**Abstract:** A ruthenium nitrosyl complex of formula  $[\text{Ru}^{\text{II}}(\text{fluorene}(\text{C6})\text{CH}_2\text{O-terpy})(\text{bipy})(\text{NO})]^{3+}$  (**AC**) in which fluorene(C6) is the 9,9-dihexylfluorene, terpy the 2,2',6',2''-terpyridine, and bipy the 2,2'-bipyridine is presented with its related  $[\text{Ru}^{\text{II}}(\text{MeO-terpy})(\text{bipy})(\text{NO})]^{3+}$  (**C**) and 9,9-dihexylfluorene 2-hydroxymethylfluorene (**A**) building blocks. The reference complex **C** undergoes NO release capabilities under irradiations at  $\lambda = 365$  nm. The effect of the introduction of the fluorescent **A** antenna within the resulting **AC** complex is discussed both experimentally and theoretically. The importance of the encaging parameter defined as  $\phi_{\text{AC}} \cdot I_{\text{AC}}$ , in which  $I_{\text{AC}}$  is the quantity of light absorbed by **AC** and  $\phi_{\text{AC}}$  the quantum yield of NO release is evidenced and found concentration dependent. The conditions of optimization of the antenna approach to maximize  $\phi_{\text{AC}} \cdot I_{\text{AC}}$  are discussed. The crystal structure of  $[\text{Ru}^{\text{II}}(\text{fluorene}(\text{C6})\text{CH}_2\text{O-terpy})(\text{bipy})(\text{NO}_2)](\text{PF}_6)$  last intermediate in the synthesis of **AC** is also presented.

## 1. Introduction

View Article Online  
DOI: 10.1039/D4DT01154F

The last two decades have witnessed a growing interest for exogenous nitric oxide (NO $\cdot$ ) donors in relation to the gradual recognition of the numerous biological roles devoted to the radical NO $\cdot$ .<sup>1-5</sup> Among them, ruthenium-nitrosyl (Ru-NO) complexes appear especially appealing due to their high design flexibility, generally good stability in solution and furthermore their capability of releasing NO $\cdot$  under irradiation exclusively, taking advantage of the noninvasive character of light.<sup>6-13</sup> These species undergo the following photoreaction:

In the starting complex, NO is present as the nitrosonium cation NO $^+$ , while the photo-released species is invariably the radical NO $\cdot$ . This observation suggests that an electron-donor ligand L could favor a large charge transfer towards the withdrawing nitrosyl ligand, and hence enhance the efficiency of the release depicted in equation 1. Following this idea, we have reported on various ruthenium-nitrosyl complexes built up from the ancillary fluorenylterpyridine ligand which contains the electron-rich fluorene fragment, introduced to bring a “push-pull” electronic character to the resulting Ru-NO complex, denoted [FTRuNO] $^{3+}$  in Chart 1.<sup>14-16</sup>

Chart 1

The A, C, AC species under investigation, with the [FTRuNO] $^{3+}$  push-pull reference.

Beside this general *push-pull* approach, an alternative strategy is based on the use of antennas which could first absorb, then induce the NO<sup>•</sup> release by energy transfer to the Ru-NO units. The use of antennas for drug delivery has been addressed in the literature.<sup>17-25</sup> An antenna refers to a fluorescent fragment of the ligand in which both ground and excited state electron densities are located (the donor), without any electronic contribution of the rest of the complex (the acceptor). After photon absorption by the antenna, an energy transfer occurs to the acceptor, followed by the desirable electronic effect. Both strategies are illustrated in Scheme 1. To date, few investigations have been reported on iron-nitrosyl complexes, in which antennas were grafted.<sup>26-29</sup> Nevertheless, and to the best of our knowledge, it was never employed for Ru-NO species.

In a continuous effort aiming at extending the scope of application of fluorene-based Ru-NO complexes, we wish to report here on a new complex **AC** in which the Ru-NO complex **C** is linked to a fluorene unit **A**. The three compounds are shown in chart 1. Contrary to the situation encountered in the *push-pull* complex [FTRuNO]<sup>3+</sup>, **A** is not  $\pi$ -conjugated with the Ru-NO fragment in **AC**, but can be used as an antenna, capable to collect photons, and finally enhance the NO<sup>•</sup> release efficiency of the reference complex **C**, by energy transfer. The organization of the manuscript is the following: theoretical aspects of the antenna approach are presented in a first section. Another section reports on our results as follows: (i) synthesis of the compounds under investigation; (ii) crystal structure of a ruthenium nitrite complex, intermediate step toward **AC**; (iii) optical properties with UV-visible spectra and fluorescence measurements; (iv) NO<sup>•</sup> release investigation. In a final section, the relevance of the antenna approach is discussed for these species.

**Scheme 1**

The two strategies employed to achieve the NO<sup>•</sup> release after photon absorption: (i) with a *push-pull* complex in which NO acts as the withdrawing group and, (ii) with an antenna (the donor) capable to transfer its energy to the Ru-NO complex (the acceptor).

## 2. Theoretical Background

View Article Online  
DOI: 10.1039/D4DT01154F

$AC$  refers to a system built from two sub-units, a photochemically active core  $C$ , and a fluorescent antenna  $A$ , non-conjugated to  $C$ , but capable to transfer part of its energy to  $C$ , once promoted to the excited state ( $A^*$ ). We can define a quantum yield ( $\phi$ ) introduced to quantify the efficiency of a photo-induced event under investigation as follows:

$$\phi = \frac{\text{number of events}}{\text{number of photons absorbed}} \quad (2)$$

For isolated  $A$  or  $C$  species,  $\phi$  is written  $\phi_A$  (quantum yield of fluorescence of  $A$ ) and  $\phi_C$  (quantum yield of photoreaction of  $C$ ). In the case of  $AC$ , the quantum yield  $\phi_{AC}$  reflect the global efficiency of  $AC$  regarding the photochemical event (e.g.  $\text{NO}^\bullet$  release from Ru-NO complex). In this present case, the photochemical reaction within the  $AC$  species can occurs from two different routes as follows:

**Scheme 2** Possible routes towards  $\text{NO}^\bullet$  release from  $AC$  complexes after photon absorption

In route (a), a photon is directly absorbed by the  $C$  fragment of  $AC$ , while in route (b) it is first absorbed by the antenna, which undergoes an energy transfer to  $C$ . Nevertheless,  $\phi_{AC}$  results from the sum of the  $\text{NO}^\bullet$  released from both route (a) and (b) divided by the sum of the photons absorbed by both electronically isolated  $A$  or  $C$  fragments. In the case of  $\text{NO}^\bullet$  release, equation (2) becomes:

$$\Phi_{AC} = \frac{\#NO_{(a)} + \#NO_{(b)}}{\#hv_A + \#hv_C} \quad (3)$$

In this equation,  $\#NO_{(a)}$  and  $\#NO_{(b)}$  are the number of  $\text{NO}^\bullet$  produced by route (a) and (b), respectively.  $\#hv_A$  and  $\#hv_C$  are the number of photons absorbed by the core  $C$  and the antenna  $A$ , respectively. Importantly, only a fraction ( $k$ ) of the photons absorbed by the antenna leads to energy transfer to  $C$ . Then, equation (3) can be written as follows:

$$\Phi_{AC} = \frac{\#NO_{(a)} + \#NO_{(b)}}{\#hv_C + (k)\#hv_A + (1-k)\#hv_A} \quad (4)$$

In this equation,  $(1-k)\#hv_A$  is the number of photons lost for the  $\text{NO}^\bullet$  release process. In the more favorable case, 100% of the photons absorbed by  $A$  lead to energy transfer to  $C$  and  $k = 1$ . In this case,  $\Phi_{AC} = \phi_C$ . But more generally, the following fundamental inequality is observed:

$$\phi_{AC} < \phi_C \quad (5)$$

To further estimate the fraction  $k$ , one can express it as the product of the quantum yield of fluorescence of the antenna ( $\phi_A$ ) by the efficiency of the  $A \rightarrow C$  energy transfer ( $E_{FRET}$ ), assuming a FRET mechanism, which is favored when long distances ( $\approx 10 \text{ \AA}$ ) prohibit the direct orbital overlap between  $A$  and  $C$ .<sup>30</sup> Therefore  $k$  must be written as follows:

$$k = \phi_A \times E_{FRET} \quad (6)$$

From the reactions depicted in Scheme 2 and equation (6), the total quantum yield of photorelease ( $\phi_{AC}$ ) appears as the sum of two components,  $\phi_{route A}$  and  $\phi_{route B}$ . The first one arising from the direct photon absorption by **C** can be expressed as follows:

$$\phi_{route A} = \frac{\varepsilon_C}{\varepsilon_C + \varepsilon_A} \cdot \phi_C \quad (7)$$

The second one, involving the antenna is expressed as follows:

$$\phi_{route B} = \frac{\varepsilon_A}{\varepsilon_C + \varepsilon_A} \cdot [\phi_A \cdot E_{FRET}] \cdot \phi_C \quad (8)$$

In these expressions,  $\varepsilon_A$  and  $\varepsilon_C$  are the molar extinction coefficients of **A** and **C**, respectively. Therefore,  $\frac{\varepsilon_A}{\varepsilon_C + \varepsilon_A}$  and  $\frac{\varepsilon_C}{\varepsilon_C + \varepsilon_A}$  denote the fraction of light absorbed by **A** and **C**, respectively.

The sum of (7) and (8) leads to the following expression of the total quantum yield of photorelease:

$$\phi_{AC} = \frac{\varepsilon_C}{\varepsilon_C + \varepsilon_A} \cdot \phi_C + \frac{\varepsilon_A}{\varepsilon_C + \varepsilon_A} \cdot \phi_A \cdot E_{FRET} \cdot \phi_C \quad (9)$$

Which can be simplified as:

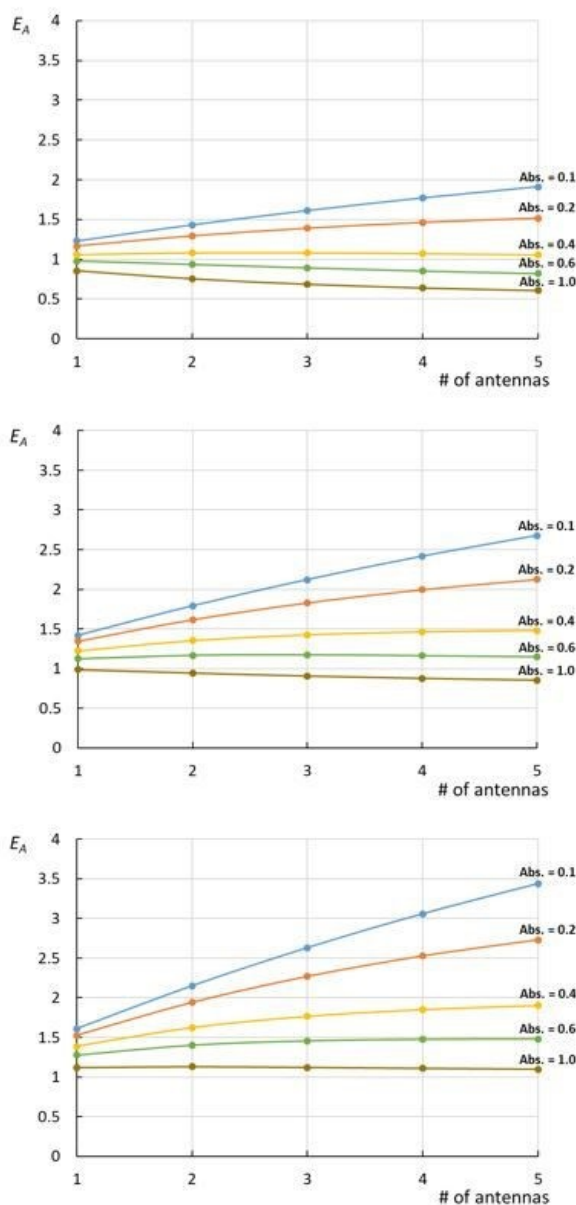

$$\phi_{AC} = \phi_C \cdot \frac{\varepsilon_C + \varepsilon_A \cdot \phi_A \cdot E_{FRET}}{\varepsilon_C + \varepsilon_A} \quad (10)$$

Equation (10) can be further completed, taking into account that (i) more than one antenna can be present in the complex and moreover (ii) the fact that the real efficiency of **AC** is not expressed by  $\phi_{AC}$ , but is better described by the engaging parameter  $\phi_{AC} \cdot I_{AC}$ , in which  $I_{AC}$  is the quantity of light absorbed by **AC**. Following this approach, the engaging parameter depends on the absorbance of **AC** ( $Abs_{AC}$ ), which is the sum of the absorbance of the **A** ( $Abs_A$ ) and **C** ( $Abs_C$ ) fragments in **AC**. Then, the efficiency of the antenna becomes concentration dependent. Thus, the relative efficiency of the molecular device ( $E_A$ ) can be described by the ratio between the engaging parameters of **AC** and **C**. Taking into account the possibility of implying more than one identical antenna, it can be expressed as:

$$E_A = \frac{\phi_{AC} \cdot I_{AC}}{\phi_C \cdot I_C} = \frac{\varepsilon_C + (n \cdot \varepsilon_A \cdot \phi_A \cdot E_{FRET})}{\varepsilon_C + (n \cdot \varepsilon_A)} \cdot \frac{1 - 10^{-(n \cdot Abs_A + Abs_C)}}{1 - 10^{-Abs_C}} \quad (11)$$

in which  $n$  is the number of antennas in **AC**. While the first term of the right part of equation (11) is always lower than 1 due to the fact that  $\phi_A \cdot E_{FRET} < 1$ , increasing  $E_A$  can be achieved if  $\frac{1 - 10^{-(n \cdot Abs_A + Abs_C)}}{1 - 10^{-Abs_C}} > 1$ . The magnitude of the concentration-dependent relative  $E_A$  efficiency, is illustrated in Figure 1, which contains computations performed in various conditions, assuming  $\varepsilon_A = \varepsilon_C$ ,  $n = 1$  to 5, and  $\phi_A \cdot E_{FRET} = 0.3, 0.5, 0.7$ , which correspond to realistic situations.

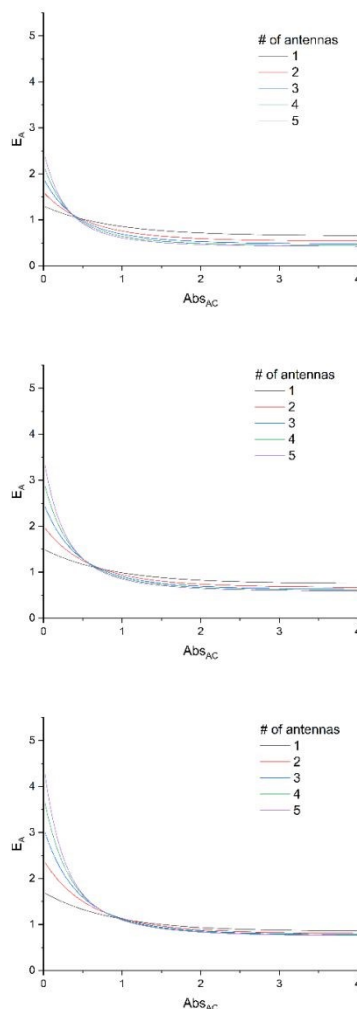

**Figure 1** Relative efficiency  $E_A$  (equation 11) expressed at various  $\Phi_A \cdot E_{FRET}$  values [0.3 (top), 0.5 (middle), and 0.7 (bottom)] for complexes bearing 1 to 5 antennas. On each graph, the curves are drawn at various of absorbance ranging from Abs. = 0.1 to 1.0, with the assumption that  $\varepsilon_A = \varepsilon_C$ .

What immediately strikes from the examination of Figure 1 is that increasing the number of antennas, does not necessarily imply that the relative efficiency of  $AC$  increases, due to the deleterious effect of modest energy transfer efficiencies ( $\Phi_A \cdot E_{FRET}$ ), in some cases. Indeed, weak  $\Phi_A \cdot E_{FRET}$  values increases the loss of photons, when the number of antennas increases, thus decreasing the  $E_A$  values. Additionally, the concentration-dependence of  $E_A$  is confirmed with better values observed at low concentrations (low absorbance), where  $E_A$  is roughly proportional to the number of antennas. This linearity arises from the fact that the absorption of photons grows linearly with the concentration at very low absorbance values, where  $\log \frac{I_0}{I} \propto \frac{I_0}{I}$ .

Additionally, the dependence of  $E_A$  on absorbance is drawn in Figure 2, for various values of  $\Phi_A \cdot E_{FRET}$ . It clearly shows that the relative efficiency of the device ( $E_A > 1$ ) requires a low absorbance.

**Figure 2**  $E_A$  expressed at various  $\Phi_A \cdot E_{FRET}$  values [0.3 (top), 0.5 (middle), and 0.7 (bottom)] for complexes bearing 1 to 5 antennas, according to equation (11), with the assumption that  $\varepsilon_A = \varepsilon_C$ .

More precisely, the limit of equation (11) at low concentration ( $c \rightarrow 0$ ) leads to the following equation:

$$\lim_{c \rightarrow 0} E_A = \frac{\varepsilon_C + (n \cdot \varepsilon_A \cdot \Phi_A \cdot E_{FRET})}{\varepsilon_C + (n \cdot \varepsilon_A)} \cdot \frac{\varepsilon_C + (n \cdot \varepsilon_A)}{\varepsilon_C} = \frac{\varepsilon_C + (n \cdot \varepsilon_A \cdot \Phi_A \cdot E_{FRET})}{\varepsilon_C} \quad (12)$$

From this equation, representative  $E_A$  values are shown in Table 1. The data gathered in the table reveal how important the  $\Phi_A \cdot E_{FRET}$  parameter is in the design of an efficient  $AC$  device.

$\Phi_A \cdot E_{FRET}$	number of antennas in the device				
	1	2	3	4	5

0.3	1.3	1.6	1.9	2.2	2.5
0.5	1.5	2.0	2.5	3.0	3.5
0.7	1.7	2.4	3.1	3.8	4.5

**Table 1** Maximum of relative efficiency ( $\lim_{c \rightarrow 0} E_A$ ) computed from equation (12) at various  $\Phi_A \cdot E_{FRET}$  values for complexes bearing 1 to 5 antennas, with the assumption that  $\varepsilon_A = \varepsilon_C$ .

In equation (11), the  $\varepsilon$  and  $\Phi$  parameters are easily available by standard UV-visible investigations and NO $\cdot$  release measurements. The estimation of  $E_{FRET}$  can be expressed as follows:<sup>31</sup>

$$E_{FRET} = \frac{aR_0^6}{aR_0^6 + R^6} = 1 - \frac{F_{AC}}{F_A} = 1 - \frac{\tau_{AC}}{\tau_D} \quad (13)$$

In this expression,  $R$  is the distance between the donor (fluorene) and the acceptor (RuNO), evaluated around  $\approx 9.5$  Å in the present AC complex (*vide infra*), and  $a$  is the number of donors ( $a = 1$  in the present investigation).  $R_0$  is the Forster radius,  $F$  and  $\tau$  are the intensity and the lifetime of fluorescence of  $A$  and  $AC$ .  $F$  and  $\tau$  are readily available by fluorescence experiment. By contrast,  $R_0$  depends on various factors (spectral overlap integral between the emission of  $A$  and the absorption of  $C$ , orientational factor between the emission transition moment of  $A$  and the absorption transition moment of  $C$ , refractive index of the medium),<sup>31</sup> and it can hardly be estimated very precisely.<sup>32</sup> Nevertheless,  $R_0$  values vary significantly depending on the donor/acceptor couple and the nature of the linker. Among representative references: 20–60 Å,<sup>33</sup> 10–100 Å,<sup>34</sup> 50–60 Å.<sup>35</sup> It is important to point out that, for distances  $R$  shorter than  $R_0$ ,  $E_{FRET}$  quickly converges to 1. For instance,  $R / R_0 = 0.6$  leads to  $E_{FRET} = 0.95$  while  $R / R_0 = 0.47$  leads to  $E_{FRET} = 0.99$ .

### 3. Results and discussion

#### 3.1. Synthesis and characterization

The first report of a Ruthenium-nitrosyl complex containing the terpyridine ligand is that of [RuCl<sub>2</sub>(NO)(terpy)]<sup>+</sup>.<sup>36</sup> It was first reported to undergo a Ru-NO  $\leftrightarrow$  Ru-ON photoisomerization in solid state,<sup>37</sup> then to lead to NO $\cdot$  photorelease under irradiation.<sup>38</sup> The modulations of the electronic properties of such complex are readily accessible by introducing substituents of various donor/acceptor capabilities on the central pyridine of the terpyridine unit.<sup>39</sup> In the context of the *push-pull* strategy towards efficient NO $\cdot$  release (*i* in Scheme 1), we have investigated various substituents  $\pi$ -conjugated to the terpyridine.<sup>40–43</sup> By contrast, the synthetic procedures afferent to the antenna strategy (*ii* in Scheme 1) require non-conjugated substituents and therefore, have to be completely reconsidered.

Fluorene appears to be a good candidate as an  $A$  antenna. Indeed, it fulfills two important requirements while incorporated in the present AC system: (*i*) the fact that  $A$  must be fluorescent (in solid state, it forms white crystals with violet fluorescence, from which its name was derived); and (*ii*) a significant overlap between its emission spectrum and the absorption spectrum of  $C$  (Scheme 1 *ii*) is observed, otherwise no  $A \rightarrow C$  energy transfer could take place.

The general synthetic route towards **A**, **C**, and **AC** is shown in Scheme 3. An ether was selected as the non-conjugated linkage between **A** and **C** in the **AC** complex. Its synthesis is based on a condensation between a 4-chloropyridine and an alcohol, in alkaline medium (“superbasic” medium in the case of **2b**).<sup>44</sup> The resulting **A** antenna, in which the electronically neutral -CH<sub>2</sub>OH substituent is present is expected to exhibit similar fluorescent properties than those of the parent non-substituted fluorene.<sup>45</sup> By contrast, introducing an oxygen in the 4'-position of the terpyridine may slightly enhance the ligand → Ru-NO charge transfer, nevertheless with the possible outcome of a better NO<sup>•</sup> release efficiency in agreement with the *push-pull* strategy. A short linker (-CH<sub>2</sub>-O-) was chosen with the expectation that the value of  $E_{FRET}$  will be close to 1, which is necessary for the efficient energy transfer according to equation (13).

**Scheme 3** Synthesis of **C** and **AC**.

The synthesis of **A** is readily achieved as previously reported in the literature.<sup>46</sup> Its purity was carefully checked by NMR, HRMS and CHN analysis, prior to any optical investigation. **C** and **AC** require a synthesis in 5 steps. In the route towards **C**, the ligand **2a** was obtained as previously published,<sup>47</sup> as were the intermediate complexes **3a** and **4a**.<sup>48</sup> Finally, the sequential synthesis of **5a** and **C** was achieved by the well-known methodology previously applies in our group.<sup>41,49</sup> In the route

towards **AC**, an aromatic nucleophilic substitution reaction of **1b** with 4'-chloro-2,2':6',2"-terpyridine in "superbasic" medium (KOH/DMSO) was performed to get the ligand **2b** in a good yield. The procedures used to get the final **AC** complex are then the same as those described for the complexes of **a**-series. Great care has to be taken in the purification of **4b** by column chromatography where a reduced amount of Al<sub>2</sub>O<sub>3</sub> must be used in order not to lose a large part of the crude compounds with the concomitant deleterious effect on the yield. The compounds were all characterized with <sup>1</sup>H NMR, <sup>13</sup>C NMR, HRMS methods. The NMR spectra are provided in *Supplementary Information*.

### 3.2. Crystal structure of **5b**

The difficulties encountered in the growth of single crystals suitable for crystal structure determination encouraged us to try to use any ruthenium complexes available in order to investigate the relative orientation of the fluorene moieties with respect to the  $\pi$ -electronic structure of the terpyridine ligand. In this context, we succeeded to obtain single crystals of the ruthenium nitrite precursor, last step towards **AC**. The compound crystallizes in the P 2<sub>1</sub>/n monoclinic space group, in which four complexes are present in the crystal unit cell. The main crystal data are gathered in Table 2. The crystal unit cell is shown in Figure 3. The presence of a single PF<sub>6</sub><sup>-</sup> anion, indicates that the ruthenium atom is in the +II oxidation state, which was invariably the case in Ru(terpy)(bipy) complexes previously investigated in our group.<sup>14-16,41,49-51</sup> In the substituted terpyridine ligand, the fluorenyl unit is planar with largest distance to the mean plane equal to 0.028 Å at C38. Similarly, the terpyridine unit is nearly planar with largest distance to the mean plane equal to 0.048 Å at C1. The distance between the ruthenium atom and the centroid of the  $\pi$ -core of the first fluorene ring (6 carbon atoms) is equal to  $\approx$  9.540 Å, which provides an idea of the value of the Forster distance (*R*) in **AC**.

Importantly, the torsion angle between fluorene and terpyridine is equal to 33.9°. As pointed out in the introduction section, the relative orientation of the antenna with respect to the complex is an important parameter, when the possibility of energy transfer has to be considered. To clarify this issue, **AC** has been optimized by DFT. It turns out that the ground state conformation is that having the fluorenyl and the terpyridine plans roughly orthogonal. It will subsequently be denoted **AC**<sub>⊥</sub> in the next section. Similarly, the excited state conformation is that having the fluorenyl and the terpyridine plans roughly parallel, and will be denoted **AC**<sub>//</sub>. Interestingly, the fluorene-ruthenium Forster distance (*R*) in the computed structures is found equal to 9.632 Å and 9.678 Å, for **AC**<sub>⊥</sub> and **AC**<sub>//</sub>, respectively. Therefore, the effect of the rotation is negligible on *R*. Furthermore, the rotation of the fluorene reveals an energy barrier of 1.4 kcal/mol (see *Supplementary Information*), roughly the half of the 3 kcal/mol found in the CC rotation of ethane.<sup>52</sup> This low value indicates a nearly free rotation of fluorene. The experimental torsional frequency is around 290 cm<sup>-1</sup> in alkyl chains,<sup>53</sup> which corresponds to rotation motions achieved in about 0.1 ps. Within typical lifetimes of fluorescence of several nanoseconds for fluorene derivatives (*vide infra*), optimized energy transfers cannot be hampered by conformational effects in **AC**.

**Table 2** Crystal data for **5b**

Chemical formula	C <sub>51</sub> H <sub>53</sub> N <sub>6</sub> O <sub>3</sub> Ru, PF <sub>6</sub>
Formula weight ( <i>M</i> )	1044.03
Unit-cell dimensions	<i>a</i> = 13.2505(2) Å <i>b</i> = 11.0878(2) Å

	$c = 32.1285(4) \text{ \AA}$
	$\alpha = 90 \text{ deg.}$

### 3.3. Optical properties

The UV-visible spectra recorded in acetonitrile are shown in Figure 4 for *A*, *C*, and *AC*. The reference complex *C* exhibits a large band around 350 nm, and a more intense band in the range of 275–325 nm. The spectrum of the antenna *A* reveals electronic transitions around 300 nm, and 275 nm. Interestingly, the spectrum of *AC* appears to be roughly the sum of those of *A* and *C*, which may suggest that both *A* and *C* units keep their individual spectral properties in *AC*. In particular, no new *push-pull* transition

arising from the electron rich **A** fragment towards the withdrawing Ru-NO complex is evidenced in **AC**. These observations have been supported computationally by DFT.

View Article Online  
DOI: 10.1039/D4DT01154F

**Figure 4** UV-visible spectra in acetonitrile, for **A**, **C**, and **AC**.

The time dependent DFT transitions are listed in Table 3. The comparison of the experimental and computed data shows a general tendency for red-shifted transitions in the computed data versus experiment. More precisely, the agreement which appears satisfactory for the Ru-NO complexes at the low energy band is more questionable in the antenna ( $\lambda_{\text{DFT}} = 261 \text{ nm}$ ,  $\lambda_{\text{UV-vis}} = 300 \text{ nm}$ ) and corresponds to  $5000 \text{ cm}^{-1}$ , a rather large difference for organic molecules.<sup>54</sup> However, the CAM-B3LYP hybrid functional is employed here for consistency with our numerous computations performed on terpyRuNO-based chromophores. CAM-B3LYP is a powerful method for electronic system with long range charge transfer effect. By contrast, the pseudo centro-symmetric  $\pi$ -electronic structure of **A** is better described by the more traditional B3LYP method. In this case, the absorption maximum is found equal to 276 nm (Table 3), which leads to an energy difference of  $2900 \text{ cm}^{-1}$  versus the experiment. The resulting discrepancy is significant, but still acceptable.<sup>54</sup>

The examination of the data gathered in Table 3 indicates that the UV-visible spectrum of **AC** arises from the sum of those of **A** and **C**. It confirms that **A** is not engaged in charge transfer transition towards **C**, which is expected from an antenna. The orbital of interest indicated in Table 3 are visualized in Figure 5. It clearly appears that both **A** and **C** fragment keep their character in the resulting **AC** complex. Consequently, the possibility for the energy collected by **A** (blue arrows in Figure 5) to be transferred to **C** (red arrows) can be investigated by fluorescence in the next section.

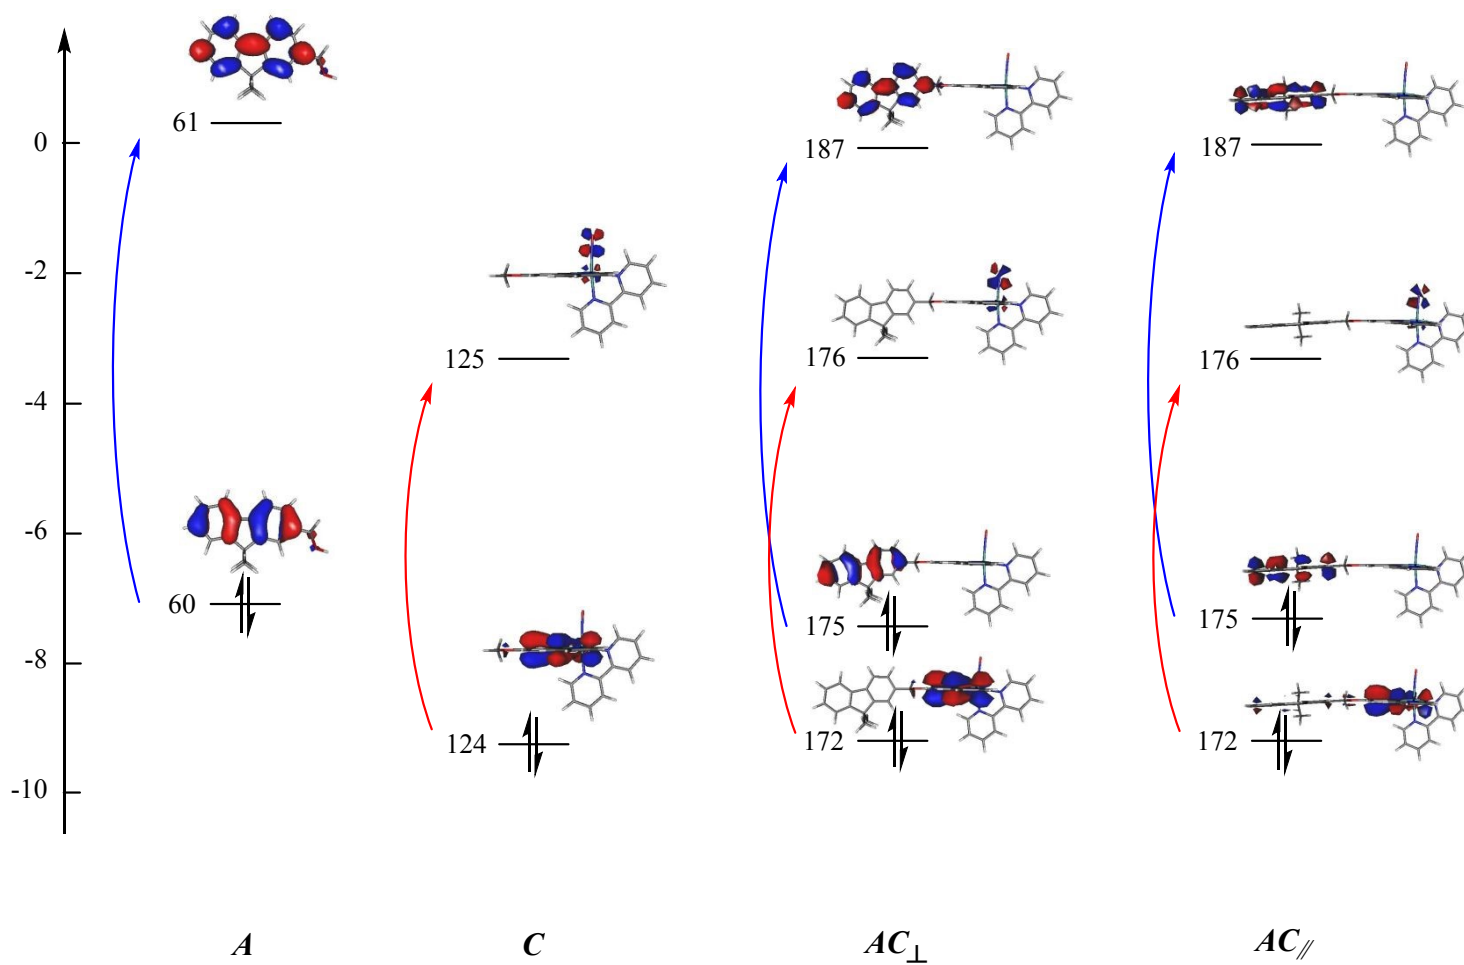

**Table 3** Relevant transitions computed by TD-DFT, with absorption maxima ( $\lambda_{\max}$ ), oscillator strength ( $f$ ), composition and charge transfer character, for **A**, **C**, and **AC** in the ground state ( $\perp$ ) and excited state ( $//$ ) conformations.

<sup>1</sup> Orbital 60(61) is the HOMO(LUMO) in **A**, 124(125) is the HOMO(LUMO) in **C**, 175(176) is the HOMO(LUMO) in **AC**.

**Figure 5**

Orbitals of interest in the electronic transitions of *A*, *C*, and *AC*. The orbitals are numbered according to Table 3: (blue) transitions restricted to the antenna ; (red) transitions centered on the complex. Orbitals 60(61), 124(125), 175(176) are the HOMO(LUMO) in *A*, *C*, and *AC*, respectively.

Fluorescence is a prerequisite for an antenna, when the possibility of energy transfer has to be considered. The quenching of fluorescence then becomes a means for measuring the efficiency of the energy transfer between the donor (*A*) and the acceptor (*C*). Thus, equation 12 relates the decrease of intensity and lifetime of the fluorescent species *A* embedded in the resulting complex *AC* to  $E_{FRET}$ . Firstly, the absolute quantum yield and the lifetime of fluorescence of *A* were measured in acetonitrile. They are equal to 0.387 and 3.6 ns respectively. However, due to low intensity of the fluorescence of *AC*, it was impossible to measure the absolute quantum yield of *AC* on our equipment (Quantaaurus QY), to estimate its value. Three experiments were carried out at constant concentration: (i) the fluorescence of *A*, (ii) the fluorescence of *A* in the presence of an equivalent amount of *C*, and (iii) the fluorescence of *A*, once chemically linked to *C* within the resulting *AC* species. The results are presented in Figure 6.

**Figure 6** Graphs of fluorescence intensities for *A* (top), *A+C* (middle) and *AC* (bottom) in acetonitrile, recorded at 3 different concentrations.

The emission of the antenna (*A*) is observed between 300 and 380 nm, which overlaps well with the absorption spectrum of *C* (Figure 4), and suggests an efficient FRET energy transfer in *AC*.

As seen in Figure 6, the shape of the emission spectrum measured for  $5 \times 10^{-5}$  M solution of the *A* differs from those obtained at lower concentrations of the antenna. This fact can be explained by the presence of a pronounced inner filter effect due to a small Stock shift of the antenna. The fluorescence intensity of the antenna solutions is higher than that of solutions of the same concentration in the presence of an equal quantity of complex *C* (middle of Figure 6). It also can be explained by the presence of the inner filter effect due to increasing the concentrations of the antenna and the complex, whose absorbance range overlaps with an emission range of the antenna. This double inner filter effect explains more pronounced fluorescence quenching with an increase of concentrations *A* and *C*.

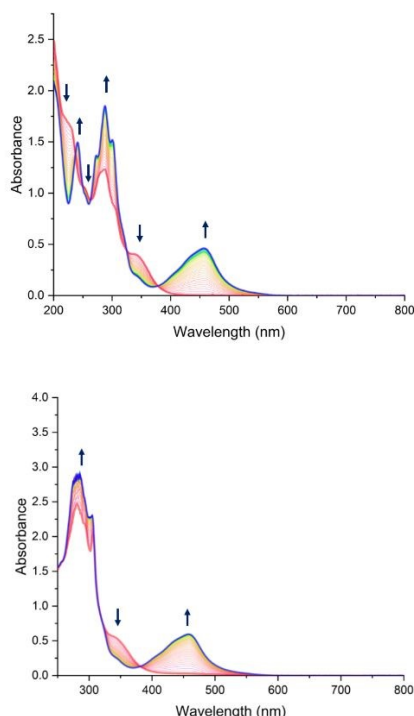

Due to a strong reabsorption of the emitted light, the fluorescence measurements were performed at lower concentration on *AC*, to minimize the inner filter effect (bottom of Figure 6) versus those of *A* and *A + C*. The signal is close to the background, with a drop in fluorescence intensity by more than 100 times. This hampers a precise evaluation of the resulting FRET efficiency, which however leads to  $E_{FRET} > 0.99$ .

It was possible to measure the lifetime of fluorescence for the residual fluorescence detected for *AC* (Figure 6). It is equal to 3.6 ns, which is strictly the same as for the free antenna *A*. This fact makes us think about the possibility of a free antenna *A* impurity, which either went through all stages of synthesis and purification, or, more likely, formed as a product of *AC* decomposition. However, we were unable to detect this potential impurity using any of the methods available to us. Regardless of the nature of the residual signal, these measurements in any case prove the efficiency of energy transfer between *A* and *C*.

### 3.4. NO release experiment

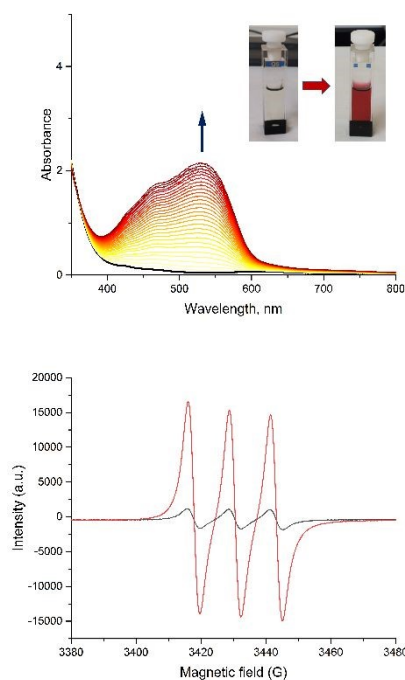

The photorelease phenomenon depicted in equation (1) is likely to be related to the low energy transition of *C* and *AC*, located around 350 nm (Figure 4 and Table 3) where the charge transfer towards NO is maximum. On the other hand, the energy transition of antenna is located at 300 nm. Based on these features, the photokinetic studies of *C* and *AC* were performed in acetonitrile at 365 nm and 300 nm. The evolution of the absorbance spectra for both species at 365 nm irradiation are shown in Figure 7. Analogous evolution of absorbance spectra at 300 nm was observed (see *Supplementary Information*).

**Figure 7** Evolution of UV-Vis spectra of *C* (top) and *AC* (bottom) in acetonitrile under 2 hours of irradiation at  $\lambda = 365$  nm, with starting complex *C* in red and photoproduct in blue.

To prove the nitric oxide release during the photoreactions, the Griess test for **C** and **AC** was carried out as well as EPR measurement in the presence of iron(II)-N-methyl-D-glucamine dithiocarbamate (Fe-MGD) spin-trap for **AC** (Figure 8). The Griess test is an indirect method for detecting NO<sup>•</sup> via its oxidation in nitrite and its consequently reaction with Griess reagent to form a pink azo dye around 540 nm.<sup>55</sup> The method of the EPR experiment for detecting NO<sup>•</sup> in the presence of spin-trap was described in our previous paper.<sup>56</sup> The adduct (Fe-MGD-NO) has a characteristic triplet signal with  $g = 2.040$  and  $a = 1.2 \times 10^{-3} \text{ cm}^{-1}$ .

**Figure 8** Griess-test showing the appearance of a pink dye with  $\lambda_{\text{max}}$  around 540 nm (top) and triplet signal from Fe-MGD-NO formed in EPR experiment (bottom) for **AC** at room temperature at  $\lambda = 365 \text{ nm}$  irradiation.

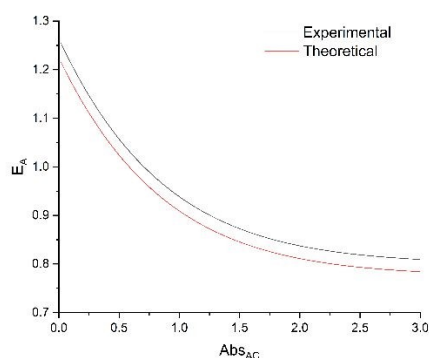

The presence of the isosbestic points in Figure 7 at  $\lambda = 365 \text{ nm}$  (and figure at  $\lambda = 300 \text{ nm}$  in *Supplementary Information*) proves the applicability of the proposed  $A \rightarrow B$  model developed by V. Pimienta *et al.*<sup>57</sup> and described in one of our previous studies.<sup>56</sup> It was used to determine the quantum yield of the photoreaction releasing NO<sup>•</sup>. The results are given in Table 4.

**Table 4** Quantum yields of NO<sup>•</sup> release for **C** and **AC** under irradiations at  $\lambda = 300 \text{ nm}$  and  $\lambda = 365 \text{ nm}$ .

$\lambda$ (nm)	$\Phi_{\text{C}}$	$\Phi_{\text{AC}}$
300	0.05	0.04
365	0.07	0.07

The antenna  $A$  does not absorb at  $\lambda = 365$  nm (Figure 4), therefore has no influence on the evolution of  $AC$  during irradiation at this wavelength. Consequently, the quantum yields for  $C$  and  $AC$ , are the same at this wavelength ( $\Phi_C = \Phi_{AC} = 0.07$ ). By contrast,  $A$  absorbs a fraction of the light available under irradiation at  $\lambda = 300$  nm. Thus, the comparison of the quantum yields at both wavelengths provides important information about the influence of the antenna effect in the  $AC$  system. At  $\lambda = 300$  nm  $\Phi_C$  and  $\Phi_{AC}$  are equal to 0.05 and 0.04, respectively. These values are significantly reduced versus those observed at  $\lambda = 365$  nm. Meanwhile,  $\Phi_C$  is higher than  $\Phi_{AC}$ , in perfect agreement with theoretical expectations, in particular with expression (5). According to equation (10),  $\frac{\Phi_{AC}}{\Phi_C} = \frac{\epsilon_C + (n \cdot \epsilon_A \cdot \Phi_A \cdot E_{FRET})}{\epsilon_C + (n \cdot \epsilon_A)}$ , which is equal to 0.8 from the experiment carried out at  $\lambda = 300$  nm (Table 4). Interestingly, it is possible to provide an additional estimation of this value by using the quantum yield of the antenna ( $\Phi_A = 0.387$ ),  $E_{FRET} = 1$ , and the  $\frac{\epsilon_{AC}}{\epsilon_C}$  ratio equal to 1.58 at 300 nm (UV-visible spectroscopy). These data lead to  $\frac{\epsilon_C + (n \cdot \epsilon_A \cdot \Phi_A \cdot E_{FRET})}{\epsilon_C + (n \cdot \epsilon_A)} = 0.775$ , a value in good agreement with the 0.8 measured by NO release experiment. It is therefore possible to evaluate the relative efficiency of the  $AC$  system before synthesizing the compound itself, on the basis of the properties of the individual  $A$  and  $C$  components. These expectations can be applied at any concentration, as illustrated in Figure 9, where the relative efficiency  $E_A$  is drawn from the NO release experiment as the “experimental” curve, compared to the “theoretical” one predicted by the data based on isolated  $A$  and  $C$  species. Note that, according to equation (12), the maximum  $E_A$  value is equal to 1.26 for the present device (“experimental” curve). Nevertheless,  $E_A > 1$  is observed in any case with absorbance lower than 0.7.

**Figure 9** Relative efficiency  $E_A$  (equation 11) calculated from NO release data ( $\Phi_C$  and  $\Phi_{AC}$ ) as the “experimental” curve, compared with the values predicted from the antenna data ( $\Phi_A = 0,387$ ) as the “theoretical” curve..

### 3.5 Concluding remarks

Two strategies can be employed in the design of NO $\cdot$  donors based on Ru-NO complexes: (i) the “*push-pull*” methodology, which to date has focused most of the research efforts in our group, and (ii) the present “*antenna*” approach. The first strategy is exemplified by [FTRuNO] $^{3+}$  (Scheme 1), in which the electron-rich fluorene unit is  $\pi$ -conjugated with the RuNO fragment. In [FTRuNO] $^{3+}$ , the donor ligand undergoes significant charge transfer towards RuNO, with the expected outcome of an enhanced NO $\cdot$  delivery. This expectation is based on the examination of the global equation (1), in which NO $^+$  must gain an electron during the photorelease process. However, this approach leads to unexpected observation in some cases. For instance, we have observed a surprisingly large quantum yield of NO $\cdot$  release in a complex, where the electron-rich fluorene was replaced by a strongly withdrawing

nitrophenyl substituent.<sup>58</sup> Similarly, complexes in which the double (-CH=CH-) and triples (-C≡C-) bonds were introduced to increase the energy of the donor and hence the *push-pull* effect led to species of surprisingly reduced quantum yield.<sup>14</sup> These unexpected results point out the fact that the *push-pull* strategy may not necessarily be the only promising one.

The relevance of NO<sup>•</sup> donors built by the “*antenna*” approach requires more discussion. The figure of merit of such a device is not  $\Phi_{AC}$  but  $E_A$ . However,  $E_A$  is concentration-dependent. There is “zero efficiency” point at which a complex with an antenna has the same efficiency as a complex without antenna. It is possible to calculate the expected relative efficiency based on the properties of the antenna and those of the starting complex (Figure 9). The main advantage of the antenna approach appears at low concentrations, however, the high  $\Phi_A$  and  $E_{FRET}$  values shift the “zero efficiency” point to higher absorbance values. Moreover, it is possible to graft more than one antenna, with the outcome of potential higher  $E_A$  values.

To summarize – the antenna approach shows its advantage at low concentrations. Considering the potential pharmaceutical utilization of RuNO complexes and the toxic effect of Ru compounds at high concentrations, this fact perfectly matches to the challenge of reaching the maximum of controlled NO<sup>•</sup> release per time unit at lowest complex concentration possible.

#### 4. Conclusion

A fluorene fragment *A* has been grafted to a ruthenium nitrosyl complex *C*. The resulting *AC* complex undergoes a photorelease process, either by direct photon absorption by the *C* unit, or by a photon absorption by *A* followed by an energy transfer to *C*, through a FRET mechanism. Due to the short *A* – *C* distance (< 10 Å) together with a significant overlap between the fluorescence spectrum of *A* and the absorbance spectrum of *C*, the efficiency of the energy transfer ( $E_{FRET}$ ) is found higher than 99%, with a disappearance of the fluorescence of *A* in *AC*. A theoretical approach points out the fact that, the factor of merit for the antenna strategy ( $E_A$ ) is concentration dependent and allows to determine a range of absorbance, which must be maintained below 0.7. Owing to a nearly perfect energy transfer, the key parameter in such molecular device appears to be the quantum yield of fluorescence of the antenna ( $\Phi_A$ ) and the possibility to be able to graft more than one antenna to the complex.

#### 5. Experimental Section

##### 5.1. Materials and equipment

4'-chloro-2,2':6',2''-terpyridine (Sigma-Aldrich) and all solvents and reagents used for synthesis and optical measurements were purchased from commercial suppliers and were used without further purification. Thin-layer chromatography (TLC) plates, Al<sub>2</sub>O<sub>3</sub> (60 Å, neutral) and SiO<sub>2</sub> (60 Å, neutral) for column chromatography were purchased and used as received. **A**,<sup>46</sup> **2a**,<sup>47</sup> **3a**,<sup>48</sup> and **4a**<sup>48</sup> were synthesized according to the published procedures. The Nuclear Magnetic Resonance (NMR) spectra were recorded on a Bruker Avance III 400 MHz spectrometer, in either CDCl<sub>3</sub> or CD<sub>3</sub>CN at 298 K. The chemical shifts ( $\delta$ ) and the scalar coupling constants (*J*) are given in ppm and Hz, respectively. Chemical shifts for <sup>1</sup>H and <sup>13</sup>C NMR data are given relative to the residual signal of non-deuterated solvent recorded at  $\delta = 7.26$  (CDCl<sub>3</sub>) and  $\delta = 1.94$  (CD<sub>3</sub>CN) ppm for <sup>1</sup>H NMR and at  $\delta = 77.16$  (CDCl<sub>3</sub>) and  $\delta = 1.32$  (CD<sub>3</sub>CN) ppm for <sup>13</sup>C NMR. NMR spectra are available in *Supplementary Information*. High-

resolution mass spectroscopy (HRMS) data were obtained on a Waters Xevo G2-QTOF UPLC spectrometer. On each spectrum the error (ppm) is provided as (observed mass – theoretical mass)  $\times 10^6$  / theoretical mass.<sup>59</sup> Infrared spectra were recorded using a diamond ATR on a Perkin Elmer Frontier FT-IR spectrometer. A diode array Hewlett Packart 8454A spectrophotometer was used to obtain UV-Vis spectra and to carry out kinetic studies on the photolysis reactions. Detailed procedure of kinetic studies was described in our previous works.<sup>43,60</sup> Data on NO<sup>•</sup> photorelease at 300 and 365 nm for **C** and **AC** are presented in *Supplementary Information*. Fluorescence spectra were recorded on a Jobin Yvon Fluoromax 4 Spectrofluorimeter. Quantum yield of **1b** was obtained on Hamamatsu Quantaurus-QY Absolute PL quantum yield spectrometer. Fluorescence lifetime studies were performed on a Horiba DeltaFlex TCSPC Lifetime Fluorometer with a Horiba DeltaDiode DD-300 diode and Horiba DPS-1 power supply unit. All optical measurements were carried out in quartz cuvettes.

### 5.2. Synthesis of **C** and **AC**

**4'-((9,9-dihexyl-9H-fluoren-2-yl)methoxy)-2,2':6',2''-terpyridine (2Hex-flu-CH<sub>2</sub>O-terpy) (2b)**. Powdered KOH (180.1 mg, 3.2 mmol) was added to 7 mL of DMSO. To the resulting stirred suspension was added a solution of **1b** (117 mg, 0.32 mmol) in 3 mL of DMSO. After 30 min of stirring, 4'-chloro-2,2':6',2''-terpyridine (85.9 mg, 0.32 mmol) was added to the suspension and the resulting mixture was stirred overnight at 60°C. After reaction completion, checked by TLC (SiO<sub>2</sub>, hexane (98%) – EtOAc (2%)), the reaction mixture was poured in water and neutralized with HCl. The resulting emulsion was saturated with NaCl, and extracted with CH<sub>2</sub>Cl<sub>2</sub> (5  $\times$  100mL). The organic phase was washed with pure water (5  $\times$  100mL), and evaporated under vacuum. The resulting solid was purified by column chromatography (SiO<sub>2</sub> 60 Å, neutral, Pentane/EtAc = 99:1), to lead to 182.3 mg of **2b** (yield: 95%). **<sup>1</sup>H NMR** (400 MHz, CDCl<sub>3</sub>)  $\delta$  8.72 (ddd, J = 4.8, 1.8, 0.9 Hz, 2H), 8.65 (dt, J = 8.0, 1.1 Hz, 2H), 8.21 (s, 2H), 7.88 (td, J = 7.7, 1.8 Hz, 2H), 7.74 – 7.68 (m, 2H), 7.50 – 7.43 (m, 2H), 7.38 – 7.29 (m, 5H), 5.43 (s, 2H), 1.97 (dd, J = 10.6, 6.0 Hz, 4H), 1.12 – 0.97 (m, 12H), 0.74 (t, J = 7.1 Hz, 6H), 0.64 – 0.56 (m, 4H). **<sup>13</sup>C NMR** (101 MHz, CDCl<sub>3</sub>)  $\delta$  167.11, 157.23, 156.19, 151.27, 151.03, 149.11, 141.25, 140.79, 136.90, 134.91, 127.21, 126.83, 126.33, 123.93, 122.96, 122.16, 121.47, 119.85, 119.84, 107.88, 70.48, 55.19, 40.46, 31.58, 29.80, 23.85, 22.67, 14.09. **HRMS** (ESI-TOF<sup>+</sup>) m/z: [M+H]<sup>+</sup> Anal. calc. for C<sub>41</sub>H<sub>46</sub>N<sub>3</sub>O: 596.3641. Found: 596.3638. Error: -0.50 ppm.

**[Ru<sup>III</sup>(2Hex-flu-CH<sub>2</sub>O-terpy)Cl<sub>3</sub>] (3b)**. To the mixture of 200 mg (0.34 mmol, 1 eq) of **2b** and 84.9 mg (0.38 mmol, 1.12 eq) of RuCl<sub>3</sub> $\cdot$ xH<sub>2</sub>O in 100 mL flask were added 40 ml of EtOH. The mixture was refluxed for 4 h. After cooling down to room temperature, the reaction mixture concentrated to 5 mL. The precipitate formed was filtered under reduced pressure, and thoroughly washed with EtOH until appearance of colorless drops of ethanol. The resulting dark brown solid was dried under the vacuum (181.6 mg, 67% yied). No NMR-characterization was made as compound is paramagnetic. **HRMS** (ESI-TOF<sup>+</sup>) m/z: [M-Cl+CH<sub>3</sub>CN]<sup>+</sup> Anal. calc. for C<sub>43</sub>H<sub>48</sub>N<sub>4</sub>ORuCl<sub>2</sub>: 808.2255. Found: 808.2255. Error: 0 ppm.

**[Ru<sup>II</sup>(2Hex-flu-CH<sub>2</sub>O-terpy)(bipy)Cl](PF<sub>6</sub>) (4b)**. **3b** (181.6 mg, 0.23 mmol), 2-2'-bipyridine (35.3 mg, 0.23 mmol) and LiCl (57.5 mg, 1.36 mmol, 6 eq) of were mixed in 50 mL round-bottom flask. After addition of 5.2 mL of H<sub>2</sub>O, 17.6 mL of EtOH and 0.17 mL (1.24 mmol, 5.5 eq) of Et<sub>3</sub>N, the mixture was refluxed for 4.5 h. The resulting solution was evaporated to dryness on rotary evaporator, and purified with column chromatography (Al<sub>2</sub>O<sub>3</sub> 60 Å, neutral, CH<sub>2</sub>Cl<sub>2</sub>/MeOH with gradient increasing of MeOH amount from 0% to 5%). Drying under vacuum, led to 65.4 mg of **4b** (Yield: 31%). **<sup>1</sup>H NMR** (400 MHz, CD<sub>3</sub>CN)  $\delta$  10.20 (ddd, J = 5.7, 1.6, 0.8 Hz, 1H), 8.59 (dt, J = 8.3, 1.1 Hz, 1H), 8.42 (ddd, J = 8.1, 1.4, 0.8 Hz, 2H), 8.32 (dt, J = 8.2, 1.2 Hz, 1H), 8.25 (s, 2H), 8.21 (ddd, J = 8.1, 7.5, 1.6 Hz, 1H), 7.91 (ddd,

J = 7.6, 5.6, 1.3 Hz, 1H), 7.88 – 7.79 (m, 4H), 7.71 – 7.69 (m, 1H), 7.67 – 7.58 (m, 4H), 7.46 – 7.42 (m, 1H), 7.39 – 7.34 (m, 3H), 7.23 (ddd, J = 7.6, 5.5, 1.3 Hz, 2H), 6.93 (ddd, J = 7.3, 5.7, 1.4 Hz, 1H), 5.61 (s, 2H), 2.09 – 2.03 (m, 4H), 1.05 – 0.88 (m, 12H), 0.68 (t, J = 7.0 Hz, 6H), 0.52 (dt, J = 10.1, 5.3 Hz, 4H). <sup>13</sup>C NMR (101 MHz, CD<sub>3</sub>CN) δ 165.73, 160.09, 159.69, 159.35, 157.66, 153.66, 153.50, 153.01, 152.20, 151.87, 142.63, 141.54, 137.84, 137.01, 136.14, 135.50, 128.53, 128.24, 128.18, 128.06, 127.70, 126.93, 124.57, 124.36, 124.10, 124.07, 120.99, 120.88, 111.35, 72.75, 56.13, 40.85, 32.22, 30.29, 24.72, 23.17, 14.21. ### 5.2. X-ray diffraction

Data were collected on a Rigaku XtaLAB Synergy Dualflex diffractometer using a PhotonJet X-ray source (CuK $\alpha$ ,  $\lambda = 1.54184$  Å). An Oxford Cryosystems Cryostream cooling device was used to collect data at low temperature (100(2) K). Omega scans were performed for data collection. An empirical absorption correction was applied and the structures were solved by intrinsic phasing method (ShelXT).<sup>61</sup> All non-hydrogen atoms were refined anisotropically by means of least-squares procedures on F<sup>2</sup> with ShelXL.<sup>62</sup> [2]. All the hydrogen atoms were refined isotropically at calculated positions using a riding model. The disorder of an alkyl chain was successfully modeled and the anisotropic displacement parameters were restrained by DELU and SIMU commands. Table for atomic coordinates, bond lengths and angles, and anisotropic displacement parameters are provide in *Supplementary Information* file. The structure is deposited at the Cambridge Crystallographic Data Centre (CCDC 2349350).

### 5.3. DFT computations

**A**, **C**, and **AC** were fully optimized using the Gaussian program package,<sup>63</sup> within the framework of the Density Functional Theory (DFT). The double- $\zeta$  basis set 6-31G\* was used for all atoms except the heavy ruthenium atom, for which the LANL2DZ basis set was applied to account for relativistic effects.<sup>64</sup> To be consistent with our numerous reports on Ru-NO complexes, we have selected the hybrid functional B3PW91 for the optimization. B3PW91 has been shown to outperform other hybrid functionals (*e.g.* B3LYP) and pure functionals (*e.g.* PW91) in numerous cases of ruthenium complexes, especially when back bonding ligands (like NO) are present.<sup>65,66</sup> The vibrational analyses were performed at the same level to verify that the stationary points correspond to minima on the potential energy surfaces. The UV-visible electronic spectra were then computed at the CAM-B3LYP/6-31G\* level, in the case of **C** and **AC**, for consistency with our previous investigation of [FTRuNO]<sup>3+</sup>.<sup>16</sup> This long-range corrected hybrid functional is well suited for studying molecules with delocalized excited states.<sup>67</sup> In the case of **A**, where no charge transfer takes place, the spectrum was also computed at the B3LYP/6-31G\* level, which led to a better accuracy with the experimental UV-visible data. Solvent effects were included by using the polarizable continuum model (PCM) implemented in Gaussian09 for acetonitrile ( $\epsilon = 35.688$ ). Molecular orbitals were plotted with GABEDIT 2.4.8.<sup>68</sup>
