its complex conjugate. Rewriting the real coefficients appearing in [Equation \(25\)](#) as $f^{(p)}$, for odd p corresponding to the odd monomial remaining:

$$\dot{z}_1 = if^{(1)}z_1 + if^{(3)}z_1^2 z_2 + if^{(5)}z_1^3 z_2^2 + \dots, \quad (26)$$

the backbone is analytic and reads, using a polar representation for (z_1, z_2) as in [Section 2.1](#), [Equation \(9\)](#):

$$\omega_{NL} = f^{(1)} + f^{(3)} \left(\frac{\rho}{2}\right)^2 + f^{(5)} \left(\frac{\rho}{2}\right)^4 + \dots \quad (27)$$

Given the expressions of the coefficients $f^{(p)}$ shown in [Equation \(25\)](#), one can see that, if one assumes $g \geq 0$ and $h \geq 0$, the quadratic and cubic nonlinearities play opposite roles in defining the hardening/softening behaviour. This has been used for a long time to predict, only from the

sign of $f^{(3)}$, the type of nonlinearity for structures, using for example the oscillator normal form, see e.g. Touzé et al. (2004); Touzé et al. (2006); Touzé et al. (2006); Touzé et al. (2008). Arbitrary order expansions allow a finer understanding of the hard/soft transition, and have already been used for rotating beams in Martin et al. (2023).

Figure 3 shows the behaviour of the coefficients $f^{(p)}$ for $p = 3, 5, 7$ and 9 . $f^{(3)}$ changes sign only once (for the case under study, with $h = 1$ fixed and varying g), meaning that the transition from hardening to softening behaviour occurs at $g = 3\sqrt{h}/10$. On the other hand, higher-order coefficients are polynomials of higher degrees in the coefficients g and h and thus have numerous zeros, see Figure 3(a-b). Figure 3(c) shows the backbone curves obtained just before and after the transition of the cubic coefficient (while the next orders don't change sign), namely for $g = 0.85$ ($f^{(3)} > 0$, and $f^{(5)} > 0$, $f^{(7)} < 0$, $f^{(9)} < 0$), and $g = 1$ ($f^{(3)} < 0$, and $f^{(5)} > 0$, $f^{(7)} < 0$, $f^{(9)} < 0$). A reference solution obtained numerically by continuation is compared to two truncations, respectively to orders 7 and 9, of the analytical backbone curve. For $g = 0.85$, the negative signs of $f^{(7)}$ and $f^{(9)}$ change the high amplitude behaviour of orders 7 and 9 truncations that depart from reference, needing orders higher than 9 to achieve convergence up to the selected amplitudes. For $g = 1$, the positive coefficient $f^{(5)}$ plays the major role since $f^{(3)}$ is close to zero.

Two other cases where the dominant behaviour is softening are shown in Figure 3(d) for $g = 1.5$ and $g = 1.65$, around the change of sign of $f^{(5)}$. Again, in such a situation, the mixed signs of the different truncations ask for high-order development to reach convergence. Nevertheless, the qualitative change of behaviours is captured. Also, the validity limit of the normal form development is probably impacted by the different values of quadratic and cubic coefficients.

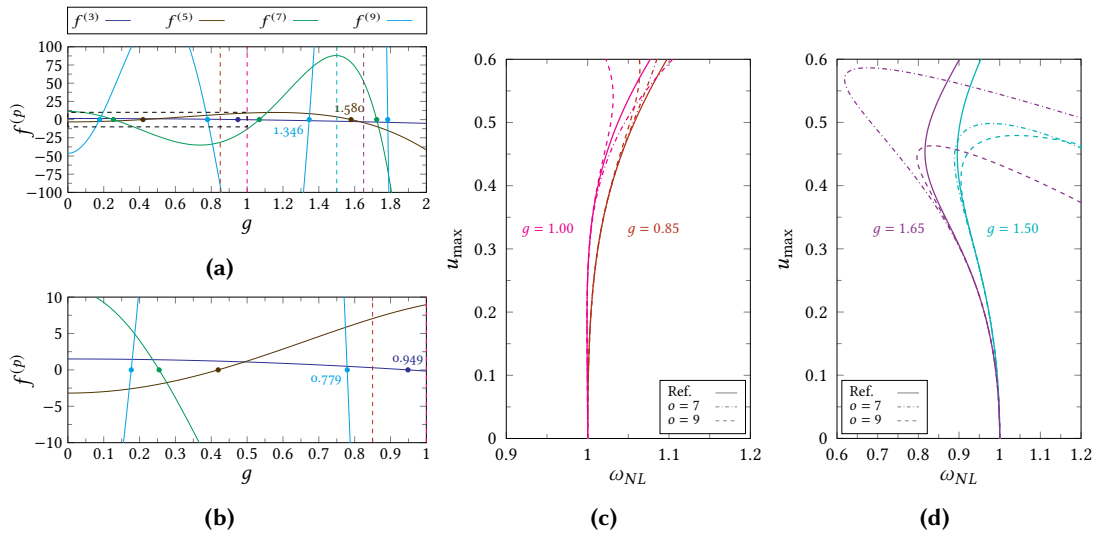

Figure 3: Hardening/softening behaviour for the Duffing oscillator with quadratic and cubic nonlinearities. A complex normal form style is used with parameter values set as $\omega = 1$, $h = 1$. (a) behaviour of the coefficients $f^{(p)}$ as a function of g . (b) zoom on the area highlighted by the black dashed box in (a). (c-d) Backbone curves for different values of g . A reference solution obtained by numerical continuation is compared to the backbone curves obtained with CNF up to orders $o = 7$ and $o = 9$.

For the sake of completeness, the RNF and ONF analysis are reported in Appendix D. In these two cases, automatic analysis of the backbone curve up to high order is more difficult.

3.2 Effect of forcing and damping

In this section, an analysis of the forced and damped Duffing oscillator with high-order normal form expansions is developed. The goal is to cover the usual results analyzed in nonlinear vibration theory by considering primary and secondary resonance, and the emphasis is put on showing how the normal form procedure allows generalizing perturbative results of current use in nonlinear vibration theory. All these results will then be helpful to understand and analyze reduced-order models with a single nonlinear normal mode assumption. The starting point is thus a forced-damped Duffing oscillator:

$$\ddot{u} + \omega^2 u + 2\xi\omega\dot{u} + hu^3 = \frac{\kappa}{2} \left(e^{+i\Omega t} + e^{-i\Omega t} \right), \quad (28)$$

where the forcing has already been rewritten with complex notation, while a viscous damping is introduced with the damping ratio ξ . We start by considering the case of a forcing frequency Ω which is far from the primary and secondary resonances.

3.2.1 Non-resonant excitation

The case of an out-of-resonance forcing frequency Ω leads to a minimal number of resonant monomials in the normal form, since only the trivial resonances are considered. Thanks to the efficient treatment of the non-autonomous forcing term presented in [Vizzaccaro et al. \(2023\)](#), an arbitrary order expansion in terms of the power of the non-autonomous term is also implemented in `MORFE_Symbolic`. This key feature allows computing and analyzing the high-order terms produced by the forcing in the normal form, a case that is not considered for example in [Breunung et al. \(2018\)](#); [Opreni et al. \(2023\)](#); [Jain et al. \(2022\)](#), where only linear terms of the forcing are included.

The method proposed in [Vizzaccaro et al. \(2023\)](#) to deal with the forcing term is to make the system autonomous by adding two additional coordinates, namely $z_3 = e^{+i\Omega t}$ and $z_4 = e^{-i\Omega t}$, augmenting the size of the original system but excluding the added variables from the sought change of coordinates. This leads to an efficient reformulation of the parametrisation method asking for slight modifications in the algorithm as compared to the autonomous case. When a single master mode (NNM) is selected, the reduced dynamics depends on four coordinates (z_1, z_2, z_3, z_4) , which can be easily reduced to (z_1, z_2) only by replacing $z_3 = e^{+i\Omega t}$ and $z_4 = e^{-i\Omega t}$.

Another key feature of the method proposed in [Opreni et al. 2023](#); [Vizzaccaro et al. 2023](#), to handle the external periodic forcing, is to compute the parametrisation for only one value of the external forcing. Rigorously speaking, the parametrisation needs to be computed for each forcing frequency, as proposed for example in [Jiang et al. 2005](#), to produce exact solutions. However, to alleviate the associated computational burden, the parametrisation can be computed for a single excitation frequency Ω_p , and this ROM can be used to draw out rapidly frequency response curves (FRC), assuming that the dependence upon Ω is small. This strategy is also adopted here to propose analytical solutions obtained with symbolic computations that lend themselves well to analysis.

The complex normal form (CNF) up to order three for the forced, undamped ($\xi = 0$) Duffing oscillator [Equation \(28\)](#), and for this out-of-resonance case, is computed at a single excitation frequency $\Omega_p = \Omega$. It reads

$$\dot{z}_1 = i\omega z_1 + i\frac{3h}{2\omega}z_1^2z_2 + i\frac{3h\kappa^2}{4\omega(\Omega^2 - \omega^2)^2}z_1z_3z_4, \quad (29)$$

where again only the first equation is shown, the second equation for z_2 being the complex conjugate. At this order, only two resonant monomials are present in the CNF. The first one, $z_1^2z_2$, has already been commented in [Section 2.1](#) in [Equation \(8\)](#). The second one, $z_1z_3z_4$, depends on the forcing, and scales as the amplitude of the forcing squared, κ^2 . This monomial is very interesting since it appears only due to the complete treatment of the forcing shown in [Vizzaccaro et al. \(2023\)](#). Since $z_3 = e^{+i\Omega t}$ and $z_4 = e^{-i\Omega t}$, the monomial can be interpreted as having a direct consequence on the nonlinear oscillation frequency. In particular, it shows the dependence of the free oscillation frequencies upon the forcing amplitude. For such conservative dynamics, the system's response is characterized by a quasi-periodic behaviour, stemming from the contributions of the free oscillations and of the forced response, whose effect is completely embedded into the nonlinear mapping equations. As commented next, the free oscillation term is generally related to the transient and is damped out when losses are taken into account. Interestingly, the monomial $z_1z_3z_4$ corresponds to a trivial resonance and will thus be present in all normal form dynamics that will be considered in the next sections (primary and secondary resonance). It will be thus further analyzed, in particular for secondary resonances, since in this case the forcing is not assumed to be small such that the dependence of the oscillation frequencies upon forcing amplitude is not negligible.

The nonlinear mapping up to order 3, leading to [Equation \(29\)](#), reads:

$$u = z_1 + z_2 + \frac{h}{8\omega^2}z_1^3 - \frac{3h}{4\omega^2}z_1^2z_2 - \frac{3h}{4\omega^2}z_1z_2^2 + \frac{h}{8\omega^2}z_2^3 - \frac{\kappa}{2(\Omega^2 - \omega^2)}(z_3 + z_4)$$

$$\begin{aligned}
& - \frac{3h\kappa}{2(\Omega^2 - \omega^2)(\Omega + \omega)(\Omega + 3\omega)} z_1^2 z_3 - \frac{3h\kappa}{2(\Omega^2 - \omega^2)(\Omega - \omega)(\Omega - 3\omega)} z_1^2 z_4 \\
& - \frac{3h\kappa}{(\Omega^2 - \omega^2)^2} z_1 z_2 (z_3 + z_4). \tag{30}
\end{aligned}$$

The velocity mapping is not shown here for the sake of brevity, and also because it can be retrieved from the derivation of Equation (30) with respect to time, see the remark in Appendix A. Note also that Equation (30) has been truncated to $\mathcal{O}(\kappa^2)$ terms only for the sake of brevity.

Equation (30) shows that one recovers the autonomous deformation of the associated invariant manifolds, already present in Equation (A.1), but also non-autonomous deformations, driven by the added coordinates z_3 and z_4 . The linear terms in z_3 and z_4 in the first line of Equation (30) accounts for a rigid-body rotation of the invariant manifold, already commented in Opreni et al. (2023). Then the terms of the next two lines show that together with this rigid-body motion, the manifold shows deformations along the phase of the forcing.

The symbolic code `MORFE_Symbolic` can be used to derive higher-order approximations of the normal form and nonlinear change of coordinates in this case of a non-resonant excitation. Interestingly, since only trivially resonant monomials are in the normal form, the dynamics will be composed of two different terms. First, the autonomous terms with resonant monomials will strictly follow those appearing in the unforced case, see Equation (8) for an example up to order 9. In addition to these, all the trivially resonant monomials will reappear, multiplied by a factor of the form $z_3^p z_4^p$ with $p \geq 1$. Higher order results are not shown here but can be automatically produced via `MORFE_Symbolic`.

Finally, the effect of the viscous damping term is investigated to close this case of non-resonant excitation. With the damping, the eigenvalues of Equation (28) reads $\lambda_{1,2} = -\xi\omega \pm i\omega\sqrt{1 - \xi^2} = \omega(-\xi \pm i\delta)$, see Equation (14). The CNF up to order three for the non-resonant response reads:

$$\dot{z}_1 = (i\delta\omega - \xi\omega) z_1 + i \frac{3h}{2\delta\omega} z_1^2 z_2 + \frac{3ih\kappa^2}{4\delta\omega((\Omega^2 - \omega^2)^2 + 4\xi^2\omega^2\Omega^2)} z_1 z_3 z_4, \tag{31}$$

the second equation for z_2 being the complex conjugate of this one. The real part in the first monomial shows that these oscillations will be damped out. Consequently, as commented in Opreni et al. (2023), the reduced dynamics is trivial and all the effects are embedded in the nonlinear mapping, where only the terms related to z_3 and z_4 will remain.

3.2.2 Primary resonance

The case of a resonant forcing with $\Omega \simeq \omega$ is here detailed. In this case of primary resonance, it has been selected to compute the parametrisation at the value of the damped oscillation frequency $\delta\omega$ (imaginary part of the eigenvalue), such that $\Omega_p = \delta\omega$. With this choice and taking the damping into account, the complex normal form (CNF) at primary resonance up to order 3 reads:

$$\dot{z}_1 = f_1 z_1 + f_2 z_1^2 z_2 + f_3 z_3 + f_4 z_1^2 z_4 + f_5 z_1 z_2 z_3 + f_6 z_1 z_3 z_4 + f_7 z_2 z_3^2 + f_8 z_3^2 z_4, \tag{32}$$

where only the first equation is given, the second on z_2 being the complex conjugate. The coefficients f_j , $j = 1, \dots, 8$, read:

$$f_1 = \lambda_1, \quad f_2 = i \frac{3h}{2\delta\omega}, \quad f_3 = -i \frac{\kappa}{4\delta\omega}, \quad f_4 = i \frac{3h\kappa}{8\delta^2\omega^3(2\delta + i\xi)} \tag{33a}$$

$$f_5 = i \frac{3h\kappa}{4\delta^2\omega^3(2\delta - i\xi)}, \quad f_6 = i \frac{3h\kappa^2}{16\delta^3\omega^5(4\delta^2 + \xi^2)}, \tag{33b}$$

$$f_7 = i \frac{3h\kappa^2}{32\delta^3\omega^5(2\delta - i\xi)^2}, \quad f_8 = i \frac{3h\kappa^3}{128\delta^4\omega^7(2\delta - i\xi)^2(2\delta + i\xi)}. \tag{33c}$$

One should notice at this point that, differently from the non-resonant case, the coefficients of the normal form are not a function of the forcing frequency Ω . This is the consequence of the choice $\Omega_p = \delta\omega$. One could have made a different choice here by selecting for example $\Omega_p = \omega$, which appears closer to the assumption made in perturbative techniques. Indeed, these two choices are almost indistinguishable for most practical cases where the small damping assumption

is met such that $\delta \approx 1$. Since the analysis developed here does not necessarily assume small damping, it appeared more coherent to expand around $\Omega_p = \delta\omega$, which also leads to simpler expressions for the coefficients. For comparison purposes, the coefficients obtained with the expansion around $\Omega_p = \omega$ are given in [Appendix E](#).

The first two monomials in [Equation \(32\)](#) are respectively the linear term and the cubic nonlinear stiffness that were already present without forcing. The third term corresponds to the direct resonant forcing. The next two monomials, $z_1^2 z_4$ and $z_1 z_2 z_3$, correspond to nonlinear parametric-like excitation terms. In the sequence, $z_1 z_3 z_4$, is the trivially resonant monomial already commented in the previous section. Its coefficient f_6 scales as $O(\kappa^2)$, like the next monomial that will create a second harmonic forcing through z_3^2 . Finally, the last coefficient f_8 scales as $O(\kappa^3)$ and is a higher-order effect of the direct forcing.

These reduced dynamics are automatically derived in the context of the parametrisation method up to high-order and are used to analyze the primary resonance of finite element models, see e.g. [Vizzaccaro et al. \(2022\)](#); [Opreni et al. \(2023\)](#); [Vizzaccaro et al. \(2023\)](#); [Jain et al. \(2022\)](#); [Li et al. \(2022\)](#). The purpose here is to give some insights into these results, which are obtained using high-order solutions that are realified with polar or cartesian representations, by analyzing the wealth of all the terms involved in the solution. Note that for obtaining the normal form given in [Equation \(32\)](#), no specific assumptions on damping or forcing have been made and the solutions are not stopped at first order for these two terms, a scheme that is generally assumed in perturbative solutions. Hence the solution given by [Equation \(32\)](#) contains a priori more information.

To give more insights to [Equation \(32\)](#), polar coordinates are introduced as

$$z_{1,2} = \frac{\rho}{2} e^{\pm i\theta}, \quad z_{3,4} = e^{\pm i\Omega t}. \quad (34)$$

An autonomous system can be derived for the amplitude ρ and the phase ψ , defined as $\psi = \theta - \phi$, where $\phi = \Omega t$ is introduced to make the system autonomous thanks to $\dot{\phi} = \Omega$. The resulting system reads

$$\dot{\rho} = A_0 + A_1^c \cos \psi + A_1^s \sin \psi + A_2^c \cos(2\psi) + A_2^s \sin(2\psi), \quad (35a)$$

$$\rho \dot{\psi} = B_0 + B_1^c \cos \psi + B_1^s \sin \psi + B_2^c \cos(2\psi) + B_2^s \sin(2\psi). \quad (35b)$$

The coefficients in [Equation \(35\)](#) have explicit expressions as functions of the coefficients f_j in [Equation \(32\)](#), which have been split according to their real part f_i^R and imaginary part f_i^I . The expressions read:

$$\begin{aligned} A_0 &= \rho f_1^R + \frac{\rho^3}{4} f_2^R + \rho f_6^R, & B_0 &= \rho f_1^I + \frac{\rho^3}{4} f_2^I + \rho f_6^I - \rho \Omega, \\ A_1^c &= 2f_3^R + \frac{\rho^2}{2} f_4^R + \frac{\rho^2}{2} f_5^R + 2f_8^R, & A_1^s &= 2f_3^I - \frac{\rho^2}{2} f_4^I + \frac{\rho^2}{2} f_5^I + 2f_8^I, \\ B_1^c &= 2f_3^I + \frac{\rho^2}{2} f_4^I + \frac{\rho^2}{2} f_5^I + 2f_8^I, & B_1^s &= -2f_3^R + \frac{\rho^2}{2} f_4^R - \frac{\rho^2}{2} f_5^R - 2f_8^R, \\ A_2^c &= \rho f_7^R, & A_2^s &= \rho f_7^I, \\ B_2^c &= \rho f_7^I, & B_2^s &= -\rho f_7^R. \end{aligned} \quad (36)$$

Deriving a closed-form expression for the FRC from the fixed points of [Equation \(35\)](#) is difficult because of the presence of the second harmonic excitation, which creates the terms with arguments 2ψ . From the analysis of the monomials in [Equation \(32\)](#), the second harmonic terms are only created by z_3^2 , such that the coefficients A_2^c , A_2^s , B_2^c and B_2^s are directly proportional to f_7 . To simplify the analysis, the usual assumption that a small forcing is enough to lead to large amplitude solutions in case of primary resonance, can be done, such that one could neglect the terms in κ^2 and κ^3 in [Equation \(32\)](#). With this assumption, which leads to disregarding f_6 , f_7 and f_8 , and using $\sin^2 + \cos^2 = 1$, one can obtain the following relationship as an expression for the frequency response curve:

$$\left(\frac{A_0}{A_1^s} + \frac{A_1^c A_0 B_1^s - A_1^s B_0}{A_1^s A_1^c B_1^c - A_1^c B_1^s} \right)^2 + \left(\frac{A_0 B_1^s - A_1^s B_0}{A_1^s B_1^c - A_1^c B_1^s} \right)^2 = 1. \quad (37)$$

This equation is still too cumbersome in order to give an explicit expression of the amplitude ρ as a function of the excitation frequency Ω for direct comparisons with a perturbative solution. To do so, one can assume that the damping ξ is small, as it is usually done in a perturbative scheme. Neglecting all high-order terms of the damping in the expressions of the coefficients f_j , $j = 1, \dots, 5$; leads to these expressions:

$$f_1^R = -\xi\omega, \quad f_1^I = \omega, \quad f_2^R = 0, \quad f_2^I = \frac{3h}{2\omega}, \quad f_3^R = 0, \quad (38a)$$

$$f_3^I = -\frac{\kappa}{4\omega}, \quad f_4^R = 0, \quad f_4^I = \frac{3h\kappa}{16\omega^3}, \quad f_5^R = 0, \quad f_5^I = \frac{3h\kappa}{8\omega^3}, \quad (38b)$$

such that an explicit expression for the FRC, with a small damping assumption, reads

$$\rho\Omega = \rho\omega + \rho^3 \frac{3h}{8\omega} \pm \frac{9h\rho^2 - 16\omega^2}{3h\rho^2 - 16\omega^2} \sqrt{\left(\frac{3h\rho^2 - 16\omega^2}{32\omega^3} \kappa\right)^2 - \rho^2 \xi^2 \omega^2}. \quad (39)$$

This expression is still more complete than the one given by a first-order perturbative solution like the method of multiple scales (MMS). In particular, it involves f_4 and f_5 coefficients, which are linked to the monomials $z_1^2 z_4$ and $z_1 z_2 z_3$ in Equation (32). Note that these two monomials refer to a nonlinear parametric excitation that is generally overlooked. Neglecting these two terms leads to considering only the first three monomials in Equation (32), and to the classical first-order perturbative solution of the FRC, see e.g. Nayfeh et al. (1979). This can be justified on the coefficients by assuming the same hypotheses as in the perturbative solution. Namely that, additionally to κ and ξ , the nonlinear coefficient h is also small, such that when expanding Equation (39) in power series and considering only the leading order terms, the classical result is found:

$$\Omega = \omega + \rho^2 \frac{3h}{8\omega} \pm \sqrt{\frac{\kappa^2}{4\rho^2 \omega^2} - \xi^2 \omega^2}. \quad (40)$$

Figure 4: FRCs for the primary resonance of the damped cubic Duffing oscillator. Parameter values are $\omega = 1.5$, $h = 1$, $\xi = 0.02$ and $\kappa = 0.1$. (a) Comparison of the analytical FRCs given by Equations (37), (39) and (40) and one obtained by symbolically solving for the fixed points of Equation (35) after replacing the numerical values of the parameters. (b) Comparison of numerically computed FRCs, obtained from MORFE_Symbolic using Matcont (Dhooge et al. 2004), with a reference solution, also obtained by continuation, and with the first-order multiple scale solution given by Equation (40), denoted as MMS.

This development shows the wealth of the automated high-order solution provided by the complex normal form, which can be simplified in order to retrieve the results of the first-order multiple scales expansion. Of course, higher-order perturbative expansions should give back the same term, but the change of paradigm in the approach proposed here is to give automatically high-order expansions that can then be analyzed by introducing asymptotic and ordering between the different terms, leading to explicit analytical expressions in the simplest cases.

Figure 4 illustrates the previous derivations by comparing analytical and numerical results. Figure 4(a) first compares analytical expressions based on the different approximations. The first-order multiple scales solution, Equation (40), is compared to the solution given by Equation (39),

for classical parameter values corresponding to usual assumptions: $\omega = 1.5$, $h = 1$, small damping with $\xi = 0.02$, and $\kappa = 0.1$, leading to a maximal vibration amplitude ρ close to 1, in order to see the effect of moderate amplitudes. It shows that neglecting the two monomials $z_1^2 z_4$ and $z_1 z_2 z_3$ in Equation (32) has an important effect on the prediction of the maximum amplitude, underlining that, when ρ is close to 1, a first-order perturbative solution is not accurate enough. The explicit expression Equation (39) is also compared to the implicit analytical expression given by Equation (37) and with an implicit solution for the fixed points of Equation (35), computed symbolically after replacing numerical values for the system parameters, showing that, at this level of amplitude and for these parameter values, the assumptions leading to Equation (39) are accurate enough.

Figure 4(b) now compares numerical solutions to show the convergence of the high-order normal form, as well as the effect of the nonlinear mapping. For the sake of illustration, the first-order multiple scales solution is also shown. Whereas the amplitude reported in Figure 4(a) is that of the normal coordinate ρ , Figure 4(b) is given for the maximum displacement of the physical coordinate u , denoted as u_{\max} . Note that, as compared to the calculations for the backbone curves shown in Section 2.1, it is not possible here to recover an easy analytic expression relating ρ to the physical displacement through the nonlinear mapping, because the forcing terms are not in phase with the autonomous ones. It should be highlighted, however, that the analytical expression (first-order perturbative solution) given by Equation (40) assumes (at first order), $u_{\max} = \rho$. The numerical solutions are computed numerically with a continuation procedure embedded in the package Matcont (Dhooge et al. 2004). Three different truncations of the normal form expansion are shown. Following Vizzaccaro et al. (2023), the selected truncation order is denoted as $\mathcal{O}(z^p, \varepsilon^q)$, meaning a maximal order p in the $z = (z_1, z_2, z_3, z_4)$ coordinate and q for the non-autonomous (z_3, z_4) variables. In this example, the case $p = q$ is selected for convenience, and $p = q = 3$ corresponds to Equation (32). These results show that, for such level of amplitude, the first-order multiple scales solution is far from the full-order solution. The order 3 expansion is also not accurate enough, while convergence is almost achieved at order 7. Besides, the effect of the nonlinear mapping is very important, as can be seen by comparing the order 3 solutions when parameterised in amplitude by ρ or the maximum displacement u_{\max} .

All this development underlines the wealth of the symbolic solution, that can be analyzed in order to produce, whenever possible, analytical expressions that can be more complete than first-order perturbative solution, as well as the fact that, when amplitudes are close to 1, one needs to resort to numerical approximations since low-order approximations are not enough accurate.

3.2.3 Superharmonic resonance

In this section, the 3:1 superharmonic resonance of the Duffing oscillator is investigated thanks to high-order normal form approximations and analytical expressions. Equation (28) is considered as starting point and the forcing frequency Ω is such that $\Omega \simeq \omega/3$. The complex normal form (CNF) up to order three is obtained thanks to MORFE_Symbolic, and the expansion point for computing the parametrisation has been selected as $\Omega_p = \omega/3$. The choice $\Omega_p = \delta\omega/3$ has not been selected in this case since it does not bring substantial simplifications to the coefficients. It reads:

$$\dot{z}_1 = \lambda_1 z_1 + i \frac{3h}{2\delta\omega} z_1^2 z_2 + \frac{243ih\kappa^2}{16\delta\omega^5 (9\xi^2 + 16)} z_1 z_3 z_4 - \frac{729h\kappa^3}{128\delta\omega^7 (3\xi - 4i)^3} z_3^3, \quad (41)$$

where the notations of the previous sections are used, and the second equation for z_2 has been omitted since it is the complex conjugate. The associated nonlinear mapping is given in Appendix G for the sake of completeness. As compared to the primary resonance, Equation (41) contains fewer terms. On the other hand, only one more resonant monomial as compared to the non-resonant case shown in Equation (29), is present. The added monomial is z_3^3 , which is indeed the resonant term due to 3:1 superharmonic resonance, since $z_3 = e^{i\Omega t}$ and $\Omega \simeq \omega/3$.

At this order three of the development, no terms in the reduced dynamics involve powers of the forcing coordinates, such as z_3^2 that was for example in Equation (32) for the primary resonance. Consequently, no higher harmonics of the forcing will appear in the solution, such

that analytical expressions for the frequency response curve could be easily derived at this order. Using the polar coordinates, redefining the phase as $\psi = \theta - 3\phi$ in order to render the system autonomous, and searching for fixed points such that $\dot{\rho} = \dot{\psi} = 0$, the following relationship is easily derived:

$$B_r + A_i \sin(\psi) + A_r \cos(\psi) = 0, \quad (42a)$$

$$B_i - A_r \sin(\psi) + A_i \cos(\psi) = 0, \quad (42b)$$

where A_r , A_i , B_r and B_i have explicit expressions as functions of the coefficients of the normal dynamics Equation (41):

$$A_r = \frac{6561h\kappa^3\xi(16 - 3\xi^2)}{64\delta(9\xi^2 + 16)^3\omega^7}, \quad A_i = -\frac{729h\kappa^3(27 - 6\delta^2)}{16\delta(9\xi^2 + 16)^3\omega^7} \quad (43)$$

$$B_r = -\rho\xi\omega, \quad B_i = \rho\delta\omega - 3\rho\Omega + \rho^3\frac{3h}{8\delta\omega} + \rho\frac{243h\kappa^2}{16\delta(9\xi^2 + 16)\omega^5}.$$

Squaring each line of Equation (42), summing and using $\sin^2\psi + \cos^2\psi = 1$ in order to eliminate the angle ψ leads to the following relationship that gives the frequency response function, *i.e.* the amplitude ρ as a function of the forcing frequency Ω :

$$A_i^2 + A_r^2 = B_i^2 + B_r^2. \quad (44)$$

From this last equation, one can derive an explicit expression for the frequency response curve, upon substitution of the coefficients from Equation (43), yielding:

$$3\rho\Omega = \rho\delta\omega + \rho^3\frac{3h}{2^3\delta\omega} + \rho\frac{3^5h\kappa^2}{2^4\delta(9\xi^2 + 16)\omega^5} \pm \sqrt{\frac{9^6h^2\kappa^6}{4^6\delta^2\omega^{14}(9\xi^2 + 16)^3} - \rho^2\xi^2\omega^2}. \quad (45)$$

This expression for the FRC of the superharmonic case is very close to the one obtained using a first-order multiple scales expansion. It is however more general since no assumption about small damping has been made yet. Using a first-order expansion on the damping term ξ , following the guideline used in the previous section, one obtains:

$$3\rho\Omega = \rho\omega + \rho^3\frac{3h}{2^3\omega} + \rho\frac{3^5h\kappa^2}{2^8\omega^5} \pm \sqrt{\frac{9^6h^2\kappa^6}{8^8\omega^{14}} - \rho^2\xi^2\omega^2}, \quad (46)$$

this last expression being exactly equivalent to the one reported in Nayfeh et al. (1979) using the first-order method of multiple scales (MMS). At this level of the asymptotic expansion (order 3), the normal form of the superharmonic solution is thus equivalent to a first-order perturbative solution. This is logical because in the present situation, the amplitude κ can no longer be considered as small, an effect that is accounted for in the multiple scales solution by assuming that the forcing appears at the order zero of the solution, since a secondary resonance is considered.

The terms which are outside the square root in Equation (45), represent a shift of the traditional backbone curve with forcing amplitude. Interestingly, this dependence only comes from the monomial $z_1z_3z_4$. The expression of this curve reads:

$$3\omega_{NL} = \delta\omega + \rho^2\frac{3h}{2^3\delta\omega} + \frac{3^5h\kappa^2}{2^4\delta(9\xi^2 + 16)\omega^5}. \quad (47)$$

When $\kappa = 0$, this last equation recovers the backbone curve of the primary resonance (see Equation (17b) truncated at the third-order), which is simply shifted to one-third of the eigenfrequency. For a fixed value of $\kappa \neq 0$, it aligns to a backbone passing through the maximum of the FRC, as illustrated in Figure 5(a).

Additionally, it is possible to derive an expression for the curve joining the maxima of the superharmonic FRCs, which can be viewed as a generalized backbone curve for this resonance scenario. It is obtained as a curve parameterised by κ : for each forcing amplitude, one finds

the ρ value such that the frequency in Equation (45) is single-valued, and uses it to find its corresponding Ω thanks to Equation (47), yielding:

$$\begin{cases} \rho(\kappa) = \sqrt{\frac{9^6 h^2 \kappa^6}{4^6 \delta^2 \omega^{16} \xi^2 (9\xi^2 + 16)^3}}, \\ \Omega(\kappa) = \frac{\delta \omega}{3} + \frac{3^{11} h^3 \kappa^6}{2^{15} \delta^3 \omega^{17} \xi^2 (9\xi^2 + 16)^3} + \frac{3^4 h \kappa^2}{16 \delta (9\xi^2 + 16) \omega^5}. \end{cases} \quad (48)$$

Equations (45) and (46) are used to plot the FRCs in Figure 5(a) for three different values of forcing amplitude: $\kappa = 0.5, 0.7, 0.9$. The other parameters are fixed as $\omega = 1, \xi = 0.2, h = 3$. The figure also shows different shifted backbones for the problem. The generalized backbone curve, following the peaks of the FRCs and given by Equation (48), is shown in red dash-dotted line. In Figure 5(a), the two expressions for the FRC, respectively without assumption on the damping, Equation (45), or assuming a first-order, Equation (46), are also shown, underlining the minimal difference that is brought about by considering accurately the damping ratio as compared to the first-order perturbative solution.

The curves are also plotted in 3D space in Figure 5(b), by adding the forcing amplitude κ as an additional coordinate. A frequency response manifold, given by Equation (44), is represented in order to highlight the set on which the solutions are. The generalized backbone curve given by Equation (48) is represented as the black line joining all the maxima of this surface.

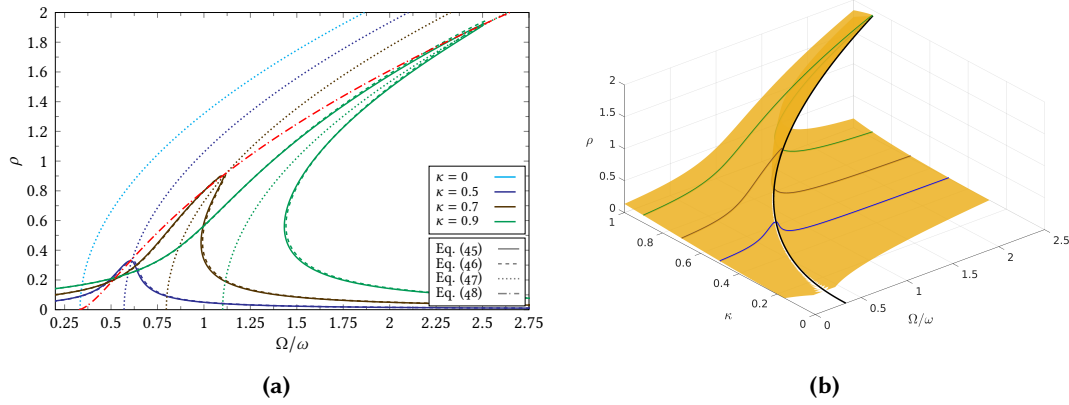

Figure 5: FRCs for the 3:1 superharmonic resonance of the damped cubic Duffing oscillator. The results are obtained using a complex normal form style, and parameter values are set as $\omega = 1, h = 3, \xi = 0.2$. (a) FRCs in the frequency-amplitude of the normal coordinate plane. Note how the forcing-dependent backbones follow the shift of the curves with increasing κ . (b) Three-dimensional view of the FRCs and of the frequency response manifold. The curve that unites the peaks of the FRCs is also shown in black.

Figure 6 completes the analysis for this case, presenting the FRCs in terms of physical displacement amplitude, u_{\max} , and for higher orders of parametrisation. The curves therein are obtained, such as in the primary resonance case, by numerical continuation with the package Matcont (Dhooge et al. 2004), since it is not possible to find an analytical expression relating u_{\max} to ρ . The figure also shows the multiple scales solution given by Nayfeh et al. (1979). It should be noted that, in contrast with the case of primary resonance, this solution does not simply assumes that $u_{\max} = \rho$. Indeed, the time series of the displacement is given as

$$u = \rho \cos(3\Omega t - \gamma) + \frac{\kappa}{\omega^2 - \Omega^2} \cos \Omega t, \quad (49)$$

with γ being a phase defined in the reference. The curve corresponding to this solution was found by calculating the maxima of this expression over a period of oscillation for different values of ρ . One should remark that, since the damping is small, the difference between this curve and the one of the $\mathcal{O}(z^3, \varepsilon^3)$ parametrisation is only due to the nonlinear mappings relating u to ρ . Consequently, even though the same FRC in terms of ρ is found for both of them, the approximation given by the normal form computation up to order 3 is more accurate in this case, thanks to the correction brought about by the mapping. Nevertheless, an order three expansion is still not enough as compared to the response of the full system, such that higher order terms need to be taken into account to converge to the exact solution, which happens at order seven.

Figure 6: FRCs for the 3:1 superharmonic resonance of the damped cubic Duffing oscillator. Parameter values are $\omega = 1.5$, $h = 1$, $\xi = 0.002$ and $\kappa = 0.5$. Comparison of numerically computed FRCs, obtained from `MORFE_Symbolic` and solved using numerical continuation, with a reference solution, also obtained by continuation but on the original equations, and with the first-order multiple scales solution (MMS).

3.2.4 Subharmonic resonance

In this section, the 1:3 subharmonic resonance, where the excitation frequency is in the vicinity of three times the natural frequency ω , is investigated, for the Duffing equation with cubic nonlinearity, Equation (28). The complex normal form (CNF) up to the third order for both autonomous and non-autonomous variables, with the expansion point for the parametrisation being $\Omega_p = 3\omega$, reads:

$$\dot{z}_1 = \lambda_1 z_1 + \frac{3ih}{2\delta\omega} z_1^2 z_2 + \frac{3ih\kappa^2}{16\delta\omega^5 (16 + 9\xi^2)} z_1 z_3 z_4 - \frac{3h\kappa(3\xi - 4i)}{8\delta\omega^3 (16 + 9\xi^2)} z_2^2 z_3. \quad (50)$$

Again, the equation for z_2 is not reported for the sake of brevity, being the complex conjugate. The nonlinear mapping up to order 3 is reported in Appendix H. The normal form dynamics looks similar to the superharmonic case, only the last monomial being changed, since now the resonant monomial with the assumption $\Omega \simeq 3\omega$ is $z_2^2 z_3$. The term $z_1^2 z_2$ refers to the cubic nonlinearity, while the second monomial $z_1 z_3 z_4$ is the trivially resonant term, scaling as the square of the forcing amplitude κ^2 , and making clearly appear the hard non-resonant excitation that is key for secondary resonances.

Proceeding similarly as in the superharmonic case to find an analytic expression for the FRC, the system to solve can be put in the following form, this time with $\psi = 3\theta - \varphi$:

$$B_r + A_i \sin(\psi) + A_r \cos(\psi) = 0, \quad (51)$$

$$B_i - A_r \sin(\psi) + A_i \cos(\psi) = 0, \quad (52)$$

with:

$$A_r = -\rho^2 \frac{3^2 h \kappa \xi}{2^4 \delta \omega^3 (16 + 9 \xi^2)}, \quad A_i = \rho^2 \frac{3 h \kappa}{2^2 \delta \omega^3 (16 + 9 \xi^2)}, \quad (53a)$$

$$B_r = -\rho \xi \omega, \quad B_i = \rho \delta \omega - \rho \frac{\Omega}{3} + \rho^3 \frac{3 h}{2^3 \delta \omega} + \rho \frac{3 h \kappa^2}{2^4 \delta \omega^5 (16 + 9 \xi^2)}. \quad (53b)$$

Solving the system, it is possible to find the following expression for the FRC:

$$A_i^2 + A_r^2 = B_i^2 + B_r^2. \quad (54)$$

Substituting coefficients A_r , A_i , B_r and B_i into this expression yields a biquadratic equation in ρ . A peculiarity of the subharmonic resonance is to give rise to detached solution branches or *isola*, that are not connected to the main solution branch (Nayfeh et al. 1979). Consequently, deriving the existence condition for such solutions is important in this context. The derivation of

this condition from the biquadratic equation is reported in [Appendix I](#). Only the result is shown here, the boundary for the region where solutions can exist being given by:

$$\Omega = 3\delta\omega + \frac{63h\kappa^2}{2^7\delta\omega^5(16+9\xi^2)} + \frac{2^5\delta\omega^7\xi^2(16+9\xi^2)}{h\kappa^2}. \quad (55)$$

From [Equation \(54\)](#) it is also possible to derive an explicit expression for the FRC:

$$\frac{\Omega}{3} = \delta\omega + \frac{3h}{2^3\delta\omega}\rho^2 + \frac{3h\kappa^2}{2^4\delta\omega^5(16+9\xi^2)} \pm \sqrt{\frac{3^2h^2\kappa^2}{2^8\delta^2\omega^6(16+9\xi^2)}\rho^2 - \xi^2\omega^2}. \quad (56)$$

As in the superharmonic case, the terms outside the square root in [Equation \(56\)](#) can be interpreted to understand the shift of the primary resonance backbone curve for this subharmonic scenario, including the effect of the monomial $z_1z_3z_4$. Its expression is given by:

$$\frac{\omega_{NL}}{3} = \delta\omega + \frac{3h}{2^3\delta\omega}\rho^2 + \frac{3h\kappa^2}{2^4\delta\omega^5(16+9\xi^2)}. \quad (57)$$

Also, by requiring [Equation \(56\)](#) to be single-valued, a generalized backbone curve joining the FRCs minima can be obtained as:

$$\begin{cases} \rho(\kappa) = \frac{2^4\omega^4\delta\xi\sqrt{16+9\xi^2}}{3h\kappa}, \\ \Omega(\kappa) = 3\delta\omega + \frac{2^5\omega^7\delta\xi^2(16+9\xi^2)}{h\kappa^2} + \frac{3^2h\kappa^2}{2^4\delta\omega^5(16+9\xi^2)}. \end{cases} \quad (58)$$

The FRC can be further simplified by adopting a small damping hypothesis. Similarly to the previous superharmonic case, this assumption allows one to recover exactly the solution given by the first-order multiple scales development ([Nayfeh et al. 1979](#)), reading:

$$\frac{\Omega}{3} = \omega + \frac{3h}{2^3\omega}\rho^2 + \frac{3h\kappa^2}{2^8\omega^5} \pm \sqrt{\frac{3^2h^2\kappa^2}{2^{12}\delta^2\omega^6}\rho^2 - \xi^2\omega^2}. \quad (59)$$

The small damping assumption allows for an additional simplification in the expression of the boundary of the existence region, [Equation \(55\)](#), that also results in the same formula as the one found with a first-order multiple scales solution:

$$\Omega = 3\omega + \frac{63h\kappa^2}{2^{11}\omega^5} + \frac{2^9\omega^7\xi^2}{h\kappa^2}. \quad (60)$$

It should be noted that [Equation \(60\)](#) is quite close to the second expression in [Equation \(58\)](#) once it is simplified to retain only first-order terms in the damping:

$$\Omega = 3\omega + \frac{3^2h\kappa^2}{2^8\delta\omega^5} + \frac{2^9\omega^7\xi^2}{h\kappa^2}. \quad (61)$$

The two curves have different interpretations, however. While [Equation \(60\)](#) gives the possible combinations of parameters Ω and κ such that non-trivial solutions might exist, [Equation \(61\)](#) only gives the frequency value at which the minimum of the FRC occurs as a function of κ . Both expressions are plotted in [Figure 7\(a\)](#), with parameter values fixed as $\omega = 1.5$, $h = 1$ and $\xi = 0.02$. It is worth mentioning that the curve defining the FRC minima lies inside the existence region given by [Equation \(60\)](#), as should be expected.

[Equations \(56\)](#) and [\(59\)](#) are used to plot the FRCs in [Figure 7\(b\)](#). For the figure, the forcing amplitude assumed three values: $\kappa = 5, 10, 15$, each of which is associated with blue, dark green and light green curves, respectively, while the other parameters remained the same as in the previous plot. The figure also shows the shifted backbones given by [Equation \(57\)](#) for the three different forcing values; and for $\kappa = 0$, with the curve depicted in cyan. The generalized backbone joining the minima of the FRCs, whose expression is found in [Equation \(58\)](#), is also shown, in red dash-dotted line.

Numerical results are also presented for this situation in [Figure 8](#), where the FRCs in terms of physical displacement amplitude u_{\max} are plotted. Once again, numerical continuation package

Figure 7: 1:3 subharmonic resonance of the damped cubic Duffing oscillator. Results obtained using a complex normal form style, with parameter values as $\omega = 1.5$, $h = 1$ and $\xi = 0.02$. (a) Comparison of the existence condition and the curve following the FRCs minima in (Ω, κ^2) space. (b) FRCs for $\kappa = 5, 10, 15$. The figure also shows the shifted backbones and generalized backbone joining the FRCs minima.

Matcont (Dhooge et al. 2004) is employed to find the FRCs stemming from MORFE_Symbolic and that of the full system. Additionally, a first-order multiple scales solution is also presented. Its displacement time series is obtained from

$$u = \rho \cos \frac{1}{3} (\Omega t - \gamma) + \frac{\kappa}{\omega^2 - \Omega^2} \cos \Omega t, \quad (62)$$

with γ defined in Nayfeh et al. (1979). The difference between the multiple scales solution and the one from the $\mathcal{O}(z^3, \varepsilon^3)$ parametrisation is even more pronounced in this case, as compared to the superharmonic resonance scenario. Again, the nonlinear mappings arising from the parametrisation method prove essential to obtain accurate approximations of the full system. Comparing the curves from the figure, it can be seen that convergence is more difficult to reach. However, an order 9 parametrisation seems to be an acceptable approximation to the reference curve.

Figure 8: FRCs for the 1:3 subharmonic resonance of the damped cubic Duffing oscillator. Parameter values are $\omega = 1.5$, $h = 1$, $\xi = 0.002$ and $\kappa = 1$. Comparison of numerically computed FRCs, obtained from MORFE_Symbolic with higher orders and solved by continuation, with a reference solution, also obtained by continuation, and with the first-order multiple scales solution (MMS).

3.3 Parametric excitation

In this section, the case of a parametric excitation is considered. The starting point is a damped cubic Duffing equation with a forcing on the right-hand side that depends on the displacement, reading:

$$\ddot{u} + \omega^2 u + 2\xi\omega\dot{u} + hu^3 = \kappa u \cos \Omega t. \quad (63)$$

There exist several parametric instabilities for different values of the excitation frequency Ω , that are generally reported in a so-called Strutt-Ince stability diagram, see *e.g.* [Nayfeh et al. \(1979\)](#); [Grandi et al. \(2021\)](#). Here, the analysis is restricted to the primary parametric resonance when the excitation frequency is close to twice the eigenfrequency, $\Omega \simeq 2\omega$. The package `MORFE_Symbolic` relies on the generic treatment of non-autonomous terms proposed in [Vizzaccaro et al. \(2023\)](#), which can handle a first-order differential-algebraic equation (DAE). Also, the starting point assumes that a quadratic recast of the equations of motion has been operated, by adding new variables to express the initial problem with only quadratic nonlinearities ([Guillot et al. 2019](#)). [Equation \(63\)](#) is thus rewritten as follows to be automatically treated by `MORFE_Symbolic`:

$$\dot{u} = v, \quad (64a)$$

$$\dot{v} = -\omega^2 u - 2\xi\omega v - h u r_1 + u r_2, \quad (64b)$$

$$0 = r_1 - u^2, \quad (64c)$$

$$0 = r_2 - \frac{\kappa}{2} (z_3 + z_4), \quad (64d)$$

$$\dot{z}_3 = i\Omega z_3, \quad (64e)$$

$$\dot{z}_4 = -i\Omega z_4. \quad (64f)$$

The complex normal form (CNF), up to the third order, is given in the equation that follows. The expansion point for the parametrisation is selected as $\Omega_p = 2\omega$.

$$\dot{z}_1 = f_1 z_1 + f_2 z_1^2 z_2 + f_3 z_2 z_3 + f_4 z_1 z_3 z_4. \quad (65)$$

Again, one can see that, as compared to the out-of-resonance scenario shown in [Equation \(31\)](#), the only added monomial to be considered for the parametric excitation is $z_2 z_3$, which is indeed resonant since $\Omega \simeq 2\omega$. The coefficients f_j , $j = 1, \dots, 4$, introduced in [Equation \(65\)](#), read

$$f_1 = \lambda_1 = -\xi\omega + i\omega\delta, \quad f_2 = i\frac{3h}{2\delta\omega}, \quad (66a)$$

$$f_3 = -i\frac{\kappa}{2^2\delta\omega}, \quad f_4 = i\frac{\kappa^2(\delta-1)}{2^5\omega^3\xi^2\delta^2}. \quad (66b)$$

Note in particular that in the present case, f_2 , f_3 and f_4 are purely imaginary, which is a consequence of the starting point [Equation \(63\)](#). However, in a more general context of parametrically excited systems, these coefficients can have a non-vanishing real part. This is observed for example in the case of continuous structures where an external forcing leads to a parametric excitation, as the case studied for example in [Opreni et al. \(2023\)](#) (beam with in-plane forcing where the parametric excitation leads to transverse vibrations), and in [Frangi et al. \(2023\)](#) (parametric excitation due to electro-mechanical coupling). Hence for the sake of generality, all the introduced coefficients will be considered as complex, with $f_j = f_j^R + if_j^I$ to distinguish real and imaginary parts. This point will be further addressed in [Section 4.2](#) where a parametrically excited two-dofs system is considered. Note finally that f_4 scales as κ^2 , it is thus a second-order term with respect to the forcing, which is neglected with first-order assumptions used in [Breunung et al. \(2018\)](#); [Jain et al. \(2022\)](#); [Opreni et al. \(2023\)](#), and also neglected in first-order perturbative solutions, such as the MMS and the method of varying amplitude, as can be seen in [Benacchio et al. \(2022\)](#).

Substituting $z_1 = \frac{\rho}{2}e^{i\theta}$ and $z_2 = \frac{\rho}{2}e^{-i\theta}$, defining $\psi = 2\theta - \Omega t = 2\theta - \varphi$ to make the system autonomous, one obtains a first-order autonomous dynamical system as:

$$\dot{\rho} = B_r + A_r \cos \psi + A_i \sin \psi, \quad (67a)$$

$$\frac{\rho}{2}\dot{\psi} = B_i - A_r \sin \psi + A_i \cos \psi. \quad (67b)$$

where the introduced coefficients are written as a function of the real and imaginary parts of the f_j (respectively denoted as f_j^R and f_j^I) as:

$$A_r = \rho f_3^R, \quad B_r = \rho f_1^R + \frac{\rho^3}{4} f_2^R + \rho f_4^R, \quad (68a)$$

$$A_i = \rho f_3^I, \quad B_i = \rho f_1^I - \rho \frac{\Omega}{2} + \frac{\rho^3}{4} f_2^I + \rho f_4^I. \quad (68b)$$

Following the same reasoning as the previous superharmonic and subharmonic cases, an implicit expression for the branches of solutions (FRC) reads:

$$A_r^2 + A_i^2 = B_r^2 + B_i^2. \quad (69)$$

Once the values of A_r , A_i , B_r and B_i are substituted for, it is possible to factor out ρ from all the terms, resulting in an equation of the form $\rho f(\Omega, \rho) = 0$. Thus, $\rho = 0$ is always a fixed point of the system, which is a known result in parametrically excited systems (Nayfeh et al. 1979). The non-zero solution in amplitude ρ , yielding an explicit expression for the bifurcated solution branches, can be found by solving for $f(\Omega, \rho) = 0$, which gives:

$$\frac{\Omega^2}{4} - g^I(\rho)\Omega + |g(\rho)|^2 - |f_3|^2 = 0, \quad (70)$$

where the complex $g(\rho) = g^R(\rho) + ig^I(\rho)$ has been introduced as:

$$g(\rho) = f_1^R + \frac{\rho^2}{4} f_2^R + f_4^R + i \left(f_1^I + \frac{\rho^2}{4} f_2^I + f_4^I \right). \quad (71)$$

The solutions to Equation (70) read:

$$\Omega = 2 \left(f_1^I + \frac{\rho^2}{4} f_2^I + f_4^I \right) \pm 2 \sqrt{|f_3|^2 - \left(f_1^R + \frac{\rho^2}{4} f_2^R + f_4^R \right)^2}, \quad (72)$$

which is an explicit expression for the FRC of the parametric excitation. In the present case for the coefficients f_j given in Equation (66), this equation writes:

$$\Omega = 2\omega\delta \left(1 + \frac{3h}{2^3\delta^2\omega^2}\rho^2 + \frac{\kappa^2(\delta-1)}{2^5\omega^4\delta^3\xi^2} \right) \pm 2\sqrt{\frac{\kappa^2}{2^4\omega^2\delta^2} - \xi^2\omega^2}. \quad (73)$$

To retrieve the solution given by a first-order multiple scales development from Equation (73), a small damping assumption is needed. With this approximation, where only the leading order term in ξ is kept and $\delta = 1$ is set, the third term scaling as κ^2 in the first bracket disappears. This is a logical consequence since this term comes from the monomial $z_1 z_3 z_4$ and is a second-order term for the forcing, which is neglected in the first-order MMS. The FRC then reads:

$$\Omega = 2\omega\delta \left(1 + \frac{3h}{2^3\delta^2\omega^2}\rho^2 \right) \pm 2\sqrt{\frac{\kappa^2}{2^4\omega^2\delta^2} - \xi^2\omega^2}. \quad (74)$$

The bifurcation points from which the non-zero solution will emerge are found by letting $\rho = 0$ in Equation (73). Let us call $\Omega_{a,b}$ these two period-doubling points, where a Hopf bifurcation occurs since a fixed point loses stability in favour of a limit cycle. They read, for the simple case of Equation (63)

$$\Omega_{a,b} = 2\omega\delta \left(1 + \frac{\kappa^2(\delta-1)}{2^5\omega^4\delta^3\xi^2} \right) \pm 2\sqrt{\frac{\kappa^2}{2^4\omega^2\delta^2} - \xi^2\omega^2}. \quad (75)$$

These two equations can be represented as a function of the forcing amplitude κ and give the marginal stability curves (or Floquet tongues) where the parametric excitation gives rise to non-zero solutions. They are presented in Figure 9(a) for different values of ξ , and retrieve the usual result with the minimum of these tongues increasing with the damping ratio. Interestingly, the curves are not symmetric, a feature already reported with MMS solutions, see e.g. Thomsen (2003), such that their shapes in the low-frequency range lead to crossing points, see Figure 9(a). About the bifurcated branches, their stability can be analyzed through a linear stability analysis. The detailed calculations for this case are presented in Appendix J.

A further level of refinement of the solution can be obtained by pushing the normal form development up to order four. In this case, the expression giving rise to the FRC becomes more complicated, but has the same form as Equation (37). For the sake of conciseness, the explicit expressions are not reported here, but are compared to the solutions given by Equations (73) and (74) in Figure 9(b), where the stability calculations developed in Appendix J are also included by indicating the unstable sections of the FRC with dashed lines. In the figure, the influence of different terms on the FRC expression can be appreciated. While passing from the multiple scales solution to the complete order three normal form development, the effect of the $z_1 z_3 z_4$ monomial is given by a shift in the midpoint between the two bifurcation points, generated by the term proportional to κ^2 inside the bracket in Equation (74). Additionally, the effect of not considering small damping ($\delta^2 \approx 1$) is responsible for a relative displacement of the bifurcation points, see Figure 9(b). Interestingly, the two bifurcated branches of the FRC do not close with a third-order approximation in the normal form. This can be easily seen from the equations since the term under the square root is constant, see also Figure 9(b). This result is however particular to the starting point used in this study and the fact that the f_j coefficients reported in Equation (66) are purely imaginary. A case with non-vanishing real parts is shown in Section 4.2 to extend the analysis. Note that, in the presented first-order perturbative solution, the solution branches are closing by using the actual forcing frequency Ω in the equations, as done for example in Thomsen (2003) for the MMS and in Benacchio et al. (2022) for the method of varying amplitude, a particular feature of these methods. In the present formulation, where the expansion is centered around fixed frequency Ω_p , a fourth-order normal form needs to be computed in order to recover the awaited solution with closing bifurcated branches.

Figure 9: Parametric excitation with parameter values set as $\omega = 1$ and $h = 1$, and a complex normal form analysis. (a) Marginal stability curves or Floquet tongues for $\xi = 0, 0.05, 0.1, 0.2$. (b) FRCs for different levels of approximation. The damping factor is set as $\xi = 0.2$ and the forcing amplitude as $\kappa = 1$.

This resonance scenario is also studied numerically in Figure 10. The FRCs for the physical maximal displacement u_{\max} are obtained from the output of MORFE_Symbolic, which is then solved numerically with a continuation procedure using the package Matcont (Dhooge et al. 2004). They are compared to the full system solutions, taken as reference, and obtained by numerical continuation directly on the initial problem. Two sets of parameter values are selected to highlight different features of the solutions. In Figure 10(a), parameter values are set as $\omega = 1$, $h = 1$, $\xi = 0.02$ and $\kappa = 0.043$. In this case, the order 3 solution is omitted, since its bifurcated branches don't close. Full convergence is obtained for an order 11 development. In Figure 10(b), the values of both the forcing and damping are severely increased to $\kappa = 0.9$ and $\xi = 0.2$, while keeping $\omega = 1$ and $h = 1$. This choice has been selected in order to better underline their effect on the bifurcation point and illustrate how these particular features are retrieved by the CNF solution. The numerical results show that the prediction of the bifurcation point given by the CNF is confirmed. MMS solutions and order three developments completely overpredict the maximum amplitude, such that higher orders are mandatorily needed. One can note however that, with this choice of parameters, the CNF does not converge to the exact solution. Even though all the features are correctly retrieved, an underestimation in the maximum amplitude persists, underlining that the validity limits of the method have been reached. Also, a small shift

in the bifurcation points that could not be captured by the CNF is visible.

Figure 10: FRCs for the parametric resonance of the damped cubic Mathieu oscillator. Common parameters for both figures are $\omega = 1$ and $h = 1$. Comparison of numerically computed FRCs, obtained from MORFE_Symbolic, with a reference solution obtained by numerical continuation. (a) Backbones for small levels of forcing and damping, with $\xi = 0.01$ and $\kappa = 0.043$. (a) Backbones for higher levels of forcing and damping, with $\xi = 0.2$ and $\kappa = 0.9$.

4 Theoretical results, high-order developments on two-dofs systems

This section aims to illustrate, with simple examples involving a two-degrees-of-freedom system, how the presence of a slave mode can modify the dynamics of the master mode. Three different cases with a master reduced dynamics considering a single NNM will be considered. First, a generic two-dofs system without internal resonance is considered in order to highlight the effects of the linear and nonlinear characteristics of the slave mode on the dynamics of the master. Then a parametrically excited two-dofs system is considered. Finally, an illustrative example is used to highlight the previous findings.

4.1 Case without internal resonance

A two-dofs system with quadratic and cubic nonlinearities is considered as the starting point:

$$\ddot{u}_1 + \omega_1^2 u_1 + g_{11}^1 u_1^2 + g_{12}^1 u_1 u_2 + g_{22}^1 u_2^2 + h_{111}^1 u_1^3 + h_{112}^1 u_1^2 u_2 + h_{122}^1 u_1 u_2^2 + h_{222}^1 u_2^3 = 0, \quad (76a)$$

$$\ddot{u}_2 + \omega_2^2 u_2 + g_{11}^2 u_1^2 + g_{12}^2 u_1 u_2 + g_{22}^2 u_2^2 + h_{111}^2 u_1^3 + h_{112}^2 u_1^2 u_2 + h_{122}^2 u_1 u_2^2 + h_{222}^2 u_2^3 = 0. \quad (76b)$$

Note that this represents the conservative dynamics. When needed, modal damping ratio under the form $2\xi_j \omega_j \dot{u}_j$, for $j = 1, 2$, can be added to take losses into account. Also, external forcing can be appended to the right-hand sides. Since the internal forces of mechanical systems generally derive from a potential energy, some symmetry relationships exist between the quadratic and cubic coefficients, see *e.g.* Appendix E in Touzé et al. (2021) for a general discussion. In the present case, one has, for the quadratic coefficients

$$g_{12}^1 = 2g_{11}^2, \quad \text{and} \quad g_{12}^2 = 2g_{22}^1, \quad (77)$$

meaning that only four free coefficients are at hand for quadratic terms. Of the 8 possible cubic nonlinear coefficients, only 5 are free since the following three relationships are fulfilled:

$$h_{112}^1 = 3h_{111}^2, \quad h_{122}^1 = h_{112}^2, \quad \text{and} \quad h_{122}^2 = 3h_{222}^1. \quad (78)$$

Let us assume that mode 1 is the master mode, and that no internal resonance exists between ω_1 and ω_2 . In that case, the reduced dynamics contains a single pair of master coordinates, (z_1, z_2) . Since the analytical expressions begin to be too cumbersome for an easy interpretation, let us begin with the case of a system with only cubic nonlinearities, such that all g_{ij}^p coefficients vanish, for $p, i, j = 1, 2$. The reduced dynamics, up to order 5, reads:

$$\dot{z}_1 = i\omega_1 z_1 + i \frac{3h_{111}^1}{2\omega_1} z_1^2 z_2 + 3i \left(\frac{(41\omega_1^2 - 5\omega_2^2)(h_{111}^2)^2}{\omega_1(9\omega_1^2 - \omega_2^2)(\omega_1^2 - \omega_2^2)} - \frac{17(h_{111}^1)^2}{16\omega_1^3} \right) z_1^3 z_2^2. \quad (79)$$

This result has been obtained with `MORFE_Symbolic` using the complex normal form style, and the assumptions given by Equation (78) have been taken into account. The nonlinear mappings relating the original coordinates (u_1, v_1, u_2, v_2) to the normal complex master variables (z_1, z_2) , are reported in Appendix K.

It is interesting to observe that only two cubic coefficients appear in the reduced dynamics: h_{111}^1 and h_{111}^2 . While h_{111}^1 refers only to the cubic term in u_1 and logically appears in Equation (79), the other cubic coefficient which plays a role is h_{111}^2 . Because of the symmetry relationship Equation (78), this coefficient is related to two different monomials: the invariant-breaking term u_1^3 in the second equation, and $u_1^2 u_2$ in the first equation. The invariant-breaking term is the only one (in such two-dofs scenario) responsible for the loss of invariance of the linear eigenspace. Consequently, only h_{111}^2 is responsible for the curvatures of the invariant manifold in phase space. This is also evidenced in the equations governing the geometry of the manifolds, which are contained in the nonlinear mappings reported in Appendix K. Indeed, one can see that enforcing $h_{111}^2 = 0$ in Equation (K.1) leads to $u_2 = v_2 = 0$, showing that the manifold has no extra curvatures in the direction of the second mode. Finally, looking in detail into the analytical equations of the nonlinear mappings shown in Appendix K, one can see that these expressions only depend on h_{111}^1 , h_{111}^2 , and h_{122}^1 . Again, it appears logical that h_{122}^1 is involved since it is linked in the first equation to the second trivially resonant monomial $u_1 u_2^2$ (but also to monomial $u_1^2 u_2$ in the second equation due to symmetry), following the terminology introduced in Touzé et al. (2004); Touzé (2014); Touzé et al. (2021). Interestingly, the present calculations underline that up to order 5 this term has an effect only on the nonlinear mappings, but not on the reduced dynamics. However, once higher-order developments are pursued, the other missing coefficients start to appear, first in the nonlinear mappings and then in the reduced dynamics equations. As a final remark on higher orders, one can also easily conclude that the monomials present in the reduced dynamics are the same as the ones examined for the Duffing equation, due to the simple rule of construction of the resonance. In the present case, only terms of the form $z_1^{p+1} z_2^p$, with $p \geq 1$, will stay in the reduced dynamics, while the coefficients are modified by the presence of the second oscillator.

Thanks to the property of the CNF already underlined in Section 2.1, the backbone curve is analytic up to the desired order. Since the coefficients are lengthy for orders higher than 5, only the fifth-order is shown here, but of course, closed-form expressions are readily available for high-order terms:

$$\frac{\omega_{NL}}{\omega_1} = 1 + \frac{3}{8} \frac{h_{111}^1}{\omega_1^2} \rho^2 + \frac{3}{16} \left(\frac{41\omega_1^2 - 5\omega_2^2}{(9\omega_1^2 - \omega_2^2)(\omega_1^2 - \omega_2^2)} \left(\frac{h_{111}^2}{\omega_1^2} \right)^2 - \frac{17}{16} \left(\frac{h_{111}^1}{\omega_1^2} \right)^2 \right) \rho^4. \quad (80)$$

Interestingly, the coefficient h_{111}^2 which appears in the cubic term might have an effect on the hardening/softening behaviour at large amplitude. If the first-order term is unequivocally dictated by the value of h_{111}^1 , one can see that the next order depends in a complicated manner also on h_{111}^2 , ω_1 and ω_2 . This is illustrated in Figure 11(a) where three different scenarios have been tested. In each case, a high-order backbone curve is computed from the expressions obtained with the parametrisation method up to order 25, and is compared to a reference solution obtained by a numerical continuation technique.

The first case is where the invariant-breaking term vanishes, *i.e.* $h_{111}^2 = 0$. In such a case, the backbone follows that of a single-dof Duffing equation. Then two other cases are selected, using $h_{111}^2 = 1$, $\omega_1 = 1$, and either $\omega_2 = 1.57$, or $\omega_2 = 0.637$. The slave mode's eigenfrequencies were purposefully selected such that no low-order resonance relationships are verified. Figure 11(a) shows the obtained results. When $\omega_2 = 1.57$, some terms in the quintic coefficient shown in Equation (80) are negative, such that the hardening behaviour turns back to softening at higher amplitudes. This effect is correctly captured by the asymptotic solution to order 25 which is close to the numerical solution up to amplitudes around 0.65. In this case, the validity limit of the asymptotic approach seems to decrease as compared to the case $h_{111}^2 = 0$. On the other hand, when the slave mode has the lowest eigenfrequency with $\omega_2 = 0.637$, the hardening behaviour is enhanced by the higher-order terms. In this case, the validity limit seems to be even smaller since the order 25 solution departs from the reference from amplitudes around 0.45.

Let us now consider the effect of the quadratic terms by considering all quadratic and cubic

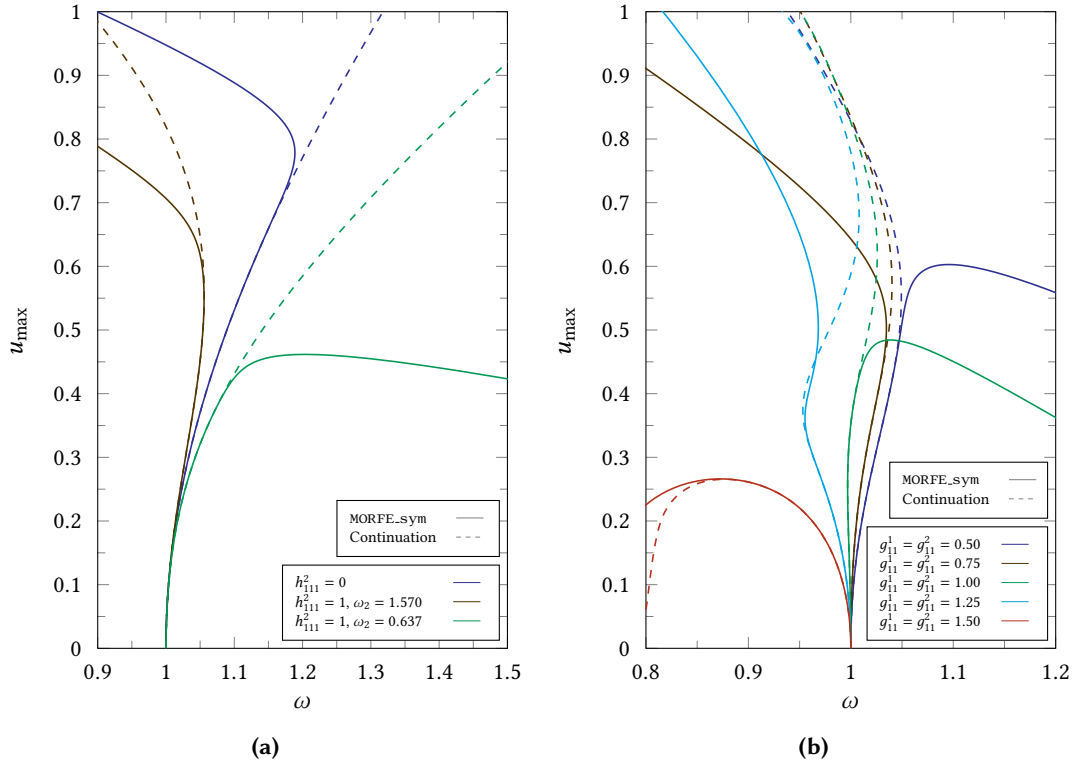

Figure 11: Backbones up to order 25 for the 2-dofs system without internal resonance. The curves were obtained using a complex normal form style, and parameter values were fixed as $\omega_1 = 1$, $h^1_{111} = 1$, h^2_{111} , g^1_{11} and g^2_{11} varying, and all other nonlinear stiffness coefficients zero (other than the ones fixed by symmetry conditions). The backbones given by the parametrisation method are compared with reference solutions obtained using the numerical continuation package Matcont (Dhooge et al. 2004). (a) Oscillator with only cubic coefficients. (b) Oscillator with quadratic and cubic coefficients. Additional parameters fixed: $\omega_2 = 1.57$, $h^2_{111} = 1$.

coefficients in Equation (76). Since the full analytical expressions begin to be lengthy, only the third-order reduced dynamics with CNF is reported to see how the quadratic coefficients aggregate to form the third-order coefficient in the normal form that dictates the hardening/softening behaviour. It reads:

$$\dot{z}_1 = i\omega_1 z_1 + i\omega_1 \left(\frac{3}{2} \frac{h^1_{111}}{\omega_1^2} - \frac{5}{3} \left(\frac{g^1_{11}}{\omega_1^2} \right)^2 - \frac{8\omega_1^2 - 3\omega_2^2}{4\omega_1^2 - \omega_2^2} \left(\frac{g^2_{11}}{\omega_1\omega_2} \right)^2 \right) z_1^2 z_2. \quad (81)$$

One can see that, at this order, two quadratic coefficients are of special interest. First, the “self-quadratic” one, g^1_{11} , which is present in a single-dof Duffing analysis, see Section 3.1. Second, the invariant-breaking quadratic coefficient g^2_{11} . One can also note that the denominator of the invariant breaking term vanishes when a 2:1 internal resonance such that $\omega_2 = 2\omega_1$ is met, a feature already discussed in Touzé et al. (2004); Touzé et al. (2006).

Figure 11(b) illustrates this effect of the quadratic terms by considering the increase of both g^1_{11} and g^2_{11} with the same trend, by imposing $g^1_{11} = g^2_{11}$, and increasing them from 0.5 to 1.5. As awaited, the quadratic nonlinearity favours the softening behaviour, and one can see that the types of behaviour ranged by this choice are various and generally well reproduced by the normal form analysis, up to a certain amplitude that should correspond to the validity limit of the asymptotic development.

4.2 Parametrically excited system

This section considers a simplified two-dofs system which is representative of a flat structure externally excited with an in-plane force, which leads to transverse vibrations through a parametric excitation. In such a case, studied numerically with a cantilever beam in Opreni et al. (2023), the external forcing transforms to a parametric excitation in the reduced dynamics. The simplest system that can reproduce such an effect needs to contain a quadratic coupling between

Figure 12: Externally forced 2-dofs system leading to a parametric resonance, Equation (82). Comparison of the results obtained with a third-order complex normal form style and the method of multiple scales (MMS). Parameter values set as $\omega_2 = 1.57$, $\xi = 0.2$, $h = 0.5$, $g = 5$ and $\kappa = 0.2$.

master and slave modes, as is the case in beam structures for example (Vizzaccaro et al. 2020; Givois et al. 2019). The model introduced in Vizzaccaro et al. (2021) is thus selected here, it reads:

$$\ddot{u}_1 + 2\xi\dot{u}_1 + u_1 + 2gu_1u_2 + hu_1^3 = 0, \quad (82a)$$

$$\ddot{u}_2 + 2\xi\omega_2\dot{u}_2 + \omega_2^2u_2 + gu_1^2 = \kappa \cos \Omega t, \quad (82b)$$

where the forcing frequency Ω is selected in the vicinity of twice the eigenfrequency of the master mode (normalized at 1 here), $\Omega \approx 2$, in order to activate the principal parametric resonance. Additionally, a small damping assumption is introduced to simplify the coefficients. In this case, the reduced dynamics up to the third order, with a parametrisation computed with the choice $\Omega_p = 2$, writes:

$$\dot{z}_1 = f_1z_1 + f_2z_1^2z_2 + f_3z_2z_3 + f_4z_1z_3z_4, \quad (83)$$

with the coefficients f_j , $j = 1, \dots, 4$ reading as:

$$f_1 = i - \xi, \quad f_3 = \frac{g\kappa(i - \xi)}{2(i\xi + 1)(\omega_2 - 2)(4i\xi + \omega_2 + 2)}, \quad f_4 = -\frac{g^2\kappa^2(2i - 7\xi)}{32(\omega_2^2 - 4)^2} \quad (84a)$$

$$f_2 = \frac{(i - \xi)(-16g^2i\xi\omega_2 + 32g^2i\xi - 6g^2\omega_2^2 + 16g^2 - 12hi\xi\omega_2^3 + 24hi\xi\omega_2^2 - 3h\omega_2^4 + 12h\omega_2^2)}{2\omega_2^2(i\xi + 1)(\omega_2 - 2)(4i\xi + \omega_2 + 2)}. \quad (84b)$$

The reduced dynamics equation is, as expected, the same as the one shown in Equation (65). In this situation, however, the coefficients f_j , and in particular f_2 , have non-vanishing real parts. As a consequence, the term under the square root in Equation (72) depends on ρ and the FRC closes at order three. This situation is illustrated in Figure 12.

From the figure, one can also note that for the selected parameter values the bifurcated branches of the FRC display a softening behaviour. Inspecting Equation (72) shows that the hardening/softening behaviour is governed by the imaginary part f_2^I of the coefficient f_2 . In the present case, it can be written explicitly as:

$$f_2^I = g^2 \frac{3\omega_2^2 - 8}{\omega_2^2(4 - \omega_2^2)} - \frac{3h}{2}. \quad (85)$$

Consequently, the hardening/softening transition occurs for this specific case when f_2^I vanishes, and a hardening behaviour is obtained for $h < g^2 \frac{6\omega_2^2 - 16}{3\omega_2^2(4 - \omega_2^2)}$. Again, the wealth of the proposed ROMs can be here underlined since they provide physical insights and predictive interpretations that can be directly checked on the numerical results. Otherwise, the same comments made in Section 3.3 also apply here. The slight shift of the bifurcation points between the multiple scales solution and the order 3 normal form development is also retrieved and is illustrated in Figure 12. A stability analysis similar to the one given in Appendix J could also be applied here, but is not done for concision, and therefore not reported in the figure.

4.3 Illustrative example: a mass connected to two nonlinear springs

This last section aims at illustrating some of the results presented in the paper to the case of a 2 dofs system consisting of a mass connected to two elastic nonlinear springs. This example has been introduced in [Touzé et al. \(2004\)](#) and then used in several articles as a benchmark study ([Touzé et al. 2006a](#); [Lamarque et al. 2012](#); [Breunung et al. 2018](#); [Liu et al. 2019](#)). The equations of motion read:

$$\ddot{u}_1 + \omega_1^2 u_1 + \frac{\omega_1^2}{2} (3u_1^2 + u_2^2) + \omega_2^2 u_1 u_2 + \frac{\omega_1^2 + \omega_2^2}{2} u_1 (u_1^2 + u_2^2) = 0 \quad (86a)$$

$$\ddot{u}_2 + \omega_2^2 u_2 + \frac{\omega_2^2}{2} (3u_2^2 + u_1^2) + \omega_1^2 u_1 u_2 + \frac{\omega_1^2 + \omega_2^2}{2} u_2 (u_1^2 + u_2^2) = 0. \quad (86b)$$

It should be highlighted that the nonlinear stiffness coefficients can be written as a function of the eigenfrequencies of the system, leading to simplified expressions for the coefficients appearing in the high-order normal forms. Up to order 5, it reads, using again the CNF and showing only the equation for z_1 :

$$\begin{aligned} \dot{z}_1 = & i\omega_1 z_1 + i \frac{4\omega_1(-3\omega_1^2 + \omega_2^2)}{4\omega_1^2 - \omega_2^2} z_1^2 z_2 \\ & + i \frac{\omega_1(-9072\omega_1^{10} + 27180\omega_1^8\omega_2^2 - 19624\omega_1^6\omega_2^4 + 5835\omega_1^4\omega_2^6 - 754\omega_1^2\omega_2^8 + 35\omega_2^{10})}{576\omega_1^{10} - 1072\omega_1^8\omega_2^2 + 652\omega_1^6\omega_2^4 - 177\omega_1^4\omega_2^6 + 22\omega_1^2\omega_2^8 - \omega_2^{10}} z_1^3 z_2^2 \end{aligned} \quad (87)$$

Furthermore, using polar realification, an analytic expression for the backbone can be found as

$$\begin{aligned} \omega_{NL} = & \omega_1 + \frac{-3\omega_1^3 + \omega_1\omega_2^2}{4\omega_1^2 - \omega_2^2} \rho_1^2 \\ & + \frac{-9072\omega_1^{11} + 27180\omega_1^9\omega_2^2 - 19624\omega_1^7\omega_2^4 + 5835\omega_1^5\omega_2^6 - 754\omega_1^3\omega_2^8 + 35\omega_1\omega_2^{10}}{16(4\omega_1^2 - \omega_2^2)^3(9\omega_1^2 - \omega_2^2)(\omega_1^2 - \omega_2^2)} \rho_1^4. \end{aligned} \quad (88)$$

Let us denote as $f^{(p)}$ the coefficient of the monomial of order p in the normal form. The third-order term, which governs the first curvature of the backbone curve and the hardening/softening behaviour, has already been analyzed in [Touzé et al. \(2004\)](#) with the oscillator normal form, leading to the same coefficient as $f^{(3)}$ reported here with the CNF. Thanks to the high-order expansions, the analysis can be pushed further by considering the variations of $f^{(5)}$, whose expression is reported in [Equation \(87\)](#), and $f^{(7)}$, not shown here for the sake of brevity, whose variations are represented in [Figure 13](#) for $\omega_1 = 1$ and varying ω_2 .

Figure 13: Behaviour of the normal form coefficients $f^{(3)}$, $f^{(5)}$ and $f^{(7)}$ for the two-dofs system given in [Equation \(86\)](#) as a function of ω_2 , with $\omega_1 = 1$.

From the figure, it is easy to predict the type of nonlinearity for the order 7 backbone curve. Taking for instance $\omega_2 = 1.5$, the system shows a softening behaviour, since all three coefficients $f^{(3)}$, $f^{(5)}$, and $f^{(7)}$ are negative. On the contrary, for $\omega_2 = 2.5$, since $f^{(3)}$ and $f^{(5)}$ are positive, the backbone will first display a hardening behaviour, turning to softening for large amplitudes since $f^{(7)}$ is highly negative and will dominate.

Figure 13 also illustrates that the coefficients have a singular behaviour when internal resonances are crossed, a typical feature resulting from the small denominator problem. The third-order coefficient $f^{(3)}$ displays a singularity when a 1:2 internal resonance $\omega_2 = 2\omega_1$ appears, a behaviour already analyzed *e.g.* in Rega et al. (2000); Touzé et al. (2004); Touzé et al. (2006); Arafat et al. (2003). Interestingly, the order five coefficient $f^{(5)}$ shows in addition a singularity for the first third-order resonances, namely the 1:1 and the 1:3 resonances defined by $\omega_2 = \omega_1$ and $\omega_2 = 3\omega_1$. This is a direct consequence that the order five coefficient is built from the elimination of the cubic terms. Continuing further, the order seven coefficient $f^{(7)}$ has an additional singularity at the 1:4 resonance $\omega_2 = 4\omega_1$, following the cancellation of the quartic terms in the normal form. Finally, it is also possible to notice that for $\omega_2 > 4$ the values of the coefficients remain virtually constant, and the backbone behaviour is hardening at low amplitudes followed by softening at high amplitudes.

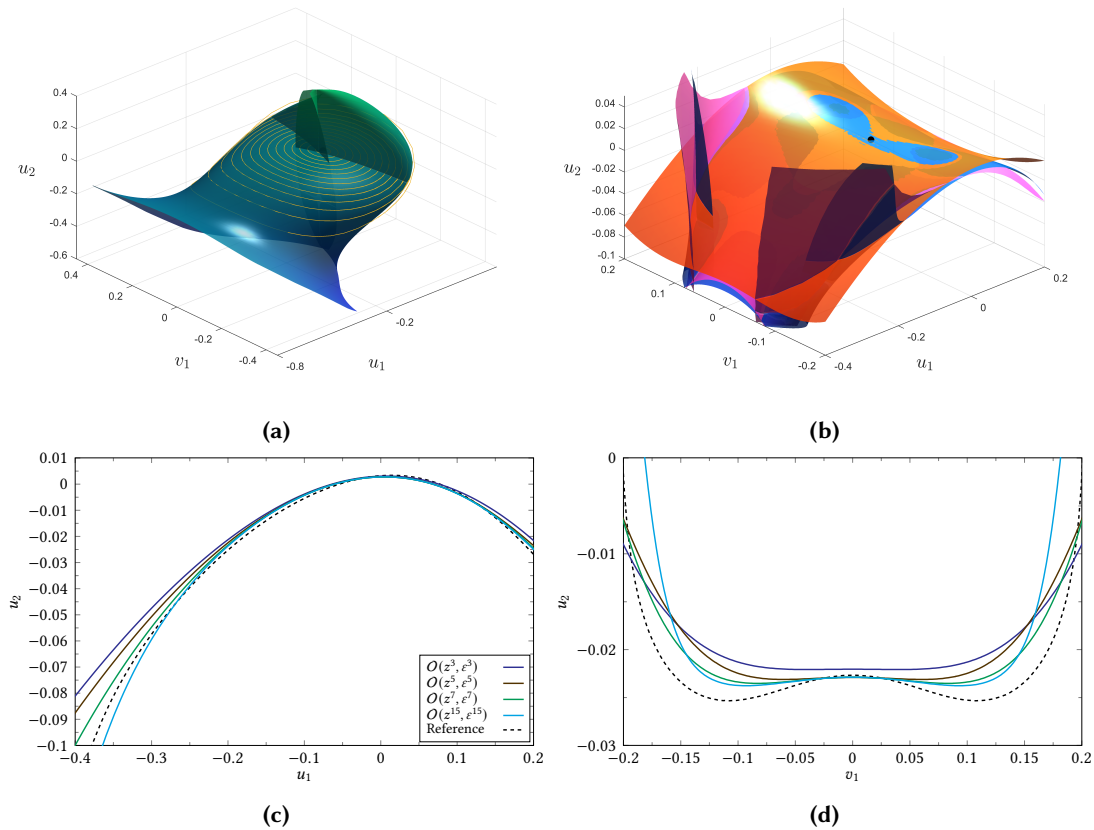

Figure 14: Phase space representation for the two-dofs system given by Equation (86). (a) Comparison of periodic orbits calculated with an order 20 parametrisation and the invariant manifold obtained by numerical continuation for $\omega_1 = 1$ and $\omega_2 = 1.57$. (b) Comparison of the manifolds of order 3 and 15 obtained by the parametrisation method with the one found by continuation for $\omega_1 = \sqrt{0.5}$ and $\omega_2 = \sqrt{6}$. The black point represents the origin. (c-d) Cross-sections at $v_1 = 0.1$ and $u_1 = -0.2$, respectively, obtained from case (b). Solutions of order 3, 5, 7 and 15 are compared to the numerical continuation reference.

Whereas most of the reported analyses have been focused on FRCs, this section closes with numerous illustrative examples highlighting the behaviour of the invariant manifold serving as a reduced-order subspace in the method. First, the convergence in terms of the geometry and the effect of higher-order terms on the computed curvatures are illustrated.

Figure 14(a) compares the exact shape of the invariant manifold, which has been computed by numerical continuation, to periodic orbits calculated using an order 20 parametrisation, with $\omega_1 = 1$ and $\omega_2 = 1.57$. It can be seen that the orbits show an almost perfect agreement with the manifold in a region surrounding the fixed point located at the origin. In the same spirit, Figure 14(b) compares the numerical manifold obtained by continuation for $\omega_1 = \sqrt{0.5}$ and $\omega_2 = \sqrt{6}$, depicted in blue, to different orders of the asymptotic expansions: order 3 in orange, and order 15, in pink. It clearly highlights that, with increasing orders, the asymptotically computed

manifolds can retrieve the complex curvatures of the exact solution. To aid the visualization, section cuts of Figure 14(b) are presented in Figures 14(c) and 14(d), where orders 5 and 7 solutions are also included to better appreciate the convergence. Note that Figure 14(d) shows a cross-section at $u_1 = -0.2$ which is quite far from the origin, hence explaining the observed discrepancies.

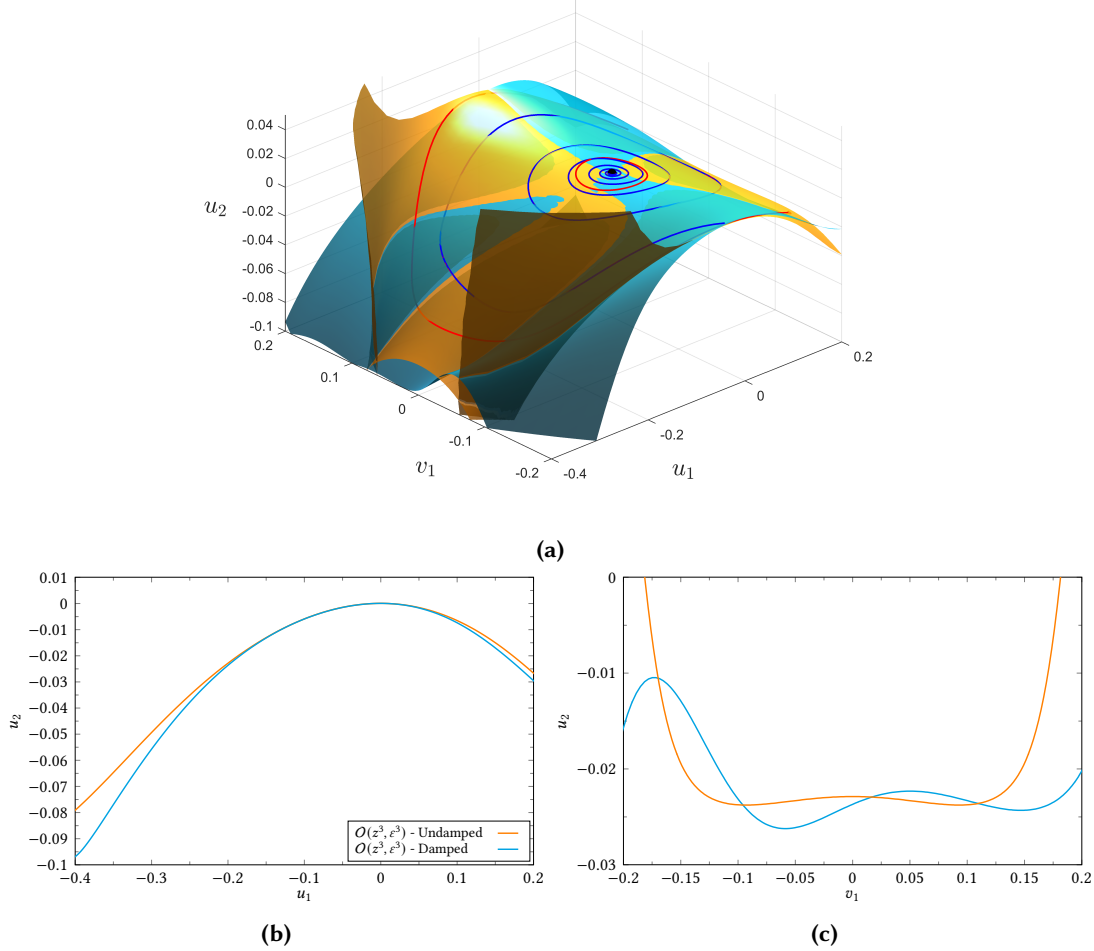

Figure 15: Influence of damping on the invariant manifolds for the mass connected to two springs. (a) Comparison of the order 15 damped (blue) and undamped (yellow) manifolds obtained by the parametrisation method with CNF style, for $\omega_1 = \sqrt{0.5}$, $\omega_2 = \sqrt{6}$ and $\xi_1 = \xi_2 = 0.1$. Two periodic orbits, in red, are also shown for the full conservative system as well as a damped orbit of the full system, in blue. The black point represents the origin. (b-c) Cuts at $v_1 = 0$ and $u_1 = -0.2$, respectively, obtained from (a).

The next case illustrates how the linear viscous damping terms might affect the shape of the invariant manifolds, thus highlighting the difference between a conservative and a damped manifold. Viscous damping of the form $2\xi_i\omega_i$, $i = \{1, 2\}$, is appended to Equation (86). Figure 15 shows the invariant manifolds computed by the parametrisation method with CNF, with system's parameters fixed as $\omega_1 = \sqrt{0.5}$, $\omega_2 = \sqrt{6}$ and $\xi_1 = \xi_2 = 0.1$. In Figure 15(a) the damped manifold, in blue, is compared with the one obtained without damping, in yellow. It is possible to notice that in the dissipative case, the curvatures of the manifold are importantly attenuated, which can be better appreciated by inspecting Figures 15(b) and 15(c), which show cross-sections of the manifolds.

Lastly, the effect of the external forcing on the manifolds is examined in Figure 16, to illustrate the behaviour of time-dependent invariant manifolds in the context of model order reduction. Two different orders of truncations relative to the forcing term, are considered. A first case where a first-order assumption on the forcing is adopted, following Opreni et al. (2023); Jain et al. (2022) (first column, Figures 16(a), 16(c) and 16(e), $O(z^3, \varepsilon^1)$ truncation). In the second case, an $O(z^3, \varepsilon^3)$ truncation is shown, highlighting the higher-order effects of the non-autonomous

terms computed thanks to the development shown in [Vizzaccaro et al. \(2023\)](#) (second column, Figures 16(b), 16(d) and 16(f)).

Additionally, three cases relative to the forcing configuration, are examined. In the first one, corresponding to Figures 16(a) and 16(b), the forcing is perfectly aligned with the master eigenspace. This case is obtained by setting a harmonic forcing only on Equation (86a). In this situation, when the development of the nonautonomous terms stops at order 1, the manifolds exhibit a rigid body rotation along a path that remains on the master eigenplane, as shown in [Opreni et al. \(2023\)](#) and illustrated in Figure 16(a). Once high-order forcing terms are considered, however, the rotation of the fixed point shows slight deviations from the linear eigenplane due to the higher-order effects. Additionally the motion of the manifold is no longer a rigid body one, and shows important deformations, as can be seen in Figure 16(b).

The second case corresponds to a forcing that is now orthogonal to the master eigenspace, obtained by setting a harmonic forcing only on Equation (86b). The first-order development for the non-autonomous part predicts a rigid body motion of the manifold along a circular motion on the slave eigenplane ([Opreni et al. 2023](#)), which when projected into the adopted representation space corresponds to a straight vertical line, as seen in Figure 16(c). With the inclusion of the high-order forcing terms once again the manifold deforms, and the motion path along the phase space is no longer circular. Its projection to the representation space, nevertheless, still remains a straight line, as can be seen in Figure 16(d), which indicates that it is entirely contained in the slave eigenspace.

Finally, Figures 16(e) and 16(f) showcase the general case where the forcing is neither orthogonal nor parallel to the master eigenspace. In this situation, as can be observed from the figures, the motion of the manifolds is a combination of the two previous situations.

5 Conclusion

High-order, automated solutions for nonlinear vibrations, have been derived and analyzed thanks to a symbolic version of the parametrisation method for invariant manifold, implemented in the package `MORFE_Symbolic`. The contribution aims to show how this general method can be used efficiently to derive several useful results to understand the reduced dynamics of large dimensional systems. It also underlines the existing continuity between low-order analytical perturbative solutions and high-order numerical solutions. When the solutions are analytically tractable, we have shown how they can easily reduce to known results obtained with perturbative methods, and how they extend by considering more effects with fewer assumptions. Indeed, a key feature of the parametrisation method is to offer high-order expansions with a single assumption on the smallness of the amplitudes. This is in contrast with perturbative solutions where a scaling of the different terms (nonlinearity, forcing, damping) needs to be introduced with an ε parameter at the first step. This is not needed here and falls automatically from the analysis.

Most of the analyses have been led here using the complex normal form (CNF), after explaining the differences between three variants of normal forms that have been derived in the nonlinear vibration literature. The symbolic package also allows one to derive the solutions obtained with graph style, a feature that has not been investigated here but which can be automatically computed to compare with normal form style. Analysis on primary, secondary and parametric resonance have been exhibited, and the scope has been limited to cases where the master dynamics contains a single master mode, but of course, the results can be extended and take into account many more scenarios.

In the course of the developments, the wealth of the computed solutions has been regularly commented on, showing how they generalize previously known results limited to first orders, and how they can converge to the exact solution by considering the effects of the higher orders. We believe that systematically using the complex normal form, in combination with the parametrisation method, defines a new powerful grammar for solving nonlinear vibration problems, from low-order analytical solutions to high-order numerical solutions. Besides, normal forms can be used for system identification since providing the skeleton of the dynamics and the simplest dynamical system reproducing a given resonance scenario.

The only limitation of the approach is the validity limit in terms of amplitude, which has

Figure 16: Influence of forcing on the invariant manifolds for the mass connected to two springs. In all figures parameter values are fixed as $\omega_1 = 1$, $\omega_2 = 1.57$ and $\xi_1 = \xi_2 = 0.01$, and a primary resonance situation is considered. For figures (a), (c) and (e) $\kappa = 1$ and an $\mathcal{O}(z^3, \varepsilon^1)$ truncation is chosen, while for figures (b), (d) and (f) $\kappa = 0.2$ and an $\mathcal{O}(z^3, \varepsilon^3)$ is adopted. (a-b) Forcing perfectly aligned with the master mode. (c-d) Forcing perfectly orthogonal to the master mode. (e-f) Forcing in both master and slave modes.

been commented on here and there in the analysis. Future work will thus consider extending the presented results to other resonance scenarios, to build a dictionary of reference solutions. As an example, general solutions for 1:2 internal resonance could be derived to generalize the results shown in Gobat et al. (2021), and resonant phase lags could also be obtained with high-order solutions to generalize the results shown in Volvert et al. (2022). Finally, the question of accurately estimating the validity limits of the method in terms of amplitudes should be tackled to provide the analyst with a priori and a posteriori amplitude bounds.

6 Backmatter information

The following subsections will be added to the accepted version of the paper.

Acknowledgements The authors would like to thank Aurélien Grolet, Olivier Thomas, Loic Salles, Alessio Colombo and Attilio Frangi for fruitful discussions related to the subject.

Authors’ contributions André de Figueiredo Stabile carried out most of the developments presented in this work, including: development and improvement on the symbolic software, analytical and numerical developments, analysis of the different cases, comparisons with perturbative solutions, results outputs and figure production. Cyril Touzé carried out the first steps of the research, developed the different normal forms, wrote the first draft of the paper and supervised the work. Alessandra Vizzaccaro produced the first code version of MORFE_Symbolic, participated in the choice of the examples analyzed, helped in producing the final version of the codes, and proposed numerous improvements in the presentation, the analytical developments and the symbolic processing. All authors read and approved the final manuscript.

Ethics approval and consent to participate Not applicable.

Consent for publication Not applicable.

Competing interests The authors declare that they have no competing interests.

A Nonlinear change of coordinates for the CNF of the Duffing equation

In this appendix, the nonlinear mappings used to compute the complex normal form of the conservative Duffing equation with only cubic nonlinearity, are given, for the sake of completeness. The normal form up to order 9 is given in the main text as Equation (8). The nonlinear mapping

allowing one to get from Equation (3) to the normal form, up to order 7, reads:

$$\begin{aligned}
u = & z_1 + z_2 + \frac{h}{8\omega^2}z_1^3 - \frac{3h}{4\omega^2}z_1^2z_2 - \frac{3h}{4\omega^2}z_1z_2^2 + \frac{h}{8\omega^2}z_2^3 + \frac{h^2}{64\omega^4}z_1^5 - \frac{39h^2}{64\omega^4}z_1^4z_2 + \frac{69h^2}{32\omega^4}z_1^3z_2^2 \\
& + \frac{69h^2}{32\omega^4}z_1^2z_2^3 - \frac{39h^2}{64\omega^4}z_1z_2^4 + \frac{h^2}{64\omega^4}z_2^5 + \frac{h^3}{512\omega^6}z_1^7 - \frac{73h^3}{512\omega^6}z_1^6z_2 + \frac{1569h^3}{512\omega^6}z_1^5z_2^2 \\
& - \frac{2139h^3}{256\omega^6}z_1^4z_2^3 - \frac{2139h^3}{256\omega^6}z_1^3z_2^4 + \frac{1569h^3}{512\omega^6}z_1^2z_2^5 - \frac{73h^3}{512\omega^6}z_1z_2^6 + \frac{h^3}{512\omega^6}z_2^7
\end{aligned} \tag{A.1a}$$

$$\begin{aligned}
v = & i\omega z_1 - i\omega z_2 + i\frac{3h}{8\omega}z_1^3 + i\frac{3h}{4\omega}z_1^2z_2 - i\frac{3h}{4\omega}z_1z_2^2 - i\frac{3h}{8\omega}z_2^3 + i\frac{5h^2}{64\omega^3}z_1^5 - i\frac{81h^2}{64\omega^3}z_1^4z_2 \\
& - i\frac{69h^2}{32\omega^3}z_1^3z_2^2 + i\frac{69h^2}{32\omega^3}z_1^2z_2^3 + i\frac{81h^2}{64\omega^3}z_1z_2^4 - i\frac{5h^2}{64\omega^3}z_2^5 + i\frac{7h^3}{512\omega^5}z_1^7 - i\frac{305h^3}{512\omega^5}z_1^6z_2 \\
& + i\frac{2691h^3}{512\omega^5}z_1^5z_2^2 + i\frac{2139h^3}{256\omega^5}z_1^4z_2^3 - i\frac{2139h^3}{256\omega^5}z_1^3z_2^4 - i\frac{2691h^3}{512\omega^5}z_1^2z_2^5 + i\frac{305h^3}{512\omega^5}z_1z_2^6 \\
& - i\frac{7h^3}{512\omega^5}z_2^7
\end{aligned} \tag{A.1b}$$

As an interesting general remark, the relationship $\dot{u} = v$ correctly translates in the nonlinear change of coordinates. Indeed, taking the derivative of Equation (A.1a) with respect to time, eliminating the time dependence thanks to the reduced dynamics given by Equation (8), then one exactly retrieves Equation (A.1b). This remark is general and can be verified in each of the treated examples, whatever the style used. It is a direct consequence of the fact that the initial problem is second-order in time, such that the velocity mapping can be expressed as a function of the displacement mapping, see e.g. Vizzaccaro et al. (2022); Opreni et al. (2023); Vizzaccaro et al. (2023) for general discussions related to this point.

It is also possible to obtain the nonlinear mappings relating normal and modal coordinates, which are here given for the sake of completeness:

$$\begin{aligned}
y_1 = & z_1 + \frac{h}{4\omega^2}z_1^3 - \frac{3h}{4\omega^2}z_1z_2^2 - \frac{h}{8\omega^2}z_2^3 + \frac{3h^2}{64\omega^4}z_1^5 - \frac{15h^2}{16\omega^4}z_1^4z_2 + \frac{69h^2}{32\omega^4}z_1^3z_2^2 + \frac{21h^2}{64\omega^4}z_1z_2^4 \\
& - \frac{h^2}{32\omega^4}z_2^5 + \frac{h^3}{128\omega^6}z_1^7 - \frac{189h^3}{512\omega^6}z_1^6z_2 + \frac{1065h^3}{256\omega^6}z_1^5z_2^2 - \frac{2139h^3}{256\omega^6}z_1^4z_2^3 - \frac{561h^3}{512\omega^6}z_1^3z_2^4 \\
& + \frac{29h^3}{128\omega^6}z_1z_2^6 - \frac{3h^3}{512\omega^6}z_2^7
\end{aligned} \tag{A.2a}$$

$$\begin{aligned}
y_2 = & z_2 - \frac{h}{8\omega^2}z_1^3 - \frac{3h}{4\omega^2}z_1^2z_2 + \frac{h}{4\omega^2}z_2^3 - \frac{h^2}{32\omega^4}z_1^5 + \frac{21h^2}{64\omega^4}z_1^4z_2 + \frac{69h^2}{32\omega^4}z_1^3z_2^2 - \frac{15h^2}{16\omega^4}z_1z_2^4 \\
& + \frac{3h^2}{64\omega^4}z_2^5 - \frac{3h^3}{512\omega^6}z_1^7 + \frac{29h^3}{128\omega^6}z_1^6z_2 - \frac{561h^3}{512\omega^6}z_1^5z_2^2 - \frac{2139h^3}{256\omega^6}z_1^4z_2^3 + \frac{1065h^3}{256\omega^6}z_1^3z_2^4 \\
& - \frac{189h^3}{512\omega^6}z_1z_2^6 + \frac{h^3}{128\omega^6}z_2^7
\end{aligned} \tag{A.2b}$$

Note that the symbolic code MORFE_Symbolic allows producing these equations up to an arbitrary order, shown here only up to order 7 for the sake of brevity.

B Additional results for the real normal form of the Duffing oscillator

In this appendix, more details on the real normal form (RNF) are given. First, for the sake of completeness and in order to draw out comparisons with CNF, the nonlinear mapping between the original and normal coordinates, is given up to order 7:

$$\begin{aligned}
u = & z_1 + z_2 + \frac{h}{8\omega^2}z_1^3 + \frac{h}{8\omega^2}z_2^3 + \frac{h^2}{64\omega^4}z_1^5 - \frac{21h^2}{64\omega^4}z_1^4z_2 - \frac{21h^2}{64\omega^4}z_1z_2^4 + \frac{h^2}{64\omega^4}z_2^5 \\
& + \frac{h^3}{512\omega^6}z_1^7 - \frac{109h^3}{512\omega^6}z_1^6z_2 + \frac{357h^3}{512\omega^6}z_1^5z_2^2 + \frac{357h^3}{512\omega^6}z_1^4z_2^3 - \frac{109h^3}{512\omega^6}z_1z_2^6 + \frac{h^3}{512\omega^6}z_2^7
\end{aligned} \tag{B.1a}$$

$$\begin{aligned}
v = & i\omega z_1 - i\omega z_2 + i\frac{3h}{8\omega}z_1^3 - i\frac{3h}{8\omega}z_2^3 + i\frac{5h^2}{64\omega^3}z_1^5 - i\frac{27h^2}{64\omega^3}z_1^4z_2 + i\frac{27h^2}{64\omega^3}z_1z_2^4 - i\frac{5h^2}{64\omega^3}z_2^5
\end{aligned}$$

$$+ i \frac{7h^3}{512\omega^5} z_1^7 - i \frac{233h^3}{512\omega^5} z_1^6 z_2 + i \frac{195h^3}{512\omega^5} z_1^5 z_2^2 - i \frac{195h^3}{512\omega^5} z_1^2 z_2^5 + i \frac{233h^3}{512\omega^5} z_1 z_2^6 - i \frac{7h^3}{512\omega^5} z_2^7 \quad (\text{B.1b})$$

These equations can be directly compared to those for the CNF shown in Equation (A.1). Since more monomials have been considered resonant and kept in the normal form for the RNF as compared to the CNF, the immediate consequence is that the nonlinear mapping for the CNF contains fewer terms.

The next added information about the RNF is some calculations and approximations in order to derive an analytical backbone curve. To that purpose, the idea is to use assumptions and calculation procedures used in Neild et al. (2011); Neild et al. (2015), that have been reinterpreted and reworked from the formalism derived in the present paper. The two main ideas used in Neild et al. (2011); Neild et al. (2015) consists of using a mixed formulation with the initial coordinates (u, v) and the normal coordinates (z_1, z_2) , and then to introduce a small bookkeeping parameter ε and asymptotic expansions to solve for the backbone order by order. Another key point is also to re-introduce oscillator-like equations with second-order derivatives in time. To that purpose, Equation (B.1b) up to order 5 can be differentiated with respect to time, yielding

$$\begin{aligned} \dot{v} = \ddot{u} = i\omega (z_1 - z_2) + i \frac{9h}{8\omega} (z_1^2 z_1 - z_2^2 z_2) \\ + i \frac{h^2}{64\omega^3} (25z_1^4 z_1 - 108z_1^3 z_2 z_1 - 27z_1^4 z_2 + 27z_2^4 z_2 + 108z_1 z_2^3 z_2 - 25z_2^4 z_2). \end{aligned} \quad (\text{B.2})$$

Then, considering that the reduced dynamics up to order 5 is given by

$$\dot{z}_1 = i\omega z_1 + i \frac{3h}{2\omega} (z_1^2 z_2 + z_1 z_2^2) - i \frac{3h^2}{16\omega^3} (5z_1^3 z_2^2 + 2z_1^2 z_2^3) \quad (\text{B.3a})$$

$$\dot{z}_2 = -i\omega z_2 - i \frac{3h}{2\omega} (z_1^2 z_2 + z_1 z_2^2) + i \frac{3h^2}{16\omega^3} (2z_1^3 z_2^2 + 5z_1^2 z_2^3), \quad (\text{B.3b})$$

and introducing it on the previous equation while neglecting terms of order higher than 5, the following relationship can be found:

$$\begin{aligned} \ddot{u} = -\omega^2 \left[z_1 + z_2 + \frac{h}{8\omega^2} (z_1^3 + z_2^3) + \frac{h^3}{64\omega^4} (z_1^5 - 21z_1^4 z_2 - 21z_1 z_2^4 + z_2^5) \right] \\ - h \left[z_1^3 + 3z_1^2 z_2 + 3z_1 z_2^3 + z_2^3 + \frac{3h}{8\omega^2} (z_1^5 + 2z_1^4 z_2 + z_1^3 z_2^2 + z_1^2 z_2^3 + 2z_1 z_2^4 + z_2^5) \right]. \end{aligned} \quad (\text{B.4})$$

In this last equation, the first term in bracket is exactly equal to u while the second to u^3 , meaning that this equation is a rewriting of the original problem (Duffing equation) where the nonlinear mapping between the initial and normal coordinates has been made explicit. In order to derive an analytical backbone curve, polar coordinates can be introduced as $z_1 = \frac{\rho}{2} e^{i\omega_{NL}t}$ and $z_2 = \frac{\rho}{2} e^{-i\omega_{NL}t}$, with ρ and ω_{NL} constant in time, and where the phase of the harmonics was taken to be zero. Additionally, in the spirit of perturbation methods, a bookkeeping parameter ε is introduced, in order to scale different orders of magnitude. Specifically, it is assumed that ρ is of $\mathcal{O}(\varepsilon)$, while ω_{NL}^2 can be decomposed in the spirit of a perturbative solution as

$$\omega_{NL}^2 = \omega_{1,0}^2 + \varepsilon\omega_{1,1}^2 + \varepsilon^2\omega_{1,2}^2 + \varepsilon^3\omega_{1,3}^2 + \varepsilon^4\omega_{1,4}^2 + \mathcal{O}(\varepsilon^5). \quad (\text{B.5})$$

Inserting these assumptions into Equation (B.1a) and taking two time derivatives yields

$$\begin{aligned} u = \varepsilon \frac{\rho}{2} (e^{i\omega_{NL}t} + e^{-i\omega_{NL}t}) + \varepsilon^3 \frac{h\rho^3}{64\omega^2} (e^{3i\omega_{NL}t} + e^{-3i\omega_{NL}t}) \\ + \varepsilon^5 \frac{h^2\rho^5}{2048\omega^4} (e^{5i\omega_{NL}t} - 21e^{3i\omega_{NL}t} - 21e^{-3i\omega_{NL}t} + e^{-5i\omega_{NL}t}), \end{aligned} \quad (\text{B.6})$$

and

$$\ddot{u} = -\varepsilon \frac{\rho}{2} \omega_{1,0}^2 (e^{i\omega_{NL}t} + e^{-i\omega_{NL}t}) - \varepsilon^2 \frac{\rho}{2} \omega_{1,1}^2 (e^{i\omega_{NL}t} + e^{-i\omega_{NL}t})$$

$$\begin{aligned}
& -\varepsilon^3 \left[\frac{\rho}{2} \omega_{1,2}^2 (e^{i\omega_{NL}t} + e^{-i\omega_{NL}t}) + \frac{9h\rho^3}{64\omega^2} \omega_{1,0}^2 (e^{3i\omega_{NL}t} + e^{-3i\omega_{NL}t}) \right] \\
& -\varepsilon^4 \left[\frac{\rho}{2} \omega_{1,3}^2 (e^{i\omega_{NL}t} + e^{-i\omega_{NL}t}) + \frac{9h\rho^3}{64\omega^2} \omega_{1,1}^2 (e^{3i\omega_{NL}t} + e^{-3i\omega_{NL}t}) \right] \\
& -\varepsilon^5 \left[\frac{\rho}{2} \omega_{1,4}^2 (e^{i\omega_{NL}t} + e^{-i\omega_{NL}t}) + \left(\frac{9h^2\rho^3}{64\omega^2} \omega_{1,2}^2 + \frac{189h^2\rho^5}{2048\omega^4} \omega_{1,0}^2 \right) \right. \\
& \quad \left. (e^{3i\omega_{NL}t} + e^{-3i\omega_{NL}t}) + \frac{25h^2\rho^5}{2048\omega^4} \omega_{1,0}^2 (e^{5i\omega_{NL}t} + e^{-5i\omega_{NL}t}) \right]. \quad (\text{B.7})
\end{aligned}$$

These expressions can be inserted, together with the polar representation of the normal variables, into Equation (B.4). Then, by equating the different ε orders, one obtains

$$\varepsilon : \omega_{1,0}^2 = \omega^2 \quad (\text{B.8})$$

$$\varepsilon^2 : \omega_{1,1}^2 = 0 \quad (\text{B.9})$$

$$\varepsilon^3 : \omega_{1,2}^2 = \frac{3h}{4} \rho^2 \quad (\text{B.10})$$

$$\varepsilon^4 : \omega_{1,3}^2 = 0 \quad (\text{B.11})$$

$$\varepsilon^5 : \omega_{1,4}^2 = \frac{3h^2}{128\omega^2} \rho^4 \quad (\text{B.12})$$

A direct solution to these equations yields the following backbone curve:

$$\omega_{NL}^2 = \omega^2 + \frac{3h}{4} \rho^2 + \frac{3h^2}{128\omega^2} \rho^4. \quad (\text{B.13})$$

This expression coincides with the one given in Neild et al. (2015). Interestingly, this solving procedure yields a backbone curve that is directly expressed with the square of the radian eigenfrequencies, a distinctive feature from other perturbative techniques, which appears to stem directly from the treatment of the second-order time derivative and the choice of the RNF. Also, in comparison to the backbone curve given by the CNF shown in Equation (11), where each new order appears with alternate signs, here only positive coefficients are present, meaning that another approximation seems to be given. Note however that the procedure to compute the backbone with the RNF is tedious and difficult to automatize, as compared to the analytical solution provided with the CNF. Hence a complete comparison of both methods at arbitrary order is not pushed further here.

C Nonlinear mapping, complex normal form for the Duffing oscillator with quadratic and cubic terms

For the sake of completeness, the nonlinear mapping for the Duffing equation with quadratic and cubic nonlinearity, Equation (24), is here reported, up to order 5. Higher order terms can be derived automatically and symbolically with MORFE_Symbolic.

$$\begin{aligned}
u = & z_1 + z_2 + \frac{g}{3\omega^2} z_1^2 - \frac{2g}{\omega^2} z_1 z_2 + \frac{g}{3\omega^2} z_2^2 + \frac{2g^2 + 3h\omega^2}{24\omega^4} z_1^3 + \frac{10g^2 - 9h\omega^2}{12\omega^4} z_1^2 z_2 \\
& + \frac{10g^2 - 9h\omega^2}{12\omega^4} z_1 z_2^2 + \frac{2g^2 + 3h\omega^2}{24\omega^4} z_2^3 + \frac{2g^3 + 9gh\omega^2}{108\omega^6} z_1^4 + \frac{178g^3 - 333gh\omega^2}{108\omega^6} z_1^3 z_2 \\
& + \frac{-68g^3 + 117gh\omega^2}{9\omega^6} z_1^2 z_2^2 + \frac{178g^3 - 333gh\omega^2}{108\omega^6} z_1 z_2^3 + \frac{2g^3 + 9gh\omega^2}{108\omega^6} z_2^4 \\
& + \frac{20g^4 + 180g^2 h\omega^2 + 81h^2\omega^4}{5184\omega^8} z_1^5 + \frac{436g^4 - 444g^2 h\omega^2 - 351h^2\omega^4}{576\omega^8} z_1^4 z_2 \\
& + \frac{3740g^4 - 9468g^2 h\omega^2 + 1863h^2\omega^4}{864\omega^8} z_1^3 z_2^2 + \frac{3740g^4 - 9468g^2 h\omega^2 + 1863h^2\omega^4}{864\omega^8} z_1^2 z_2^3 \\
& + \frac{436g^4 - 444g^2 h\omega^2 - 351h^2\omega^4}{576\omega^8} z_1 z_2^4 + \frac{20g^4 + 180g^2 h\omega^2 + 81h^2\omega^4}{5184\omega^8} z_2^5 \quad (\text{C.1a})
\end{aligned}$$

$$\begin{aligned}
v = & i\omega z_1 - i\omega z_2 + i\frac{2g}{3\omega}z_1^2 - i\frac{2g}{3\omega}z_2^2 + \frac{2ig^2 + 3ih\omega^2}{8\omega^3}z_1^3 + \frac{-10ig^2 + 9ih\omega^2}{12\omega^3}z_1^2z_2 \\
& + \frac{10ig^2 - 9ih\omega^2}{12\omega^3}z_1z_2^2 + \frac{-2ig^2 - 3ih\omega^2}{8\omega^3}z_2^3 + \frac{2ig^3 + 9igh\omega^2}{27\omega^5}z_1^4 + \frac{118ig^3 - 279igh\omega^2}{54\omega^5}z_1^3z_2 \\
& + \frac{-118ig^3 + 279igh\omega^2}{54\omega^5}z_1z_2^3 + \frac{-2ig^3 - 9igh\omega^2}{27\omega^5}z_2^4 + \frac{100ig^4 + 900ig^2h\omega^2 + 405ih^2\omega^4}{5184\omega^7}z_1^5 \\
& + \frac{356ig^4 - 492ig^2h\omega^2 - 243ih^2\omega^4}{192\omega^7}z_1^4z_2 + \frac{-3740ig^4 + 9468ig^2h\omega^2 - 1863ih^2\omega^4}{864\omega^7}z_1^3z_2^2 \\
& + \frac{3740ig^4 - 9468ig^2h\omega^2 + 1863ih^2\omega^4}{864\omega^7}z_1^2z_2^3 + \frac{-356ig^4 + 492ig^2h\omega^2 + 243ih^2\omega^4}{192\omega^7}z_1z_2^4 \\
& + \frac{-100ig^4 - 900ig^2h\omega^2 - 405ih^2\omega^4}{5184\omega^7}z_2^5
\end{aligned} \tag{C.1b}$$

Comparing these equations to Equation (A.1), one can see how the quadratic term complexifies the result in terms of the nonlinear mapping, which now contains all even and odd powers. Also, letting $g = 0$ in Equation (C.1), one directly retrieves Equation (A.1) as awaited.

D RNF and ONF developments for the Duffing oscillator with quadratic and cubic terms

This appendix completes the analysis led on the Duffing oscillator with quadratic and cubic terms, Equation (24), by providing the results that can be obtained when analyzing with either real normal form (RNF) or oscillator normal form (ONF). The case of the RNF is first considered, and the reduced dynamics up to order 5 reads:

$$\begin{aligned}
\dot{z}_1 = & i\omega z_1 + i\frac{-10g^2 + 9h\omega^2}{6\omega^3}z_1^2z_2 + i\frac{-10g^2 + 9h\omega^2}{6\omega^3}z_1z_2^2 \\
& + i\frac{-1940g^4 + 6228g^2h\omega^2 - 405h^2\omega^4}{432\omega^7}z_1^3z_2^2 \\
& + i\frac{-1060g^4 + 3060g^2h\omega^2 - 81h^2\omega^4}{216\omega^7}z_1^2z_2^3,
\end{aligned} \tag{D.1}$$

with the second one being its complex conjugate. Additionally, the displacement nonlinear mapping is

$$\begin{aligned}
u = & z_1 + z_2 + \frac{g}{3\omega^2}z_1^2 - \frac{2g}{\omega^2}z_1z_2 + \frac{g}{3\omega^2}z_2^2 + \frac{2g^2 + 3h\omega^2}{24\omega^4}z_1^3 + \frac{2g^2 + 3h\omega^2}{24\omega^4}z_2^3 + \frac{2g^3 + 9gh\omega^2}{108\omega^6}z_1^4 \\
& + \frac{358g^3 - 495gh\omega^2}{108\omega^6}z_1^3z_2 + \frac{-26g^3 + 42gh\omega^2}{3\omega^6}z_1^2z_2^2 + \frac{358g^3 - 495gh\omega^2}{108\omega^6}z_1z_2^3 + \frac{2g^3 + 9gh\omega^2}{108\omega^6}z_2^4 \\
& + \frac{20g^4 + 180g^2h\omega^2 + 81h^2\omega^4}{5184\omega^8}z_1^5 + \frac{212g^4 - 268g^2h\omega^2 - 63h^2\omega^4}{192\omega^8}z_1^4z_2 \\
& + \frac{212g^4 - 268g^2h\omega^2 - 63h^2\omega^4}{192\omega^8}z_1z_2^4 + \frac{20g^4 + 180g^2h\omega^2 + 81h^2\omega^4}{5184\omega^8}z_2^5,
\end{aligned} \tag{D.2}$$

while the velocity one is simply given by its time derivative.

As compared to the results given by the CNF reported in Section 3.1, one can observe that the cubic coefficient for both CNF and RNF has the same expression, such that the prediction of the transition hardening/softening behaviour shall happen for $g^2 = 9h\omega^2/10$. However, for the next order, one can observe in Equation (D.1) that the two quintic coefficients in front of $z_1^3z_2^2$ and $z_1^2z_2^3$ do not have the same expression. combined with the fact that deriving an explicit analytical backbone curve for the RNF for arbitrary order needs to employ further assumptions, see the analysis reported in Appendix B, one can conclude that it is more difficult to analyze the successive sign change of the different coefficients to infer the trend of the backbone curve in the RNF as compared to CNF.

For the ONF, the result reported here is limited to the third-order because its automation appears cumbersome to code and has not been implemented in MORFE_Symbolic. Indeed, attempts to compute higher orders even in simple cases have shown that the processing of the

term is more complex, see *e.g.* Shami et al. (2022) for an example of processing the cubic terms with a second-order internal resonance. On the other hand, calculations up to order three have global analytical expressions reported in Touzé et al. (2004); Touzé et al. (2006). Using these general formula, one arrives for Equation (24) to the following nonlinear change of coordinates:

$$u = U - \frac{g}{3\omega^2}U^2 - \frac{2g}{3\omega^4}V^2, \quad (\text{D.3})$$

while the second equation of the nonlinear mapping for v is not reported for the sake of brevity, since it can be easily recovered using $v = \dot{u}$. The dynamics in the normal coordinates (U, V) up to order three reads:

$$\ddot{U} + \omega^2 U + \left(h - \frac{2g^2}{3\omega^2} \right) U^3 - \frac{4g^2}{3\omega^4} UV^2 = 0. \quad (\text{D.4})$$

Since oscillator equations are enforced by the method, two monomials are present in Equation (D.4), U^3 and UV^2 . A backbone curve for Equation (D.4) can be derived with a first-order perturbative method, yielding the nonlinear oscillation frequency ω_{NL} as a function of the amplitude a as (Touzé et al. 2004):

$$\omega_{NL} = \omega(1 + \Gamma a^2), \quad (\text{D.5})$$

where Γ combines the two coefficients of the cubic monomials and reads:

$$\Gamma = \frac{-10g^2 + 9h\omega^2}{24\omega^4}. \quad (\text{D.6})$$

The prediction of hardening/softening behaviour transition point for the first-order term of the backbone curve is thus also predicted with ONF to occur at $g^2 = 9h\omega^2/10$.

E Reduced dynamics coefficients, complex normal form for the forced-damped cubic Duffing oscillator at primary resonance computed at another excitation frequency Ω_p

This appendix gives coefficients of the complex normal form (CNF) of the forced-damped cubic Duffing oscillator in a primary resonance scenario. Differently from the main text where the parametrisation has been computed at the value $\Omega_p = \delta\omega$, here we show the analytical obtained result when the parametrisation is computed for $\Omega_p = \omega$. The eight coefficients of the resonant monomials shown in Eq. (32) then reads:

$$f_1 = \lambda_1, \quad f_2 = i\frac{3h}{2\delta\omega}, \quad f_3 = -i\frac{\kappa}{4\delta\omega}, \quad f_4 = \frac{3h\kappa(1 - \delta + i\xi)}{16\xi\delta^2\omega^3} \quad (\text{E.1a})$$

$$f_5 = -\frac{3h\kappa(1 - \delta - i\xi)}{8\xi\delta^2\omega^3}, \quad f_6 = \frac{3ih\kappa^2(1 - \delta)}{32\xi^2\delta^3\omega^5}, \quad (\text{E.1b})$$

$$f_7 = -\frac{3ih\kappa^2(-\xi^2 + i\delta\xi - \delta - i\xi + 1)}{64\xi^2\delta^3\omega^5}, \quad f_8 = \frac{3h\kappa^3(\xi^2 - i\delta\xi + 2\delta + i\xi - 2)}{512\xi^3\delta^4\omega^7}. \quad (\text{E.1c})$$

One should notice that considering a small damping hypotheses, these coefficients are equivalent to those given by Equation (33). However in the general case the expression slightly differ and are longer in the present case.

F Nonlinear mapping, complex normal form for the forced-damped cubic Duffing oscillator: primary resonance

This appendix gives the nonlinear mappings for the forced cubic Duffing oscillator in a situation of primary resonance. The parametrisation is pushed to order 3 only, but higher order parametrisations can be easily obtained with MORFE_Symbolic.

$$u = z_1 + z_2 - i\frac{\kappa}{4\xi\omega^2}z_3 + i\frac{\kappa}{4\xi\omega^2}z_4 + \frac{h}{9\delta^2\omega^2 + 12i\delta\xi\omega^2 - 3\xi^2\omega^2 - \omega^2}z_1^3$$

$$\begin{aligned}
& + \frac{-3h\delta + 3ih\xi}{\delta^3\omega^2 - i\delta^2\xi\omega^2 + \delta\xi^2\omega^2 + 3\delta\omega^2 - i\xi^3\omega^2 + i\xi\omega^2} z_1^2 z_2 \\
& - \frac{3ih\kappa}{16\delta^2\xi\omega^4 + 16i\delta\xi^2\omega^4 + 16\delta\xi\omega^4 + 8i\xi^2\omega^4} z_1^2 z_3 \\
& + \frac{3ih\kappa}{16\delta^2\xi\omega^4 + 16i\delta\xi^2\omega^4 - 16\delta\xi\omega^4 - 8i\xi^2\omega^4} z_1^2 z_4 \\
& + \frac{-3h\delta - 3ih\xi}{\delta^3\omega^2 + i\delta^2\xi\omega^2 + \delta\xi^2\omega^2 + 3\delta\omega^2 + i\xi^3\omega^2 - i\xi\omega^2} z_1 z_2^2 - \frac{3h\kappa}{4\xi^2\omega^4} z_1 z_2 z_3 - \frac{3h\kappa}{4\xi^2\omega^4} z_1 z_2 z_4 \\
& - \frac{3h\kappa^2}{16\delta^2\xi^2\omega^6 + 64\delta\xi^2\omega^6 + 16\xi^4\omega^6 + 48\xi^2\omega^6} z_1 z_3^2 \\
& + \frac{-3h\delta\kappa^2 + 3ih\kappa^2\xi}{8\delta^3\xi^2\omega^6 - 24i\delta^2\xi^3\omega^6 - 24\delta\xi^4\omega^6 + 24\delta\xi^2\omega^6 + 8i\xi^5\omega^6 - 8i\xi^3\omega^6} z_1 z_3 z_4 \\
& - \frac{3h\kappa^2}{16\delta^2\xi^2\omega^6 - 64\delta\xi^2\omega^6 + 16\xi^4\omega^6 + 48\xi^2\omega^6} z_1 z_4^2 + \frac{h}{9\delta^2\omega^2 - 12i\delta\xi\omega^2 - 3\xi^2\omega^2 - \omega^2} z_2^3 \\

\end{aligned} \tag{F.2}$$

G Nonlinear mapping, complex normal form for the forced cubic Duffing oscillator for the 3:1 superharmonic resonance

This appendix gives the nonlinear displacement mapping for the forced cubic Duffing oscillator when a 3:1 superharmonic forcing is considered. The parametrisation is pushed to order 3 only, but higher order parametrisations can be easily obtained with MORFE_Symbolic. The velocity mapping can be obtained as the derivative of the displacement.

$$\begin{aligned}
u = & z_1 + z_2 - \frac{9i\kappa}{12\xi\omega^2 - 16i\omega^2} z_3 + \frac{9i\kappa}{12\xi\omega^2 + 16i\omega^2} z_4 + \frac{h}{9\delta^2\omega^2 + 12i\delta\xi\omega^2 - 3\xi^2\omega^2 - \omega^2} z_1^3 \\
& + \frac{-3h\delta + 3ih\xi}{\delta^3\omega^2 - i\delta^2\xi\omega^2 + \delta\xi^2\omega^2 + 3\delta\omega^2 - i\xi^3\omega^2 + i\xi\omega^2} z_1^2 z_2 \\

H Nonlinear mapping, complex normal form for the forced cubic Duffing oscillator for the 1:3 subharmonic resonance

This appendix gives the nonlinear displacement mapping for the forced cubic Duffing oscillator when a 1:3 subharmonic forcing is considered. The parametrisation is pushed to order 3 only, but higher order parametrisations can be easily obtained with `MORFE_Symbolic`. The velocity mapping can be obtained as the derivative of the displacement.

$$u = z_1 + z_2 - \frac{ik}{12\xi\omega^2 + 16i\omega^2}z_3 + \frac{ik}{12\xi\omega^2 - 16i\omega^2}z_4 + \frac{h}{9\delta^2\omega^2 + 12i\delta\xi\omega^2 - 3\xi^2\omega^2 - \omega^2}z_1^3 \\ + \frac{-3h\delta + 3ih\xi}{\delta^3\omega^2 - i\delta^2\xi\omega^2 + \delta\xi^2\omega^2 + 3\delta\omega^2 - i\xi^3\omega^2 + i\xi\omega^2}z_1^2z_2 \\ - \frac{3ih\kappa}{48\delta^2\xi\omega^4 + 64i\delta^2\omega^4 + 48i\delta\xi^2\omega^4 + 80\delta\xi\omega^4 + 192i\delta\omega^4 + 72i\xi^2\omega^4 + 128i\omega^4}z_1^2z_3 \\ + \frac{3ih\delta\kappa - 3h\kappa\xi}{C_1}z_1^2z_4 \\ + \frac{-3h\delta - 3ih\xi}{\delta^3\omega^2 + i\delta^2\xi\omega^2 + \delta\xi^2\omega^2 + 3\delta\omega^2 + i\xi^3\omega^2 - i\xi\omega^2}z_1z_2^2 \\ - \frac{3h\kappa}{36\xi^2\omega^4 + 64\omega^4}z_1z_2z_3 - \frac{3h\kappa}{36\xi^2\omega^4 + 64\omega^4}z_1z_2z_4 \\ - \frac{3h\kappa^2}{C_2}z_1z_3^2 + \frac{-3h\delta\kappa^2 + 3ih\kappa^2\xi}{C_3}z_1z_3z_4 - \frac{3h\kappa^2}{C_4}z_1z_4^2 \\ + \frac{h}{9\delta^2\omega^2 - 12i\delta\xi\omega^2 - 3\xi^2\omega^2 - \omega^2}z_2^3 \\ + \frac{-3ih\delta\kappa - 3h\kappa\xi}{C_5}z_2^2z_3 \\ + \frac{3ih\kappa}{48\delta^2\xi\omega^4 - 64i\delta^2\omega^4 - 48i\delta\xi^2\omega^4 + 80\delta\xi\omega^4 - 192i\delta\omega^4 - 72i\xi^2\omega^4 - 128i\omega^4}z_2^2z_4 \\ - \frac{3h\kappa^2}{C_6}z_2z_3^2 + \frac{-3h\delta\kappa^2 - 3ih\kappa^2\xi}{C_7}z_2z_3z_4 - \frac{3h\kappa^2}{C_8}z_2z_4^2 \\ - \frac{h\kappa^3}{31104\xi^4\omega^8 + 262656i\xi^3\omega^8 - 718848\xi^2\omega^8 - 811008i\xi\omega^8 + 327680\omega^8}z_3^3 \\ + \frac{3h\kappa^3}{10368\xi^4\omega^8 + 27648i\xi^3\omega^8 + 49152i\xi\omega^8 - 32768\omega^8}z_3^2z_4 \\ + \frac{3h\kappa^3}{10368\xi^4\omega^8 - 27648i\xi^3\omega^8 - 49152i\xi\omega^8 - 32768\omega^8}z_3z_4^2$$

I Detailed calculation of the existence region for the 1:3 subharmonic resonance

This Appendix is concerned with the derivation of the expression that gives the boundary of the region such that nontrivial solutions exist for the 1:3 subharmonic resonance of the cubic Duffing oscillator. The starting point is Equation (54). Upon substitution of coefficients A_r , A_i , B_r and B_i , it is possible to find a biquadratic equation in ρ :

$$\underbrace{\frac{9h^2}{64\delta^2\omega^2}}_a \rho^4 + \underbrace{\left[\frac{3h}{4\delta\omega} \left(\delta\omega - \frac{\Omega}{3} \right) + \frac{27h^2\kappa^2}{256\delta^2\omega^6(16+9\xi^2)} \right]}_b \rho^2 + \underbrace{\left(\delta\omega - \frac{\Omega}{3} \right)^2 + \frac{9h^2\kappa^4}{256\delta^2\omega^{10}(16+9\xi^2)^2} + \frac{3h\kappa^2}{8\delta\omega^5(16+9\xi^2)} \left(\delta\omega - \frac{\Omega}{3} \right) + \xi^2\omega^2}_c = 0. \quad (\text{I.1})$$

For the existence of real solutions, two conditions have to be satisfied, namely $b < 0$ and $\Delta = b^2 - 4ac \geq 0$. After algebraic manipulations, the first condition yields

$$\Omega > 3\delta\omega + \frac{27h\kappa^2}{64\delta\omega^2(16+9\xi^2)}, \quad (\text{I.2})$$

while the second gives

$$\frac{63h^2}{1024\delta^2\omega^{10}(16+9\xi^2)^2}\kappa^4 - \frac{h(\Omega-3\delta\omega)}{16\delta\omega^5(16+9\xi^2)}\kappa^2 + 2\xi^2\omega^2 \leq 0, \quad (\text{I.3})$$

which is in itself a biquadratic inequality in κ . The above expression is negative once κ is between its two roots, such that the boundary of the existence region is given by

$$\frac{63h\kappa^2}{64\delta\xi\omega^6(16+9\xi^2)} = \frac{\Omega-3\delta\omega}{\xi\omega} \pm \sqrt{\frac{(\Omega-3\delta\omega)^2}{\xi^2\omega^2} - 63}. \quad (\text{I.4})$$

Explicitly isolating Ω gives the sought expression for existence condition of subharmonic resonance as:

$$\Omega = 3\delta\omega + \frac{63h\kappa^2}{128\delta\omega^5(16+9\xi^2)} + \frac{32\delta\omega^7\xi^2(16+9\xi^2)}{h\kappa^2}. \quad (\text{I.5})$$

As a last comment, it should be noted that Equation (I.5) automatically guarantees that Equation (I.2) is verified.

J Linear stability analysis for the parametrically excited oscillator

This Appendix is concerned with the linear stability analysis of the bifurcated branches for the case of parametric excitation, see Equation (63) in Section 3.3. The dynamical system from Equation (67) serves as the starting point. Assuming $\rho \neq 0$, substituting the coefficients from Equation (68), and considering the fixed points $\dot{\rho} = \dot{\psi} = 0$, it can be rewritten as

$$\rho f_1^R + \frac{\rho^3}{4} f_2^R + \rho f_4^R + \rho f_3^R \cos \psi + \rho f_3^I \sin \psi = 0 \quad (\text{J.1a})$$

$$2f_1^I - \Omega + \frac{\rho^2}{2} f_2^I + 2f_4^I - 2f_3^R \sin \psi + 2f_3^I \cos \psi = 0. \quad (\text{J.1b})$$

Then, in order to perform the linear stability analysis, the Jacobian of the vector field defining the dynamical system from Equation (67) is calculated:

$$\mathbf{J} = \begin{bmatrix} f_1^R + \frac{3\rho^2}{4} f_2^R + f_4^R + f_3^R \cos \psi + f_3^I \sin \psi & -\rho f_3^R \sin \psi + \rho f_3^I \cos \psi \\ \rho f_2^I & -2f_3^R \cos \psi - 2f_3^I \sin \psi \end{bmatrix} \quad (\text{J.2a})$$

$$= \begin{bmatrix} 0 & \rho \left(\frac{\Omega}{2} - \delta\omega - \rho^2 \frac{3h}{8\delta\omega} - \frac{\kappa^2(\delta-1)}{32\omega^2\xi^3\delta^2} \right) \\ \rho \frac{3h}{2\delta\omega} & -2\xi\omega \end{bmatrix}, \quad (\text{J.2b})$$

where the coefficient expressions from Equation (66) have been substituted and Equation (J.1) has been used in order to simplify the Jacobian. Then, calculating its eigenvalues corresponds to solving the following two quadratic equations in λ :

$$\lambda^2 + 2\xi\omega\lambda \pm \rho^2 \frac{3h}{2\delta\omega} \sqrt{\frac{\kappa^2}{16\omega^2\delta^2} - \xi^2\omega^2}, \quad (\text{J.3})$$

which has been obtained from $\det(\mathbf{J} - \lambda\mathbf{I}) = 0$ by substituting Ω from Equation (73). If the plus sign is considered first, one has

$$\lambda = -\xi\omega \pm \sqrt{\xi^2\omega^2 + \rho^2 \frac{3h}{2\delta\omega} \sqrt{\frac{\kappa^2}{16\omega^2\delta^2} - \xi^2\omega^2}}. \quad (\text{J.4})$$

In this case, the real part of at least one eigenvalue is always positive, since the term under the square root is larger than $\xi\omega$. Thus, the right branch of the FRC, corresponding to the plus sign in Equation (73), is unstable. Analogously, for the minus sign case, the eigenvalues are

$$\lambda = -\xi\omega \pm \sqrt{\xi^2\omega^2 - \rho^2 \frac{3h}{2\delta\omega} \sqrt{\frac{\kappa^2}{16\omega^2\delta^2} - \xi^2\omega^2}}. \quad (\text{J.5})$$

Therefore, using a similar argument, the left branch of the FRC is stable. From the stability of the bifurcated branches, the one from the main branch can be deduced: it is unstable between the bifurcation points and stable outside them. Note that the above analysis assumes a hardening Duffing oscillator with $h > 0$. In the softening case with $h < 0$, the FRC is bent to the left, and the analysis before has just to be changed: the unstable branch corresponds to the left bifurcation point, with smaller frequency, while the stable branch corresponds to the right point with higher frequency.

K Nonlinear mappings for the two dofs system, free of internal resonance

The nonlinear mappings for the two dofs system with only cubic coefficients and no internal resonance are given below. Calculations were pursued up to order 5, and only displacement mappings are given since velocity ones can be obtained as their time derivatives.

$$\begin{aligned}
u_1 = & z_1 + z_2 + \frac{h_{111}^1}{8\omega_1^2} z_1^3 - \frac{3h_{111}^1}{4\omega_1^2} z_1^2 z_2 - \frac{3h_{111}^1}{4\omega_1^2} z_1 z_2^2 + \frac{h_{111}^1}{8\omega_1^2} z_2^3 \\
