## Abstract

The present article describes the synthesis of the bis(1,4-diazabicyclo[2.2.2]octane))[*meso*-tetra(*para*-chlorophenyl)porphyrinato]magnesium(II) chloroform disolvate with the formula [Mg(TCIPP)(DABCO)<sub>2</sub>] $\cdot$ 2CHCl<sub>3</sub> (**1**) and its characterization by <sup>1</sup>H NMR, IR, UV/Vis, fluorescence, and mass spectrometry as well as by cyclic voltammetry. The molecular structure of **1** was obtained by single crystal X-ray diffraction technique and the intermolecular interactions in the crystal lattice of **1** were investigated via Hirshfeld surfaces analysis. These electronic and structural properties of complex **1** are typical for pentacoordinated and hexacoordinated Mg(II) reported metalloporphyrins with *N*-donor axial ligands. The DFT studies on complex **1** were performed at the B3LYP/LANL2DZ levels of theory. The structural characteristics and global reactivity descriptors such as the chemical potential, global hardness, global softness, and the electrophilicity were investigated indicate that the title compound is very reactive and presents an important electron-accepting property.

Our new magnesium(II) metalloporphyrin species was tested to be a good inhibitor of two COVID-19 viruses and two oxidase enzymes using docking calculations. Furthermore, complex **1** exhibits encourageant catalytic degradation yield of the Rhodamine B dye.

## 1. Introduction

Magnesium(II) porphyrin complexes have a wide range of applications in various fields, including (i) catalysis: these coordination compounds can act as catalysts in many reactions, such as oxidation, reduction, and isomerization reactions [1-3], (ii) biomedical: these compounds have been studied for their potential use in treating various diseases, including cancer, cardiovascular disease, and neurodegenerative disorders [4,5,6], (iii) materials science: Mg(II) metalloporphyrins have been incorporated into various materials, including polymers and thin films, for applications such as electronic devices and sensors [7,8], (iv) energy: Mg(II) porphyrin species have been studied for their potential use in energy-related applications, such as solar cells and fuel cells [9,10] and (v) environmental: Magnesium(II) porphyrin complexes have been used in environmental applications such as water purification and air pollution control [11,12]. On the other hand, porphyrins and porphyrin-metal species are known to have antiviral and antibacterial properties. Recent studies have suggested that these compounds may have the potential to inhibit the activity of the COVID-19 virus [13-16]. It is interesting to note that among the 80 structures of magnesium(II) metalloporphyrins reported in the Cambridge Structural Database (CSD Version 5.43, last update September 2022) [17], 37 are pentacoordinated and 29 are hexacoordinated complexes. The pentacoordinated coordination compounds are of type  $[\text{Mg}(\text{Porph})(\text{X})]^-$  (Porph = *meso*-arylporphyrin and X = anionic ligand) or  $[\text{Mg}(\text{Porph})(\text{L})]$  where L is a neutral *N*-donor or *O*-donor ligand while the hexacoordinate complexes are all type  $[\text{Mg}(\text{Porph})(\text{L})_2]$  where L is a neutral *N*-donor or *O*-donor ligand. To predict and understand the penta- and hexa- coordination modes of Mg(II) porphyrin complexes is not so easy but it should depend, inter alia, on both the natures of the *meso*-arylporphyrin and the axial ligand. Back in 1976, Kadish *et al.*, [18] classified the following *meso*-arylporphyrins substituted in *para* positions of the phenyl groups by increasing electron donor effect (Figure 1) :  $\text{H}_2\text{T}(\text{CN})\text{PP} < \text{H}_2\text{TFPP} < \text{H}_2\text{T}(t\text{-Bu})\text{PP} < \text{H}_2\text{TCIPP} < \text{H}_2\text{TPP} < \text{H}_2\text{T}(\text{OMe}) = \text{H}_2\text{TMPP} < \text{H}_2\text{TBrPP} < \text{H}_2\text{TTP} < \text{H}_2\text{T}(\text{OH})\text{PP}$  where:  $\text{H}_2\text{T}(\text{CN})\text{PP}$

is the *meso*-tetra(*para*-cyanophenyl)porphyrin, H<sub>2</sub>TFPP is the *meso*-tetra(*para*-fluorophenyl)porphyrin, H<sub>2</sub>T(*t*-Bu)PP is the *meso*-tetra(*para*-*tert*-butylphenyl)porphyrin, the H<sub>2</sub>TCIPP is the *meso*-tetra(*para*-chlorophenyl)porphyrin, H<sub>2</sub>TTP is the *meso*-tetraphenylporphyrin, the H<sub>2</sub>T(OMe) = H<sub>2</sub>TMPP is the *meso*-tetra(*para*-methoxyphenyl)porphyrin, the H<sub>2</sub>TBrPP is the *meso*-tetra(*para*-bromophenyl)porphyrin, the H<sub>2</sub>TTP is the *meso*-tetra(*para*-tolyl)porphyrin and H<sub>2</sub>T(OH)PP is the *meso*-tetra(*para*-hydroxyphenyl)porphyrin.

If we take the example of the three aqua magnesium(II) complexes: Mg(TPP)(H<sub>2</sub>O)] [19], [Mg(TMPP)(H<sub>2</sub>O)] [20] and [Mg(TBrPP)](H<sub>2</sub>O)<sub>2</sub>] [21] since the electron donor effect of the TPP, TMPP and TBrPP porphyrinates increases in the following order: TPP < TMPP < TBrPP, one can predict the increasing electronic density of the porphyrin core in the same order leading to the decrease of the electron deficiency of the Mg(II) center metal. Therefore, the probability of obtaining the di-aqua complex is higher than that of obtaining the mono-aqua. What we obtained is the opposite of what we expected because in solid state, we got the di-aqua with the TBrPP and the mono-aqua with the TPP and TMPP porphyrinates. With the 4-dimethylaminopyridine (DMAP) ligand in the solid state, with the TTP porphyrinate the bis-DMAP species exists with the formula [Mg(TTP)(DMAP)<sub>2</sub>] [22] while with the TCIPP porphyrinate the mono-DMAP [Mg(TCIPP)(DMAP)] [23] complex is isolated. This is what is expected since the TTP porphyrinate is more electron donor than TCIPP.

These examples of porphyrin complexes of Mg(II) with the aqua and DMAP ligands show that the use of the electron donor/withdrawing properties of a *meso*-arylporphyrins does not always explain the obtaining of a pentacoordinated or hexacoordinated Mg(II) metallo-*meso*-arylporphyrin complexes.

Figure 1. Schematic representation of some *meso*-arylporphyrins.

In this paper we report the preparation of a new hexacoordinated magnesium(II) porphyrin complex namely the bis(1,4-diazabicyclo[2.2.2]octane)[*meso*-tetra(*para*-chlorophenyl)porphyrinate]magnesium(II) chloroform disolvate with the formula [Mg(TCIPP)(DABCO)<sub>2</sub>] $\cdot$ 2CHCl<sub>3</sub> (**1**). This new Mg(II) metaloporphyrin was characterized by UV/Vis, fluorescence, IR, <sup>1</sup>H NMR and mass spectrometry as well as by cyclic voltammetry. The molecular structure of **1** was determined by single crystal X-ray diffraction and the intermolecular interactions of **1** was studied by Hirshfeld surface analysis.

For further study of the electronic properties and chemical reactivity of complex **1**, theoretical calculations were performed. Complex **1** was tested as a catalyst in the degradation of the rhodamine B (RhB) dye by aqueous solution of hydrogen peroxide and by irradiation using blue light. In order to test the efficiency of complex **1** as inhibitor of the COVID-19 virus and oxidase enzymes, and to study how complex **1** species can anchor itself to the binding sites of these different receptors, docking calculations have been carried out with the iGEMDOCK program.

## 2. Experimental Section

### 2.1. Materials and methods

The CHN elementary analysis results were made by the “*Institut National de Recherche et d’Analyse Physico-chimique du Technopole de Sidi Thabet (INRAP)*”, Tunisia.

<sup>1</sup>H NMR spectra were recorded at room temperature on a Bruker 300 Ultrashield spectrometer and chemical shifts are reported in ppm downfield from internal tetramethylsilane (TMS). Fourier-transformed IR spectra were recorded on a PerkinElmer Spectrum Two FT-IR spectrometer. UV/Vis spectra were recorded at room temperature under air using a WinASPECT PLUS (validation for SPECORD PLUS version 4.2) scanning spectrophotometer. Electrospray (ESI) mass spectrometry spectra were carried out using an amaZon speed ion trap instrument. Samples were ionized by electrospray ionization (ESI; capillary temperature = 320 °C, vaporizer temperature = 320°C, sheath gas flow rate = 5 mL/min).

The emission spectra were recorded at room temperature with a Horiba Scientific Fluoromax-4 Spectrofluorometer. The luminescence lifetime measurements were performed for excitation at  $\lambda = 450$  nm using the second harmonic of a titanium–sapphire laser (picosecond Tsunami laser spectra physics 3950-M1BB and 39868-03 pulse picker doubler) at an 800 kHz repetition rate. Fluotime 200 from AMS technologies was used for the decay acquisition. It consists of a GaAs microchannel plate photomultiplier tube (Hamamatsu model R3809U-50) followed by a time-correlated single photon counting system from Picoquant (PicoHarp300). The ultimate time resolution of the system is close to 30 ps. The luminescence decays were analyzed with the FLUOFIT software available from Picoquant. The quantum yields were determined at room temperature in dichloromethane solutions by using the optically dilute method [24]. [Zn(TPP)] in air-equilibrated dichloromethane solution was used as a quantum yield standard ( $\phi_f = 0.031$ ) [25].

Cyclic voltammetry (CV) experiments were performed with a CH-660B potentiostat (CH Instruments). All analytical experiments were conducted at room temperature under an argon atmosphere (argon stream) in a standard one compartment, three-electrode electrochemical cell. Tetra-*n*-butylammonium perchlorate (TBAP) was used as a supporting electrolyte (0.2 M) in dichloromethane distilled over calcium hydride under argon. An automatic ohmic drop compensation procedure was systematically implemented before the CV data were recorded with electrolytic solutions containing the studied compounds at concentrations of ca.  $10^{-3}$  M. CH Instruments vitreous carbon ( $\phi = 3$  mm) working electrodes were polished with 1 mm diamond paste before each recording. The Ag/AgNO<sub>3</sub> 0.01 M (TBAP 0.2 in CH<sub>2</sub>Cl<sub>2</sub>) redox couple was used as the reference electrode. The potential of the ferrocene/ferrocenium redox couple was used as an internal reference (86 mV vs. Ag/AgNO<sub>3</sub> under our experimental conditions). For comparison with previously published data, all potentials given in the text have been converted to values relative to the saturated calomel electrode (SCE) according to the following relationship:  $E(\text{SCE}) = E(\text{Ag}/\text{AgNO}_3) + 298$  mV.

## 2.2. Synthetic methods

All reagents for the synthesis were used without any further purification. Solvents used in the spectroscopic and electrochemical measurements were of spectroscopic grade. The *meso*-tetra(*para*-chlorophenyl)porphyrin (H<sub>2</sub>TCIPP) and the [Mg(TCIPP)] starting materials were prepared as described in the literature [26,27].

## 2.3. Synthesis of [Mg(TCIPP)(DABCO)<sub>2</sub>] $\cdot$ 2CHCl<sub>3</sub> (1)

50 mg of the [Mg(TCIPP)] starting material (0.064 mmol) and 100 mg of 1,4-diazabicyclo[2.2.2]octane (DABCO) (0.892 mmol) were dissolved in 10 mL of chloroform. The color of the starting solution changed from purple to green after four hours of reaction at room temperature. X-ray quality crystals of the title compound were obtained by slow diffusion of *n*-hexane through the chloroform solution after about one week (54 mg, 85 %).

Elemental analysis calcd (%) for C<sub>58</sub>H<sub>50</sub>Cl<sub>10</sub>MgN<sub>8</sub> (Molecular weight = 1237.93), C 56.27, H 4.07, N 9.05; found: C 56.69, H 4.13, N 9.11; (ESI) (dichloromethane): *m/z* [Mg(TCIPP)(L)<sub>2</sub>]<sup>+</sup> (L = 1,4-diazabicyclo[2.2.2]octane C<sub>6</sub>H<sub>12</sub>N<sub>2</sub>) calcd for C<sub>56</sub>H<sub>48</sub>Cl<sub>4</sub>MgN<sub>8</sub>: 999.15; found 992.06; UV-vis:  $\lambda_{\max}$  (nm) in CH<sub>2</sub>Cl<sub>2</sub>: 430, 567, 606; FT-IR [solid neat,  $\bar{\nu}$  (cm<sup>-1</sup>): [ $\nu$ (CH) DABCO]] 3040,  $\nu$ [(CH) Porph] 2970–3024, [ $\nu$ (C=C) and  $\delta$ (CCH) Porph] 992; <sup>1</sup>H NMR (300 MHz, CDCl<sub>3</sub>  $\delta$  (ppm): 8.81 (H $\beta$ -pyrrol), 8.12–8.10 (H<sub>o,o</sub> Porph), 7.74–7.72 (H<sub>m,m'</sub> Porph), 5.29 (H<sub>L</sub> DABCO).

## 2.4. Quantum chemical calculations

All calculations (geometric parameters, electronic and vibrational properties) were performed by using Gaussian 09 program [28] and visualized in GaussView program [29].

## 2.5. X-ray structure determination

A purple prism shaped single crystal of dimensions 0.56 x 0.45 x 0.37 mm of complex **1** was chosen for an X-ray diffraction study. The data were collected at 150 K on a D8 VENTURE Bruker AXS CCD diffractometer using Mo K $\alpha$  radiation of wavelength 0.71073 Å. The data were corrected for absorption effects by using the SADABS program (Bruker AXS 2014) [30]. The structure was solved by the direct methods by using SIR-2019 program [31] and refined by full-matrix least-squares techniques on  $F^2$  by using the SHELXL-2014 program [32]. The chlorine atom of one phenyl group of the TCIPP porphyrinate is disordered in two positions (C11A and C11B) with refined position occupancies of 0.851 (6) and 0.149 (6), respectively. The atomic displacement parameters of the C29B,

Cl3B and Cl4B atoms are restrained to be equivalent and the C29B-Cl3B, C29B-Cl3B and C29B-Cl4B bond distances were restrained during the refinement using DFIX command [33]. All H atoms attached to C atoms were fixed geometrically and treated as riding with C—H = 0.93 Å (aromatic), 0.97 Å (methylene) and 0.98 Å (methine) with  $U_{iso}(H) = 1.2U_{eq}(C)$ . A total of 840 parameters are refined with 5579 unique reflections and 4942 observed reflections [ $F_o > 4\sigma(F_o)$ ]. The geometrical calculations were carried out using the program PLATON [34]. The molecular and packing diagrams were generated using the software MERCURY [35]. The crystallographic data and the structural refinement details for **I** are reported in Table 1. Selected bond lengths and angles for the compound are listed in Table 2.

## 2.6. Oxidative degradation and photodegradation with H<sub>2</sub>O<sub>2</sub>

Oxidative degradation and photodegradation experiments of RhB dye were performed at room temperature in the absence and presence of light using 10 mg of the catalyst compound and 5 mL of an aqueous solution of RhB dye (at pH = 6, c = 25 mg/L) and H<sub>2</sub>O<sub>2</sub> (10 mL/L). The dye – complex **1** molar ratio is 6.5. Stirring was maintained at 500 rpm. The resulting mixture was filtered, and then the concentration was recorded by measuring the absorbance at 554 nm for the RhB dye.

The decolonization yields (R%) are given by the following relationship (Equation 1):

$$\text{Yield (\%)} = (A_0 - A_t / A_0) * 100 \quad (\text{Eq. 1})$$

where  $A_0$  is the initial Absorption of dyes and  $A_t$  is the Absorption at different time intervals.

## 3. Results and Discussion

### 3.1. Synthesis of [Mg(TCIPP)(DABCO)<sub>2</sub>] $\cdot$ 2CHCl<sub>3</sub> (1)

The reaction of the [*meso*-tetra(*para*-chlorophenyl)porphyrinato]magnesium(II) ([Mg(TCIPP)]) starting material with an excess of 1,4-diazabicyclo[2.2.2]octane (DABCO) in chloroform at room temperature yields the bis( $\kappa$ N-DABCO)[*meso*-tetra(*para*-chlorophenyl)porphyrinato]magnesium(II)

chloroform disolvate with the formula  $[\text{Mg}(\text{TCIPP})(\text{DABCO})_2] \cdot 2\text{CHCl}_3$  (**1**) as given by the X-ray molecular structure (Scheme 1). We obtained, as expected, the bis-*N*-donor-DABCO  $[\text{Mg}(\text{TCIPP})(\text{DABCO})_2] \cdot 2\text{CHCl}_3$  complex, and not the mono-*N*-donor-  $\kappa N$ -DABCO magnesium(II) TCIPP coordination complex  $[\text{Mg}(\text{TCIPP})(\text{DABCO})]$  since the TCIPP porphyrinate presents a quite good electron withdrawing character. This electronically depletes the center metal Mg(II) and therefore increases the probability for accepting more electrons by  $\text{Mg}^{2+}$ . On the other hand, in a previous work, we reported the preparation and the characterization of the bis- $\kappa N$ -DABCO-Mg(II)  $[\text{Mg}(\text{TPBP})(\text{DABCO})_2]$  species [36] where TPBP is the *meso*-tetrakis[4(benzoyloxy)phenyl]porphinate which also presents a good withdrawing character.

Scheme 1. Scheme of the preparation of  $[\text{Mg}(\text{TCIPP})(\text{DABCO})_2] \cdot 2\text{CHCl}_3$  (**1**)

### 3.2. Mass spectrometry data of complex 1

Electrospray ionization (ESI) mass spectrometry experiment on **1** was performed in positive and negative ion modes where several peaks have been characterized (Figure 2, Table S1). The presence of the  $[\text{Mg}(\text{TCIPP})+3\text{H}]^{3+}$  and  $[\text{Mg}(\text{TCIPP})(\text{DABCO})+2\text{H}]^{2+}$  fragments in the MS ESI (+ and -) is an indication of the presence of the bis( $\kappa N$ -DABCO)-Mg(II)-TCIPP (**1**) derivative in solution.

**Figure 2.** Electrospray mass spectrometry (ESI+ spectra of complex **1**. The spectra were recorded in dichloromethane with a concentration of  $5 \cdot 10^{-3}$  M.

### 3.3. Proton NMR and IR spectroscopy

The  $^1\text{H}$  NMR spectrum of **1** is depicted in [Figure 3](#). The  $\beta$ -pyrrolic protons ( $\text{H}_\beta$ ) and the  $\text{H}_{o,o'}$ ,  $\text{H}_{m,m'}$  protons of the *meso*-phenyl rings of the TCIPP moiety resonate at 8.81, 8.12/8.10 and 7.74/7.72 ppm, respectively. The values of these chemical shifts are very close to those of the corresponding free base porphyrin  $\text{H}_2\text{TCIPP}$  indicating the diamagnetic character for complex **1**. The protons of the  $-\text{CH}_2-\text{N}-$  groups of the two DABCO axial ligands resonate at 5.29 ppm which are low field shifted compared to those of the non-coordinated DABCO molecule which resonate at 2.46 ppm. This could be explained by the withdrawing effect of the chlorine atoms at the *para* positions of the phenyl groups of the TCIPP moiety leading to the decrease of the electronic density of the DABCO ligands and therefore increasing the chemical shift of these protons.

**Figure 3.** <sup>1</sup>H NMR spectrum of [Mg(TCIPP)(DABCO)<sub>2</sub>]<sup>+</sup>·2CHCl<sub>3</sub><sup>-</sup> (**1**) recorded in CDCl<sub>3</sub> at room temperature with concentration  $C \sim 10^{-3}$  M.

**Figure 4** illustrates the IR spectrum of complex **1**. The weak absorption band at  $3040\text{ cm}^{-1}$  is attributed to the  $\nu(\text{CH})$  stretching vibration of the DABCO axial ligand. This value of  $\nu(\text{CH})$  is very close to that attributed to the DABCO axial ligand coordinated to the magnesium(II) and cobalt(II) porphyrin complexes [Mg(TPBP)(DABCO)<sub>2</sub>] (TPBP = *meso*-tetrakis[*para*-(benzoyloxy)phenyl]porphyrinate) [36] and [Co<sup>II</sup>(TPBP)(DABCO)<sub>2</sub>] [37] with values of  $3032$  and  $3030\text{ cm}^{-1}$ , respectively.

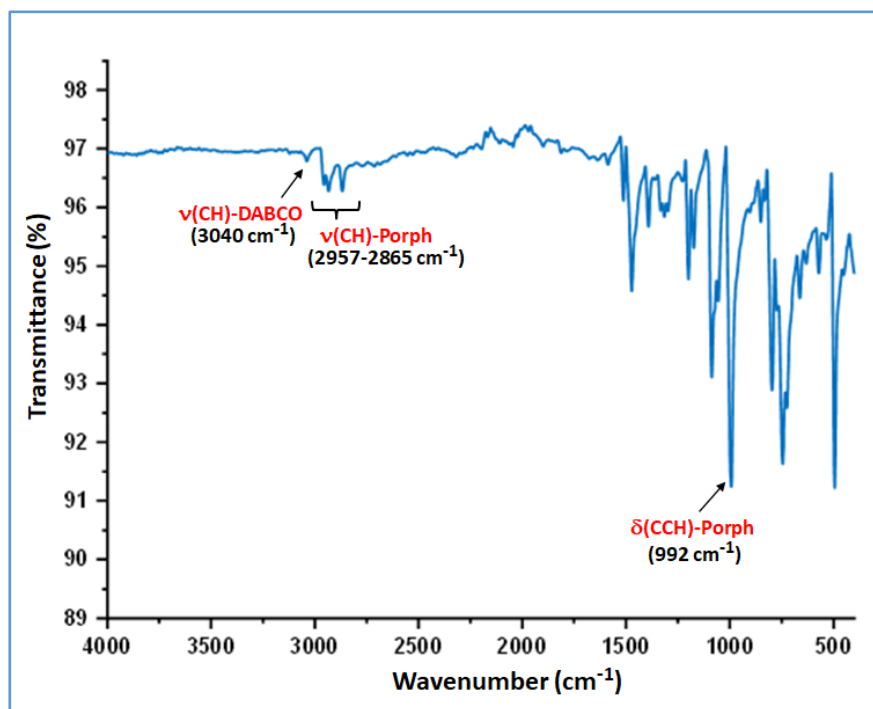

Figure 4. Neat IR spectrum of complex 1.

### 3.4. Photophysical properties of complex 1

The absorption spectrum of complex 1 (Figure 5) consists of a strong Soret band ( $S_0 \leftarrow S_2$  transition) centered at 430 nm and two weaker absorption bands known as Q bands ( $S_0 \leftarrow S_1$  transition): Q(0,1) (567 nm) and Q(0,0) (607 nm). These absorption values of  $[\text{Mg}(\text{TCIPP})(\text{DABCO})_2] \cdot 2\text{CHCl}_3$  (**1**) are very close to those of the related Mg(II) *meso*-arylmetalloporphyrins (Table S2), e.g., for the  $[\text{Mg}(\text{TCIPP})(\text{DMAP})]$  (DMAP = 4-dimethylaminopyridine) [23] the  $\lambda_{\text{max}}$  values of the Soret and the Q(1,0) et Q(0,0) are 432, 570 and 609 nm, respectively.

An inspection of Table S2 shows that the Soret band value of the tetraordinated, pentacoordinated and hexacoordinated magnesium(II) *meso*-arylporphyrin complexes range between 424 and 435 nm, the Q(1,0) band value of these species are in the range [563 – 576] nm while the Q(0,0) band value of all three types of Mg(II) *meso*-arylporphyrins is between 608 and 620 nm. This indicates that the UV/Vis spectroscopy technique is not able to differentiate between a tetra-, penta- and hexacoordinated Mg(II) *meso*-arylporphyrin coordination compounds in solution.

The emission spectrum of complex 1 is illustrated along with its absorption spectrum in Figure 5. The later spectrum corresponds to the  $S_0 \leftarrow S_1$  transition where the Q(1,0) and Q(0,0) emission bands are

centered at 609 nm and 664 nm, respectively. These values are very close to those of the [Mg(TCIPP)(DMAP)] and [Mg(TTP)(4-pypo)<sub>2</sub>] (TTP = *meso*-tetratolylporphyrinate, 4-pypo = 4-pyrrolidinopyridine) [23,38] related species with  $\lambda_{\text{max}}$  values of 612/611 and 666/663 nm of the Q(1,0) and Q(0,0), respectively. This indicates that the photophysical properties of Mg(II) metalloporphyrins didn't depend on the nature of the *meso*-arylporphyrin or the nature of the *N*-donor neutral axial ligand (Table S2).

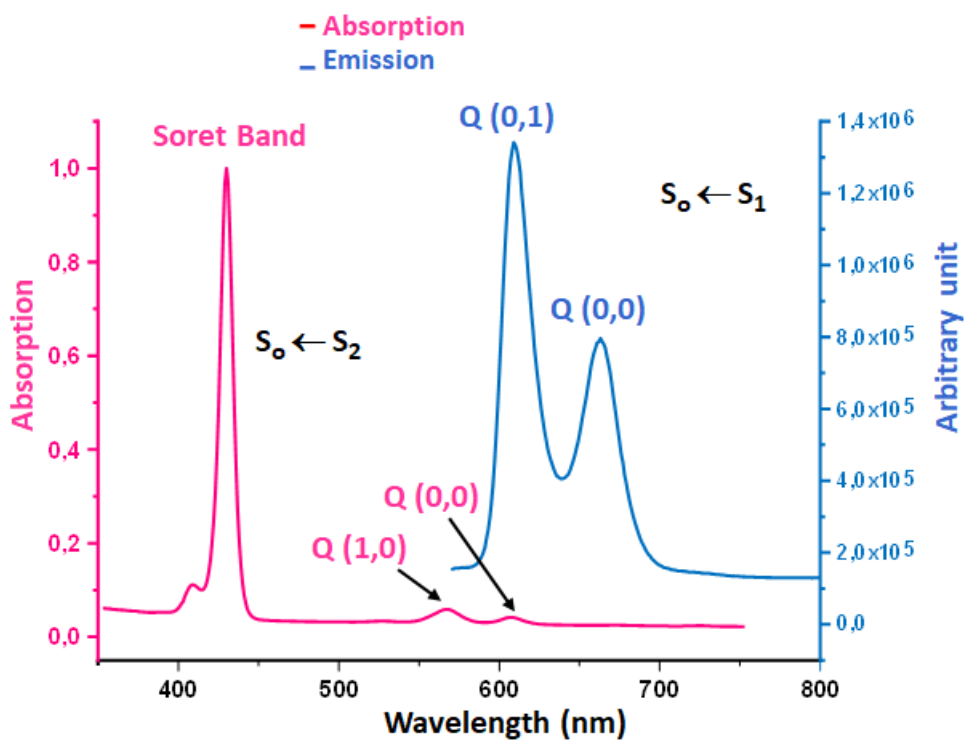

Figure 5. UV/Vis spectrum (red color) and fluorescence spectrum (blue color) of complex **1**. Spectra recorded in dichloromethane with concentrations  $\sim 10^{-6}$  M.

The optical gap energy ( $E_{g\text{-opt}}$ ) of **1** was determined from the  $(\alpha h\nu)^2$  versus the photon energy ( $E = h\nu$ ) [39] where  $\alpha$  is absorption coefficient,  $h$  is the Planck constant and  $\nu$  is the frequency ( $\nu = 1/\lambda$ ) (Figure S1). The value of  $E_{g\text{-opt}}$  of complex **1** is 1.995 eV which is normal for *meso*-arylporphyrins and metalloporphyrins and is indicative of a semi-conductor character of [Mg(TCIPP)(DABCO)<sub>2</sub>] $\cdot$ 2CHCl<sub>3</sub> (**1**).

### 3.5. X-ray Structures of [Mg(TCIPP)(DABCO)<sub>2</sub>].2CHCl<sub>3</sub> (1)

The asymmetric unit of **1** contains one half [Mg(TCIPP)(DABCO)<sub>2</sub>] complex and one disorder chloroform solvent molecule. The space group is *C2/c* with four formula units by cell leading to the formula [Mg(TCIPP)(DABCO)<sub>2</sub>].2CHCl<sub>3</sub> for **1** (Figure S2). A selection of distances and angles of complex **1** is given in Table 2 while Figure 6 depicts an Ortep view of [Mg(TCIPP)(DABCO)<sub>2</sub>].

Figure 6. ORTEP drawing of [Mg(TCIPP)(DABCO)<sub>2</sub>] with thermal ellipsoids drawn at 50% probability. The hydrogen atoms are removed for clarity and only the major position of the disordered chlorine atom Cl1A of the porphyrin is shown.

The average equatorial distance between the magnesium(II) central ion and the nitrogen atoms of the porphyrin ring (Mg–N<sub>p</sub>) of complex **1** is 2.0733(15) which is quite higher than those of the two Mg(II) related metalloporphyrins [Mg(TPBP)(DABCO)<sub>2</sub>] (TPBP = *meso*-tetrakis[4-(benzoyloxy)phenyl]porphinate) [36] and [Mg(Porph1)(μ<sub>2</sub>-DABCO)(Porph2)Zn] (Porph1 = 4-(2-(diphenylphosphino)ethylthio)phenyl)-10,20-bis(mesityl)porphyrinate, Porph2 = 4-(2-(diphenylphosphino)ethoxy)phenyl)-10,20-bis(mesityl)porphyrinate) [50] with values of 2.066 and 2.061 Å, respectively. Nevertheless, the Mg–N<sub>p</sub> bond length of **1** is in the range [2.061 – 2.074] Å of hexacoordinated magnesium(II) metalloporphyrins but quite smaller than those of the pentacoordinated Mg(II) porphyrin complexes which are in the range [2.082(3) – 2.1197(16)] Å (Table 3). The

Mg–N(DABCO) distance value of 2.4741(17) Å for complex **1** is very close to that of the [Mg(TPBP)(DABCO)<sub>2</sub>] related complex which is 2.487 Å indicating that the nature of the *meso*-arylporphyrin has no effect on the geometry of the [Mg(Porph)(DABCO)<sub>2</sub>] species.

**Table 3.** Selected bond lengths [Å] and angles [°] for [Mg(TCIPP)(DABCO)<sub>2</sub>] $\cdot$ 2CHCl<sub>3</sub> (**1**) and several related Mg(II) porphyrin complexes.

<sup>a</sup>: Mg–N<sub>p</sub> = average equatorial M–Npyrrole bond length, <sup>b</sup>: Mg–X<sub>L</sub> = distance between Mg atom and the nitrogen atom of axial ligand, <sup>c</sup>: Mg–P<sub>C</sub> = distance between Mg and the mean plane made by the 24-atom core of the porphyrin (P<sub>C</sub>), <sup>d</sup>: TBrPP = *meso*-tetra(*para*-bromophenyl)porphyrinate, <sup>e</sup>: TPP = *meso*-

tetraphenylporphyrinate, <sup>f</sup>: TMPP = *meso*-tetra(*para*-methoxyphenyl)porphyrinate, <sup>g</sup>: 222 = cryptand-222, <sup>h</sup>: TPBP = *meso*-tetrakis[4(benzyloxy)phenyl]porphinate, <sup>i</sup>: Porph1 = 4-(2-(diphenylphosphino)ethylthio)phenyl)-10,20-bis(mesityl)porphyrinate, <sup>j</sup>: Porph2 = 4-(2-(diphenylphosphino)ethoxy)phenyl)-10,20-bis(mesityl)porphyrinate, <sup>l</sup>: TTP = *meso*-tetra(*para*-tolyl)porphyrinate.

In the crystal packing of complex **1**, the [Mg(TCIPP)(DABCO)<sub>2</sub>] molecules form 1D chains parallel to the [001] direction (Figure 7). These [Mg(TCIPP)(DABCO)<sub>2</sub>] molecules and the chloroform solvent molecules are weakly bonded by C—H⋯Cl non-conventional hydrogen bonds (Table S3).

Figure 7. Projection of the crystal lattice of **1** down the c axis.

### 3.6. Hirshfeld Surface Analysis

The Crystal Explorer 17.5 program [56] was used to generate the Hirshfeld Surface (HS) and 2D fingerprint plots of complex **1**. The normalized contact distance,  $d_{norm}$ , based on the  $d_e$ ,  $d_i$  (from the HS to the nearest atom outside-inside and inside-internal the surface, respectively) and the van der Waals radii of the atom ( $r^{vdW}$ ) is given by the following equation :

$$d_{norm} = \frac{d_i - r_i^{vdW}}{r_i^{vdW}} + \frac{d_e - r_e^{vdW}}{r_e^{vdW}} \quad (\text{Eq. 2})$$

The  $d_{norm}$  HS shows all the contacts of the crystal structure. The blue and white regions of the HS indicate that the contacts are longer and closer to the van der Waals of the involved atoms, while the red regions indicate the shorter contacts than the sum of the van der Waals radii (Figure 8). The intermolecular interactions C–H...Cl present practically the same distance values that those obtained using the PLATON program (see the X-ray molecular structure section) The overall two-dimensional fingerprint plot for complex **1** are illustrated in Figure S3 and the percentage contributions from the different interatomic contacts to the Hirshfeld surfaces are as follows: H...Cl (33.8%), H...H (33.5%), H...C (10.3%) and H...N (1.8%).

Figure 8. Hirshfeld surfaces of complex **1** mapped over  $d_{norm}$ .

The sharp index mapped on HS of complex **1** is depicted in Figure 9-a showing the absence of blue and red triangles indicates that there are no  $\pi \cdots \pi$  stacking interactions in the crystal structure of **1**. The curvedness plots did not exhibit flat surface patches indicating the absence of planar stacking (Figure 8-b).

Figure 9. (a): Shape index surfaces of complex **1**, (b): Curvedness surfaces of complex **1**.

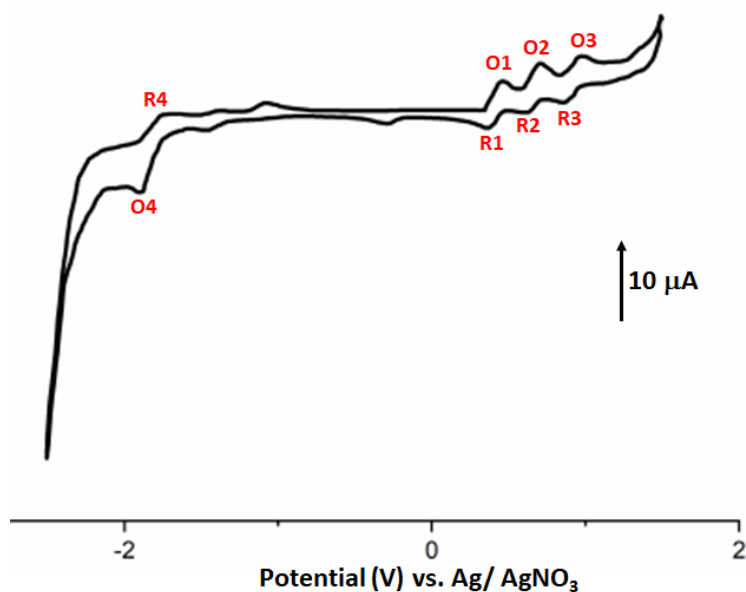

### 3.7. Cyclic voltammetry

The cyclic voltammogram of **1** is depicted in Figure 10. In the anodic part of this voltammogram are shown three one-electron reversible oxidation waves (O1/R1, O2/R2 and O3/R3) attributed to the oxidation of the porphyrin core of complex **1** (Scheme 2). One reversible reduction wave attributed to the oxidation of the porphyrin macrocycle is observed in the negative part of the voltammogram of [Mg(TCIPP)(DABCO)<sub>2</sub>]<sub>2</sub>·2CHCl<sub>3</sub> (**1**) (R4/O4, Scheme 2).

Scheme 2. Redox equations involving the reductions and the oxidations waves of complex **1**.

The half potential values of these four waves are 0.71, 0.96, 1.21 and -1.54 V for O1/R1, O2/R2; O3/R3 and R4/O4, respectively which are very close to those of the related pentacoordinated and hexacoordinated Mg(II) *meso*-arylporphyrins, e.g., for [Mg(TTP)(4-pypo)<sub>2</sub>] and [Mg(TCIPP)(DMAP)] [38,23] the E<sub>1/2</sub> values of the reversible waves O1/R1, O2/R2; O3/R3 and R4/O4 are 0.62/0.63, 1.04/0.91, 1.26/1.22 and -1.60/-1.42 V, respectively. As a conclusion of the cyclic voltammetry investigation on complex **1** we notice that magnesium(II) *meso*-arylporphyrin coordination compounds exhibit very close electrochemical properties whatever the type of the functional group present in the *para*-positions of the phenyls of the *meso*-porphyrin and whatever the nature of the axial *N*-donor ligand(s).

**Figure 10.** Cyclic voltammogram of complex **1**. The solvent used is  $\text{CH}_2\text{Cl}_2$ , and the concentration is ca.  $10^{-3}$  M in 0.2 M TBAP, 50 mV/s, vitreous carbon working electrode ( $\varnothing = 3$  mm).

### 3.8. Computational calculations

#### 3.8.1. The optimized molecular structure

The optimized molecular structure of  $[\text{Mg}(\text{TCIPP})(\text{DABCO})_2] \cdot 2\text{CHCl}_3$  (**1**) is depicted in [Figure 11](#) determined by using the density functional theory (DFT) at the B3LYP/LANL2DZ method.

**Figure 11.** Optimized molecular structure of  $[\text{Mg}(\text{TCIPP})(\text{DABCO})_2]$  (**1**) using DFT/ B3LYP/LANL2DZ method in gas phase.

In [Table S4](#) are given the experimental and the theoretical bond distances and angle values of complex **1**. As shown in this table, the calculated geometry parameters of **1** are close to those given by the X-ray molecular structure. Thus, the experimental bond distances Mg-N1, Mg-N2 and Mg-N4 are 2.0812(15), 2.0653(15) and 2.4741(17 Å, respectively while the theoretical distance values are 2.052/2.085, 2.052/2.100, and 2.330 Å, respectively. These slight differences between experimental and theoretical distances in complex **1** are attributed to the fact that the theoretical values were obtained considering a single isolated molecule in the gaseous phase.

### 3.8.2. Molecular electrostatic potential (MEP)

Molecular electrostatic potential (MEP) surface of  $[\text{Mg}(\text{TCIPP})(\text{DABCO})_2] \cdot 2\text{CHCl}_3$  (**1**) was calculated and plotted by the Gaussview 05 program. It is used to observe the charge distributions of different species [\[57-59\]](#). This surface makes it possible to predict the behavior and reactivity of molecular systems. It is related to the electron density, which recognizes electrophilic and nucleophilic sites, as well as hydrogen-type interactions. [Figure 12](#) shows the MEP map of the complex **1**. As clearly seen, the negative potential regions are represented by red color and the major positive potential regions are shown in blue.

We used the DFT/B3LYP/LanL2DZ process to determine the MEP contour maps of the electrostatic potential of **1**. The color code used to indicate the potential increase is in the order : red < orange < yellow < blue. The blue color refers to the potential positive values while the red color refers to the potential negative values. This color code was used to obtain the MEP maps by mapping electrostatic potential to the total electron density ([Figure 12](#)). In this figure, the color code of the maps is between  $-1.2 \cdot 10^{-2}$  u.a. (red color) and  $1.2 \cdot 10^{-2}$  u.a. (blue color). The electrophilic reactivity of a molecule indicates the strongest attraction is represented in blue in the MEP map while nucleophilic reactivity of a given molecule indicates the strongest repulsion of electrons, is shown in red color in a MEP map. The green color of a MEP map is indicative of zero potential. Two MEP maps of complex **1** are shown in [Figure 12](#) indicating that the accepting strength (blue color) is important around the Mg(II) center metal and the DABCO axial ligands. This leads us to conclude that a nucleophilic substitution of the DABCO ligand is possible.

Figure 12. Calculated electrostatic potential surface of complex 1.

### 3.8.3. Frontier molecular orbitals (FMOs): HOMO and LUMO analysis

The lowest unoccupied molecular orbital (LUMO) and the highest occupied molecular orbital (HOMO) are the most important orbitals in a molecule. They are very useful to understand the chemical stability of the molecule [60,59]. The 3D plots of the HOMO, HOMO-1, LUMO and LUMO+1 frontier orbitals of  $[\text{Mg}(\text{TCIPP})(\text{DABCO})_2] \cdot 2\text{CHCl}_3$  (1) are given in Figure 13 and Figure S4, respectively.

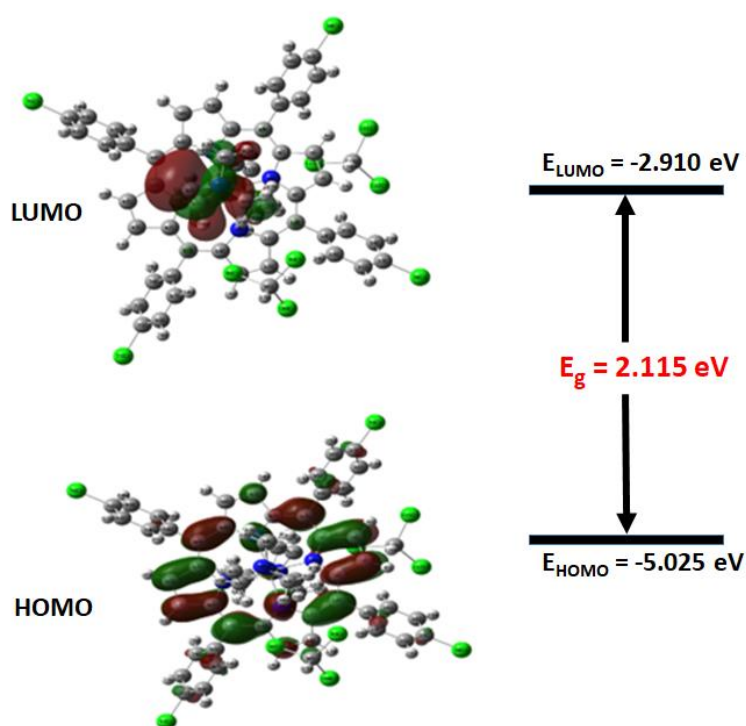

Figure 13. The HOMO and LUMO frontier molecular orbitals of complex 1.

The HOMO-LUMO Gap energy ( $E_g$ ) values were calculated in gas phase by TD-DFT/B3LYP/LANL2DZ level. As shown in Figure 13, the negative phase is presented in green color and the positive phase is illustrated in red. The calculation results reveal that the energy difference  $E_{HOMO}-E_{LUMO}$  ( $E_g$ ) is equal to 2.155 eV while the calculated  $E_{HOMO-1} - E_{LUMO+1}$  energy is 2.392 eV.

The capacity of complex **1** to donate or accept electrons is given by the global reactive parameters (Table 4). These parameters are also used to confirm the stability and the chemical reactivity of studied molecules. The calculated electrophilic index  $\psi$  value is 7.444 eV indicating that complex **1** is a good acceptor of electrons better than that of the related species [Mg(TCIPP)(DMAP)] [23] with a value of 5.553 eV. The chemical hardness ( $\eta$ ) value of **1** is 1.057 eV which is slightly smaller than that of the [Mg(TCIPP)(DMAP)] complex ( $\eta = 1.300$  eV) indicates that complex **1** is not very hard while the softness value is  $0.473$  (eV)<sup>-1</sup>. The high negative value of the chemical potential ( $\mu = -3.967$  eV) which testifies to the high stability of [Mg(TCIPP)(DABCO)<sub>2</sub>].2CHCl<sub>3</sub> (**1**). All these parameters' values let us suppose that complex **1** is stable, quite soft and reactive. In this connection, and to test the reactivity of complex **1**, we studied the degradation activity of this coordination compound on the Rhodamine B dye (see section 3.9).

**Table 4.** TD-DFT calculations of complex **1**, [Mg(TTP)(DMAP)<sub>2</sub>] [22] and [Mg(TCIPP)(DMAP)] [23] at the B3LYP/LanL2DZ level of theory (gas phase) of HOMO-LUMO energy gap, chemical potential, electronegativity, global hardness, global softness, and electrophilicity index.

Function	Values		
	Complex <b>1</b>	[Mg(TTP)(DMAP) <sub>2</sub> ]* [22]	[Mg(TCIPP)(DMAP)]** [23]

### 3.8.4. Molecular docking analysis

#### 3.8.4.1. Computational details

Molecular docking calculations of proteins (PDB codes: 1HD2, 1H4O, ACE2 and ORF8) with  $[\text{Mg}(\text{TCIPP})(\text{DABCO})_2]\cdot 2\text{CHCl}_3$  (**1**) complex was carried out using the iGEMDOCK program [61]. This program is based on a generic evolutionary method (GA) and an empirical scoring function, the setting of which is the following: the size of the population is 800, the number of generations is 80 and the number of solutions is equal to 10. The 3D structures of the different proteins were extracted from the RCSB PDB database of the Structural Bioinformatics Research Laboratory (<http://www.rcsb.org>) [62]. Both proteins (receptors) and the ligand (complex **1**) were adapted with Discovery Studio Visualizer software [63].

#### 3.8.4.2. Docking calculations

A molecular docking investigation was carried out on complex **1** to test the efficiency of this porphyrinic complex as inhibitor of the COVID-19 virus and several oxidase enzymes using docking calculations known to be a powerful theoretical method for studying molecular interactions [23,64,65]. This is how it is possible to determine the orientation of molecules (inhibitors) associated with their targeted proteins (receptors) in order to calculate their energy scores.

#### 3.8.4.3. Docking results of complex **1** with ACE2 and ORF8 proteins

Molecular docking calculations were carried out with two structures of SARS-COV-2 protein. The first protein is the Angiotensin-Converting enzyme 2 "ACE2" (PDB code: 1H4O). The second is the Open Reading Frame 8 "ORF8" protein (PDB code: 7F5F). The structures of the target proteins were adapted with Discover Studio Visualizer software. Moreover, all crystallographic water molecules were removed. While docking calculations, we have determined ten poses but we presented only the best ones, which correspond to the minimal energies. Bond energies, such as van der Waals, hydrogen bond and electrostatic interaction that occurred between complex **1** and proteins were identified (as shown in Table 5). Binding energy informs us on the strength compound binds to the pocket of a protein. We have also plotted in Figure 14 the different interactions of  $[\text{Mg}(\text{TCIPP})(\text{DABCO})_2]\cdot 2\text{CHCl}_3$  (**1**) (ligand) in the active sites of 1HD2 protein and in Figure S5, 1H4O protein. Evidently, the ligand is linked to the receptor by several interactions such as alkyl,  $\pi$ -alkyl,  $\pi$ -anion,  $\pi$ -donor, conventional hydrogen bonding, carbon-hydrogen bond, etc. The examination of Table 5 revealed that the ACE2-MgTCIPP(DABCO)<sub>2</sub> system possesses the strongest energy score which is equal to -125.15 kcal/mol. Note that this energy is the sum of the three energy interactions: hydrogen bond, vdW and electronic interactions. As well, it has the strongest van der Waals interaction with a value of -122.82 kcal/mol. Thereafter, the ORF8-

MgTCIPP(DABCO)<sub>2</sub> system exhibits a total energy score equal to -101.15 kcal/mol with an important van der Waals interaction ( $E_{VDW} = -101.15$  kcal/mol). For the same Angiotensin-Converting enzyme 2 SARS-COV-2 protein, complex **1** presents much better inhibition than using the triorganotin(IV) carboxylate complex R<sub>3</sub>SnL (R = C<sub>4</sub>H<sub>9</sub>, L = the 2-chlorophenyl ethanoate) [66].

It can be concluded that complex **1** is a good inhibitor of the coronavirus and can therefore be effective in controlling this disease.

peroxiredoxin 5 (PRDX5) protein, results show that complex **1** has bonded effectively with the target sites of the receptor with total energy equal to -72.80 and EVDW = -72.80 kcal/mol (as illustrated in Table 5).

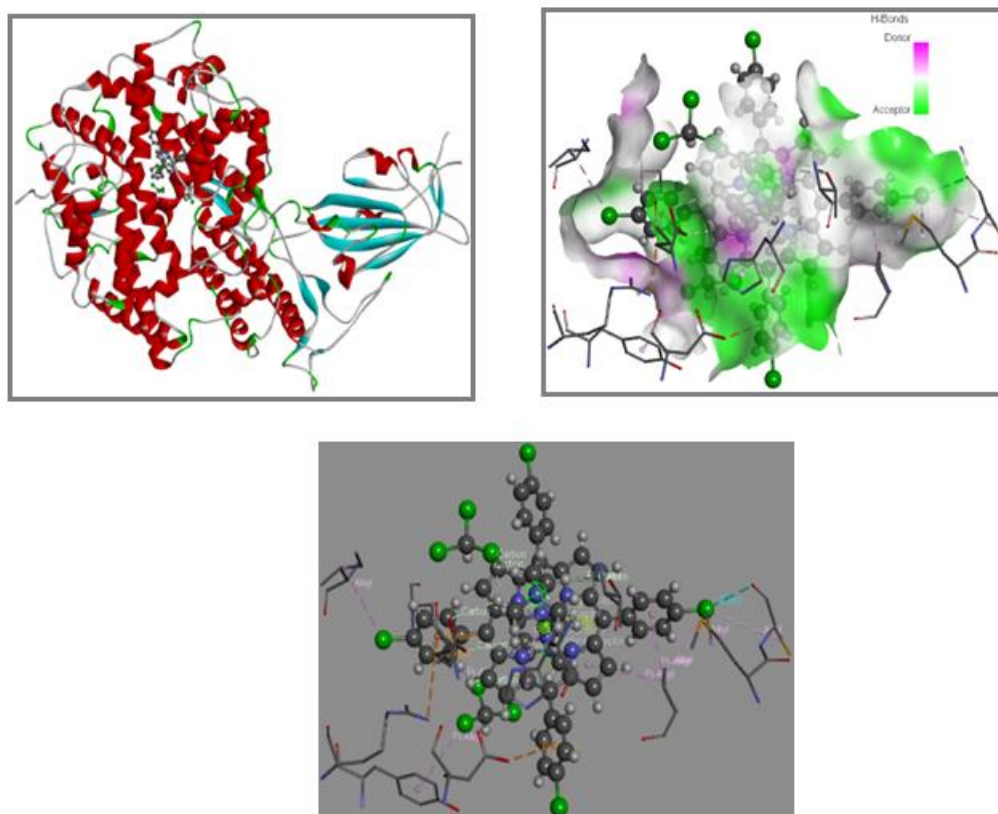

Figure 15. Orientation of complex **1** in the active sites of ACE2 and (d) ORF8 receptor.

Table 5. Docking score energies of complex **1** with Human Peroxidase, Peroxiredoxin 5, Angiotensin-Converting and Open Reading Frame 8 receptors.

Ligand	[Mg(TCIPP)(DABCO) <sub>2</sub> ].2CHCl <sub>3</sub> ( <b>1</b> )			
	Oxidase enzymes		SARS-COV-2

<b>Electronic</b>	0	0	0	0

### 3.9. Oxidative degradation of Rhodamine B dye using complex 1

#### 3.9.1. Degradation using an aqueous solution of H<sub>2</sub>O<sub>2</sub> using complex 1

It is noteworthy that synthetic dyes constitute a large part of water pollutants due to the sewage discharge containing such very harmful and even carcinogenic chemical species. This is why for more than three decades a very important number of investigations concerning the degradation of these toxic species were performed [67-70]. According to IUPAC nomenclature, rhodamine B (RhB) is called N-[9-(ortho-carboxyphenyl)-6-(diethylamino)-3H-xanthen-3-ylidene] diethyl ammonium chloride. It exhibits maximum absorbance at a wavelength of 554 nm [71]. This dye is very toxic and according to Gao *et al.*, [72] it has also been associated with the disruption of central nervous systems and other vital organs, including the liver, brain and kidney. Several methods have been reported concerning the degradation of the RhB dye [73,74]. In order to get more insights into the degradation procedures to RhB dye, we investigated the use of our Magnesium(II) bis(DABCO) porphyrin complex (**1**) in the degradation of the RhB dye.

The UV/vis spectroscopy was employed to investigate the oxidative degradation of the rhodamine B (RhB) dye using aqueous solution of hydrogen peroxide as the oxidant in the presence of complex **1** as catalyst. In Figure 16 represents the absorption of the RhB dye in the absence (Reference = blank) and presence of H<sub>2</sub>O<sub>2</sub> for several degradation times. The degradation of RhB was monitored by following the variation of  $\lambda_{\max}$  of the absorption band of the RhB species at ~ 554 nm (in aqueous solution at room temperature).

Figure 16. Evolution of the absorbance of RhB over time in H<sub>2</sub>O at pH = 7 and 25 °C; (a): without catalyst and presence of H<sub>2</sub>O<sub>2</sub>, (b): 10 mg of complex **1**, (at pH = 6, c = 25 mg/L) and H<sub>2</sub>O<sub>2</sub> (10 mL/L).

As shown by Figure 16, without the use of complex 1 as catalyst, no degradation of the organic dye occurs even after 180 min of reaction.

As was reported by Nyamunda *et al.*, [75], the use of metallic compounds as catalysts in the oxidation of organic species by H<sub>2</sub>O<sub>2</sub> is known to involve OH• radicals. The degradation of the RhB dye by the oxidation with a hydrogen peroxide solution in the presence of complex 1 as catalyst can be explained using the following equation 2:

$$\frac{dC}{dt} = -k \cdot C \cdot [OH\cdot] \quad (\text{Eq. 3})$$

where  $C$  is the concentration of RhB dye at time  $t$  and  $k$  is defined as the second order rate constant of the RhB species with OH•. Given the fact that the concentration of OH• is constant, assuming the steady state situation for the formation rate of these intermediates. The equation can be further simplified if one considers that the concentration of OH• is constant, assuming the steady state situation for the net formation rate of these intermediates. Therefore, the degradation rate of the RhB dye with H<sub>2</sub>O<sub>2</sub> in presence of complex 1 is given by Equation 4:

$$\frac{dC}{dt} = -k_o \cdot C \quad (\text{Eq. 4})$$

where  $k_o$  (in min<sup>-1</sup>) is the pseudo-first order rate constant. The degradation yield [ $R(\%)$ ] of the RhB dye in the above-mentioned conditions is shown in Figure S7 where the  $C_t/C_o$  curves are plotted versus time.  $C_t$  and  $C_o$  are the concentration of RhB at the instants  $t$  and  $t = 0$ , respectively. The degradation yield ( $R\%$ ) is given by equation 5 as follows:

$$R(\%) = \left(1 - \frac{C_t}{C_o}\right) \cdot 100 \quad (\text{Eq. 5})$$

As shown in Figure S7, when we used only the RhB dyes with the aqueous H<sub>2</sub>O<sub>2</sub> solution, there was no degradation of the organic dye. The use of the aqueous H<sub>2</sub>O<sub>2</sub> solution ( $C_o = 10 \text{ mg}\cdot\text{L}^{-1}$ ) led to a degradation yield of 48.9%, after three hours of reaction. The degradation is best described by a pseudo first-order kinetics with :  $\text{Ln} \frac{C_t}{C_o} = -k_o \cdot t$  (Eq. 5) (Figure S7) and the  $k_o$  value of the pseudo-first order degradation rate constant regarding the RhB-H<sub>2</sub>O<sub>2</sub> complex dye systems is 0.004 min<sup>-1</sup> ( $R^2 = 0.9915$ ).

### 3.9.2. Photodegradation of RhB dye with H<sub>2</sub>O<sub>2</sub> using complex 1

The photodegradation reaction of the RhB dye using complex 1 as catalyst was monitored by UV/vis spectroscopy. To follow the photodegradation of RhB we utilized the  $\lambda_{\text{max}}$  of the absorption band of the RhB species at ~ 554 nm (in aqueous solution at room temperature). In Figure 17 we report the variation of the  $\lambda_{\text{max}}$  of the absorption of the RhB dye upon radiation time, using complex 1 as catalyst. Figure S8-

a shows that the degradation yield of RhB dye in water under light for 180 min at pH = 7 and 25 °C in presence of complex is 73.4% while in absence of light, this degradation is less than 25%

The  $\ln \frac{C_t}{C_0}$  versus time plot is depicted in Figure S8. The photodegradation is also described by a pseudo first-order kinetics with :  $\ln \frac{C_t}{C_0} = -k_o.t$  (Eq. 6) (Figure S8-b) where  $k$  is the rate constant which was determined to be equal to  $0.008 \text{ min}^{-1}$  ( $R^2 = 0.9503$ ).

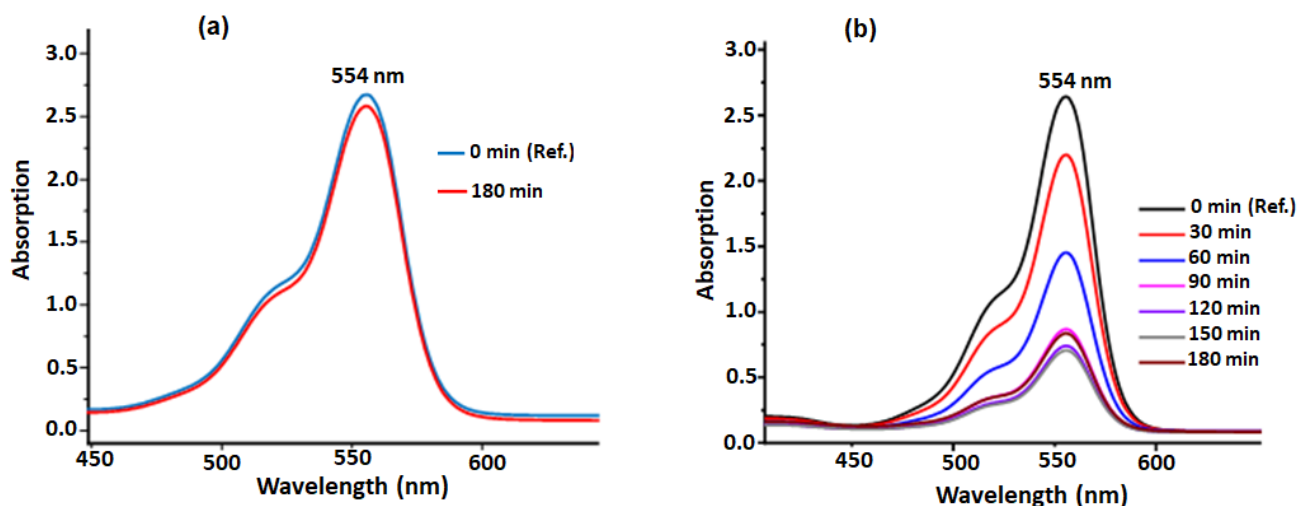

Figure 17. Evolution of the absorbance of the RhB dye over time under visible light in H<sub>2</sub>O at pH = 7 and 25 °C. (a): without catalyst, (b): 10 mg of complex **1**, (at pH = 6, C=25 mg/L) and H<sub>2</sub>O<sub>2</sub> (10 mL/L).

The reusability of complex **1** as catalyst in this photodegradation of the rhodamine (RhB) dye was investigated. The catalyst was separated by filtration after each degradation cycle, washed with distilled water and then dried. It was found that the regeneration process could be repeated for four cycles, with efficiencies decreasing from 73.4% to 69.8% after 4 cycles (180 min each).

#### 4. Conclusion

In this work we synthesized and characterized by physicochemical techniques the bis(1,4-diazabicyclo[2.2.2]octane)[*meso*-tetra(*para*-chlorophenyl)porphyrinate]magnesium(II) chloroform disolvate complex with the formula [Mg(TCIPP)(DABCO)<sub>2</sub>]<sub>2</sub>·2CHCl<sub>3</sub> (**1**). The UV/Vis, fluorescence, <sup>1</sup>H NMR and cyclic voltammetry data are typical for magnesium(II) *meso*-arylporphyrin complexes. The X-ray molecular structure of **1** shows that this porphyrinic species is hexacoordinated and the average equatorial distance Mg-N(pyrrole) is very close to those of the related pentacoordinated and hexacoordinated Mg(II) metalloporphyrins indicating that the nature of the *N*-donor axial ligand don't have important geometric role on this type of porphyrin complexes.

The optimized molecular structure of **1** indicates that the theoretical and experimental distances and angles values are very close. The MEP contour maps of complex **1** show that the Mg(II) center metal and the two DABCO axial ligands exhibit an important electron-accepting properties which is an indication that the DABCO could be easily substituted.

The bis(DABCO) magnesium(II) metalloporphyrin (**1**) was also analyzed by molecular docking methods against two SARS-COV-2 proteins (ACE2 and ORF8) and two oxidase enzymes [Human Peroxidase enzyme (PDB code 1HD2) and Peroxiredoxin 5 (PRDX5) (PDB code 1H4O)]. This study indicates (i) that the ACE2-MgTCIPP(DABCO)<sub>2</sub> system possesses the strongest energy score equal to -125.15 kcal/mol and (ii) the “ Human Peroxidase-[Mg(TCIPP)(DABCO)<sub>2</sub>]-2CHCl<sub>3</sub> “ system presents the highest total energy value of -89.68 kcal/mol with an important van der Waals interaction (-89.68 kcal/mol). Furthermore, complex **1** was tested as a catalyst in the degradation of the Rhodamine B dye in presence of a H<sub>2</sub>O<sub>2</sub> solution with and in absence of irradiation showing that the photodegradation gives a better yield of 73%.

### Supporting information

CCDC-2236148 contain the supplementary crystallographic data of complex **1**. These data can be obtained free of charge from the Cambridge Crystallographic Data Centre via [www.ccdc.cam.ac.uk/data\\_request/cif](http://www.ccdc.cam.ac.uk/data_request/cif).
