**HAL** is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers. L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

## Introduction

Body and head movements require compensatory eye adjustments to maintain a stable visual field. Our previous findings from *in vitro* experiments on Xenopus laevis revealed that during locomotion, such gaze stabilization is produced not only by classical visuo-vestibular reflex feedback but also by feed-forward signaling from the spinal locomotor central pattern generator (CPG) itself. However, the latter's precise influence on oculomotor behavior remains poorly understood. Here, we aimed to provide a fine *in vivo* quantification of compensatory eye movements produced by the locomotor CPG efference copy before metamorphosis, during larval undulatory swimming. Moreover, we studied in the same stages the development of visuo-vestibular reflexes in order to explore the relationship between the maturation of the efference copy signal and that of visuo-vestibular reflexes. Our results show that a co-maturation of the two systems ensures a high degree of compensatory eye movement at all developmental stages.

# **Materials and Methods**

Recordings of locomotor and oculomotor behavior: Movement patterns of Xenopus tadpoles (stages 40 to 58), which were fixed by the head on sylgard inside a petry dish, were recorded by a high frequency camera placed above. 3 angles from the body axis were measured from video recordings using home-made software: i, tail angle; ii, left eye angle; iii, right eye angle.

*Visuo and vestibular stimulation:* With the same recording setup, the petry-dish was placed on a turn (vertical and horizontal axis) table in order to stimulate vestibular reflexes. A small drum centered on the table provided visual stimuli to induce optokinetic reflexes.
