ABSTRACT

Lipomas are among the most common benign soft tissue tumors of the body. They are commonly encountered in neck, trunk and upper extremity. Hand localization remains rare and only represents 1% to 3.8% of cases [1]. Anatomical Snuffbox (Radial Fossa) lipoma are exceptional. Management of anatomical snuffbox lipomas may be challenging due to its particular anatomy. In this article we will discuss the surgical approach to anatomical snuffbox lipomas through two cases.

Keywords: *Lipoma; anatomical snuffbox; radial fossa; tumor; radial nerve; radial artery; extensor.*

1. INTRODUCTION

Lipomas are among the most common benign soft tissue tumors of the body. They are commonly encountered in neck, trunk and upper extremity. Hand localization remains rare and only represents 1% to 3.8% of cases [1]. Anatomical Snuffbox lipoma (ASL) are exceptional. Management of anatomical snuffbox lipomas may be challenging due to its particular anatomy.

The aim of this article is to elucidate the diagnosis, characteristics and management of lipomas in this area.

2. CASE PRESENTATION

2.1 Case 1

A 71-year-old female patient with a history of vitiligo presents with a tumor of the anatomical snuffbox of the left hand, evolving for 2 years. Patient described paresthesia at the level of first web space.

Clinical examination showed a well-circumscribed, mobile soft tumor. Pseudo-Tinel sign (tingling sensation upon percussing the nerve) was positive. Posch sign (hardening and shrinking of the tumor after ice application) was positive. The X-ray of the hand was normal. Ultrasound examination suspected the diagnosis of lipoma.

Intraoperative findings revealed fatty yellowish tumor displacing the sensory branch of the radial nerve (SBRN) (Fig. 1). The histopathological examination confirmed the diagnosis of a lipoma.

2.2 Case 2

A 68-year-old male patient with no prior medical history presents with a swelling in the anatomical snuffbox of the left hand. Patient complains of paresthesia at the level of the first web space. Clinical examination reveals a soft and mobile tumor. Posch and Tinel's sign were positive. Ultrasound examination suggested a lipoma. Intraoperative findings showed a fatty tumor displacing the SBRN (Fig. 2). Histopathological examination confirmed a lipoma.

3. DISCUSSION

3.1 History

The earliest description of the term anatomical snuff box comes from a text written by the French doctor Xavier Bichat in 1850. Afterwards, this term was introduced into anatomy textbooks as the “Tabatière anatomique de Cloquet” or the anatomical snuffbox of Cloquet.

The name comes from using this depression on the dorsum of the hand to place and inhale the powdered tobacco in 19th century [2].

3.2 Anatomy

The hand is a small, densely packed area containing a complex network of tiny and delicate structures. It is highly represented in Penfield's Cortical Homunculus. The hands occupy a significant portion of both the motor and sensory cortices. This reflects the hand's delicate and

intricate anatomy [3]. Therefore, hand surgery requires a deep understanding of the hand's complex anatomy and a high level of precision.

The anatomical snuffbox is a triangular hollow on the dorsum of the hand that becomes prominently visible upon thumb abduction and wrist extension and ulnar deviation.

It is bounded radially by the tendons of the *Extensor pollicis brevis* and the *Abductor pollicis longus*, and medially by the tendon of the *Extensor pollicis longus*. The floor is formed by the base of the first metacarpal bone distally, the styloid process of the radius proximally, scaphoid and trapezium bones. Through it passes the radial artery, the superficial branch of the radial nerve (SBRN) and the cephalic vein (Fig. 3) [4].

SBRN is responsible of the innervation of the dorsum of the hand and of the two and a half digits from the radial aspect of the hand [5].

3.3 Lipoma

3.3.1 Diagnosis

3.3.1.1 Clinical aspect

Lipoma is a fatty tumor that is usually soft, mobile, painless, well-circumscribed and respects local structures [6]. Lipomas can be solitary or multiple, occurring as part of a lipomatosis.

Posch described a test to guide the clinical diagnosis of lipoma. It consists on a hardening

and shrinking of the tumor after ice application [7].

Etiology of Lipoma is still unknown, many theories including trauma, obesity and genetics are proposed [8].

3.3.1.2 Histology

Lipomas appear as well-delineated masses composed of mature adipocytes separated by thin fibrous septa in within blood vessels may be present (Fig. 4) [9].

Fig. 4. Lipoma: Histological section

3.3.1.3 Imaging

On ultrasound, lipomas generally appear as well-defined, variably echogenic masses with a homogeneous echotexture. They are typically characterized by a smooth, lobulated margin and may have an echogenic capsule surrounding them. The internal structure is usually uniform, and there is often no significant vascularity within the lipoma on Doppler imaging (Fig. 5) [10].

On MRI, lipomas typically appear as well-circumscribed, homogeneous masses with a signal intensity similar to subcutaneous fat across all imaging sequences. In STIR (Short Tau Inversion Recovery) sequences, the fat signal of lipomas is suppressed, which helps in differentiating them from surrounding tissues. Internal septa, if present, show low signal intensity on T1- and T2-weighted images [11].

3.3.1.4 Particularities in hand

Hand is an unusual localization of lipomas. They can appear anywhere on the hand, typically presenting on the palmar aspect of the hand.

Hand lipomas are usually small ranging from 3-5 cm. Giant lipomas are defined by a size greater than 5cm [12].

Due to the intricate anatomy of the hand, Lipomas can cause paresthesia, discomfort and movement restriction when they grow near a nerve, a tendon or an articular zone.

Tinel sign is a tingling elicited by tapping on a nerve proximally with paresthesia in the corresponding cutaneous territory of the nerve. It indicated nerve irritation or injury [13].

Depending on its location, lipoma can lead to: Carpal tunnel syndrome (Median nerve compression) [14,15], Guyon's canal syndrome (Ulnar nerve compression) [16], Digital nerve compression [17], Trigger finger (*flexor digitorum* tendon compression).

When the size of the lipoma exceeds a functional unit of the hand, it can cause movement impairment: limited opposition of the thumb [18], limited flexion of finger [19].

However, only one case report of anatomical snuffbox lipoma is reported [20].

Patients with ASL may experience paresthesia in the first web space / dorsal aspect of the thumb, and mechanical discomfort due to the possible tendinous compression.

3.3.2 Differential diagnosis

Hand tumors comprise a vast array of lesions including cutaneous, cystic, nervous, vascular, fibrous ... tumors. The majority of tumors in the hand are benign [6].

Some authors suggest an excision of giant lipoma ($\geq 5\text{cm}$) due to its risk of transformation [12].

The most common malignant differential diagnosis of adipocytic neoplasm is liposarcoma.

Liposarcoma is mainly seen in middle-aged adults and clinically suspected in the case of a rapidly progressive tumor that invades local structures.[21]

Fig. 5. Lipoma: Ultrasound appearance

MRI is valuable in case of malignancy suspicion. It evaluates the size and extension of the tumor to the adjacent structures. Liposarcoma contains less fat than benign Lipoma. It can contain multiple non-fatty nodules. Additionally, MRI allows for the analysis of the internal septa of the tumor: the septa of lipomas are very thin, slightly enhanced with gadolinium, corresponding histologically to fibrosis. In contrast, liposarcomas exhibit thickened septum-like septa corresponding to muscular fibers [11].

Liposarcoma can be well-differentiated or poorly differentiated. Well-differentiated liposarcoma, or atypical lipomatous tumor (ALT), can have a misleading histological appearance that resembles a lipoma-like tumor [12].

Advances in molecular biology have shed light on additional genomic alterations to differentiate benign Lipoma from ALT [22–24].

Mouse Double Minute 2 (MDM2) is a protein that plays a significant role in regulating the p53 tumor suppressor pathway. It is a crucial tumor suppressor protein involved in regulating cell cycle, apoptosis, and DNA repair. MDM2 is often overexpressed and amplified in well-differentiated liposarcoma and dedifferentiated liposarcoma. This overexpression can lead to the inhibition of p53 [22–24].

Elevated levels of MDM2 can also be associated with a more aggressive disease course and poorer prognosis. MDM2 has been targeted in therapeutic approaches and are being explored as potential treatments for liposarcoma and other cancers with MDM2 overexpression [25,26].

3.3.3 Surgical approach

In our cases, surgery is performed under locoregional anesthesia with the use of a tourniquet. General anesthesia or WALANT (Wide Awake Local Anesthesia No Tourniquet) surgery can be used.

WALANT surgery has evolved significantly in recent years. We did not use WALANT surgery due the non-availability of Epinephrine Antidote [27].

An arciform incision centered on the tumor is done.

Dissection is carried out to expose proximally the SBRN. A particular attention to not traumatize

the nervous, arterial and tendinous structures. The dissection must follow the course of the normal nerve towards the lesion from proximal and distal directions. The nerve is then protected using a surgical loop or a fine Farabeuf retractor after its complete identification and exposure.

4. CONCLUSION

Anatomical snuffbox lipomas are exceptional. Surgical excision must be meticulous to avoid damaging the surrounding anatomical structures. We recommend the use of magnification to preserve nerve structures and the use of small and precise instruments specially scissors (such as Steven's scissor) allowing delicate and fine dissection. Blunt dissection can be useful in some cases. These recommendations can also be applied for tendinous and vascular structures.
