#### Abstract

Given sets $S$ and $S^{\prime}$, a labeled 2-structure is a function $\sigma$ from ( $S \times$ $S) \backslash\{(s, s): s \in S\}$ to $S^{\prime \prime}$. The set $S$ is called the vertex set of $\sigma$ and denoted by $V(\sigma)$. The label set of $\sigma$ is the set $L(\sigma)$ of $l \in S^{\prime}$ such that $l=\sigma(v, w)$ for some $v, w \in V(\sigma)$. Given $W \subseteq V(\sigma)$, the 2 -substructure $\sigma_{(广(W \times W) \backslash\{(s, s): s \in W\})}$ of $\sigma$ is denoted by $\sigma[W]$. The dual $\sigma^{*}$ of $\sigma$ is defined on $V\left(\sigma^{*}\right)=V(\sigma)$ as follows. For distinct $v, w \in V\left(\sigma^{*}\right), \sigma^{*}(v, w)=\sigma(w, v)$. A labeled 2-structure $\sigma$ is reversible provided that for $x, x^{\prime}, y, y^{\prime} \in S$ such that $x \neq y$ and $x^{\prime} \neq y^{\prime}$, if $\sigma(x, y)=\sigma\left(x^{\prime}, y^{\prime}\right)$, then $\sigma(y, x)=\sigma\left(y^{\prime}, x^{\prime}\right)$. We only consider reversible labeled 2 -structures whose vertex set is finite.

Let $\sigma$ and $\tau$ be 2-structures such that $V(\sigma)=V(\tau)$. Given $2 \leq k \leq$ $|V(\sigma)|, \sigma$ and $\tau$ are $k$-hemimorphic if for every $W \subseteq V(\sigma)$ such that $|W| \leq k, \sigma[W]$ is isomorphic to $\tau[W]$ or $(\tau[W])^{*}$. Furthermore, let $\sigma$ be a 2 -structure. Given $2 \leq k \leq|V(\sigma)|, \sigma$ is $k$-forced if $\sigma$ and $\sigma^{\star}$ are the only 2 -structures $k$-hemimorphic to $\sigma$. We characterize the 3 -forced 2 -structures. Lastly, we provide a large class of 4 -forced 2 -structures.

Mathematics Subject Classifications (2010): 2-structure, $k$-hemimorphy, $k$-forcing.

Key words: $05 \mathrm{C} 20,05 \mathrm{C} 75,05 \mathrm{C} 76$.

## 1 Introduction

Given a digraph $D$, the dual $D^{\star}$ of $D$ is obtained from $D$ be reversing all its arcs. A digraph is self-dual if it is isomorphic to its dual. Consider two digraphs $D$ and $\Delta$ such that $V(D)=V(\Delta)$. Given $2 \leq k \leq|V(D)|$, we say that $D$ and $\Delta$ are $k$-hemimorphic if for every $W \subseteq V(D)$ such that $|W| \leq k, D[W]$ is isomorphic to $\Delta[W]$ or $(\Delta[W])^{\star}$. Furthermore, let $D$ be a digraph. Given $2 \leq k \leq|V(D)|$, $D$ is $k$-forced if $D$ and $D^{\star}$ are the only digraphs $k$-hemimorphic to $D$.

[^0]Given a digraph $D$, a subset $M$ of $V(D)$ is a module of $D$ if for any $x, y \in M$ and $v \in V(D) \backslash M$, we have

$$
\begin{aligned}
x v \in A(D) & \Longleftrightarrow y v \in A(D) \\
& \text { and } \\
v x \in A(D) & \Longleftrightarrow v y \in A(D)
\end{aligned}
$$

For instance, $\varnothing,\{v\}(v \in V(D))$, and $V(D)$ are modules of $D$, called trivial modules of $D$. A digraph $D$ is said to be prime if $|V(D)| \geq 3$ and all its modules are trivial.

Gallai [8, 13] proved that prime partial orders are 3-forced. Afterward, Boussaïri et al. [4, 5] established that prime tournaments are 3-forced as well. In general, a prime digraph is not 3 -forced. But, a prime digraph becomes 3 forced if all its prime subdigraphs of size 3 are self-dual. We denote by $F$ the digraph $(\{0,1,2\},\{01,10,12\})$. The only prime digraphs of size 3 that are not self-dual are $F$ and $F^{\star}$. They are called the flags (see Definition 31). Boussaïri et al. $[4,5]$ proved that prime digraphs without flags are 3-forced. Boussaïri [2] characterized the 3 -forced prime digraphs. This result was published in [3]. Lastly, given a digraph $D$, the set of the unordered pairs $\{v, w\}$ of vertices of $D$ such that $|\{v w, w v\}| \cap A(D) \mid=1$ is denoted by $O(D)$. Boussaïri [2] proved that a prime digraph $D$ such that the graph $(V(D), O(D))$ is connected is 4-forced. Dammak obtained this result as an easy consequence of the main results proved in [6].

Our purpose is to extend the characterization of 3 -forced digraphs (see Theorem 8) and the result on 4 -forced digraphs above (see Theorem 10) to reversible labeled 2 -structures.

Given sets $S$ and $S^{\prime}$, a labeled 2-structure is a function $\sigma$ from $(S \times S)$ \ $\{(s, s): s \in S\}$ to $S^{\prime}$. The set $S$ is called the vertex set of $\sigma$ and denoted by $V(\sigma)$. The label set of $\sigma$ is the set $L(\sigma)$ of $l \in S^{\prime}$ such that $l=\sigma(v, w)$ for some $v, w \in V(\sigma)$. A labeled 2-structure $\sigma$ is reversible [7] provided that for $x, x^{\prime}, y, y,^{\prime} \in S$ such that $x \neq y$ and $x^{\prime} \neq y^{\prime}$, we have

$$
\begin{equation*}
\text { if } \sigma(x, y)=\sigma\left(x^{\prime}, y^{\prime}\right), \text { then } \sigma(y, x)=\sigma\left(y^{\prime}, x^{\prime}\right) \tag{1}
\end{equation*}
$$

In what follows, we only consider reversible labeled 2-structures whose vertex set is finite. Given such a 2-structure $\sigma$, set $v(\sigma)=|V(\sigma)|$.

For instance, we associate with a digraph $D$ the 2 -structure $\sigma_{D}$ defined on $V\left(\sigma_{D}\right)=V(D)$ with $L\left(\sigma_{D}\right) \subseteq \mathbb{Z}_{4}$ as follows. For any $v, w \in V\left(\sigma_{D}\right)$ such that $v \neq w$,

$$
\sigma_{D}(v, w)=\left\{\begin{array}{l}
0 \text { if } v w, w v \notin A(D) \\
2 \text { if } v w, w v \in A(D) \\
1 \text { if } v w \in A(D) \text { and } w v \notin A(D), \\
3 \text { if } w v \in A(D) \text { and } v w \notin A(D)
\end{array}\right.
$$

Hence, given distinct $v, w \in V\left(\sigma_{D}\right)$, we have $\sigma_{D}(v, w)=-\sigma_{D}(w, v)(\bmod 4)$.

Let $\sigma$ be a 2-structure. With each $W \subseteq V(\sigma)$, we associate the 2-substructure $\sigma[W]$ of $\sigma$ induced by $W$ defined by

$$
\sigma[W]=\sigma_{\uparrow(W \times W) \backslash\{(w, w): w \in W\}}
$$

When $W=V(\sigma) \backslash W^{\prime}, \sigma[W]$ is also denoted by $\sigma-W^{\prime}$, and by $\sigma-w$ when $W^{\prime}=\{w\}$.

### 1.1 Definitions and notations

Definition 1. A 2-structure $\sigma$ is constant if $|L(\sigma)|=1$. A 2-structure $\sigma$ is linear if there exist distinct $l, l^{\prime} \in L(\sigma)$ such that $\left(V(\sigma), \sigma^{-1}(l)\right)$ and $\left(V(\sigma), \sigma^{-1}\left(l^{\prime}\right)\right)$ are linear orders (in this case, we obtain $L(\sigma)=\left\{l, l^{\prime}\right\}$ and $\left(V(\sigma), \sigma^{-1}\left(l^{\prime}\right)\right)=$ $\left.\left(V(\sigma), \sigma^{-1}(l)\right)^{\star}\right)$.

Let $\sigma$ be a 2-structure. Set

$$
\widetilde{L}(\sigma)=\left\{\{\sigma(v, w), \sigma(w, v)\}:\{v, w\} \in\binom{V(\sigma)}{2}\right\}
$$

Let $p, q \in \widetilde{L}(\sigma)$. By (1), we have $p=q$ or $p \cap q=\varnothing$. We consider the function

$$
\begin{aligned}
& \widetilde{\sigma}:\binom{V(\sigma)}{2} \longrightarrow \widetilde{L}(\sigma) \\
& \{v, w\} \quad \longmapsto \quad\{\sigma(v, w), \sigma(w, v)\} .
\end{aligned}
$$

For each $i=1$ or 2 , set

$$
\widetilde{L}_{i}(\sigma)=\{p \in \widetilde{L}(\sigma):|p|=i\}
$$

Furthermore, set

$$
E_{i}(\sigma)=\left\{\{v, w\} \in\binom{V(\sigma)}{2}: \widetilde{\sigma}(\{v, w\}) \in \widetilde{L}_{i}(\sigma)\right\}
$$

We consider the graph $G_{\sigma}$ defined on $V\left(G_{\sigma}\right)=\widetilde{L}_{2}(\sigma)$ in the following manner. For any $p, q \in V\left(G_{\sigma}\right)$ such that $p \neq q, p q \in E\left(G_{\sigma}\right)$ if there exists $W \subseteq V(\sigma)$ satisfying $|W|=3, \sigma[W]$ is prime, and $p, q \in \widetilde{L}(\sigma[W])$. For a digraph $D$, the edge set of $G_{\sigma_{D}}$ is empty because $\left|\widetilde{L}_{2}\left(\sigma_{D}\right)\right| \leq 1$.

We associate with a 2-structure $\sigma$ the 2-structure $\vec{\sigma}$ defined on $V(\vec{\sigma})=V(\sigma)$ as follows. If $\left|\widetilde{L}_{1}(\sigma)\right| \leq 1$, then $\vec{\sigma}=\sigma$. Now, suppose that $\left|\widetilde{L}_{1}(\sigma)\right| \geq 2$. Choose $l \in L(\sigma)$ such that $\{l\} \in \widetilde{L}_{1}(\sigma)$. For any $v, w \in V(\sigma)$ such that $v \neq w$,

$$
\vec{\sigma}(v, w)=\left\{\begin{array}{l}
\sigma(v, w) \text { if }\{v, w\} \in E_{2}(\sigma) \\
l \text { if }\{v, w\} \in E_{1}(\sigma)
\end{array}\right.
$$

For instance, consider a digraph $D$ such that there exist $v, v^{\prime}, w, w^{\prime} \in V(D)$ satisfying $v \neq w, v^{\prime} \neq w^{\prime}$, vw, wv $\in A(D)$, and $v^{\prime} w^{\prime}, w^{\prime} v^{\prime} \notin A(D)$. We obtain $\widetilde{L}_{1}\left(\sigma_{D}\right)=\{\{0\},\{2\}\}$. Now, choose $l=0$. Consider the oriented graph $\vec{D}$ defined
on $V(\vec{D})=V(D)$ by $A(\vec{D})=A(D) \backslash A\left(D^{\star}\right)$, where $D^{\star}$ is the dual of $D$ defined on $V\left(D^{\star}\right)=V(D)$ by $A\left(D^{\star}\right)=\{v w: w v \in A(D)\}$. We obtain

$$
\overrightarrow{\left(\sigma_{D}\right)}=\sigma_{\vec{D}}
$$

Later, in Convention 26, we set out the choice of the label "l" when we consider several 2-structures sharing the same label set.

Definition 2. We associate with a 2 -structure $\sigma$ its dual $\sigma^{\star}$ defined on $V\left(\sigma^{\star}\right)=$ $V(\sigma)$ as follows. For any $v, w \in V\left(\sigma^{\star}\right)$ such that $v \neq w, \sigma^{\star}(v, w)=\sigma(w, v)$.

Consider 2-structures $\sigma$ and $\tau$ such that $V(\sigma)=V(\tau)$. Given $2 \leq k \leq v(\sigma)$, we say that $\sigma$ and $\tau$ are $k$-hemimorphic if for every $W \subseteq V(\sigma)$ such that $|W| \leq k$, $\sigma[W]$ is isomorphic to $\tau[W]$ or $(\tau[W])^{\star}$.

Given $2 \leq k \leq v(\sigma)$, a 2-structure $\sigma$ is $k$-forced if $\sigma$ and $\sigma^{\star}$ are the only 2 -structures that are $k$-hemimorphic to $\sigma$.

Remark 3. For a digraph $D$, we obtain $\left(\sigma_{D}\right)^{\star}=\sigma_{\left(D^{\star}\right)}$. Consider digraphs $D$ and $\Delta$ such that $V(D)=V(\Delta)$. Given $2 \leq k \leq|V(D)|$, it follows that two digraphs $D$ and $\Delta$ are $k$-hemimorphic if and only if $\sigma_{D}$ and $\sigma_{\Delta}$ are $k$ hemimorphic. Let $D$ be a digraph. Given $2 \leq k \leq|V(D)|$, we obtain that $D$ is $k$-forced if and only $\sigma_{D}$ is.

### 1.2 Modular decomposition

For this section, we refer to $[8,13]$ for graphs, [5] for digraphs, [10] for binary structures, and $[7,11]$ for 2 -structures.

Let $\sigma$ be a 2-structure. A subset $M$ of $V(\sigma)$ is a module of $\sigma$ if for any $x, y \in M$ and $v \in V(\sigma) \backslash M$, we have $\sigma(x, v)=\sigma(y, v)$. For instance, $\varnothing, V(\sigma)$ and $\{v\}(v \in V(\sigma))$ are modules of $\sigma$, called the trivial modules of $\sigma$. A 2-structure $\sigma$ is indecomposable if all its modules are trivial, otherwise it is decomposable. A 2-structure $\sigma$ is prime if it is indecomposable with $v(\sigma) \geq 3$.

Let $\sigma$ be a 2 -structure. For disjoint modules $M$ and $N$ of $\sigma$, we have $\sigma(x, y)=$ $\sigma\left(x^{\prime}, y^{\prime}\right)$ for any $x, x^{\prime} \in M$ and $y, y^{\prime} \in M$. This property allows us to define the quotient as follows. A modular partition of $\sigma$ is a partition of $V(\sigma)$ in modules of $\sigma$. With a modular partition $P$ of $\sigma$, we associate the quotient of $\sigma$ by $P$ defined on $V(\sigma / P)=P$ as follows. For distinct $X, Y \in P,(\sigma / P)(X, Y)=\sigma(x, y)$, where $x \in X$ and $y \in Y$.

Let $\sigma$ be a 2 -structure. A subset $M$ of $V(\sigma)$ is a strong module of $\sigma$ if $M$ is a module of $\sigma$ satisfying: for every module $N$ of $\sigma$, if $M \cap N \neq \varnothing$, then $M \subseteq N$ or $N \subseteq M$. For instance, the trivial modules of $\sigma$ are strong modules too. We denote by $\mathscr{G}(\sigma)$ the family of the strong modules of $\sigma$ which are maximal under inclusion among the proper strong modules of $\sigma$. Gallai's decomposition theorem follows.

Theorem 4. Given a 2-structure $\sigma$ such that $v(\sigma) \geq 2, \mathscr{G}(\sigma)$ is a modular partition of $\sigma$, and the quotient $\sigma / \mathscr{G}(\sigma)$ is constant, linear, or prime.

### 1.3 The main results

Since it is not difficult to verify the next fact, we omit its proof.
Fact 5. Given a 2-structure $\sigma$ such that $\left(V(\sigma), E_{2}(\sigma)\right)$ admits an isolated vertex $v, \sigma$ is 3 -forced if and only if $\sigma-v$ is as well.

In Section 3, we show the next preliminary result.
Lemma 6. Given a 2-structure $\sigma, \sigma$ is 3 -forced if and only if $\vec{\sigma}$ is 3-forced.
Remark 7. The next assumption follows from Fact 5 and Lemma 6. To characterize the 2 -structures $\sigma$ that are 3-forced, we can assume that $\sigma=\vec{\sigma}$ and $\left(V(\sigma), E_{2}(\sigma)\right)$ does not have isolated vertices.

The two main theorems follow.
Theorem 8. Let $\sigma$ be a 2-structure. Suppose that $\sigma=\vec{\sigma}$ and $\left(V(\sigma), E_{2}(\sigma)\right)$ does not have isolated vertices. The 2-structure $\sigma$ is 3-forced if and only if $\sigma$ satisfies the following three statements
(T1) $G_{\sigma}$ is connected;
(T2) for each $M \in \mathscr{G}(\sigma), E_{2}(\sigma[M])=\varnothing$;
(T3) if $|\mathscr{G}(\sigma)| \geq 3$, then $\sigma / \mathscr{G}(\sigma)$ is prime.
Remark 9. Theorem 8 is obtained by Boussaïri [2] for digraphs. Clearly, Statement (T1) is unnecessary for digraphs because it is trivially satisfied. Theorem 8 for digraphs is proved in [3].

Theorem 10. Let $\sigma$ be a prime 2-structure. If $\left(V(\sigma), E_{2}(\sigma)\right)$ is connected, then $\sigma$ is 4-forced.

## 2 Preliminaries

### 2.1 Prime 2-structures

The next result is classical in the study of prime 2-structures (for instance, see Ehrenfeucht et al. [7]).

Lemma 11. Given a prime 2-structure $\sigma$, there exists $X \subseteq V(\sigma)$ such that $|X|=3$ or 4 and $\sigma[X]$ is prime.

To obtain prime 2-substructure of larger sizes, we use the following subsets.
Notation 12. Let $\sigma$ be a 2-structure. Given $X \mp V(\sigma)$ such that $\sigma[X]$ is prime, consider the following subsets of $V(\sigma) \backslash X$

- $\operatorname{Ext}_{\sigma}(X)$ denotes the set of $v \in V(\sigma) \backslash X$ such that $\sigma[X \cup\{v\}]$ is prime;
- $\langle X\rangle_{\sigma}$ denotes the set of $v \in V(\sigma) \backslash X$ such that $X$ is a module of $\sigma[X \cup\{v\}]$;
- for each $y \in X, X_{\sigma}(y)$ denotes the set of $v \in V(\sigma) \backslash X$ such that $\{y, v\}$ is a module of $\sigma[X \cup\{v\}]$.

The set $\left\{\operatorname{Ext}_{\sigma}(X),\langle X\rangle_{\sigma}\right\} \cup\left\{X_{\sigma}(y): y \in X\right\}$ is denoted by $p_{(\sigma, X)}$.
Using the fact that the family of the modules of a 2 -structure is weakly partitive (for instance, see Ille and Woodrow [12]), it is not difficult to verify the following claim.

Claim 13. Given a 2-structure $\sigma$, consider $X \subseteq V(\sigma)$ such that $\sigma[X]$ is prime. The set $p_{(\sigma, X)}$ is a partition of $V(\sigma) \backslash X$.

Using the subsets described in Notation 12, Ehrenfeucht et al. [7] obtained the following result (see [7, Theorem 6.5]).
Proposition 14. Given a prime 2-structure $\sigma$, consider $X \subseteq V(\sigma)$ such that $\sigma[X]$ is prime. If $|V(\sigma) \backslash X| \geq 2$, then there exist $v, w \in V(\sigma) \backslash X$ such that $v \neq w$ and $\sigma[X \cup\{v, w\}]$ is prime.

The next result is an immediate consequence of Lemma 11 and Proposition 14.

Corollary 15. Let $\sigma$ be a prime 2-structure. If $v(\sigma) \geq 5$, then there exists $X \mp V(\sigma)$ such that $\sigma[X]$ is prime and $|V(\sigma) \backslash X| \leq 2$.

The next result follows from Proposition 14.
Lemma 16. Given a 2-structure $\sigma$ such that $v(\sigma) \geq 5$, Suppose that there exists $X q V(\sigma)$ such that $\sigma[X]$ is prime. If $\sigma$ is prime, then there exist elements $y_{0}, \ldots, y_{v(\sigma)-|X|-1}$ of $V(\sigma) \backslash X$ fulfilling the next three statements
(S1) $X \cup\left\{y_{0}, \ldots, y_{v(\sigma)-|X|-1}\right\}=V(\sigma)$;
(S2) if $\sigma\left[X \cup\left\{y_{0}\right\}\right]$ is decomposable, then there exists $z \in X$ such that $\left\{z, y_{0}\right\}$ is a module of $\sigma\left[X \cup\left\{y_{0}\right\}\right]$.
(S3) for each $k \in\{1, \ldots, v(\sigma)-|X|-2\}$, if $\sigma\left[X \cup\left\{y_{0}, \ldots, y_{k}\right\}\right]$ is decomposable, then the following assertions hold

- $k$ is even,
- $\sigma\left[X \cup\left\{y_{0}, \ldots, y_{k-1}\right\}\right]$ is prime,
- there exists $z \in X \cup\left\{y_{0}, \ldots, y_{k-1}\right\}$ such that $\left\{z, y_{k}\right\}$ is a module of $\sigma\left[X \cup\left\{y_{0}, \ldots, y_{k}\right\}\right]$.

In particular, for every $k \in\{0, \ldots, v(\sigma)-|X|-1\}, \sigma\left[X \cup\left\{y_{0}, \ldots, y_{k}\right\}\right] / \mathscr{G}(\sigma[X \cup$ $\left.\left.\left\{y_{0}, \ldots, y_{k}\right\}\right]\right)$ is prime.

Proof. It suffices to define $y_{0}$ and $y_{1}$, and then to pursue by proceeding by induction. By Proposition 14, there exist $v, w \in V(\sigma) \backslash X$ such that $v \neq w$ and $\sigma[X \cup\{v, w\}]$ is prime. If $v, w \in\langle X\rangle_{\sigma}$ (see Notation 12), then $X$ is a
module of $\sigma[X \cup\{v, w\}]$, which contradicts the fact that $\sigma[X \cup\{v, w\}]$ is prime. Consequently, we have $\{v, w\} \backslash\langle X\rangle_{\sigma} \neq \varnothing$. It follows from Claim 13 that

$$
\{v, w\} \cap\left(\operatorname{Ext}_{\sigma}(X) \cup\left(\bigcup_{y \in X} X_{\sigma}(y)\right)\right) \neq \varnothing
$$

For instance, assume that $v \in \operatorname{Ext}_{\sigma}(X) \cup\left(\cup_{y \in X} X_{\sigma}(y)\right)$. Clearly, for $t \in X_{\sigma}(y)$, where $y \in X$, we have

$$
\begin{gathered}
\mathscr{G}(\sigma[X \cup\{t\}])=\{\{y, t\}\} \cup\{\{z\}: z \in X \backslash\{y\}\} \\
\text { and } \\
\sigma[X \cup\{t\}] / \mathscr{G}(\sigma[X \cup\{t\}]) \text { is prime. }
\end{gathered}
$$

Hence, we can choose $y_{0}=v$ and $y_{1}=w$.
Lemma 17. Given a 2-structure $\sigma$ such that $v(\sigma) \geq 5$, if $\sigma / \mathscr{G}(\sigma)$ is prime, then there exists $v \in V(\sigma)$ such that $(\sigma-v) / \mathscr{G}(\sigma-v)$ is prime as well.

Proof. The result is obvious when $\sigma$ is decomposable. Hence, suppose that $\sigma$ is prime. By Corollary 15, there exists $X \mp V(\sigma)$ such that $\sigma[X]$ is prime and $|V(\sigma) \backslash X| \leq 2$. To conclude, it suffices to apply Lemma 16.

### 2.2 Critical 2-structures

A prime 2-structure $\sigma$ is critical if for every $v \in V(\sigma), \sigma-v$ is decomposable. Critical digraphs were characterized by Schmerl and Trotter [14] (see also Boudabbous and Ille [1]) .

Notation 18. Given $n \geq 2$, we denote by $\Sigma_{2 n}$ the sets of the 2 -structures $\sigma$ defined on $V(\sigma)=\{0, \ldots, 2 n-1\}$ such that $\left|\widetilde{L}_{2}(\sigma)\right|=2, \widetilde{\sigma}(\{0,1\}) \neq \widetilde{\sigma}(\{0,2\})$, and for $p, q \in\{0, \ldots, 2 n-1\}$ such that $p<q$, we have

$$
\sigma(p, q)=\left\{\begin{array}{l}
\sigma(0,1) \text { if } p \text { is even and } q \text { is odd }  \tag{2}\\
\sigma(0,2) \text { otherwise }
\end{array}\right.
$$

Claim 19. Given $n \geq 2$, the elements of $\Sigma_{2 n}$ are critical 2-structures.
Proof. To begin, we prove that the elements of $\Sigma_{2 n}$ are prime. We proceed by induction on $n \geq 2$. When $n=2$, we verify directly the result. Now, suppose that the elements of $\Sigma_{2 n}$ are prime, where $n \geq 2$. Consider $\sigma \in \Sigma_{2(n+1)}$. Clearly, $\sigma-\{2 n, 2 n+1\} \in \Sigma_{2 n}$. By induction hypothesis, $\sigma-\{2 n, 2 n+1\}$ is prime. Set

$$
X=\{0, \ldots, 2 n-1\} .
$$

We have $2 n+1 \in X_{\sigma}(2 n-1)$ and $2 n \in\langle X\rangle_{\sigma}$ (see Notation 12). Consider a module $M$ of $\sigma$ such that $|M| \geq 2$. We must show that $M=V(\sigma)$. Since $M \cap X$ is a module of $\sigma[X]$, we have $|M \cap X| \leq 1$ or $X \subseteq M$. For a contradiction, suppose that $|M \cap X| \leq 1$. Since $2 n$ and $2 n+1$ do not belong to the same block
of $p_{(\sigma, X)}, M \neq\{2 n, 2 n+1\}$. Thus, there exists $y \in X$ such that $M \cap X=\{y\}$. Since $|M| \geq 2, M \backslash X \neq \varnothing$. Clearly, $(M \backslash X) \subseteq X_{\sigma}(y)$. By Claim 13, $p_{(\sigma, X)}$ is a partition of $V(\sigma) \backslash X$. It follows that $M=\{2 n-1,2 n+1\}$, which is impossible because $\widetilde{\sigma}(\{2 n-1,2 n\}) \neq \widetilde{\sigma}(\{2 n, 2 n+1\})$. Consequently, $X \subseteq M$. Clearly, $(V(\sigma) \backslash M) \subseteq\langle X\rangle_{\sigma}$. Since $p_{(\sigma, X)}$ is a partition of $V(\sigma) \backslash X$, we obtain $2 n+1 \in M$. Furthermore, since $\widetilde{\sigma}(\{2 n-1,2 n\}) \neq \widetilde{\sigma}(\{2 n, 2 n+1\}), X \cup\{2 n+1\}$ is not a module of $\sigma$. It follows that $M=V(\sigma)$.

Lastly, we verify that elements of $\Sigma_{2 n}$ are critical. Given $n \geq 2$, consider $\sigma \in \Sigma_{2 n}$. We have

- $\{2, \ldots, 2 n-1\}$ is a module of $\sigma-0$;
- $\{0, \ldots, 2 n-3\}$ is a module of $\sigma-(2 n-1)$;
- for each $p \in\{1, \ldots, 2 n-2\},\{p-1, p+1\}$ is a module of $\sigma-p$.

Therefore, $\sigma$ is critical.
Example 20. Let $n \geq 2$. We consider the graph $G_{2 n}$ defined on $V\left(G_{2 n}\right)=$ $\{0, \ldots, 2 n-1\}$ by

$$
E\left(G_{2 n}\right)=\{2 i(2 j+1): i \leq j \in\{0, \ldots, n-1\}\} .
$$

The graph $G_{2 n}$ is critical. Furthermore, $G_{2 n}$ is a comparability graph. We consider the unique transitive orientation $Q_{2 n}$ of $G_{2 n}$ such that $0<_{Q_{2 n}} 1$. The complement of $G_{2 n}$ is a comparability graph too. We consider also the unique transitive orientation $R_{2 n}$ of the complement of $G_{2 n}$ such that $0<_{R_{2 n}} 2$. The partial orders $Q_{2 n}$ and $R_{2 n}$ are critical. We consider the 2 -structure $\gamma_{2 n}$ defined on $V\left(\gamma_{2 n}\right)=\{0, \ldots, 2 n-1\}$ with $L\left(\gamma_{2 n}\right)=\mathbb{Z}_{5} \backslash\{0\}$ as follows. For distinct $v, w \in V\left(\gamma_{2 n}\right)$,

$$
\gamma_{2 n}(v, w)=\left\{\begin{array}{l}
1 \text { if } v<_{Q_{2 n}} w \\
4 \text { if } w<_{Q_{2 n}} v \\
2 \text { if } v<_{R_{2 n}} w \\
3 \text { if } w<_{R_{2 n}} v
\end{array}\right.
$$

Clearly, $\gamma_{2 n}$ satisfies (2). Furthermore, $\widetilde{\gamma_{2 n}}(\{0,1\})=\{1,4\}$ and $\widetilde{\gamma_{2 n}}(\{0,2\})=$ $\{2,3\}$. Hence, we have $\widetilde{\gamma_{2 n}}(\{0,1\}) \neq \widetilde{\gamma_{2 n}}(\{0,2\})$ and $\left|\widetilde{L}_{2}\left(\gamma_{2 n}\right)\right|=2$. Therefore, $\gamma_{2 n} \in \Sigma_{2 n}$. It follows from Claim 19 that $\gamma_{2 n}$ is critical.

Lastly, suppose for a contradiction that there exists $X \mp V\left(\gamma_{2 n}\right)$ such that $|X|$ is odd and $\gamma_{2 n}[X]$ is prime. Since $V\left(\gamma_{2 n}\right)$ is even, it follows from Proposition 14 applied several times that there exists $v \in V\left(\gamma_{2 n}\right)$ such that $\gamma_{2 n}-v$ is prime, which contradicts the fact that $\gamma_{2 n}$ is critical. Consequently, for every $X \nsubseteq$ $V\left(\gamma_{2 n}\right)$ such that $\gamma_{2 n}[X]$ is prime, we have $|X|$ is even. Thus, for every $X \mp$ $V\left(\gamma_{2 n}\right)$ such that $|X|=3, \gamma_{2 n}[X]$ is decomposable. It follows that $E\left(G_{\gamma_{2 n}}\right)=\varnothing$, and hence $G_{\gamma_{2 n}}$ is disconnected. Therefore, $\gamma_{2 n}$ does not satisfy Statement (T1) of Theorem 8 .

## 3 The 3-hemimorphy

The next result is obvious.
Fact 21. A 2-structure $\sigma$ is 2-forced if and only if $\left|E_{2}(\sigma)\right| \leq 1$.
Consider 2-hemimorphic 2-structures $\sigma$ and $\tau$. We associate to $\sigma$ and $\tau$ the graph $\mathcal{E}(\sigma, \tau)$ defined on $V(\sigma)$ as follows. For distinct $v, w \in V(\sigma), v w \in$ $E(\mathcal{E}(\sigma, \tau))$ if $\sigma(v, w)=\tau(v, w)$ and $\{v, w\} \in E_{2}(\sigma)$. We associate also to $\sigma$ and $\tau$ the graph $\mathcal{D}(\sigma, \tau)$ defined on $V(\sigma)$ as follows. For distinct $v, w \in V(\sigma)$, $v w \in E(\mathcal{D}(\sigma, \tau))$ if $\sigma(v, w) \neq \tau(v, w)$ (and hence $\left.\{v, w\} \in E_{2}(\sigma)\right)$. Note that

$$
\left\{\begin{array}{l}
\mathcal{D}(\sigma, \tau)=\mathcal{E}\left(\sigma, \tau^{\star}\right),  \tag{3}\\
\text { and } \\
E(\mathcal{D}(\sigma, \tau)) \cup E(\mathcal{E}(\sigma, \tau))=E_{2}(\sigma) .
\end{array}\right.
$$

Thus,

$$
\begin{equation*}
\text { if } E_{1}(\sigma)=\varnothing \text {, then } \mathcal{E}(\sigma, \tau) \text { is the complement of } \mathcal{D}(\sigma, \tau) \text {. } \tag{4}
\end{equation*}
$$

Definition 22. Let $\sigma$ be a 2 -structure. Given $W \subseteq V(\sigma)$, the 2 -structure $\operatorname{Inv}(\sigma, W)$ is defined on $V(\operatorname{Inv}(\sigma, W))=V(\sigma)$ as follows. Given distinct $v, w \in$ $V(\operatorname{Inv}(\sigma, W))$,

$$
\operatorname{Inv}(\sigma, W)(v, w)=\left\{\begin{array}{l}
\sigma(w, v) \text { if } v, w \in W \\
\sigma(v, w) \text { otherwise }
\end{array}\right.
$$

It is easy to show the next fact.
Fact 23. Let $\sigma$ be a 2-structure. For a module $M$ of $\sigma, \sigma$ and $\operatorname{Inv}(\sigma, M)$ are 3-hemimorphic.

Fact 24. Given 3-hemimorphic 2-structures $\sigma$ and $\tau$ such that $v(\sigma)=3$. If $E(\mathcal{D}(\sigma, \tau))$ and $E(\mathcal{E}(\sigma, \tau))$ are nonempty, then there exist distinct $v, w \in V(\sigma)$ such that

- $\{v, w\}$ is a module of $\sigma$ and $\tau$;
- $E(\mathcal{D}(\sigma, \tau))=\{v w\}$ or $E(\mathcal{E}(\sigma, \tau))=\{v w\}$;
- $E_{1}(\sigma)=\varnothing$ (so $\mathcal{E}(\sigma, \tau)$ is the complement of $\mathcal{D}(\sigma, \tau)$ by (4)).

Proof. We can assume that $V(\sigma)=\{0,1,2\}, 01 \in E(\mathcal{D}(\sigma, \tau))$, and $02 \in E(\mathcal{E}(\sigma$, $\tau)$ ). If $|\widetilde{L}(\sigma)|=3$, then the only isomorphism from $\sigma$ onto $\tau$ or $\tau^{\star}$ is $\operatorname{Id}_{\{0,1,2\}}$, which is impossible because $E(\mathcal{D}(\sigma, \tau))$ and $E(\mathcal{E}(\sigma, \tau))$ are nonempty. It follows that $|\widetilde{L}(\sigma)| \leq 2$.

To begin, suppose that $\widetilde{\sigma}(\{0,1\})=\widetilde{\sigma}(\{0,2\})$. If $\widetilde{\sigma}(\{0,1\}) \neq \widetilde{\sigma}(\{1,2\})$, then one among $\sigma$ or $\tau$ is prime whereas the other one is decomposable. It follows that $\widetilde{\sigma}(\{0,1\})=\widetilde{\sigma}(\{1,2\})$. Hence, $\sigma$ and $\tau$ are linear. Moreover, we obtain that $\{1,2\}$ is a module of $\sigma$ or $\tau$. For instance, assume that $\{1,2\}$ is a module of $\sigma$.

By exchanging $\tau$ and $\tau^{\star}$ if necessary, we can assume that $12 \in E(\mathcal{D}(\sigma, \tau))$. We obtain that $\{0,2\}$ is a module of $\sigma$ and $\tau$. Furthermore, $E(\mathcal{E}(\sigma, \tau))=\{02\}$.

Now, suppose that $\widetilde{\sigma}(\{0,1\}) \neq \widetilde{\sigma}(\{0,2\})$. Since $|\widetilde{L}(\sigma)| \leq 2$, we can assume that $\widetilde{\sigma}(\{0,1\})=\widetilde{\sigma}(\{1,2\})$. For a contradiction, suppose that $\{0,2\}$ is not a module of $\sigma$. Since $\sigma$ and $\tau$ are both prime or not, we obtain $12 \in E(\mathcal{D}(\sigma, \tau))$. It is not difficult to verify that $\sigma$ is isomorphic neither to $\tau$ nor to $\tau^{\star}$. Consequently, $\{0,2\}$ is a module of $\sigma$. Hence, $\tau$ is decomposable. It follows that $E(\mathcal{E}(\sigma, \tau))=$ $\{02\}$, and hence $\{0,2\}$ is a module of $\tau$.

The next fact is an immediate consequence of Fact 24.
Fact 25. Given a 2-structure $\sigma$ such that $v(\sigma)=3$, if $\sigma$ is prime, then $\sigma$ is 3-forced.

It is not difficult to show the next result. Nevertheless, we have to adopt the following convention.

Convention 26. Let $\sigma$ and $\tau$ be 2-hemimorphic 2 -structures. We have $\widetilde{L}(\sigma)=$ $\widetilde{L}(\tau)$, and hence $\widetilde{L}_{1}(\sigma)=\widetilde{L}_{1}(\tau)$. Suppose that $\left|\widetilde{L}_{1}(\sigma)\right| \geq 2$. We choose the same $l \in L(\sigma) \cap L(\tau)$ such that $\{l\} \in \widetilde{L}_{1}(\sigma) \cap \widetilde{L}_{1}(\tau)$ to define $\vec{\sigma}$ and $\vec{\tau}$. Otherwise, $\vec{\sigma}$ and $\vec{\tau}$ would not be 2-hemimorphic.

Lemma 27. Given 2-hemimorphic 2-structures $\sigma$ and $\tau, \sigma$ and $\tau$ are 3-hemimorphic if and only if $\vec{\sigma}$ and $\vec{\tau}$ are 3-hemimorphic too.

Now, we are ready to prove Lemma 6 (with Convention 26).
Proof of Lemma 6. To begin, suppose that $\sigma$ is 3 -forced. Consider a 2-structure $\tau$ which is 3 -hemimorphic to $\vec{\sigma}$. There exists a unique 2 -structure $\rho$ such that $\sigma$ and $\rho$ are 2 -hemimorphic and $\vec{\rho}=\tau$. By Lemma $27, \sigma$ and $\rho$ are 3 -hemimorphic. Since $\sigma$ is 3 -forced, we obtain $\sigma=\tau$ or $\tau^{\star}$. It follows that $\vec{\sigma}=\vec{\rho}$ or $(\vec{\rho})^{\star}$.

Conversely, suppose that $\vec{\sigma}$ is 3 -forced. Consider a 2 -structure $\tau$ which is 3 -hemimorphic to $\sigma$. By Lemma 27, $\vec{\sigma}$ and $\vec{\tau}$ are 3 -hemimorphic. Since $\vec{\sigma}$ is 3-forced, we obtain $\vec{\sigma}=\vec{\tau}$ or $(\vec{\tau})^{\star}$. Since $\sigma$ and $\tau$ are 2-hemimorphic, we have $\sigma=\tau$ or $\tau^{\star}$.

Example 28. Consider a set $S$ admitting a partition $P=\left\{X_{0}, \ldots, X_{n-1}\right\}$, where $n \geq 4$. We consider the partial order $O$ defined on $S$ satisfying

- $P$ is a modular partition of $O$;
- $O / P$ is the linear order $X_{0}<X_{1}<\cdots<X_{n-1}$;
- for each $i \in\{0, \ldots, n-1\}$, the arc set of $O\left[X_{i}\right]$ is empty.

Moreover, we consider the partiel order $Q$ defined on $S$ satisfying

- $P$ is a modular partition of $Q$;
- $O / P$ is the linear order $X_{2}<X_{0}<X_{3}<\cdots \leq X_{n-1}<X_{1}$;
- for each $i \in\{0, \ldots, n-1\}$, the arc set of $Q\left[X_{i}\right]$ is empty.

Clearly, $\sigma_{O}$ and $\sigma_{Q}$ are 3-hemimorphic. It is not difficult to verify that $P$ is also a modular partition of $\mathcal{D}\left(\sigma_{O}, \sigma_{Q}\right)$ and $\mathcal{E}\left(\sigma_{O}, \sigma_{Q}\right)$ such that

- $E\left(\mathcal{D}\left(\sigma_{O}, \sigma_{Q}\right) / P\right)=\left\{X_{0} X_{2}\right\} \cup\left\{X_{1} X_{i}: i \in\{2, \ldots, n-1\}\right\} ;$
- $\mathcal{E}\left(\sigma_{O}, \sigma_{Q}\right) / P$ is the complement of $\mathcal{D}\left(\sigma_{O}, \sigma_{Q}\right) / P$.

It follows that $\mathcal{D}\left(\sigma_{O}, \sigma_{Q}\right)$ and $\mathcal{E}\left(\sigma_{O}, \sigma_{Q}\right)$ are both connected. Hence, $\sigma_{O}$ is not 3 -forced. It is not difficult to verify that $P=\mathscr{G}\left(\sigma_{O}\right)$ and $\sigma_{O} / \mathscr{G}\left(\sigma_{O}\right)$ is linear; whence the necessity of Statement (T3) in Theorem 8. Furthermore, $X_{0} \cup X_{1}$ is a module of $\sigma_{O}$ such that $E_{2}\left(\sigma\left[X_{0} \cup X_{1}\right]\right) \neq \varnothing$; whence the necessity of Statement (T4) in Theorem 42.
Example 29. Given $n \geq 2$, consider the critical 2-structures $\gamma_{2 n}$ introduced in Example 20. We consider also the 2-structure $\rho_{2 n}$ defined on $V\left(\rho_{2 n}\right)=$ $\{0, \ldots, 2 n-1\}$ in the following manner. For any $p, q \in\{0, \ldots, 2 n-1\}$ such that $p<q$,

$$
\rho_{2 n}(p, q)=\left\{\begin{array}{l}
\gamma_{2 n}(q, p) \text { if } p \text { is even and } q \text { is odd },  \tag{5}\\
\gamma_{2 n}(p, q) \text { otherwise. }
\end{array}\right.
$$

By Claim 19, $\rho_{2 n}$ is critical. It is not difficult to verify that $\gamma_{2 n}$ and $\rho_{2 n}$ are 3 -hemimorphic. Nevertheless, by considering $\{0,1,2,3\}$, we see that $\gamma_{2 n}$ and $\rho_{2 n}$ are not 4-hemimorphic. Clearly, we have

$$
E\left(\mathcal{D}\left(\gamma_{2 n}, \rho_{2 n}\right)\right)=E\left(G_{2 n}\right) \text { (see Example 20). }
$$

By (3), $\mathcal{E}\left(\gamma_{2 n}, \rho_{2 n}\right)$ is the complement of $\mathcal{D}\left(\gamma_{2 n}, \rho_{2 n}\right)$. It follows that $\mathcal{D}\left(\gamma_{2 n}, \rho_{2 n}\right)$ and $\mathcal{E}\left(\gamma_{2 n}, \rho_{2 n}\right)$ are both connected. Hence, $\gamma_{2 n}$ is not 3 -forced (see Problem 41). As seen in Example 20, $\gamma_{2 n}$ does not satisfy Statement (T1) of Theorem 8; whence the necessity of Statement (T1) in Theorem 8.

Fact 30. Let $\sigma$ and $\tau$ be two 3-hemimorphic 2-structures. Suppose that $v(\sigma)=4$. If $\mathcal{D}(\sigma, \tau)$ and $\mathcal{E}(\sigma, \tau)$ are both connected, and if $\sigma / \mathscr{G}(\sigma)$ is prime, then there exists an isomorphism $\varphi$ from $\sigma$ onto an element of $\Sigma_{4}$ (see Notation 18), which is also an isomorphism from $\mathcal{D}(\sigma, \tau)$ onto $G_{4}$ (see Example 20).

Proof. Since $\mathcal{D}(\sigma, \tau)$ and $\mathcal{E}(\sigma, \tau)$ are connected, $K_{1,3}$ and $K_{3}$ do not embed into $\mathcal{D}(\sigma, \tau)$ and $\mathcal{E}(\sigma, \tau)$. It follows that $\mathcal{D}(\sigma, \tau)$ and $\mathcal{E}(\sigma, \tau)$ are isomorphic to $P_{4}$. Hence, $\mathcal{D}(\sigma, \tau)$ is the complement of $\mathcal{E}(\sigma, \tau)$. Up to isomorphism, we can assume that $V(\sigma)=\{0,1,2,3\}$ and $\mathcal{D}(\sigma, \tau)=G_{4}$. Since $01,03 \in E(\mathcal{D}(\sigma, \tau))$ and $13 \in E(\mathcal{E}(\sigma, \tau))$, it follows from Fact 24 that $\{1,3\}$ is a module of $\sigma[\{0,1,3\}]$. Hence, we have $\sigma(0,1)=\sigma(0,3)$. Similarly, we have $\sigma(0,3)=\sigma(2,3)$ and $\sigma(0,2)=\sigma(1,2)=\sigma(1,3)$. Therefore, $\sigma$ satisfies (2). If $\widetilde{\sigma}(\{0,1\})=\widetilde{\sigma}(\{0,2\})$, then $\sigma$ is linear, which contradicts the fact that $\sigma / \mathscr{G}(\sigma)$ is prime. It follows that $\widetilde{\sigma}(\{0,1\}) \neq \widetilde{\sigma}(\{0,2\})$. Thus, $\sigma \in \Sigma_{4}$.

Definition 31. Recall that a digraph is a flag [9] if it is isomorphic to the digraph $(\{0,1,2\},\{01,10,12\})$. A simple generalization to 2 -structures follows. A 2-structure $\sigma$ defined on $V(\sigma)=\{0,1,2\}$ is a flag if $\left|\widetilde{L}_{1}(\sigma)\right|=2$ and $\left|\widetilde{L}_{2}(\sigma)\right|=1$.

Hagendorf and Lopez [9] showed the next result for digraphs. The generalization to 2-structures is not difficult. Its proof uses mainly Fact 24.

Fact 32. Let $\sigma$ and $\tau$ be two 3-hemimorphic 2-structures. Suppose that $\sigma$ does not contain flags. Each component of $\mathcal{D}(\sigma, \tau)$ (or of $\mathcal{E}(\sigma, \tau)$ ) is a module of $\sigma$ and $\tau$.

Lemma 33. Let $\sigma$ and $\tau$ be two 3-hemimorphic 2-structures. Suppose that $v(\sigma) \geq 5$. If $\mathcal{D}(\sigma, \tau)$ and $\mathcal{E}(\sigma, \tau)$ are both connected and if $\sigma / \mathscr{G}(\sigma)$ is prime, then the following two statements hold

1. there exits $v \in V(\sigma)$ such that $(\sigma-v) / \mathscr{G}(\sigma-v)$ is prime;
2. for each $v \in V(\sigma)$ such that $(\sigma-v) / \mathscr{G}(\sigma-v)$ is prime, $\mathcal{D}(\sigma-v, \tau-v)$ and $\mathcal{E}(\sigma-v, \tau-v)$ are both connected.

Proof. We begin with the following observation. Consider 3-hemimorphic 2structures $\gamma$ and $\rho$. By Lemma 27, $\vec{\gamma}$ and $\vec{\tau}$ are 3 -hemimorphic. We have $\mathcal{D}(\gamma, \rho)=\mathcal{D}(\vec{\gamma}, \vec{\rho})$ and $\mathcal{E}(\gamma, \rho)=\mathcal{E}(\vec{\gamma}, \vec{\rho})$. Moreover, suppose that the graph $\left(V(\gamma), E_{2}(\gamma)\right)$ is connected. It follows from Theorem 4 that $\gamma / \mathscr{G}(\gamma)$ is linear or prime. Similarly, it follows from Theorem 4 that $\vec{\gamma} / \mathscr{G}(\vec{\gamma})$ is linear or prime. Clearly, $\gamma / \mathscr{G}(\gamma)$ is linear if and only if $\vec{\gamma} / \mathscr{G}(\vec{\gamma})$ is as well. Therefore, $\gamma / \mathscr{G}(\gamma)$ is prime if and only if $\vec{\gamma} / \mathscr{G}(\vec{\gamma})$ is as well.

Consequently, we can assume that $\sigma=\vec{\sigma}$ and $\tau=\vec{\tau}$. In particular, $\sigma$ and $\tau$ do not contain flags.

The first statement follows from Lemma 17. For the second statement, consider $v \in V(\sigma)$ such that $(\sigma-v) / \mathscr{G}(\sigma-v)$ is prime. For a contradiction, suppose that $\mathcal{D}(\sigma-v, \tau-v)$ and $\mathcal{E}(\sigma-v, \tau-v)$ are not both connected. By exchanging $\sigma-v$ and $(\sigma-v)^{\star}$ if necessary, we can assume that $\mathcal{D}(\sigma-v, \tau-v)$ is disconnected. By Fact 32, the components of $\mathcal{D}(\sigma-v, \tau-v)$ are modules of $\sigma-v$ and $\tau-v$. Since $\mathcal{E}(\sigma, \tau)$ is connected, there exists $x \in V(\sigma) \backslash\{v\}$ such that

$$
x v \in E(\mathcal{E}(\sigma, \tau))
$$

Denote by $C$ the component of $\mathcal{D}(\sigma-v, \tau-v)$ containing $x$. Furthermore, since $(\sigma-v) / \mathscr{G}(\sigma-v)$ is not linear, there exists a component $D$ of $\mathcal{D}(\sigma-v, \tau-v)$ such that $D \neq C$ and $\sigma(z, x) \neq \sigma(v, x)$ for $z \in D$. Lastly, recall that $\mathcal{D}(\sigma, \tau)$ is connected. By considering a shortest path in $\mathcal{D}(\sigma, \tau)$ from $v$ to an element of $D$, we obtain $z \in D$ such that

$$
z v \in E(\mathcal{D}(\sigma, \tau))
$$

It follows from Fact 24 that $\sigma[\{x, z, v\}]$ and $\tau[\{x, z, v\}]$ are not 3-hemimorphic, which contradicts the fact that $\sigma$ and $\tau$ are 3 -hemimorphic. Consequently, $\mathcal{D}(\sigma-v, \tau-v)$ and $\mathcal{E}(\sigma-v, \tau-v)$ are both connected.

The next result is an immediate consequence of Fact 30 and Lemma 33.
Corollary 34. Let $\sigma$ and $\tau$ be two 3-hemimorphic 2-structures. Suppose that $v(\sigma) \geq 4$. If $\mathcal{D}(\sigma, \tau)$ and $\mathcal{E}(\sigma, \tau)$ are both connected and if $\sigma / \mathscr{G}(\sigma)$ is prime, then there exits $W \subseteq V(\sigma)$ such that $\sigma[W]$ and $\tau[W]$ are isomorphic to an element of $\Sigma_{4}$ (see Notation 18).

Remark 35. Consider 3-hemimorphic digraphs $D$ and $\Delta$. The definitions of the modular partition $\mathscr{G}(D)$ and of the graphs $\mathcal{D}(D, \Delta)$ and $\mathcal{E}(D, \Delta)$ in [5] are similar to those given for 2-structures here. It is easy to see that $\mathscr{G}(D)=\mathscr{G}\left(\sigma_{D}\right)$, $\mathcal{D}(D, \Delta)=\mathcal{D}\left(\sigma_{D}, \sigma_{\Delta}\right)$, and $\mathcal{E}(D, \Delta)=\mathcal{E}\left(\sigma_{D}, \sigma_{\Delta}\right)$. Boussaïri et al. [4, 5] proved the following. If $D / \mathscr{G}(D)$ is prime, then $\mathcal{D}(D, \Delta)$ and $\mathcal{E}(D, \Delta)$ are not both connected.

The next result follows from Corollary 34 and Fact 32.
Corollary 36. Let $\sigma$ be a 2-structure such that $v(\sigma) \geq 4$. Suppose that $\sigma$ contains neither flags nor elements of $\Sigma_{4}$. If $\sigma$ is prime, then $\sigma$ is 3-forced.

Proof. Let $\tau$ be a 2-structure, which is 3-hemimorphic to $\sigma$. Clearly, $\sigma / \mathscr{G}(\sigma)$ is prime because $\sigma$ is prime. Since $\sigma$ does not contain elements of $\Sigma_{4}$, it follows from Corollary 34 that $\mathcal{D}(\sigma, \tau)$ and $\mathcal{E}(\sigma, \tau)$ are not both connected. By exchanging $\sigma$ and $\sigma^{\star}$ if necessary, we can assume that $\mathcal{D}(\sigma, \tau)$ is disconnected. Let $C$ be any component of $\mathcal{D}(\sigma, \tau)$. Since $\sigma$ does not contain flags, it follows from Fact 32 that $V(C)$ is a module of $\sigma$. Lastly, since $\sigma$ is prime, $V(C)$ is a singleton. Consequently, the edge set of $\mathcal{D}(\sigma, \tau)$ is empty, which means $\sigma=\tau$.

Remark 37. For digraphs, Boussaïri et al.. [4, 5] obtained the analogous result without forbidding the elements of $\Sigma_{4}$. Indeed, they proved that a prime digraph without flags is 3 -forced. As seen in Example 29, it is also necessary to forbid the elements of $\Sigma_{4}$ for 2 -structures.

## 4 Proofs of Theorems 8 and 10

Proposition 38. Let $\sigma$ be a 2-structure. Suppose that $\sigma=\vec{\sigma}$ and $\left(V(\sigma), E_{2}(\sigma)\right)$ does not have isolated vertices. If $\sigma$ is 3-forced, then $\sigma$ satisfies Statements (T1), (T2), and (T3) (see Theorem 8).

Proof. To begin, suppose that $G_{\sigma}$ is disconnected. Let $C$ be a component of $G_{\sigma}$. We consider the 2-structure $\tau$ defined on $V(\tau)=V(\sigma)$ as follows. Given distinct $v, w \in V(\tau)$,

$$
\tau(v, w)=\left\{\begin{array}{l}
\sigma(w, v) \text { if } \widetilde{\sigma}(\{v, w\}) \in V(C) \\
\sigma(v, w) \text { otherwise }
\end{array}\right.
$$

We verify that $\sigma$ and $\tau$ are 3 -hemimorphic. Clearly, $\sigma$ and $\tau$ are 2 -hemimorphic. Let $W \subseteq V(\sigma)$ satisfying $|W|=3$. If $\widetilde{L}_{2}(\sigma[W]) \subseteq V(C)$, then $\tau[W]=(\sigma[W])^{\star}$. Furthermore, if $\widetilde{L}_{2}(\sigma[W]) \cap V(C)=\varnothing$, then $\tau[W]=(\sigma[W])$. Therefore, suppose
that there exist $p \in \widetilde{L}_{2}(\sigma[W]) \cap V(C)$ and $q \in\left(\widetilde{L}_{2}(\sigma[W]) \backslash V(C)\right)$. By definition of $G_{\sigma}, \sigma[W]$ is decomposable. It follows that $\widetilde{L}_{2}(\sigma[W])=\{p, q\}$. Consider distinct $v, w \in W$ such that $\{v, w\}$ is a nontrivial module of $\sigma[W]$. If $\widetilde{\sigma}(\{v, w\})=$ $p$, then $\tau[W]$ is isomorphic to $\sigma[W]$. Moreover, if $\widetilde{\sigma}(\{v, w\})=q$, then $\tau[W]$ is isomorphic to $(\sigma[W])^{\star}$. Consequently, $\sigma$ and $\tau$ are 3-hemimorphic. It follows that $\sigma$ is not 3 -forced. In what follows, we suppose that Statement (T1) holds.

To continue, suppose that there exists $M \in \mathscr{G}(\sigma)$ such that $E_{2}(\sigma[M]) \neq$ $\varnothing$. By Fact $23, \sigma$ and $\operatorname{Inv}(\sigma, M)$ are 3 -hemimorphic. Since $E_{2}(\sigma[M]) \neq \varnothing$, $\operatorname{Inv}(\sigma, M) \neq \sigma$. Let $v \in V(\sigma) \backslash M$. Since $\left(V(\sigma), E_{2}(\sigma)\right)$ does not have isolated vertices, there exists $w \in V(\sigma) \backslash\{v\}$ such that $\{v, w\} \in E_{2}(\sigma)$. Since $\{v, w\} \backslash M \neq$ $\varnothing, \operatorname{Inv}(\sigma, M) \neq \sigma^{\star}$. It follows that $\sigma$ is not 3 -forced. In what follows, we suppose that Statement (T2) holds.

Lastly, suppose that $|\mathscr{G}(\sigma)| \geq 3$ but $\sigma / \mathscr{G}(\sigma)$ is not prime. By Theorem 4, $\sigma / \mathscr{G}(\sigma)$ is constant or linear. Let $M \in \sigma / \mathscr{G}(\sigma)$. Consider $v \in M$. Since $\left(V(\sigma), E_{2}(\sigma)\right)$ does not have isolated vertices, there exists $w \in V(\sigma) \backslash\{v\}$ such that $\{v, w\} \in E_{2}(\sigma)$. Furthermore, since Statement (T2) holds, $w \notin M$. It follows that $\sigma / \mathscr{G}(\sigma)$ is not constant, so $\sigma / \mathscr{G}(\sigma)$ is linear. Let $M_{0}$ and $M_{1}$ be the first two elements of $\sigma / \mathscr{G}(\sigma)$. Clearly, $M_{0} \cup M_{1}$ is a module of $\sigma$. By Fact $23, \sigma$ and $\operatorname{Inv}\left(\sigma, M_{0} \cup M_{1}\right)$ are 3-hemimorphic. For $v_{0} \in M_{0}$ and $v_{1} \in M_{1}$, we have $\left\{v_{0}, v_{1}\right\} \in E_{2}(\sigma)$, and hence $\operatorname{Inv}(\sigma, M) \neq \sigma$. Since $|\mathscr{G}(\sigma)| \geq 3$, there exists $v \in V(\sigma) \backslash\left(M_{0} \cup M_{1}\right)$. We obtain $\left\{v_{0}, v\right\} \in E_{2}(\sigma)$, and hence $\operatorname{Inv}(\sigma, M) \neq \sigma^{\star}$. It follows that $\sigma$ is not 3 -forced. Consequently, Statement (T3) holds.

Proposition 39. Let $\sigma$ be a prime 2-structure. Suppose that $\sigma=\vec{\sigma}$. If $\sigma$ satisfies Statement (T1), then $\sigma$ is 3-forced.

Proof. Consider a 2-structure $\tau$ which is 3 -hemimorphic to $\sigma$. To begin, suppose that $\left|\widetilde{L}_{2}(\sigma)\right|=1$. Since $\sigma=\vec{\sigma}, \sigma$ does not contain flags. Furthermore, since $\left|\widetilde{L}_{2}(\sigma)\right|=1, \sigma$ does not contain elements of $\Sigma_{4}$. It follows from Corollary 36 that $\tau=\sigma$ or $\sigma^{\star}$.

Now, suppose that $\left|\widetilde{L}_{2}(\sigma)\right| \geq 2$. Since $G_{\sigma}$ is connected by Statement (T1), there exists $X \subseteq V(\sigma)$ such that $|X|=3$ and $\sigma[X]$ is prime. By Lemma 16 , there exist elements $y_{0}, \ldots, y_{v(\sigma)-4}$ of $V(\sigma) \backslash X$ such that Statements (S1), (S2), and (S3) hold. For a contradiction, suppose that $\mathcal{D}(\sigma, \tau)$ and $\mathcal{E}(\sigma, \tau)$ are both connected. By applying several times Lemma 33, we obtain that $\mathcal{D}\left(\sigma\left[X \cup\left\{y_{0}\right\}\right], \tau\left[X \cup\left\{y_{0}\right\}\right]\right)$ and $\mathcal{E}\left(\sigma\left[X \cup\left\{y_{0}\right\}\right], \tau\left[X \cup\left\{y_{0}\right\}\right]\right)$ are both connected. By Fact 30, $\sigma\left[X \cup\left\{y_{0}\right\}\right]$ is isomorphic to an element of $\Sigma_{4}$ (see Notation 18). By Claim 19, $\sigma\left[X \cup\left\{y_{0}\right\}\right]$ is critical, which is impossible because $\sigma[X]$ is prime. Consequently, $\mathcal{D}(\sigma, \tau)$ and $\mathcal{E}(\sigma, \tau)$ are not both connected. By exchanging $\tau$ and $\tau^{\star}$ if necessary, we can assume that $\mathcal{D}(\sigma, \tau)$ is disconnected. As shown at the end of the proof of Corollary 36, we obtain $\sigma=\tau$.

The next result is an immediate consequence of Propositions 38 and 39.
Corollary 40. Let $\sigma$ be a prime 2-structure. Suppose that $\sigma=\vec{\sigma}$. The 2structure $\sigma$ is 3-forced if and only if $\sigma$ satisfies Statement (T1).

Problem 41. A 2-structure $\sigma$ is said to be asymmetric if $\widetilde{L}_{1}(\sigma)=\varnothing$. Describe the structural form of a prime asymmetric 2 -structure $\sigma$ such that there exists a 2 -structure $\tau$ satisfying

- $\sigma$ and $\tau$ are 3-hemimorphic;
- $\mathcal{D}(\sigma, \tau)$ and $\mathcal{E}(\sigma, \tau)$ are both connected.

As seen in Example 29, $\gamma_{2 n}$ is such a 2 -structure.
Proof of Theorem 8. To begin, suppose that $\sigma$ is 3 -forced. By Proposition 38, $\sigma$ satisfies Statements (T1), (T2), and (T3). Conversely, suppose that $\sigma$ satisfies Statements (T1), (T2), and (T3). If $\sigma$ is prime, then it follows from Proposition 39 that $\sigma$ is 3-forced. Hence, suppose that $\sigma$ is decomposable. Consider a 2-structure $\tau$ which is 3 -hemimorphic to $\sigma$. Since $\sigma$ satisfies Statement (T2), it follows from Fact 24 that $\mathscr{G}(\sigma)$ is a modular partition of $\tau$ as well.

To continue, we show that for each $M \in \mathscr{G}(\sigma)$, there exists $N \in \mathscr{G}(\sigma) \backslash\{M\}$ such that

$$
\begin{equation*}
\{x, y\} \in E_{2}(\sigma) \tag{6}
\end{equation*}
$$

for any $x \in M$ and $y \in N$. Let $M \in \mathscr{G}(\sigma)$. Consider $v \in M$. Since $\left(V(\sigma), E_{2}(\sigma)\right)$ does not have isolated vertices, there exists $w \in V(\sigma) \backslash\{v\}$ such that $\{v, w\} \in$ $E_{2}(\sigma)$. Furthermore, since Statement (T2) holds, $w \notin M$. By denoting by $N$ the element of $\mathscr{G}(\sigma)$ containing $w$, we obtain that (6) holds.

We conclude as follows. First, suppose that $|\mathscr{G}(\sigma)|=2$. It follows from (6) that $\sigma / \mathscr{G}(\sigma)$ is linear. Since $\sigma$ and $\tau$ are 3-hemimorphic, we have $E_{2}(\tau[M])=\varnothing$ for each $M \in \mathscr{G}(\sigma)$. Lastly, since $\mathscr{G}(\sigma)$ is a modular partition of $\tau$, we obtain $\tau=\sigma$ or $\sigma^{\star}$.

Second, suppose that $|\mathscr{G}(\sigma)| \geq 3$. Since $\sigma$ satisfies Statement (T3), $\sigma / \mathscr{G}(\sigma)$ is prime. Consider the set $\mathcal{T}$ of $X \subseteq V(\sigma)$ such that $|X \cap M|=1$ for each $M \in \mathscr{G}(\sigma)$. For every $X \in \mathcal{T}$, we verify that

$$
\begin{equation*}
\tau[X]=\sigma[X] \text { or }(\sigma[X])^{\star} \tag{7}
\end{equation*}
$$

Let $X \in \mathcal{T}$. Since $\sigma / \mathscr{G}(\sigma)$ is prime, $\sigma[X]$ is prime. Since $\sigma$ satisfies Statements (T1), (T2), and (T3), $\sigma[X]$ satisfies Statement (T1). Since $\sigma[X]$ and $\tau[X]$ are 3 -hemimorphic too, it follows from Proposition 39 that $\tau[X]=\sigma[X]$ or $(\sigma[X])^{\star}$. Consequently, (7) holds. Finally, by (6), there exist distinct $M, N \in \mathscr{G}(\sigma)$ such that $\{x, y\} \in E_{2}(\sigma)$ for any $x \in M$ and $y \in N$. Since $\mathscr{G}(\sigma)$ is a modular partition of $\tau$, we obtain

$$
\begin{aligned}
& \text { for any } x \in M \text { and } y \in N, x y \in E(\mathcal{D}(\sigma, \tau)) \\
& \text { or } \\
& \text { for any } x \in M \text { and } y \in N, x y \in E(\mathcal{E}(\sigma, \tau)) \text {. }
\end{aligned}
$$

By exchanging $\tau$ and $\tau^{\star}$ if necessary, we can assume that $x y \in E(\mathcal{E}(\sigma, \tau))$ for any $x \in M$ and $y \in N$. For every $X \in \mathcal{T}$, it follows from (7) that $\tau[X]=\sigma[X]$. We obtain $\sigma=\tau$.

An equivalent statement of Theorem 8 follows.
Theorem 42. Let $\sigma$ be a 2-structure. Suppose that $\sigma=\vec{\sigma}$ and $\left(V(\sigma), E_{2}(\sigma)\right)$ does not have isolated vertices. The 2-structure $\sigma$ is 3-forced if and only if the following two statements hold
(T1) $G_{\sigma}$ is connected;
(T4) for each nontrivial module $M$ of $\sigma, E_{2}(\sigma[M])=\varnothing$.
We conclude with the proof of Theorem 10.
Proof of Theorem 10. Suppose that $\sigma$ is prime and $\left(V(\sigma), E_{2}(\sigma)\right)$ is connected. If $v(\sigma)=3$, then it suffices to apply Fact 25 . Hence, suppose that $v(\sigma) \geq 4$. Consider a 2 -structure $\tau$ which is 4 -hemimorphic to $\sigma$. We have to show that $\tau=\sigma$ or $\sigma^{\star}$.

For a contradiction, suppose that $\mathcal{D}(\sigma, \tau)$ and $\mathcal{E}(\sigma, \tau)$ are both connected. By applying several times Lemma 33, we obtain $X \subseteq V(\sigma)$ satisfying

- $|X|=4 ;$
- $\sigma[X] / \mathscr{G}(\sigma[X])$ is prime;
- $\mathcal{D}(\sigma[X], \tau[X])$ and $\mathcal{E}(\sigma[X], \tau[X])$ are both connected.

By Fact 30 , there exists an isomorphism $\varphi$ from $\sigma[X]$ onto an element of $\Sigma_{4}$ (see Notation 18), which is also an isomorphism from $\mathcal{D}(\sigma[X], \tau[X])$ onto $G_{4}$ (see Example 20). As already noted in Example 29, $\sigma[X]$ is never isomorphic to either $\tau[X]$ or $(\tau[X])^{\star}$, which contradicts the fact that $\sigma$ and $\tau$ are 4hemimorhic. Consequently, $\mathcal{D}(\sigma, \tau)$ and $\mathcal{E}(\sigma, \tau)$ are not both connected.

By exchanging $\sigma$ and $\sigma^{\star}$ if necessary, we can assume that $\mathcal{D}(\sigma, \tau)$ is disconnected. Consider a component $C$ of $\mathcal{D}(\sigma, \tau)$. We verify that $V(C)$ is a module of $\sigma$. Let $v \in V(\sigma) \backslash V(C)$. We distinguish the following two cases.

1. There exists $x \in V(C)$ such that $\{x, v\} \in E_{2}(\sigma)$. Since $v \notin V(C)$, we have $x v \in E(\mathcal{E}(\sigma, \tau))$. Let $y \in V(C)$ such that $x y \in E(\mathcal{D}(\sigma, \tau))$. We prove that

$$
\sigma(x, v)=\sigma(y, v)
$$

It follows from Fact 24 that either $\{x, y\}$ is a module of $\sigma[\{x, y, v\}]$ and $\tau[\{x, y, v\}]$ or $\{x, v\}$ is a module of $\sigma[\{x, y, v\}]$ and $\tau[\{x, y, v\}]$. If $\{x, v\}$ is a module of $\sigma[\{x, y, v\}]$ and $\tau[\{x, y, v\}]$, then $y v \in E(\mathcal{D}(\sigma, \tau))$, which contradicts the fact that $C$ is a component of $\mathcal{D}(\sigma, \tau)$. Hence, $\{x, y\}$ is a module of $\sigma[\{x, y, v\}]$ and $\tau[\{x, y, v\}]$. Thus, we have $\sigma(x, v)=\sigma(y, v)$. Now, by considering $z \in V(C)$ such that $y z \in E(\mathcal{D}(\sigma, \tau))$, we obtain in the same manner that $\sigma(y, v)=\sigma(z, v)$, and hence $\sigma(x, v)=\sigma(z, v)$. Since $C$ is a component of $\mathcal{D}(\sigma, \tau)$, we obtain $\sigma(x, v)=\sigma(t, v)$ for every $t \in V(C)$.
2. For every $x \in V(C),\{x, v\} \in E_{1}(\sigma)$. Since $\left(V(\sigma), E_{2}(\sigma)\right)$ is connected, there exists $y \in V(C)$ and $w \in V(\sigma) \backslash V(C)$ such that $\{y, w\} \in E_{2}(\sigma)$. By the first case above, we have $\sigma(y, w)=\sigma(t, w)$ for every $t \in V(C)$. Let $z \in V(C)$ such that $y z \in E(\mathcal{D}(\sigma, \tau))$. We have $\sigma(y, w)=\sigma(z, w)$ and $z w \in E(\mathcal{E}(\sigma, \tau))$. Since $\sigma$ and $\tau$ are 4-hemimorphic, there exists an isomorphism $f$ from $\sigma[\{y, z, v, w\}]$ onto $\tau[\{y, z, v, w\}]$ or $(\tau[\{y, z, v, w\}])^{\star}$. Since $v$ is the unique element of $\{y, z, v, w\}$ such that

$$
\left|\left\{t \in\{y, z, v, w\}:\{t, v\} \in E_{1}(\sigma)\right\}\right| \geq 2
$$

we have $f(v)=v$. We obtain $f=(y z)$ or (ywz). In both cases, we have $\sigma(y, v)=\sigma(z, v)$. We conclude as in the first case above by using the fact that $C$ is a component of $\mathcal{D}(\sigma, \tau)$.

It follows that $V(C)$ is a module of $\sigma$. Since $\sigma$ is prime, $V(C)$ is a singleton. Consequently, the edge set of $\mathcal{D}(\sigma, \tau)$ is empty, which means $\sigma=\tau$.
