David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 2/82

Why abstract interpretation

Over-approximations of behavior of programs. (And also under-approximations.)

- ▶ Prove that programs satisfy specifications.
- Study program behavior.
- Enable optimizations in compilers.

David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 3/82

Abstract interpretation in a nutshell

- What can happen in the program: R (undecidable as per Rice's theorem) What we compute: R *♯*
- **Soundness:** R *⊆* R *♯*

Program takes a step from R to R *′* We compute: R *♯ ′*

Limits of this tutorial

Vast topic

Will skim over many aspects

Focus on **numerical abstraction** because easier to visualize (But will talk about other kinds of abstraction)

Will not cover underapproximations Will not cover termination analysis

David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 5/82

Rule of signs

Abstract integers into *{***-***,* **0***,* **+***}*. To each $z \in \mathbb{Z}$, associate $s(z) = \cdot$ if $z > 0$, $s(z) = -$ if $z < 0$, $s(0) = 0$.

⊤ = *{***-***,* **0***,* **+***}*

Refinement for known constants

$$
\begin{array}{c|c}\nx & x+1 \\
\hline\n-\{-,0\} \\
0 & + \\
+ & + \\
\end{array}
$$

David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 9/82

From variable to state

Finite number of variables: abstract each variable separately. Concrete state: (x_1, \ldots, x_n) Abstract state: $(\alpha(x_1), \ldots, \alpha(x_n))$

Transform concrete *→* into abstract *→[♯]* e.g. $(x, y) \xrightarrow{y:=x+y} (x', y')$ defined by $(x, y) \rightarrow (x, x+y)$ $(x^{\sharp}, y^{\sharp}) \xrightarrow{y=x+y} (x^{\sharp}, y^{\sharp'})$ for all $y^{\sharp'}$ in the plus abstract table. e.g. (**+***,***-**) *→[♯]* (**+***,* **+**) (**+***,***-**) *→[♯]* (**+***,* **0**) (**+***,***-**) *→[♯]* (**+***,***-**)

Control locations

The control location is just another variable, often not abstracted.

If instruction from control location p to control location p *′* is $y := x + y$ $(p, x, y) \rightarrow (p', x', y')$ and proceed as above

David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 11/82

Simple data abstractions

Abstraction To each s *∈* Σ attach *α*(s) *∈* Σ *♯* . To each $S \subseteq \Sigma$, define $\alpha(S) = \{\alpha(s) \mid s \in S\}.$ Replace $\mathcal{P}(\Sigma)$ (infinite) by $\mathcal{P}(\Sigma^{\sharp})$ (finite).

Soundness $\sigma \to \sigma' \implies \alpha(\sigma) \to^{\sharp} \alpha(\sigma')$ Most precise: $\sigma^{\sharp} \rightarrow^{\sharp} \sigma^{\sharp'}$ iff $\exists \sigma, \sigma' \; \alpha(\sigma) = \sigma^\sharp \wedge \alpha(\sigma') = \sigma^{\sharp'} \wedge \sigma \to \sigma'$

David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 12 / 82

Reachability analysis

Reachable states for *→[♯]* are computable, because finite state, if *→[♯]* is decidable.

Worklist graph traversal algorithm:

- ▶ start from initial state σ_0^{\sharp} $_{0}^{\sharp},$ add σ_{0}^{\sharp} $\frac{1}{0}$ to worklist
- ▶ until worklist empty, take *σ ♯* from worklist, if not marked as "reached", mark it and add all its successors to worklist

David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 13 / 82

Note on algorithmic results

Reachability in the abstract is uniquely defined.

The above algorithm computes the same set of abstract states regardless of worklist ordering.

Choices of ordering \implies cost of analysis issue only (e.g. order worklist using **reverse postorder**)

David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 14/82

Collecting by program point

We collect abstract states $(p,\textit{v}_1^{\sharp})$ $\frac{1}{1}, \ldots, \nu_n^{\sharp}$). We can group them by control location (program point) p.

For each program point, compute a set of reachable abstract states (v *♯* 1 *, . . . ,* v *♯* n) where v1*, . . . ,* vⁿ *∈ {***-***,* **0***,* **+***}*.

In other words, to each p , associate $R^{\sharp}(p) \subseteq \{\text{-}, \textbf{0}, \textbf{+}\}^n$ similar to collecting $R(p)$ reachable program states at control location p.

David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 15/82

Plan

Introduction

Vanilla: finite lattices

Mapping to finite state Smaller lattices Invariant inference algorithm Examples from the real world

Coffee: paths and direction

Fudge: widenings

Blackcurrant: accelerated solving

Fiore di latte: conclusion

David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 16 / 82

Independent abstraction between variables

Instead of any $R^{\sharp}(p) \subseteq {\{\text{-},\text{0},\text{+}\}}^n$ consider only Cartesian products $\prod_{i=1}^{n} R^{\sharp}(p, i)$ where $R^{\sharp}(p, i) \subseteq \{-, 0, +\}$

In other words: $R^{\sharp}(p)$ is either

- ▶ *⊥* "location is unreachable"
- ▶ a map from 1... *n* to $\mathcal{P}(\{\text{-}, \text{0}, \text{+}\}) \setminus \{\}$

"Smashed bottom" = "if one variable cannot contain a value, then the instruction is unreachable"

David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 17/82

Difference between dependent and independent abstraction

1:
$$
y := x
$$
\n2: if $x = 0$:\n3: if $y \neq 0$:\n4: here

Variables: x*,* y

Dependent R *♯* (2) = *{*(**-***,***-**)*,*(**0***,* **0**)*,*(**+***,* **+**)*}* $R^{\sharp}(3) = \{ (0, 0) \}$ $R^{\sharp}(4) = \emptyset$

Independent $R^{\sharp}(2) = \{-, \mathbf{0}, \mathbf{+}\} \times \{-, \mathbf{0}, \mathbf{+}\}$ $R^{\sharp}(3) = \{0\} \times \{-, 0, +\}$ $R^{\sharp}(4) = \{0\} \times \{-, +\}$

Powerset lattice

To each program location and each variable, attach a nonempty subset of *{***-***,* **0***,* **+***}*.

David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 19 / 82

A simpler lattice

To each program location and each variable, attach an element of this lattice L *♯*

 n variables, take "smashed bottom" product lattice $\left(L^\sharp\right)^n$ (one \bot = \bot everywhere)

David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 20 / 82

What this means, variable per variable

Concretization function

γ maps a lattice element to the values it represents. *γ*(*⊤*) = Z *γ*(**-**) = (-∞, 1] *γ*(**0**) = {0} *γ*(**+**) = [1, +∞)

Abstraction function

 $\alpha(\emptyset) = \perp$ For $S \subseteq (-\infty, 1], S \neq \emptyset, \alpha(S) = -$ For $S \subseteq [1, +\infty)$, $S \neq \emptyset$, $\alpha(S) = +$ $\alpha({0}) = 0$ $\alpha(S) = \top$ otherwise

Abstraction for a vector of variables

Concretization *γ*v(l *♯* $\mathbf{X}_{1}^{\sharp}, \ldots, \mathbf{X}_{n}^{\sharp}$ = $\{x_{1}, \ldots, x_{n} | \forall i x_{i} \in \gamma(\mathbf{X}_{i}^{\sharp})\}$ i)*}*

Abstraction $\alpha_{\rm v}(A) = \{a_1^\sharp$ $a_n^{\sharp}, \ldots, a_n^{\sharp}\}$ $a_i^{\sharp} = \bigsqcup_{x_1,\ldots,x_n \in A} \alpha(x_i)$

α, γ form a **Galois connection**.

David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 22 / 82

David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 23 / 82

An algorithm for inferring invariants

Worklist graph traversal algorithm:

- ▶ start from initial state $(\rho_0, \sigma_0^{\sharp}$ 0 $\Big),$ set $R^\sharp(p_0):=\sigma_0^\sharp$ $\frac{1}{0}$, add p_0 to worklist
- \blacktriangleright until worklist empty, take p in worklist; for each transition *p* $\stackrel{op}{\longrightarrow}$ *p*′:
	- ▶ compute $y^{\sharp} := R^{\sharp}(p') \sqcup op^{\sharp}(R^{\sharp}(p))$ ▶ if $y^{\sharp} \neq R^{\sharp}(p')$, set $R^{\sharp}(p') := y^{\sharp}$ and add p' to the worklist

David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 24 / 82

Termination and soundness

Termination

At every iteration, at least one $\mathcal{R}^{\sharp}(p)$ increases, within a finite domain

Soundness

When it terminates, for any transition $\rho \stackrel{op}{\to} p' \colon op^{\sharp} (R^{\sharp}(p)) \sqsubseteq (R^{\sharp}(p')).$ $\textsf{Consequence: if } (\rho, \sigma) \stackrel{op}{\rightarrow} (\rho', \sigma'), \alpha(\sigma) \in R^{\sharp}(\rho), \text{ then } \alpha(\sigma') \in R^{\sharp}(\rho').$

In other words, the $R^{\sharp}(p)$ define inductive invariants.

David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 25 / 82

Optimality

Assuming

- ▶ op*[♯]* is monotone
- ▶ *⊔* computes least upper bound

Then this algorithm computes the least fixed point. $R^{\sharp}(p)$ everywhere for least inductive invariant expressed by α .

David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 26/82

Optimal only among inductive invariants

i = 6;
\n**do** { i –=2; } **while** (i
$$
\neq
$$
 0);
\n*i* := *i* – 2; *i* \neq 0
\n
$$
p_1 \xrightarrow{i := 6} \begin{cases} 1 \\ p_2 \xrightarrow{i := 0} p_3 \end{cases}
$$

Concrete reachable states at p_2 : $\{6, 4, 2\}$. *α*(*{*6*,* 4*,* 2*}*) = *{***+***}*

Abstract reachable states at p_2 : $\{-$, 0, + $\}$ (because 1 *→ −*1, 1 abstractly reachable but not concretely)

Plan

Introduction

Vanilla: finite lattices

Mapping to finite state Smaller lattices Invariant inference algorithm

Examples from the real world

- Coffee: paths and direction
- Fudge: widenings
- Blackcurrant: accelerated solving
- Fiore di latte: conclusion

David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 28 / 82

Constant propagation

David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 29 / 82

Example: CompCert

CompCert (2022 ACM System Software Award)

"Value analysis" computes fixed point in a (complicated) finite lattice with points-to analysis:

- \blacktriangleright constant propagation
- local strength reduction of instructions with known parameters

Distinguishes pointers

- ▶ points into local stackframe, at known or unknown offset
- points out of local stackframe
	- ▶ points into global variable, at known or unknown offset

"Is matched by"

CompCert has predicates:

- ▶ pointer *p* is matched by abstract pointer p^{\sharp} [according to block classification C]
- ▶ pointer *v* is matched by abstract value v^{\sharp} [according to block classification C]

 $\gamma(\mathbf{v}^{\sharp}) = \{ \mathbf{v} \mid \mathsf{vmatch}(C,\mathbf{v}^{\sharp},\mathbf{v}) \}$

Proofs that if $\forall i$, *vmatch*(*C*, *v_i*, v_i^{\sharp} i), $vmatch(C, op(v_1, \ldots, v_n), op^{\sharp}(v_1^{\sharp})$ $\begin{pmatrix} \sharp \\ 1, \ldots, \check{v}_n^{\sharp} \end{pmatrix}$

Fixed-point proof: if fixed-point iterations converge within N steps, then the result is inductive.

David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 31/82

Example: forward dataflow analysis

Finite set P_1, \ldots, P_n of predicates over program states = subsets of program states Abstract element: S *[♯] ⊆ {*1 *. . .* n*}* $\gamma(S^{\sharp}) = \bigcap_{i \in S^{\sharp}} P_i$

 $S^\sharp\sqsubseteq S^{\sharp'}$ iff $S^{\sharp'}\subseteq S^{\sharp}$

Note: opposite direction, dataflow analysis usually presented with opposite ordering as abstract interpretation

Coffee: paths and direction

Plan

Introduction

Vanilla: finite lattices

Mapping to finite state Smaller lattices Invariant inference algorithm Examples from the real world

Coffee: paths and direction

David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 33 / 82

Coffee: paths and direction

Convex polyhedra

David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 34 / 82

Coffee: paths and direction

Convex polyhedra: widening

(Possibility: thresholds = linear inequalities found in program)

David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 35 / 82
Convex polyhedra

Two overapproximations: the abstraction + the widening!

David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 36 / 82

Note about Galois connections

 $\alpha(S)$ is the **best overapproximation** of S in the abstract domain.

A disc has no best overapproximation as a convex polyhedron.

Cannot define *α* in general.

"Constructive" views of abstract interpretation often just define *γ*.

David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 37 / 82

Absolute value

$$
y = abs(x);
$$

if (y >= 1) {
assert (x != 0);
}

David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 38 / 82

Intervals

Intervals:

$$
/* -1000 \le x \le 2000 */
$$
\nif $(x < 0) y = -x$; $\frac{1}{x} 0 \le y \le 1000 */$ \nelse $y = x$; $\frac{1}{x} 0 \le y \le 2000 */$ \nif $(y >= 1) \{ \frac{1}{x} 1 \le y \le 2000 * \frac{1}{x} \text{ assert } (x != 0); \frac{1}{x} -1000 \le x \le 2000 \text{ !} \}$

David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 39 / 82

Polyhedra

Branch $x \geq 0$

David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 40 / 82

Other branch

Branch x *<* 0

David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 41/82

After first test

 $y = |x|$ = union of the two red lines. Not a convex. Convex hull = pink polyhedron

David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 42 / 82

At second test

Note: includes $(x, y) = (0, 1)$.

David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 43 / 82

Disjunction

Possible if we do a union of two polyhedra:

$$
\begin{array}{l}\blacktriangleright \ x \geq 0 \land y = x \\
\blacktriangleright \ x < 0 \land y = -x\n\end{array}
$$

But with n tests?

David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 44 / 82

Sources of imprecision

- ▶ Need to distinguish **each path** and compute one polyhedron for each.
- \blacktriangleright But 2ⁿ paths.
- ▶ **Too costly** if done naively.
- ▶ Use SMT-solving to distinguish individual paths (as e.g. PAGAI tool, see [Henry's PhD thesis\)](https://theses.hal.science/tel-01485202)

David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 45 / 82

Forward analysis, reminder

Compute I_p^{\sharp} at all position p in forward direction (next-state) $\gamma(\it I_p^{\sharp})$ contains all memory/variable states reachable at control position p

To prove that an undesirable control position p is unreachable: check I *♯* ^p = *⊥*

Forward / backward analysis

Compute I_p^{\sharp} at all position p by combined forward/backward

We want:

 $\gamma(\it I_p^{\sharp})$ contains all memory/variable states at control position p reachable (from program start) and co-reachable from error location

Compute back from error location

$$
x * false * /\nif (x >= 0)\ny = x; \nelse\ny = -x; \nif (y >= 1) { \n assert(x != 0); \n /* x = 0 \land -x ≥ 1 ≡ false * /
\n assert(x != 0);
\n /* x = 0 \land y ≥ 1 */
\n}
$$

 $\sqrt{\frac{1}{2}}$

David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 48 / 82

Forward / backward

More generally: compute forward from program start, then backward from error location, possibly forward again.

Forward restricted to postcondition $y^{\sharp'} = \text{forward}(op, x^{\sharp}, x^{\sharp'})$

$$
\forall x, x', x \in \gamma(x^{\sharp}) \land x \xrightarrow{op} x' \land x' \in \gamma(x^{\sharp'}) \implies x' \in \gamma(y^{\sharp'})
$$

Backward restricted to precondition $y^{\sharp} =$ backward $(op, x^{\sharp'}, x^{\sharp})$

$$
\forall x, x', x' \in \gamma(x^{\sharp'}) \land x \xrightarrow{op} x' \land x \in \gamma(x^{\sharp}) \implies x \in \gamma(x^{\sharp})
$$

Why restrictions to precondition/postcondition

(See optional parameter in e.g [APRON](https://antoinemine.github.io/Apron/doc/))

 $\text{backward}(op, x^{\sharp \prime}, x^{\sharp}) = \text{backward}(op, x^{\sharp \prime}) \sqcap x^{\sharp}$ would be valid. But less precise!

Precondition: $x \in [0, 3]$, postcondition \top , instruction: assume $x \leq y$. Backward analysis of assume x *≤* y from *⊤* in the interval domain: *⊤*, intersection with x *∈* [0*,* 3] is x *∈* [0*,* 3]

Backward analysis knowing $x \in [0, 3]$ yields $x \in [0, 3] \wedge y \in [0, \infty)$

Fudge: widenings

Plan

Introduction

Vanilla: finite lattices

Mapping to finite state Smaller lattices Invariant inference algorithm Examples from the real world

Coffee: paths and direction

Fudge: widenings

Blackcurrant: accelerated solving

Fiore di latte: conclusion

David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 51/82

Bounded interval analysis

Elements of the lattice: pairs of integers (a, b) , $a \leq b$, or \perp

$$
\alpha(S) = (\min S, \max S) \gamma((a, b)) = a \dots b
$$

$$
(a, b) \sqsubseteq (a', b') \text{ is } \le a \le b \le b'
$$

(note: \sqsubseteq a kind of decidable inclusion, we need
 $l \sqsubseteq l' \implies \gamma(l) \subseteq \gamma(l')$)

Finite height lattice, largest [MIN_INT*,* MAX_INT]

David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 52 / 82

On an example

First iteration: $[0, 0]$ goes through $i < 10$, $[1, 1]$ at line 3, \sqcup at line 2 yields [0*,* 1] Ensuing iterations at line 2: [0*,* 2], [0*,* 3], [0*,* 4], …, [0*,* 10]

David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 53 / 82

Objection

What if we have to iterate to *⊤* = [MIN_INT*,* MAX_INT]?

 2^{31} or even 2^{63} iterations.

Need a way to accelerate!

David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 54 / 82

Standard widening operator on intervals

Ascending right bounds [0*,* 1], [0*,* 2]…try [0*,* MAX_INT] (or [0*,* +*∞*)).

[0*,* MAX_INT] indeed an inductive invariant for $i = 0$: **while** (**i** < 10) { $i + +$: }

Obviously not the strongest! (which is [0*,* 10])

David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 55 / 82

Thresholds

(Reinvented several times)

- ▶ Notice (syntactically or by dynamic recording) that there is a i < 10 \equiv i < 9 comparison.
- ▶ Widen to 9 then 10 instead of MAX_INT

Gets i *∈* [0*,* 10]

Narrowing step

If at location 2, we come from 1 or 3:

- ▶ either we start the loop, $i \in [0, 0]$
- either we have already gone through the loop, $2 \rightarrow 3 \rightarrow 2$, thus executing $i < 10$; $i := i + 1$ from $i \in [0, MAX_INT]$: getting i *∈* [1*,* 10]
- Thus at 2, i must be in [0*,* 10]!

A more mathematical view

We have an inductive invariant *S*: $f(S) \subset S$.

 f (concrete semantics) is monotone (more states in precondition, more states in the outcome): $f(f(S)) \subset f(S)$ $f(S)$ is also an inductive invariant, and maybe $f(S) \subseteq S!$

David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 58 / 82

Narrowing works

$$
i = 0;
$$
\nwhile (true) { $1 - \frac{i := 0}{\sqrt{\frac{i + 1}{i + 1}}}$, $2 \frac{i := i + 1}{\sqrt{\frac{i - 10}{i + 1}}}$, $5 \frac{i \ge 10}{\sqrt{\frac{i - 10}{i + 1}}}$, $6 \frac{i \ge 10}{\sqrt{\frac{i - 10}{i + 1}}}$

Widening: i *∈* [0*,* MAX_INT] Narrowing: i *∈* [0*,* 9]

David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 59 / 82

Narrowing is foiled

Because of the self-loop, the "next iteration" operator satisfies $S \subseteq f(S)$ and thus narrowing never narrows.

David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 60 / 82

Wider precondition

No iterations needed, we have the invariant [0*,* 9] straight from the start!

Non-monotonic behavior

Precondition $i = 0$: analysis computes $i \in [0, MAX_INT]$ Precondition $i \in [0, 9]$: analysis computes $i \in [0, 9]$

A more precise precondition leads to a less precise analysis result!

Counter-intuitive for end users.

Fudge: widenings

(Other cause of non-monotonic behavior)

A long time ago in a galaxy far, far away.

David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 63 / 82

(Other cause of non-monotonic behavior)

A long time ago in a galaxy far, far away. In the **[Astrée analyzer](https://www.astree.ens.fr/)**.

```
Rewriting system + intervals v \in [0, 10]y \rightarrow x + 1z \rightarrow 3 \times y
```
Straight computation for $t := z + 1$ yield \top . Full rewriting of $t := z + 1$ yields $t := 3(x + 1) + 1$, yields \top . Partial rewriting (forget $y \rightarrow x+1$) yields $t := 3y + 1$, yields t *∈* [1*,* 31].

Partial propagation of information for efficiency *→* **non-monotonic** behavior.

Plan

Introduction

Vanilla: finite lattices

- Mapping to finite state Smaller lattices Invariant inference algorithm Examples from the real world
- Coffee: paths and direction
- Fudge: widenings
- Blackcurrant: accelerated solving

Fiore di latte: conclusion

David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 64 / 82

The problem on which narrowing failed

1 i = 0 ; 2 w hi l e (t r u e) { 3 i f (∗) { 4 i + + ; 5 i f (i >= 1 0) 6 i = 0 ; 7 } 8 }

Write the interval analysis symbolically (forget handling of possibly empty intervals): $[-l_1, h_1] = [0, 0],$ $[-l_2, h_2] = [-\max(l_1, l_8), \max(h_1, h_8)], [-l_5, h_5] = [-(l_2 - 1), h_2 + 1],$ [*−*l6*,* h6] = [*−*l5*,* min(h5*,* 9)], [*−*l7*,* h7] = [*−* max(l6*,* 0)*,* max(h6*,* 0)], $[-l_8, h_8] = [-\max(l_2, l_7), \max(h_2, h_7)].$

David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 65 / 82

In a nutshell

$$
l_2 = max(0, max(l_2, max(l_2 - 1, 0)))
$$

$$
h_2 = max(0, max(h_2, max(min(h_2 + 1, 9), 0)))
$$

(separated equations on this simple examples, in general not)

Any solution in (l_2, h_2) yields an inductive invariant in intervals. How to solve such equations? (Outside of SMT-solving them.)

Descending policy iterations

(Many publications in E. Goubault's group, see also P.L. Garoche, P. Roux)

"min(a, b) must be equal to either a or b "

$$
h_2 = \max(0, \max(h_2, \max(\min(h_2 + 1, 9), 0))) \text{ can become}
$$

\n
$$
h_2 = \max(0, \max(h_2, \max(h_2 + 1, 0))) \colon h_2 = +\infty \text{ as only solution}
$$

\n(no real solution)

 \blacktriangleright h_2 = max(0, max(h_2 , max(9,0))): h_2 = 9 as only solution Thus $h_2 = 9$ as only solution!

David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 67/82

Heuristic for descending iterations

- $h_2 = \max(0, \max(h_2, \max(h_2 + 1, 0)))$ and
- $h_2 = \max(0, \max(h_2, \max(9, 0)))$ correspond to the original program with one guard (test) over-approximated:
- i *<* 10 means the interval for i
	- \triangleright either is the same (the bound has no effect, the test is always taken)
	- \triangleright or is truncated by 9

Heuristic: tests are likely to be useful, not always taken, thus try the second case first!

David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 68 / 82

Solving the simplified system

Ordinary abstract interpretation

Run a regular abstract interpreter on a simplified program (simpler interpretation of guards/tests).

Exact solving

Least solution of $h_2 = \max(0, \max(h_2, \max(h_2 + 1, 0)))$: by monotonicity, least solution of

$$
h_2 \ge 0
$$

\n
$$
h_2 \ge h_2
$$

\n
$$
h_2 \ge h_2 + 1
$$

Solve by linear programming: no real solution.

David Monniaux (CNRS / VERIMAG) Flavors of abstract interpretation April 9, 2024 69 / 82

Downward iterations

Assume we solve and get $h_2 = +\infty$. Evaluate max(0, max(h_2 , max(min($h_2 + 1, 9$), 0))) with $h_2 = +\infty$, get 9. The solution of the simplified system is not a solution of the original system.

Flip the choice for min to a number yielding a lower value in the current solution!

Downward policy iteration

"Strategy" or "policy" iteration by similarity with approach for solving Markov decision processes and games.

- \triangleright Pick argument for min or even inf occurring in the equation system (= simplify tests and reductions).
- \triangleright Solve the simplified problem exactly or approximately.
- \blacktriangleright Replace the solution into the original problem, check if solution.
- \blacktriangleright If not solution, switch to other choices for min or inf and restart.

All intermediate systems over-approximate the original, thus their solved solutions over-approximate the least solution of the original system.

Can stop at any point and remain sound!

Treatment of relational abstract domains

$$
x \le A
$$

$$
y \le B
$$

$$
x + y \le C
$$

 $\mathsf{can} \text{ be reduced with e.g. } x + y \leq A + B \text{ thus } C' = \mathsf{min}(C, A + B)$

min or inf operations occur explicitly or implicity in bound computations (e.g. dual linear programming = take a minimum over Farkas witnesses)

Also to be treated by downward policy iteration!

Take-home message

Downward policy iteration

- ▶ computes downward sequence of simpler fixed-points
- sequence may be stopped at any time, producing a valid inductive invariant
- \triangleright not guaranteed to converge to least fixed-point (= least inductive invariant in the abstract domain) but often does
- \triangleright good heuristic choice of initial "policy" (choice of min-argument) matters

Max-policies

$$
h_2=\mathsf{max}(0,h_2,\mathsf{min}(h_2+1,9))
$$

Each max operator has value one of its arguments, add also *−∞*

Start with $h_2 = -\infty$.

Max-policy iterations

(Many publications from H. Seidl)

- 1. $h_2 = -\infty$ replaced in max(0, h_2 , min($h_2 + 1$, 9)): max(0, $-\infty$, min($-\infty$ + 1, 9) = 0 > $-\infty$, pick 0 (2nd argument) instead
- 2. $h_2 = 0$ replaced in max(0, h_2 , min($h_2 + 1$, 9)): $max(0, 0, min(0 + 1, 9)) = 1 > 0$, pick 1 (3rd argument) instead
- 3. $h_2 = min(h_2 + 1, 9)$; solve for least solution and get $h_2 = 9$

Max-policy iterations in a nutshell

Replace a least fixed-point computation by an ascending sequence of fixed-point computations

Must go on until no "improvement" possible.

Converges to strongest inductive invariant in domain / least fixed point

Another example

```
i = 0;
while (true) {
  i + +:
  if ( i = 10 )
     i = 0;}
```
Widening to +*∞*, narrowing does not help.

Idea: replace an invariant computation over the full program by a sequence of invariant computations over partial programs. Partial program = subset of control-flow graph

Introduction

Vanilla: finite lattices

Mapping to finite state Smaller lattices Invariant inference algorithm Examples from the real world

- Coffee: paths and direction
- Fudge: widenings

Blackcurrant: accelerated solving

Fiore di latte: conclusion

An intriguing problem

Given a class of programs (with unreachability assertions) and an abstract domain, is the existence of inductive invariants suitable for proving unreachability decidable?

E.g. for template polyhedra, intervals etc. decidable because existence of invariants expressible in a decidable arithmetic theory (real closed fields, Presburger…)

How about general convex polyhedra, for linear programs? (if nonlinear: [undecidable\)](https://arxiv.org/abs/1709.04382)

Fiore di latte: conclusion

More generally: relative completeness

Design methods that will not "lose" inductive invariants if they exist in the abstract domain.

E.g. [certain analyses on abstractions of functions/maps/arrays can be](https://hal.science/hal-03214475/) [expressed as syntactic transformation without losing completeness](https://hal.science/hal-03214475/)

Conclusion

- devil in the details
- widenings lead to non-monotonicity and brittleness
- ▶ rough lattices (intervals…) can regain precision by splitting along paths and/or using forward/backward
- exact methods in some cases
