Abstract

Social support networks play a key role in human livelihood security, especially in vulnerable communities. Here we explore how evolutionary ideas of kin selection and intra-household resource competition can explain individual variation in daily-support network size and composition in a South-Central Ethiopian agricultural community. We consider both domestic and agricultural help across two generations with different large-wealth transfer norms that yield different contexts for sibling competition.

For farmers who inherited land rights from family, first-borns were more likely to report daily support from parents and to have larger non-parental kin networks (n=180). Compared with other farmers, first-borns were also more likely to reciprocate their parents' support, and to help non-parental kin without reciprocity.

For farmers who received land rights from the government (n=151), middle-born farmers reported more non-parental kin in their support networks compared with other farmers; non-reciprocal interactions were particularly common in both directions. This suggests a diversification of adult support networks to non-parental kin, possibly in response to a long-term parental investment disadvantage of being middle-born sons. In all instances regardless of inheritance, last-born farmers were the most disadvantaged in terms of kin support.

Overall, we found that non-reciprocal interactions among farmers followed kin selection predictions. Direct reciprocity explained a substantial part of the support received from kin, suggesting the importance of the combined effects of kin selection and reciprocity for investment from kin.

4 **Introduction**
5
6

7 Social capital, alongside natural capital, physical or produced capital, and human capital, is an important
8 part of sustainable development. Because social capital can be defined as “the features of social
9 organization, such as networks, norms, and social trust that facilitate coordination and cooperation for
10 mutual benefit” (Putnam 2000), social capital, by virtue of its collective nature, has an important influence
11 on resource sustainability at a population/community level (Pretty 2003). In developing countries that lack
12 resource access, infrastructure, or social policies to support vulnerable communities, networks have been
13 shown to not only provide the social insurance and safety nets that foster resilience and recovery in times of
14 hardship (Fafchamps and Lund 2003, Caudell, Rotolo and Grima 2015), but also to build human capital,
15 material capital, and improve community well-being (Narayan and Pritchett 1999, Aldrich 2012, Aldrich
16 and Meyer 2014).
17
18

19 Using an evolutionary perspective, this research aims to investigate daily support networks as strategies
20 used by individuals and families in rural South-Central rural Ethiopia and to identify the most vulnerable
21 among them. This agricultural population is largely dependant of land for cereals and vegetables
22 production. Personal support networks are comprised of kin and non-kin supporters, which is an important
23 distinction from an evolutionary perspective: kin-selection theory predicts that kin will allocate resources to
24 their relatives in a manner that enhances transmission of their common genes (Hamilton 1964). In other
25 words, kin support is an investment in one’s own fitness, either directly (via direct descendants) or
26 indirectly (in other kin), where fitness is defined as the survival of the biological lineage across generations,
27 or the number and quality of descendants achieved by accumulation of social, material, and biological
28 capital. According to kin selection, individuals face trade-offs in their effort to acquire finite resources;
29 thus, they make decisions (consciously or not) about resource allocation in their support networks
30 according to genetic relatedness (Hamilton 1964). Recipient characteristics other than genetic relatedness
31 also influence resource allocation decisions, such as reproductive potential and survival rate, which are
32 shaped by gender (Trivers 1972, Trivers and Willard 1973) and birth order (Clutton-Brock 1984; Hrdy and
33 Judge 1993). In theory, any individual characteristics influencing reproductive potential and survival rate

2
3
4 might possibly influence kin investment decision. In rural Ethiopia, land access influences livelihood
5 security and reproduction and is, thus, probably important to kin investment patterns.
6
7

8
9 Parental investment, which is the most fundamental kin investment, significantly influences the fitness of
10 parents and children (Trivers 1974); it includes various investments, from parental care and education
11 (Gibson and Sear 2010, Gibson and Lawson 2011), to wealth transfers during life and at death (Judge and
12 Hrdy 1992, Hrdy and Judge 1993, Gibson and Gurmu 2011). Among the various land owner societies
13 facing limited resources around the world, a gradient of wealth transfer systems has evolved from biased
14 multigeniture (Clarke and Low 1992, Towner 2001, Faurie, Russel and Lumma, 2009, Gibson and Gurmu
15 2011) to unigeniture (Boone 1986, Hrdy and Judge 1993, Voland and Dunbar 1995, Strassman and Clarke
16 1998), favouring some children over others, possibly to ensure lineage survival across generations and/or to
17 avoid capital fragmentation and economic decline within very few generations. As a consequence, favoured
18 children enjoy a better resource status and, possibly, might enjoy larger kin support because they represent
19 safer investment for the future of the lineage compared with their sibling.

28
29
30

31
32 Research on parental investment, has yielded variable and occasionally conflicting results about birth
33 order (Draper and Hames 2000, Faurie, Russel and Lumma, 2009, Stanton et al. 2014). In Ethiopia, a first-
34 born son advantage for agricultural productivity, marriage, and reproductive success has been shown in
35 the context of family land transfers but was not observed when no family land transfers occurred (Gibson
36 and Gurmu 2011), suggesting that inequalities in intra-household material resource access for brothers
37 only arise in the context of competition for limited resources.
38
39
40
41
42
43
44

45
46 The importance of kin selection and reciprocity for cooperation with kin is discussed in the literature
47 (Clutton-Brock 2009, Jaeggi and Gurven 2013, Taborsky 2013, Carter and Wilkinson 2013). Some
48 individuals might actively engage in network manipulation by seeking extra interactants to secure
49 additional support; one way to lower the cost for potential interactants is through reciprocity, which lowers
50 the costs for interactants (Trivers 1971).
51
52
53
54
55

56
57 Herein, we investigate whether patterns in the kin and non-kin make-up of adult children's support
58 networks, reinforces or offsets patterns of material resource access for two generations of Ethiopian
59

4 agriculturalists with different large-wealth transfer patterns.
5
6

7 The Ethiopian context offers a unique setting to look directly at the effects of intra-household competition
8 and kin investment. Ethiopia's recent political past, including the Marxist revolution that led to land
9 confiscation and subsequent redistributions in 1975, 1988, and 1990 in this agricultural area, provides a
10 natural experiment to study two cohorts of farmers that received land either from family transfer (inheritor
11 group) or from government (redistribution group). In the study community, family land transfers primarily
12 concern male farmers. Even the successive government redistributions targeted male heads of household.
13 Nowadays, by law, all children, females and males, have the right to claim their share of inheritance. In
14 practice, most families provide land to their sons and provide other type of goods to their daughters, who
15 marry out their communities. Because of rapid population growth and limited land availability, farmland is
16 becoming a scarce resource in this part of Ethiopia, so we expect this to increase the investment biases
17 predicted by kin selection, but in different ways for the two farmer groups.
18
19
20
21
22
23
24
25
26
27
28
29

30 Farmers in the younger group became adults after the government redistribution programs ended; thus,
31 their land access was completely determined by their parents, they received farmland before or for their
32 marriage and received or might receive additional land upon their parents' deaths. Previous research
33 suggests a multigeniture with a first-born son advantage for the youngest generation (Gibson and Gurm
34 2011).
35
36
37
38
39

40 The oldest group's parents were not permitted to favour any of their sons for large wealth transfers because,
41 in theory, all sons received land of equal size and quality from the government; furthermore, this sweeping
42 policy likely affected other types of parental and kin investment besides wealth transfers. Studies on
43 parental investment in the context of equal resource access suggest that first and last-born children tend to
44 be advantaged over middle-born children (Hertwig, Davis and Sulloway 2002), who receive fewer
45 cumulative investment due to competition with younger and older siblings. Faurie, Russel and Lumma
46 (2009) corroborated Hertwig, Davis and Sulloway's (2002) finding among sons of rural pre-industrial
47 Finns: middle-born sons appeared to produce significantly less offspring than first- or lastborn sons.
48 Concerning relational capital biases, cues from studies of Western societies suggested that disadvantaged
49 children might offset their parental-investment disadvantage by manipulating their networks through

4 diversification of support including other kin (Salmon and Daly 1998, Rhode et al. 2003,) or non-kin
5
6 (Salmon and Daly 1998, Salmon 2003).
7
8

9
10 Thus, to understand the complexity of support patterns, it is important to discriminate among sources of
11 support (e.g., parents, non-parental kin, and non-kin), to identify the directions of support interactions (non-
12 reciprocal or reciprocal), and to discriminate between birth order and intra-sex birth order. Finally, the daily
13 agricultural and domestic support networks of household heads should be an accurate proxy for measuring
14 social capital in a mixed economy where cash is not widespread, because such support entails meaningful
15 energetic and material costs and has direct impacts on household wellbeing. Because this study population
16 is patriarchal, patrilineal, and patrilocal, with strong gender differences in socio-economic activities that
17 could affect individuals' social networks, we focused on the support networks of male heads of household.
18
19
20
21
22
23
24

25
26 This paper aims to test two sets of evolutionary predictions about daily support network size and
27 composition among Ethiopian farmers: 1) Daily support networks will vary according to sibling
28 competition, with different birth-order biases for the generation groups. 2) Farmers' daily support networks
29 will pattern in a way that is consistent with reciprocity and kin-selection theory.
30
31
32
33
34

35 Prediction 1: We will observe birth-order biases in support network size and composition
36

37 At the outset, we expect to observe two scenarios regarding daily subsistence and domestic support:
38
39

- 40 1. In the context of limited resources, first-born sons might interact more with parents and with non-
41 parental kin compared with other birth-order categories, because, first-born sons represent a less
42 risky investment for lineage survival (Hrdy and Judge 1993, Gibson and Gurmu 2011). Later-born
43 sons being disadvantaged in kin interactants, might diversify their networks to include non-kin,
44 possibly through reciprocity
45
46
47
48
49
- 50 2. For farmers who received their land from the government without discrimination, first and last-
51 born sons might have enjoyed extra-parental investment in terms of cumulative investment in their
52 lifetimes (Kidwell 1982, Sulloway 1996, Hertwig, Davis and Sulloway 2002, Faurie, Russel and
53 Lumma 2009). If those differences held into adulthood, middle-born sons might still represent
54 worthwhile investment for non-parental kin, especially if they are more active in diversifying their
55 networks. They may do this by diminishing the costs of investment for the givers through
56
57
58
59
60
61
62
63
64
65

1
2
3
4 reciprocity (Trivers 1971, Salmon 2003). This strategy would result in middle-born sons having
5
6 larger non-parental kin and non-kin networks compared with first and last-born sons.
7

8
9 Prediction 2: Variation in farmers' support networks is consistent with reciprocity and kin-selection
10
11 theories

12
13 Reciprocity is a strategy by which people obtain greater resource security and social support by
14
15 diversifying their networks and engaging in interactions with more people. However, because of time and
16
17 cognitive constraints (Dunbar 2008) that limit the number of social contacts a person can meaningfully
18
19 manage, the benefits of a reciprocal support strategy are limited. We expect that most non-kin interactions
20
21 would be based on reciprocity, while non-direct reciprocity (unidirectional interactions) would be more
22
23 common with kin and even more common with close-kin, according to expected benefits of inclusive
24
25 fitness (Hamilton 1964; Trivers 1972). Kin might constitute an important proportion of men's reciprocated
26
27 social ties, because kin interactants can benefit from both inclusive fitness and reciprocity.

3
4 **Methodology**
5

6 **Participants and study sites**
7

8 Data were collected from two representative neighbouring villages with high out-migration, during 2009
9 and 2010. The communities were selected from a pool of villages previously studied by Gibson (2002) in
10 the Oromia region, Ethiopia, in the green midlands (altitude of 2200 to 2700m) between the town of Iteya
11 and the city of Assala, where the socio-economics and demographic context is well known. The study
12 communities had no electricity access, no direct road access and no working tap-water access at the time of
13 the data collection. Community members relied mostly on a mixed economy, where cash was sporadically
14 available. The altitude and the relatively temperate climate permits growth of a variety of cereals (wheat,
15 teff, barley, sorghum, maize), vegetables (cabbages, carrots, potatoes, lentils, onions etc) and smaller
16 quantities of other crop types (tobacco, oil seeds, eucalyptus) on their small farmland plot (landsize of 5ha
17 maximum). Farmers cultivate their land with animal-drawn plows. Remittances from out-migration were
18 rare (Gibson and Gurmu 2012) despite a relative proximity to urban centres (~10–15km). The ethnic
19 composition of the study population includes Shoa Oromo, Arsi Oromo, and Amara. Shoa and Amara
20 families have been intermarrying for several generations and are Christians, while Arsi Oromo are Muslims
21 and do not usually intermarry with non-Muslims. Our sample included mostly Oromo farmers and a small
22 number of Amara farmers (20.5% of the redistribution group and 20.6% of the inheritor group) that did not
23 allow for more detailed analyses. Traditionally, Oromo and Amara have different inheritance systems.
24 Contrary to most of Oromo women, Amara women had access to family land. However, governmental
25 redistribution focused on the head of household, resulting in women being excluded from redistribution and
26 land access. Amara women from the youngest generation are more likely to receive land from their family
27 compared with Oromo women. However, a study on land access for an Amara population has shown a
28 first-born son advantage for inheritance (Congdon Fors, Hounbedji, Lindskog 2017), suggesting similar
29 patterns of parental bias for Oromo and Amara for the young generation. All families arrived between the
30 19th century and the last Italian war (1935), and have known a system of small landlords, tenants, small
31 landholders and landless workers. The Marxist Derg regime came to power in 1974 and started an agrarian
32 reform in 1975. In 1975, land lordism, tenancies, inheritances were abolished, and all lands came under
33 government control. The peasant associations (PAs), which are the lowest local administrative units,
34

57
58
59
60
61
62
63
64
65

1
2
3
4 controlled land access. PAs confiscated and redistributed periodically lands, in 1975, 1988, and 1990 to
5
6 households based on family size, land availability and land quality (Tefera et al. 2002). Today, a vast
7
8 majority of farmers in the study sites are still members of the PAs, and take part in meetings about local
9
10 development and agriculture. Informal contractual tenure arrangements were not resported as widespread in
11
12 those villages by the farmers, but might be underestimated due to their unofficial status (–up to 24% of all
13
14 farmlands in the same area might be under contract, Gavian and Ehui 1999). It is also not known to what
15
16 extent contracts are made within the family, and are, thus, not reported. Focus group discussions have
17
18 revealed numerous family strategies for land sharing among sons, including brothers sharecropping a piece
19
20 of land provided by their father, fathers passing on officially the land rights to their sons or on contrary
21
22 fathers officially maintaining their land rights while their sons farm the land, suggesting other ways to land
23
24 access than official wealth transfer from family or government. Within families, siblings reported different
25
26 roles according to birth-order rank. Elder sons were expected to take care of younger siblings, and, when
27
28 possible, to offer some large gift (i.e.: a cow) for younger brothers’ wedding. Younger brothers, on the
29
30 other hands, were expected to be obey older siblings and to serve them back through labour. Finally, some
31
32 informants specified that last-borns were expected to remain with their parents and care for them as they
33
34 age; this, in turn, might increase their access to their parents’ land. The education level is relatively low,
35
36 with few individuals finishing high-school education outside the village (11.9% and 19.4% of the
37
38 redistribution and inheritor groups, respectively). Finally, some impoverished villagers labored as daily
39
40 workers for other farmers. Non-agricultural jobs in the villages were rare and consisted mostly of
41
42 governmental jobs or religious jobs. Non-agricultural cash-generating activities (local business, crafts)
43
44 mostly served as side income to farming and were not widespread.

47 **Recruitment**

48
49
50 All households in the villages were visited and heads of households (hh) were interviewed (N=590).
51
52 Multiple visits were sometimes necessary and only a few households (<10) were not recruited due to the
53
54 long-term absence of their head of household. Because the study communities are patriarchal, patrilineal
55
56 and patrilocal and present strong gender roles and enforce strong gender roles for socio-economics
57
58 activities, which likely affects people’s social networks, we focused on male head-of-household support
59
60
61

4 network. Support networks considered here include daily supports for farming and domestic activities in a
5 broad, such a help with farm activities (ploughing, seeding, weeding, cattle care, and gifting or loan of
6 seeds, crops, and other materials including animals), help with domestic activities (gifting or loan of food,
7 clothes, money, water, firewood, or other materials), help during sickness (transport or care), help with
8 house construction, and ceremonial duties. Because first-born and last-born sons might enjoy some extra-
9 parental investment (Kidwell 1982, Hertwig, Davis and Sulloway 2002, Faurie, Russel and Lumma 2009),
10 and because birth rank does not discriminate for the last-born category, we used three intra-sex birth-order
11 categories (firstborn, middle born and lastborn sons) instead of birth rank. Thus, only heads of household
12 with at least two brothers born from the same father, who survived until fifteen years old, were included in
13 the models (N=331). Only farmers owning land rights were included, to focus on the impact of wealth
14 transfers. Landless male farmers generally worked for other farmers, joined another household or,
15 increasingly, moved to the city; these men likely had very different social characteristics compared with
16 landowners.

30 31 **Procedures** 32

33
34 The Ethics Committee of the University of Bristol approved all study materials and methods. Research
35 permits were obtained from national, regional, zonal, and local Ethiopian authorities. All participants were
36 informed about the nature of the study, data confidentiality, and of their rights to withdraw at anytime.
37
38 Participants were required to either sign or fingerprint an informed consent document before participating.
39
40 A pilot study was organised in a similar neighbouring community, to confirm that the questions were
41 appropriate for the local context (e.g., non-sensitive and understood by the local community) and to
42 identify any errors in translation or terminology. Our mixed-methods data collection approach included
43 questionnaires, focus group discussions and semi-directed qualitative interviews. Interviews and semi-
44 structured questionnaires following standard anthropological data collection (Fowler 1995; Krosnick and
45 Fabrigar 1997; Bernard 2002) were undertaken. A team of seven fluent Amharic-Oromic speakers collected
46 questionnaires from the heads of households. Questionnaires were translated from English to Oromic and
47 then back translated. A fluent Amharic-Oromic-English speaker assisted with all interviews and focus
48 group discussions.

5
6

7 The Marxist revolution, which resulted in a massive land confiscation and land redistributions, in 1975,
8 1988 and 1990, allows for a natural experiment to study two farmer groups who received land from
9 different sources, one from the government through the PAs and the other from their family. Because
10 farmers did not all marry and start a family at the same age, some men from the older generations were
11 excluded from governmental redistribution and some from the younger generation who married very early
12 might have benefited from it. Individuals who were not part of the PA for any reason might have been
13 excluded from governmental land access. Patterns of land transfer can be complex, however, the vast
14 majority of men received land rights through similar pathways as their generational peers. Participants in
15 the older group (>40 years old) mostly received their land rights from government land redistribution
16 (redistribution farmers). 93.4% received land rights from the government. Some received it from their
17 family (6%), and only one bought it with credit. Some men had parents who received land from
18 governmental redistribution; thus, they might receive inheritance upon their parents' death, thus
19 accumulating land from the government and from their family, but only a small proportion already received
20 both government and family land (9.3%). However, most men in the older generation received land parcels
21 equal in land and quality from the government. Respondents of the younger group (<41 years old) mostly
22 obtained their land after the last governmental land redistribution, and where thus, dependent upon their
23 parents (=inheritor farmers) for land access. 89.4% received land from their families. 10% received land
24 from the government only. Only one farmer bought it. A small proportion received land from both their
25 family and the government (10%).

46 **Data**
47

48 Socio-economic, demographic and support network data about households and household heads were
49 collected with questionnaires during interviews. Support network data were generated from both questions:
50 1) Whom do you help on a daily basis for agricultural and domestic support? 2) Who are your daily helpers
51 for agricultural and domestic support? For both questions, respondents gave the person's full name,
52 relationship, place of residence, and type of support provided. When the same person was cited for both
53 responses, we labeled the contact as a (direct) reciprocator, when the person was cited for only one answer;
54
55
56
57
58
59
60
61
62
63
64
65

1
2
3
4 we labeled the contact a non-direct reciprocator. Herein, we define reciprocity as here current direct
5 reciprocity at the time of data collection; and we define non-direct reciprocity as all other bi-directional
6 interactions (e.g., contingent reciprocity on longer timescale) or unidirectional (altruism or indirect
7 reciprocity, which are difficult to discriminate from each others). We preferred the terminology “non-
8 direct reciprocity” over “altruism”, because it includes indirect reciprocity (through one, several or many
9 peers), and also delayed reciprocity. Degrees of reciprocity were too complex to be measured, for example,
10 help received and given might or might not be of equal value, intrinsically or relatively to the mutual
11 interactants (considering each person’s age, wealth or social status, physical condition, energy needs and
12 expenditure etc.), nor of perceived equal value. We extracted the network configuration (presence or
13 absence of support -received and/or given) and support network size (number of supporters or number of
14 persons helped) from each participant’s responses.

15
16 Respondent age, farmland size (ha), village (1 or 2), parents being alive or deceased and number of
17 brothers or sibling who survived to 15 years old were included in the models when possible.

18
19 Because there are redundancies across religious affiliation and ethnicity (Amara and Shoa Oromo are
20 Christians, while Arsi Oromo are Muslims), religion (Christians/Muslims) was preferred as a main-effect
21 variable over ethnicity (Shoa/Arsi/Amara) because it better represents the between-group differences in
22 among the participants. We also included education level (finished high school education/not) in our
23 models.

24
25 Farmers from village 1 have significantly smaller plots of land (1.24 ± 1.06) compared to village 2
26 (1.70 ± 1.20 ; Mann Withney U Test: $U=9848.00$, $z=-4.091$, $p=0.0001$), they also reported
27 (mean \pm sd= 3.10 ± 1.47) significantly smaller network sizes than village 2 farmers (3.69 ± 1.18 , Mann
28 Whitney U test, $U=10322.00$, $z=-3.614$, $p=0.000$), which is why we discriminated between villages 1 and 2
29 in the models.

30
31 Some studies have suggested that of network size and structure remain relatively consistent across the
32 lifespan, despite individual variations (e.g. Dunbar 2008). Those variations might affect network
33 composition and network size, which is why we also explored age (Hill and Dunbar 2003) and wealth
34 effects. For example, young parents might receive more support from kin for domestic work and might
35 require more support from experienced and older farmers. Young people might be capable of providing

3
4 more support due to their youth and physical strength, while people might begin to receive support as they
5
6 age.

7
8 Connections between material capital and social capital have been shown many times (Lewis 2010). We
9
10 choose farmland size as a proximate for material capital, because it is a key resource in our study for
11
12 survival and reproductive outcomes (Gibson and Gurmú 2011) was chosen. Previous pilot studies showed
13
14 that wealth oriented questions were sensitive. Indeed, we found that farmers were uncomfortable answering
15
16 questions about wealth, but accepted questions about the size of their land, which is public knowledge
17
18 anyway. Questions about livestock appeared to be fairly sensitive.

19
20 Thus we narrowed our questions about wealth to farmland size. Because most of the farming is agricultural
21
22 a focus on farmland size was adequate, especially considering that both villages had similar ecologies and
23
24 agro-systems. Furthermore, because farmers use oxen for animal traction to work the land, the number of
25
26 oxen owned is usually proportionated to the farmland size.

27
28 Variation in farmland size is reduced (range: 0.25-5ha only), probably because the last Marxist
29
30 redistribution was fairly recent (1992), and it may be that not enough time has passed for inequalities to
31
32 grow. However, because social capital includes a collective dimension through interactions between
33
34 community members, it was relevant to consider respondent relative wealth in their village. We tested for
35
36 an interaction effect between land size and village, but we did not include them in final models when they
37
38 yielded non-significant results.

39 40 **Database and data analyses**

41
42 Socio-economic, demographic, and social-network data were input in into a Microsoft Access (Redmond,
43
44 WA, USA) database. IBM SPSS Statistics for Macintosh, version 22.0. software was used for all analyses.
45
46 (IBM, Armonk, NY, USA). We created one large data frame that included socio-economic, demographic,
47
48 and network size and composition data for each respondent. Descriptive statistics are presented in the
49
50 appendix.

51
52 Generalized linear models with Poisson regressions were fit to compare birth-order categories effects on
53
54 full network size, kin network size, non-parental kin network size, number of non-parental kin reciprocators
55
56 and number of non-kin reciprocators. Independent variables were: age, land size, village, religion,

education, sibling size or male sibling size, land origin, and generational group. Estimated marginal means are presented in the figures.

We fit logistic regressions with independent variables to identify effects of birth-order categories associated with parental interactions among farmers' support networks. We only performed analyses of parent interactions for the inheritor group, because a large proportion of the redistribution group (respondent > 40 years old) have elderly or deceased parents or deceased parents (87% of the inheritor group had at least one parent being alive, for 36% of the redistribution group). Logistic regressions were performed for three types of interactions: 1) parents cited as interactants (helpers or receivers) 2) parents are named as helpers 3) parents are named as reciprocators. Independent variables we included in the models were: age, education, religion, land size and respondent village, intra-sex birth-order categories, and survival of at least one parent/none.

Wilcoxon signed ranks tests were performed for respondents of both groups to compare the number of kin to the number of non-kin, the number of close kin (parents, children and sibling) to the number of distant kin (other kin).

1
2
3
4 **Results**
5
6

7 We estimated that mean (\pm sd) network sizes for domestic and agricultural interactions were 3.48 ± 1.24 for
8 the inheritor group and 3.18 ± 1.51 for the redistribution group. Two major trends emerged from our
9 analyses: 1) Support networks varied according to competition among brothers and 2) reciprocity and kin-
10 selection shaped farmers' daily support networks.
11
12
13
14

15
16 Prediction 1: Support networks varied according to birth-order biases
17

18 We fit GLMs with Poisson regression to explore the impact of intra-sex birth order on network size and kin
19 network size, while controlling for age, number of male siblings, land size, and village (Table 1). In model
20 1, only village had an effect on total network size (kin and non-kin), where village 1 respondents reported
21 smaller networks than village 2 respondents (village 1/2 ratio: expB (95% CI)=0.8 (0.7–1.0), P=0.010).
22 When focusing on the number of kin cited (model 2), an intra-sex birth-order effect was present among
23 first-born sons (expB (95% CI)=1.5 (1.1–2.0), P=0.005) and middle-born sons (expB (95% CI)=1.5 (1.2–
24 2.0), P=0.002) who both reporting more kin than last-born sons. Because the law states that both males and
25 females can inherit, a similar model that includes birth order for all children instead of just brothers was
26 tested (Model 4, Table 1), but no significant birth-order effect was observed, suggesting that indeed intra-
27 sex birth order is a better measure of competition than overall sibling birth order.
28
29
30
31
32
33
34
35
36
37

38 Age did not have a significant effect on network size in the above models. However, when we
39 discriminated between the inheritor and redistribution generations and when we controlled for an
40 interaction effect between generation and birth order, significant differences in kin network sizes were
41 observable according to birth-order categories (Table 1, Model 3, Figure 1), with first-born sons of the
42 inheritor group and middle-born sons of the redistribution group having the most kin in their networks.
43
44
45
46
47
48
49
50
51

52 **Fig. 1** Number of kin, listed in support networks, presented as marginal means +SE (N=331) for each intra-
53 sex birth-order categories (first, middle and last-born sons) and generations (inheritor and redistribution
54 groups). Covariates appearing in the model are fixed at the following values: male sibling size=5, land
55 size=1.43ha. Controlling for village and generations (inheritor vs. redistribution group). FB=first-born,
56 MB=middle-born, LB=last-born
57
58
59
60
61
62
63
64
65

1
2
3
4
5
6
7 Across generation, kin accounted for over half of the people in respondents' networks (57.1% and 51.2%
8 for the inheritor and redistribution groups, respectively, Table 2). Interactions with parents accounted for
9 17.1% and 6.0% of respondents' total interactions for the inheritor and redistribution groups, respectively.
10
11 Interactions with non-parental kin (40.0% and 45.2% overall for the inheritor and redistribution groups,
12
13 respectively) were distributed as follows: 22.5% and 17.7% were with brothers, 0.6% and 15.8% were with
14
15 children, and 4.5% and 2.3% were with sisters. The small proportion of daily interactions with sisters is due
16
17 to the local custom of women marrying outside their community.
18
19
20

21 To understand how direct reciprocity and non-direct reciprocity contribute to individual support networks,
22
23 different types of interactions were explored for each of the main interactant categories, which included
24
25 parents and non-parental kin.
26
27

28 **1.1 Interactions with parents**

29

30 Among the inheritor farmers (n=180), 55% named at least one parent as an interactant, and half of those
31
32 reported a reciprocating relationship (n=49). Reciprocal relationships with parents were reported by 67.4%,
33
34 47.6%, and 61.3% of first-born, middle-born, and last-born sons, respectively. Parents as helpers were
35
36 reported by 43.5%, 27.2%, and 29.0% of first-borns, middle-borns, and last-borns, and 63.0%, 45.6% and
37
38 58.1% reported helping a parent. Middle-born sons reported parent interactants significantly less often than
39
40 other sons (likelihood-ratio=5.416, df=1, P=0.020), because first-born sons reported a parent helper
41
42 (likelihood-ratio=3.855, df=1, P=0.050) and a reciprocating parent ((likelihood-ratio=4.227, df=1, P=0.040)
43
44 most often, while middle-born sons reported helping their parents less than other sons (likelihood-
45
46 ratio=4.216, df=1, P=0.040).
47

48 As expected, when controlling for birth order, village, religion, and having a living parent among farmers
49
50 in the same generation, younger farmers were more likely to cite parents in their networks than older
51
52 farmers (age: OR (95% CI)=0.9 (0.8–1.0), P=0.025; Model 1, Table 3).
53

54 Consistent with our expectations, we also found a first-born positive bias in citing parents in networks.
55
56 However, when comparing birth-order categories, middle-born sons were significantly less likely to cite a
57
58 parent in their network compared with first-born sons (OR (95% CI)=0.4 (0.2–1.0), P=0.045), but we found
59
60
61
62
63
64
65

1
2
3
4 no significant difference between first- and last-born sons (OR (95% CI)=0.8 (0.3–2.3), P=0.726; Model 1,
5
6 Table 3). These results suggest that first- and last-born sons are more likely to have parent interactants than
7
8 middle-born sons.
9

10 Parents invest in their children in various ways, providing, for example, education and material wealth.
11
12 When education and land-size transfers were included in the model, evidence for birth-order biases were
13
14 insignificant (OR (95% CI)=0.5 (0.2–1.1), P=0.075 and OR (95% CI)=0.9 (0.3–2.6), P=0.841; Model 2),
15
16 suggesting that daily interactions with parents might not be biased in favour of birth order when other types
17
18 of investment are controlled for. Farmers who completed high school were significantly more likely to
19
20 report their parents as interactants compared with other farmers, (OR (95% CI)=4.0 (1.5–10.7), P=0.006;
21
22 Model 2). Finally, we found no birth-order biases among sons reporting a parent as a reciprocator (OR
23
24 (95% CI)=0.5 (0.2–1.1), P=0.101 and OR (95% CI)=0.5 (0.2–1.5), P=0.241; Model 3) or among sons
25
26 reporting a parent as a direct supporter (OR (95% CI)=0.5 (0.2–1.1), P=0.095 and OR (95% CI)=0.5 (0.2–
27
28 1.4), P=0.172; Model 4).
29

30 **1.2 Non-parental kin and non-kin support**

31
32 Non-parental interactions comprised an important component of social-support networks in our dataset:
33
34 42.28% of interactants were non-parental kin, including 40.03% among the inheritor group and 45.21%
35
36 among the redistribution group.
37

38
39 GLMs with Poisson regression revealed a significant difference in the total number of non-parental kin
40
41 interactants cited by inheritor farmers across the three different birth-order categories, controlling for age,
42
43 number of male siblings, land size, village, education, and religion. We observed a decrease in the number
44
45 of non-parental kin cited with successive birth-order categories (Fig. 2). Middle-born and last-born sons
46
47 reported fewer non-parental kin in their networks compared with first-born sons (expB (95% CI)=0.7 (0.6–
48
49 1.0), P=0.062, expB (95% CI)=0.5 (0.3–0.8), P=0.003, reciprocally). None of the control variables had a
50
51 significant effect on model fit (Table 4). Those birth-order biases appeared to result from non-direct-
52
53 reciprocal interactions. There was not a significant difference in reporting reciprocators among sons of
54
55 different birth-order categories (reciprocally expB (95% CI)=0.9 (0.6–11.4), P=0.817, (expB (95% CI)=0.7
56
57 (0.4–1.3), P=0.257). Among the control variables, only village had an effect, with respondents from village
58
59 1 reporting fewer reciprocators than those in village 2 (expB (95% CI)=0.6 (0.4–0.9), P=0.018).
60
61

65

1
2
3
4
5
6
7 **Fig.2** Effect of intra-sex birth-order categories on the number of non-parental kin cited in daily support
8 networks for the two groups.
9

10
11 **Fig.2a** Number of non-parental kin cited presented as marginal means (+SE); n=180, first-born sons (FB)
12 n=46; middle-born sons (MB) n=103, last-born sons (LB) n=31. Covariates appearing in the model are
13 fixed at the following values: number of male siblings=5.07, land size=0.64 ha, age of respondent=31.48
14 years. We controlled for religion, education level, village, and land origin
15
16
17
18

19
20 **Fig.2b** Number of non-parental kin cited are presented as marginal means (+SE); n=151, first-born sons
21 (FB) n=48; middle-born sons (MB) n=79; last-born sons (LB) n=24. Covariates appearing in the mode are
22 fixed at the following values: number of male siblings=4.91, land size=2.38 ha, respondent age =57.75
23 years. We controlled for religion, education level, land origin, and village
24
25
26
27
28
29
30

31 Results for the redistribution group followed a different pattern, where we found significant differences
32 across the three birth-order categories. First- and last-born sons reported fewer non-parental kin in their
33 networks compared with middle-born sons (expB (95% CI)=0.6 (0.5–0.9), P=0.010 and expB (95%
34 CI)=0.5 (0.3–0.8), P=0.004). Only religion had a significant effect as a control variable, with Christians
35 having larger networks than Muslims (expB (95% CI)=1.8 (1.0–3.1), P=0.045). Due to our small sample
36 size, pairwise comparisons of the estimated marginal means were run for middle-born sons compared with
37 other birth-order sons for both religions. Similar patterns were noticeable for Christians and Muslims, with
38 middle-born sons citing more non-parental kin compared with other sons (Christians: mean difference
39 (middle-born vs. other sons)±SE=0.61±0.19, P=0.001; Muslims: mean difference (middle-born vs. other
40 sons)±SE=0.35±0.16, P=0.016). Religion did not impact patterns of birth-order biases. Birth-order biases in
41 non-parental kin network size were dependent of non-reciprocal interactions as we found no significant
42 differences in the number of reciprocators according to birth order (expB (95% CI)=1.0 (0.6–1.6), P=0.924
43 and expB (95% CI)=0.9 (0.5–1.8), P=0.814). When controlling for all other variables, village, high-school
44 education, land size, and land origin (redistribution vs. inheritance) had a significant effect on the number
45 of reciprocators. Farmers from village 1 reported fewer reciprocators (expB (95% CI)=0.5 (0.3–0.8),
46

1
2
3
4 P=0.009), as did farmers without a high-school education (expB (95% CI)=0.3 (0.2–0.7), P=0.002).
5
6 Farmers with larger land holdings reported more reciprocators (expB (95% CI)=1.4 (1.0–1.8), P=0.027),
7
8 and, finally, farmers who did not receive land from family reported having more reciprocators (expB (95%
9
10 CI)=2.0 (1.0–4.2), P=0.050).

11 12 Prediction 2: Reciprocity and kin-selection shape farmers' daily support networks

13
14 The inheritor group cited more kin than non-kin ($z=-2.455$, $P=0.014$, Wilcoxon signed-rank test), while the
15
16 redistribution group cited as many kin as non-kin ($z=-0.236$, $P=0.814$). A substantial component of kin
17
18 interactions was based on daily direct reciprocity: 49.7% of kin interactions of the inheritor farmers and
19
20 37.4% of kin interactions of the redistribution farmers were direct-reciprocal interactions, which suggests
21
22 the importance of direct payoff even with kin.

23
24 Respondents reported significantly more close-kin reciprocators than distant-kin reciprocators ($N=331$, $z=-$
25
26 8.849 , $P<0.0001$, Wilcoxon signed-rank tests), suggesting that reciprocity with close kin might be favoured
27
28 because of the compound profits of direct-reciprocity payoffs and indirect-fitness payoffs from kin
29
30 selection. Both farmer groups reported significantly more reciprocal interactions with close kin than distant
31
32 kin (inheritor farmers: $n=180$, $z=-6.313$, $P<0.0001$; redistribution farmers: $n=151$, $z=-4.857$, $P<0.0001$,
33
34 Wilcoxon signed-rank tests).

35
36 Farmers reported significantly more non-reciprocal interactions with kin than with non-kin (all
37
38 respondents: $N=331$, $z=-5.545$, $P<0.0001$; inheritor group: $n=180$, $z=-4.402$, $P<0.0001$; redistribution
39
40 group: $n=151$, $z=-3.444$, $P=0.001$, Wilcoxon signed-rank tests). They also reported significantly more non-
41
42 reciprocal interactions with close kin than with distant kin (all respondents: $N=331$, $z=-8.296$, $P<0.0001$;
43
44 inheritor group: $n=180$, $z=-5.727$, $P<0.0001$; redistribution group: $n=151$, $z=-6.025$, $P<0.0001$, Wilcoxon
45
46 signed-rank tests). This trend held when considering only non-reciprocal helpers: farmers reported
47
48 significantly more non-reciprocal kin helpers than non-reciprocal non-kin helpers (all respondents: $N=331$,
49
50 $z=-2.545$, $P=0.011$) and significantly more close-kin non-reciprocal helpers than distant-kin non-reciprocal
51
52 helpers (all respondents: $N=331$, $z=-4.762$, $P=0.0001$).

4 **Discussion**
5

6 The findings from this natural experiment allow us to identify patterns of intra-household inequalities in
7 terms of support networks for two wealth transmission modalities. Where material wealth is inherited,
8 support network inequalities follow patterns of material inequalities, like the ones observed by Gibson and
9 Gurmu (2011), suggesting that social capital in support networks reinforces material inequalities between
10 brothers in the context of limited resources. When wealth is not inherited and all sons had equal access to
11 land, other patterns of support network biases appeared, suggesting that social capital might at least partly
12 offset the disadvantage of sons receiving the least cumulative parental investment, which is consistent with
13 findings from Salmon (2003), Rhode et al. (2003), Salmon and Daly (1998). Overall, our findings suggest
14 that heritable wealth and land transfers, by influencing material and social capital, might have an important
15 role in the emergence and persistence of inequality in this agricultural population, similar to findings by
16 Smith et al. (2010). Our findings also imply that direct reciprocity appears to explain an important part of
17 kin cooperation, providing additional support for a more nuanced explanation of kin cooperation compared
18 with sole kin selection, as found in a number of different contexts (Jaeggi and Gurven 2013). Here,
19 support-network sizes were consistent with predictions from the literature, particularly Dunbar’s work on
20 biological constraints on human social networks, which predicts that “natural” support-network sizes range
21 from 3–5 people (Dunbar & Spoor 1995, Zhou et al. 2005, Hamilton et al. 2007).

38
39 Prediction 1: Birth-order biases in support-network size and composition
40

41 We found strong evidence of kin-selection, coinciding with multigeniture with a first-born son advantage,
42 in the inheritor group. First-born farmers were more likely to name parents as daily support partners,
43 particularly as reciprocators. Thus, first-borns preferentially received parental investment, but also, by
44 reciprocating, reduced their parents’ potential kin-selection costs. However, when controlling for other
45 variables, this effect was weaker and, at best, an insignificant tendency. Non-parental kin support size was
46 biased toward first-born sons, an effect that was not driven by reciprocity. This pattern reveals that first-
47 born farmers are advantaged in terms of both material (Gibson and Gurmu 2011) and social capital, which
48 decreases their household vulnerability relative to other farmers. We also found that middle-born and last-
49 born sons diversified their networks by reciprocating with more non-kin compared with first-born sons.
50

57
58
59
60
61
62
63
64
65

1
2
3
4 networks, possibly because they diversified their networks to include more non-parental kin (Salmon and
5
6 Daly 1998, Salmon 2003, Rhode et al. 2003). Middle-born farmers reported more non-parental kin in their
7
8 networks than did other farmers, and these interactions were mostly characterized by non-direct reciprocal
9
10 interactions, suggesting other non-exclusive mechanisms than direct reciprocity, such as kin selection,
11
12 delayed reciprocity, or indirect reciprocity. For both groups, last-born sons were among the most
13
14 disadvantaged in terms of their kin-support networks, as they reported fewer kin than other inheritor
15
16 farmers. According to Gibson and Gurmu (2011), “the number of elder brothers reduces a man’s
17
18 agricultural productivity, marriage, and reproductive success, as resources diminish and competition
19
20 increases with each additional sibling.” Thus, a last-born disadvantage in material resources and fitness was
21
22 sufficiently impactful to generate a negative bias in daily kin support and to drive last-borns to diversify
23
24 their network to non-kin through reciprocity. A negative kin bias might be even more dramatic for last-born
25
26 sons who had no land access, possibly forcing them to leave their community for low-skilled jobs in urban
27
28 centres.
29

30
31 Last-born farmers from the redistribution group were also disadvantaged. Alongside first-born sons, they
32
33 reported less non-parental kin support compared with middle-born sons, but they tended to report more
34
35 diversification via reciprocity with non-kin compared with their brothers. These results suggest a possible
36
37 continuity of first-born son preference during the redistribution period, which might not have been entirely
38
39 offset by the governmental land redistribution. Despite sweeping redistribution policies of the revolution-
40
41 era government, evidence suggests that not all intra-household and inter-household resource inequalities
42
43 were dismantled. Our focus group discussions and qualitative-interview informants told us that the socio-
44
45 economic statuses of families in past generations were still important for arranging marriages. Brothers
46
47 might not have had to compete for a critical livelihood resource because they all received equal plots from
48
49 the government, but there are other pathways through which sibling competition could arise. On the one
50
51 hand, a first-born son advantage could persist into later years, which could lead to first-born sons being
52
53 more family oriented and less non-kin oriented than other sons. On another hand, last-born sons might
54
55 work harder and take more risks to build non-kin relationships through direct reciprocity, which is
56
57 consistent with farmer comments during focus groups. Last-born sons were said to be “more difficult to
58
59 discipline” in younger ages, but also more “free, more rebellious, more obstinate, more friend-oriented, and
60
61
62
63
64
65

1
2
3
4 also more risky and adventurous,” compared with their older brothers. Sulloway (1996) claimed that
5
6 parental investment and sibling competition create a niche effect during childhood that influences
7
8 construction of personality and sociability constructs that persist into adulthood. Other studies have
9
10 investigated the influence of family size and composition on personality and social attitudes at young ages
11
12 (Salmon and Daly, 1998, Salmon 2003); some of these studies found that biases persist into adulthood
13
14 when offspring are less dependent on parental investment (Salmon 1998), but others found that parental-
15
16 investment biases are less influential (Pollet and Nettle 2009) or absent (Rhode et al. 2003, Pollet and
17
18 Nettle 2007, 2009) in adulthood, possibly because of adjustments in support-network configuration over a
19
20 lifetime. We observed significant biases among adult farmers in our study sample, suggesting the
21
22 importance of material and social resources in shaping support.
23

24 Respondent age tended to affect network size, probably only because parents were more often cited as
25
26 interactants by the younger-generation farmers. Age was not associated with non-parental kin and non-kin
27
28 interactions, even when we evaluated the two generations separately. Within the inheritor group, younger
29
30 farmers were expected to interact more with kin than older farmers, because they had higher reproductive
31
32 value, probably had less agricultural experience, had less labour power within their households because
33
34 their children were still very young, and had younger parents with more ability to help. On the one hand,
35
36 older farmers in the redistribution group could be expected to interact with more people generally,
37
38 including kin, because of their elder status; on the other hand, they could be expected to interact with fewer
39
40 people, because they have less ability to reciprocate support. Our results suggest that compositional changes
41
42 in agricultural and domestic interactions, rather than network size changes, might occur during farmers’
43
44 lifetimes; such compositional changes include interactant identities, interaction type, and direction of
45
46 interaction.
47

48
49 We also found that religion, education, and village had a significant effect on networks, revealing the
50
51 importance of individual and community context. Muslims were a minority in the study villages, so they
52
53 might have had fewer kin in their village and might have had a preference for Muslim interactants; hence,
54
55 Muslim inheritors would have fewer non-parental kin and redistribution farmers would have fewer non-kin
56
57 reciprocators than Christians. High-school education appears to be an attractive characteristic for
58
59 reciprocity among non-parental kin, in the context of equal land access, because high-school educated
60
61
62
63
64
65

1
2
3
4 farmers from the redistribution group reported more non-parental kin reciprocators. Finally, we observed a
5
6 significant village effect, with farmers from village 1 reporting significantly smaller networks compared to
7
8 farmers in village 2.
9

10
11 In this population, wealth, as measured by land size, did not seem to influence farmers' networks, apart
12
13 from the number of non-parental kin reciprocators in the redistribution group, suggesting that origin of land
14
15 access (inheritor vs. redistribution) was more impactful than land size on kin investment in daily support
16
17 networks. Land size among our sample was fairly homogenous and the variance was small; furthermore,
18
19 only landowners were included and they were all from large families with at least three sons. Because of
20
21 unmeasured informal arrangements for land access (Gavian and Ehui 1999), official land size might be an
22
23 underestimated proxy for the actual land size used for production. Therefore, it might be fruitful to explore
24
25 other types of wealth. Cues about the connection between support networks and material resources,
26
27 especially in difficult times, have been identified. For example, Caudell, Rotolo and Grima (2015), showed
28
29 that, among the Sidamo people of southern Ethiopia, charismatic individuals in informal lending networks
30
31 were wealthier than other farmers in terms of cattle herd size. Other work, identified non-linear wealth
32
33 dynamics on the formation of informal insurance networks, with the poorest being excluded from those
34
35 networks (Santos and Barrett 2006).
36

37 However, in our pilot work in the study site, low variation was observed in herd sizes. Farmers used a pair
38
39 of oxen to work their land, and might have two pairs if they have larger land holdings. Thus, more complex
40
41 indexes might be necessary to evaluate wealth. It is also possible that resources might have a smaller
42
43 impact on daily interactions compared with their impact on insurance networks, where resources increase
44
45 resilience in difficult times.
46

47 Prediction 2: Reciprocity and kin-selection shape farmers' daily support networks

48
49 Our results showed that kin make up an important proportion of support networks, which is consistent with
50
51 kin-selection theory (Hamilton 1964). In small-scale societies, close kin are overrepresented compared with
52
53 distant kin and non-kin (Gurven et al. 2000, Patton 2005). Kin over-representation is also visible in
54
55 Western societies (Dunbar and Spoons 1995). However, reciprocity (including reciprocal altruism as per,
56
57 Trivers 1971) plays an important role in shaping support ties among kin (Patton 2005, Gurven et al. 2000).
58
59 For instance, Hames (1987) suggested that, in Venezuela, "the Ye'kwana system of garden labour
60
61
62
63
64
65

1
2
3
4 exchange is a form of reciprocity biased by kinship.” Additionally, food transfers on an Ache reservation in
5 northeastern Paraguay “accords better with reciprocal altruism theory than with kin selection theory”
6 (Allen-Arrave, Gurven and Hill 2008). Finally a meta-analysis of 23 studies from 32 populations of humans
7 and primates highlighted the importance of reciprocity on shaping cooperation, and demonstrated that the
8 relative effect of reciprocity for sharing was similar to those of kinship and tolerated scrounging (Jaeggi
9 and Gurven 2013).

10
11
12
13
14
15
16
17 Non-reciprocal interactions should be more common among kin than non-kin, and among close kin than
18 distant kin, because of indirect fitness payoffs. Reciprocity theory (Trivers 1971) potentially explains most
19 interactions with non-kin, as well as many kin interactions, especially distant kin with whom indirect-
20 fitness profits from helping behaviour are relatively lower (Hames 1987, Gurven et al. 2000, Allen-Arrave,
21 Gurven and Hill 2008). We expected most non-kin interactions to be reciprocal, but expected more
22 variation in reciprocity among kin interactions. In fact, support networks constituted multi-directional
23 interactions: respondents stimulated and modulated their support by lowering the giver’s costs through
24 some amount of daily direct and indirect reciprocity. Interestingly, kin were frequently included in
25 reciprocal relationships, even though the frequency of non-reciprocal interactions among kin increased with
26 genetic relatedness. Delayed (contingent) reciprocity, which is difficult to evaluate and identify, might have
27 been mistaken in our dataset for non-reciprocal interactions, and so there may be even more variations and
28 higher quantities of reciprocal relationships among these farmer communities. According to these results,
29 even when considering classification of direct reciprocity/non-direct reciprocity and even when the last
30 category includes contingent (delayed) and indirect reciprocity (through another person), patterns for non-
31 reciprocal interactions followed predictions of kin selection while reciprocity, alongside kin selection,
32 appeared to be an important driver of daily reciprocal kin interactions. In other words, kin selection does
33 not appear to be the sole explanation for support received from kin.

51 **Conclusion**

52
53
54
55 Two major implications can be drawn from our findings in this natural-experiment context. First, we were
56 able to understand how heritable wealth shapes daily support networks in a contemporary agricultural
57 community and how it contributes to intra-household inequality. Our findings are consistent with Smith et

al (2010) and Boone (1992) who concluded that the control and transmission of scarce inelastic wealth, such as farmland, was an important factor in the emergence of inequality.

Second, in this small-scale land-based community, both kin selection and reciprocity shaped adult farmers' daily support networks, suggesting that reciprocity is important for cooperation among kin, as also shown by Jaeggi and Gurven (2013) in a number of contexts.

Our findings shed light on the behaviour and evolution of human social interactions by showing that people and their kin adjust their daily support behaviour in a complex manner that is consistent with fitness predictions. Increased socio-demographic and economic changes are expected in Ethiopia. Contraception has recently become more widespread (Alvergne et al. 2012), leading to a smaller average family size, which might change future intra-household resource distribution by reducing resource dilution. However, because of on-going population growth, land erosion, and limited arable land (Tefera et al. 2002)—all of which will only grow more serious with climate change and geo-political instability—resource scarcity and livelihood insecurity are likely to increase and further aggravate competition and inequalities, within and between households. Some individuals will likely have greater resilience in times of shock because they can rely on their networks (Caudell, Rotolo and Grima 2015), while the poorest and most vulnerable might not have the social resources to respond (Santos and Barrett 2006) and may be pushed to urban areas.

Lucie Clech obtained a PhD in Evolutionary Anthropology from the University of Bristol, focusing on human behavioural ecology of migration in Ethiopia, before undertaking postdoctoral research at Stanford University. Her research covers topics about poverty and family dynamics and includes migration, social interactions, education and health in resource-limited communities. Her interdisciplinary background in ecology and social sciences led her to focus especially on dynamics of livelihood strategies in response to modifications in their socio-economic and demographic environment.

Ashley Hazel holds a PhD in Natural Resource Ecology from the University of Michigan, and she is currently a Research Scientist at Stanford University in the Department of Earth System Science. Her research interests include human disease ecology, social network theory, and subsistence migration.

Mhairi Gibson is an Associate Professor in Anthropology at the University of Bristol. As an applied evolutionary anthropologist her work applies ideas from human behavioural ecology to emerging population health issues in low-income settings. Her fieldwork-based research has explored the causes and consequences of human population and health change in rural Ethiopia, and the social dynamics of normative practices which are harmful to women. Mhairi Gibson was lead editor (with David Lawson) of 'Applied evolutionary anthropology: Darwinian approaches to contemporary world issues', published by Springer Science & Business Media (2014).

Response to the reviewers

Does kin-selection theory help to explain support networks among farmers in South-Central Ethiopia?

Dear Dr Lancaster,

It is with great pleasure that we received your message.

The bio-sketches were updated and included in a separate file, the line numbers were removed from the manuscript, and separated files were created for the images.

Kind regards,
Lucie Clech

Dear Dr Clech,

Thank you very much for your careful revisions and response to the manuscript review.

You have ably met the editorial concerns and your manuscript entitled "Does kin-selection theory help to explain support networks among farmers in South-Central Ethiopia?" is ready for publication in Human Nature.

There are a few additional things I will need from you in order to ready the manuscript for copy-editing;

1. The revised manuscript in a clean format with no line numbers or embedded images. Please consult Springer Science Instructions for Authors available on Human Nature's website, so that you can have everything in order.
2. A biographical sketch of each author.
3. The signed Disclosure of Interest Form, which is also available on Human Nature's website, mailed or emailed to me. The lead author can sign for both after first getting confirmation and clearly so indicating on the form.

In order to submit your corrected manuscript, please access the following web site:

<https://www.editorialmanager.com/huna/>

Congratulations, I look forward to publishing your manuscript.

Sincerely yours,

Jane B. Lancaster
