The convergence of atomic spectroscopy, MEMS cell technologies and integrated photonics has led to the deployment of high-precision chip-scale atomic devices [1]. In this talk, we will present in-progress studies at FEMTO-ST Institute, France, for the development of microcell-based microwave and optical atomic clocks, with enhanced stability performances.

In the first part, we will talk about the demonstration of CPT-based microwave cell clocks with stability at 1 day in the low  $10^{-12}$  range [2], made possible thanks to the combination of advanced Ramsey-based interrogation sequences [3] and cells built with low gas permeation windows [4-5].

In the second part, we will discuss the in-progress development of a microcell-based optical frequency reference based on the two-photon transition of Rb atom at 778 nm. An encouraging short-term stability of  $3 \times 10^{-13}$  at 1 s and  $3 \times 10^{-14}$  at 100 s has been recently achieved [6]. Future studies will be briefly discussed.
