13 **ABSTRACT**

14 Porous solids with highly microporous structures for effective carbon dioxide uptake and  
15 separation from mixed gases are highly desirable. Here we present the use of polyethylene  
16 glycol (20,000 g/mol) as a soft template for the simple and rapid synthesis of a highly  
17 microporous Cu-BTC (denoted as HKUST-1). The polyethylene glycol-templated  
18 HKUST-1 obtained at room temperature in 10 min exhibited a very high Brunauer-  
19 Emmett-Teller (BET) surface area of 1904 m<sup>2</sup>/g, pore volume of 0.87 cm<sup>3</sup>/g, and average  
20 micropore size of 0.84 nm. However, conventional HKUST-1 exhibits a BET surface area  
21 of 700-1700 m<sup>2</sup>/g. X-ray powder diffraction and electron microscopy analysis confirm the  
22 formation of highly crystalline and uniform octahedral particles with sizes ranging from  
23 100 nm to 120 μm. Adsorption isotherms recorded at temperatures between 273 K to 353  
24 K and pressures up to 40 bar revealed a more favorable adsorption capacity of HKUST-1  
25 for CO<sub>2</sub> vs. CH<sub>4</sub> and N<sub>2</sub> (708 mg (CO<sub>2</sub>)/g, 214 mg (CH<sub>4</sub>)/g and 177 mg (N<sub>2</sub>)/g at 298 K and  
26 40 bar). The Langmuir isotherm model and isosteric heats of adsorption were evaluated.  
27 The CO<sub>2</sub> interaction at PEG-templated HKUST-1 is physical, exothermic and spontaneous  
28 with  $\Delta H^\circ = -6.52$  kJ/mol,  $\Delta S^\circ = -13.72$  J/mol,  $\Delta G^\circ = -2.43$  kJ/mol at 298 K at 40 bar. The  
29 selectivities in equimolar mixtures were determined as 53 and 24, respectively, for CO<sub>2</sub>  
30 over N<sub>2</sub> and CH<sub>4</sub>. CO<sub>2</sub> adsorption-desorption tests reveal high adsorbent reusability. The  
31 cost-effective and quickly prepared PEG-templated HKUST-1 demonstrates high efficacy  
32 as a gas adsorbent, particularly in selectively capturing CO<sub>2</sub>.

33 **Keywords:** Metal organic framework; polymer templated MOF; PEG templated synthesis;  
34 carbon dioxide adsorption; methane adsorption.

## 1. Introduction

Global warming linked to the accumulation and generation of gases such as carbon dioxide and methane is one of the most significant problems facing the international community. The concentration of CO<sub>2</sub> emissions in the atmosphere has significantly increased in the past century from 280 to 400 ppm, and is expected to increase to 570 ppm by 2100. Likewise, CH<sub>4</sub> emissions have increased by more than double during this time [1-3]. The development of economical methods to selectively capture and adsorb CO<sub>2</sub> and CH<sub>4</sub> from the environment is necessary to alleviate the global burden. This is particularly relevant for flue gases where selective CO<sub>2</sub> capture and uptake is required in the presence of uncombusted N<sub>2</sub> [4]. The development of materials for storage/adsorption of CO<sub>2</sub>, CH<sub>4</sub> and N<sub>2</sub>, separation of CO<sub>2</sub>/N<sub>2</sub> from flue gas, and separation of CO<sub>2</sub>/CH<sub>4</sub> from natural gas, is essential to help combat greenhouse gas emissions [4]. Several studies on the storage and separation of CO<sub>2</sub>, CH<sub>4</sub> and N<sub>2</sub> gases have been reported involving the use of commonly-employed porous adsorbents such as zeolites [5] and activated carbon [6]. Both zeolites and activated carbons are highly developed nanostructured porous structures that are widely used as commercial adsorbents and filters to remove contaminants including volatile organics and as well as waste gases. Microporous activated carbon, for example, has been used to effectively adsorb carbon dioxide due to its high porosity, some selectivity, and low moisture sensitivity [6, 19]. Activated carbons are also economically affordable [6, 19]. The adsorption of CO<sub>2</sub> was investigated to study the equilibrium and kinetic behavior utilizing activated carbons; and a maximum adsorption capacity of 10 mmol/g (440 mg(CO<sub>2</sub>)/g) was reported for activated carbon (GCA-1240) [30].

Porous materials such as zeolites and activated carbon have a relatively high energy requirement for regeneration, and relatively limited adsorption capacities as well as selectivity for CO<sub>2</sub> [7, 8]. Metal organic frameworks (MOFs) are a new class of crystalline and porous materials with multi-dimensional networks formed by coordination bonds between inorganic clusters (metal ions) and diverse organic linkers (ligands) [9-11]. Their unique architectures generally offer high specific surface area and pore volume, and the possibility to tune chemical functionality and pore structure. Their attractive textural properties have resulted in them being extensively studied over the last decade for the storage and adsorption of gases such as CO<sub>2</sub> and CH<sub>4</sub>, for gas separations, and for catalysis [12-15]. Amongst the MOFs, Cu<sub>3</sub>(BTC)<sub>2</sub>, (also known as MOF-199, Cu-BTC or HKUST-1) [16] is a 3-D face-centered cubic (fcc) crystal MOF formed via the association of

68 dimeric cupric carboxylate units with benzene-1,3,5-tricarboxylate. The cubic structure  
69 consists of octahedral cages that share paddlewheel units to define larger micropores of  
70 about 0.9 nm in diameter and smaller tetrahedral side pocket ultramicropores of about 0.5  
71 nm in diameter. The small pores are linked to the main channels via triangular windows of  
72 about 0.35 nm diameters [17]. Cu-BTC (HKUST-1) MOF with its octahedral structure  
73 offers benefits for gas adsorption linked to its a large BET surface area, various micropore  
74 sizes, high porosity, high crystallinity, and the Lewis<sup>s</sup> acidity of its open metal sites [18,  
75 19].

76 The HKUST-1 MOF with specific BET surface areas ranging between 692 and 1656 m<sup>2</sup>/g  
77 can be synthesized by numerous methods; including, solvothermal [16], ultrasonic  
78 irradiation [20], microwave [21] and mechanochemical [22] methods. The high  
79 temperature syntheses and/or organic solvents used in classical solvothermal methods are  
80 commonly employed and are beneficial for high crystallinity and purity of the product. The  
81 use of high temperatures up to 523 K, the long crystallization times to achieve practical  
82 yields, typically beyond 1 day, and the presence of significant amounts of CuO and Cu<sub>2</sub>O  
83 by-products are however undesirable [23, 24]. Nevertheless, rapid room temperature  
84 synthesis of HKUST-1 nanoparticles in 1 hour with a moderate BET surface area of 1346  
85 m<sup>2</sup>.g<sup>-1</sup> has been reported [25].

86 Ultrasonic irradiation and microwave techniques provide access to rapid synthesis but can  
87 be difficult to reproduce due to the use of diverse synthesis setups with variable exposure  
88 parameters [26, 27]. The facile and rapid preparation of MOFs is very attractive to  
89 facilitate fundamental studies of these materials as well as towards their eventual practical  
90 application in industry. Recently, we have started to develop room temperature synthesis  
91 methods for MOFs based on a soft polymer template approach. The use of certain  
92 polymers as templates can improve simplicity, reduce reaction times or temperatures, and  
93 improve yields, purities and reproducibility [28-30]. Numerous MOF structures have been  
94 realized by diverse methods, including polymer-templating, and assessed as potential CO<sub>2</sub>  
95 and CH<sub>4</sub> adsorbents, as summarized below in Table S1 [28-47].

96 In this work, we report the synthesis of a new highly porous HKUST-1, herein referred to  
97 as PEG-templated HKUST-1, via a soft polymer template synthesis strategy, and explore  
98 its application for CO<sub>2</sub> and CH<sub>4</sub> adsorption and separation. To the best of our knowledge,  
99 this is the first time that an inexpensive polymer template such as polyethylene glycol has  
100 been used for HKUST-1 synthesis. Herein we report the optimized protocol for facile

101 synthesis that benefits from a short reaction time of only 10 min at room temperature and  
102 ambient pressure. Adsorption isotherms models were investigated to gain new insight into  
103 the adsorbate-adsorbent interaction. Three models were applied to understand the gas-solid  
104 adsorption mechanism. Diverse characterizations are reported to shed new light on the  
105 relationship between the pore structure and gas adsorption and separation performance.  
106 Finally, the adsorption selectivity, heat of adsorption, and regeneration performance of our  
107 adsorbent will also be presented.

## 108 2. Materials and methods

### 109 2.1 Materials

110 Copper nitrate ( $\text{Cu}(\text{NO}_3)_2 \cdot 2.5\text{H}_2\text{O}$ , 99%), 1,3,5-benzenetricarboxylic acid ( $\text{H}_3\text{BTC}$ , 99%)  
111 dimethylsulfoxide (DMSO, 99%), methanol (99%), triethylamine (TEA;  $(\text{C}_2\text{H}_5)_3\text{N}$ ; 99%) and  
112 polyethylene glycol (PEG, average molecular weight of 20,000 g/mol) were obtained from  
113 Sigma-Aldrich and used as received. The all gases used for these analyses were of high purity  
114 (99.99%) and obtained from Sigma-Aldrich.

### 115 2.2 Synthesis of PEG-templated metal organic framework adsorbent: HKUST-1

116 PEG-templated Cu-HKUST-1 MOF was prepared at room temperature from high-purity  
117 precursors:  $\text{Cu}(\text{NO}_3)_2 \cdot 2.5\text{H}_2\text{O}$  and benzene-1,3,5-tricarboxylic acid ( $\text{H}_3\text{BTC}$ ) with  
118  $\text{PEG}_{20,000}$  used as a soft template. The use of PEG was encouraged by its ability to form  
119 homogenous solutions with metallic salts via micellar and dispersion effects that in turn  
120 promote the uniform growth of MOF particles with reduced agglomeration, and have  
121 proven to provide access to higher surface area adsorbents for gas adsorption [28, 29]. The  
122 polymer is considered also to adsorb on the surface of the metal clusters and coordinated  
123 ligands, resulting in modification of crystal growth and changes in the pore structure of the  
124 resulting MOF; for example, the PEG molecules may specifically interact via hydrogen  
125 bonding with the ligand. In the first step, PEG (0.4 g) was added to DMSO (12 g) then Cu  
126  $(\text{NO}_3)_2 \cdot 2.5\text{H}_2\text{O}$  (0.177 g, 0.76 mmol) was subsequently added. The mixture was stirred for  
127 5 min to form a well-defined suspension (solution 1). In parallel, the  $\text{H}_3\text{BTC}$  ligand (0.246  
128 g, 1.17 mmol) was dissolved in a DMSO (12 g) solution. TEA (used as a base; 0.49 ml  
129 (3.51 mmol) was then combined with the ligand solution (solution 2). The  $\text{PEG}_{20,000}$   
130 suspension (solution 1) was then combined with the solution 2 and the resulting mixture  
131 stirred at room temperature for 10 min. Blue colloids formed and were subsequently  
132 collected after centrifugation (3000 rpm, 15 min), extraction, and washing five times with  
133 methanol to remove any undissolved precursors including the polymer. The blue-colored

134 product, HKUST-1, was finally dried in a vacuum oven at 423 K for 24 h. The resulting  
 135 solid was characterized by infrared (FTIR), powder X-ray diffraction (PXRD), scanning  
 136 electron microscopy (SEM), thermogravimetric analysis (TGA) and N<sub>2</sub> adsorption  
 137 experiments.

### 138 2.3 Characterization methods: FTIR, PXRD, SEM, TGA, DSC and N<sub>2</sub> adsorption

139 Fourier transform infrared (FTIR) spectra were recorded on a Perkin Elmer Spectrum Two  
 140 Fourier transform infrared spectrometer using the attenuated total reflectance (ATR)  
 141 method with a diamond crystal [28, 29]. Spectra were obtained on powders without  
 142 addition of KBr. X-ray diffraction patterns was recorded with a Bruker D8 Discover  
 143 diffractometer (2θ values between 2 and 70°, Cu K<sub>α</sub> radiation with a wavelength of  
 144 0.15406 nm on dried powders [28, 29]. For comparison, a simulated XRD pattern of  
 145 HKUST-1 (Cu<sub>3</sub>(BTC)<sub>2</sub>) was produced using Winplot X.2 software from the CCDC web  
 146 site (deposition number 112954) [16]. The morphological features of materials were  
 147 examined by SEM on a Philips XL30-FEG scanning electron microscope. Particle size  
 148 analysis was performed using Image J software. BET (Brunauer Emmett Teller) surface  
 149 areas were determined using a Micrometrics ASAP-2420 instrument with N<sub>2</sub> at 77 K. Prior  
 150 to measurements; the powders were outgassed for 24 h under vacuum at 423 K [28, 29].  
 151 The pore size distribution was determined using the Horvath-Kawazoe (H–K) model [28].  
 152 Thermogravimetric (TGA) analysis was carried out using a TG Mettler Toledo STARE  
 153 apparatus under air from 298 K up to 973 K with a temperature ramp of 10 K/min.  
 154 Differential scanning calorimetry (DSC) was performed using a Mettler-Toledo TGA/DSC  
 155 3+ [28, 29].

## 159 2.4 Adsorption isotherms: CO<sub>2</sub>, CH<sub>4</sub> and N<sub>2</sub>

160 The adsorption isotherms of CO<sub>2</sub>, CH<sub>4</sub> and N<sub>2</sub> on the PEG-templated HKUST-1 MOF were  
 161 measured by gravimetric analysis (Autosorb-iQ-MP analyzer) in the pressure range of 0-40  
 162 bar, and at four temperatures varying from 273 to 353 K. Prior to the measurement, the  
 163 powder was outgassed at 423 K for 24 h to desorb any air and moisture desorbed on the  
 164 surface. The CO<sub>2</sub> and CH<sub>4</sub> gases were of high purity (99.99%) and obtained from Sigma-  
 165 Aldrich. The thermodynamics parameters ( $\Delta H^\circ$ ,  $\Delta S^\circ$  and  $\Delta G^\circ$ ) [700] and isosteric heats of  
 166 adsorption ( $Q_{st}$ ) were calculated based on sorption isotherms measured up to 40 bar at 273,  
 167 298, 323 and 353 K. The isotherms were fitted with the Langmuir isotherm model [500].  
 168 The isosteric heats of adsorption were calculated by applying the Clausius-Clapeyron  
 169 equation [800].

## 2.5 Separation of gas mixtures: CO<sub>2</sub>/N<sub>2</sub>, CH<sub>4</sub>/N<sub>2</sub> CO<sub>2</sub>/CH<sub>4</sub>

Breakthrough experiments were performed using a stainless steel column with a length of 10 cm and an internal diameter of 10 mm. The column was packed with 4.5 g of the adsorbent, PEG-templated HKUST-1, and was activated under helium flow [48]. Breakthrough curve measurements were carried out in two steps. Prior to flowing the feed gas into the adsorption column, the gas was bubbled in an equilibrium column for 10 min to achieve a stabilized and equilibrated system. Separation measurements were subsequently performed at 298 K and at atmospheric pressure. CO<sub>2</sub>/N<sub>2</sub>, CH<sub>4</sub>/N<sub>2</sub> CO<sub>2</sub>/CH<sub>4</sub> mixtures (50/50, v/v) were tested at flow rates of 15 and 30 mL/min. The gas stream was analyzed by gas chromatography at the outlet of the column.

## 3. Results and discussion

### 3.1 Physico-chemical characterization of PEG-templated HKUST-1 MOF

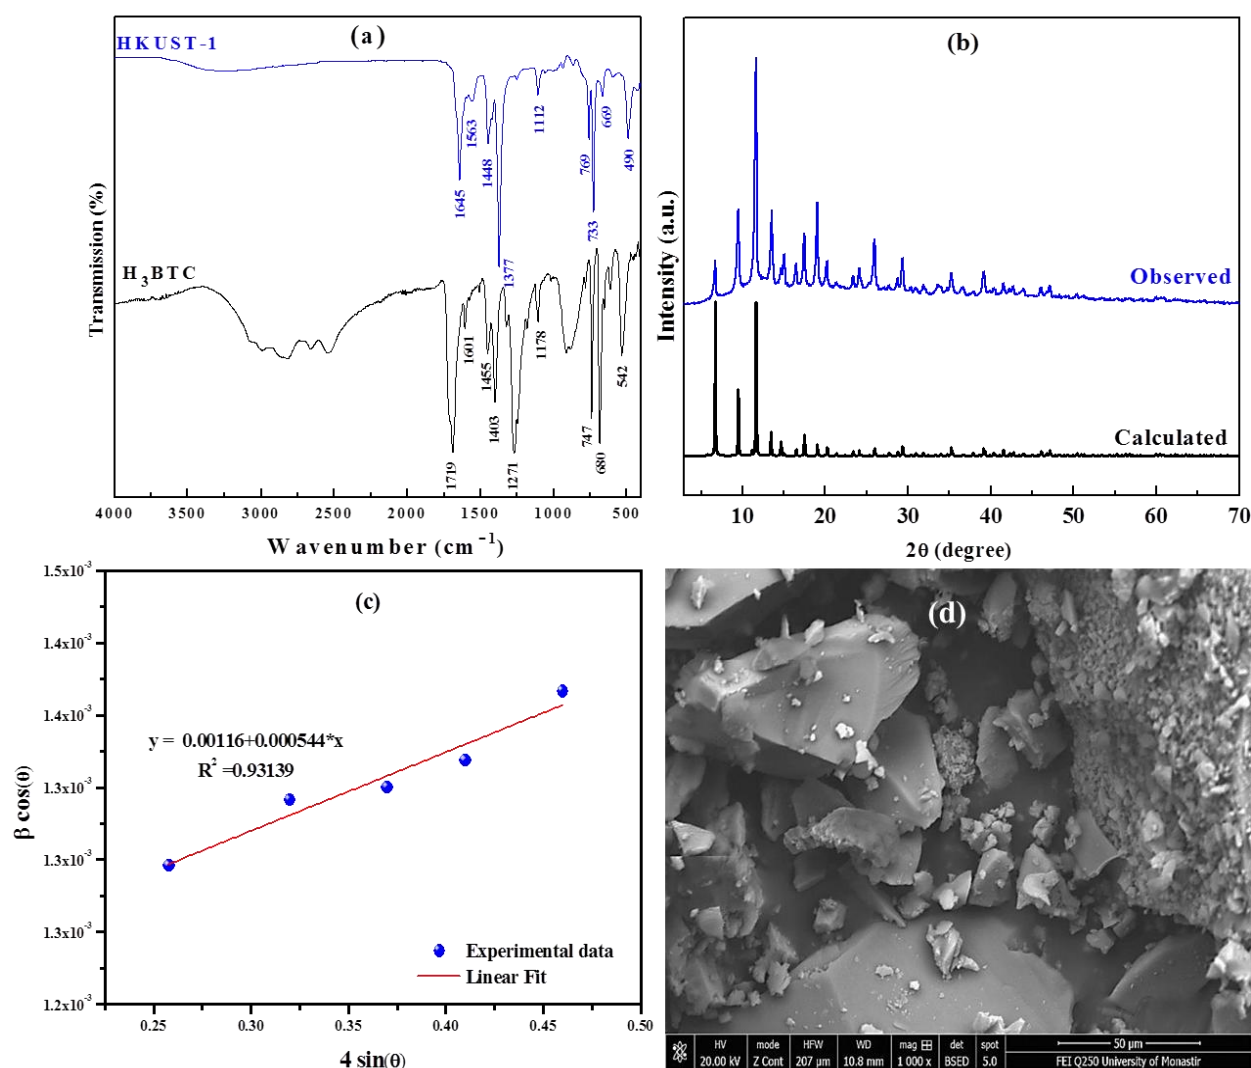

The structure of the new adsorbent was first characterized by FTIR. The FTIR spectrum of the new PEG-templated HKUST-1 is presented in Fig. 1 (a) alongside the spectrum of the ligand precursor. The first zone (fingerprint region) for PEG-templated HKUST-1 from 600 to 1300 cm<sup>-1</sup> corresponds to the various vibration signals of the H<sub>3</sub>BTC ligand. Particularly, the band at 1093 cm<sup>-1</sup> is attributed to the C-O-Cu stretching mode of HKUST-1. The zone between 1300 and 1700 cm<sup>-1</sup> is related to the carboxylate groups of the ligand and is thus indicative of the coordination of benzene-1,3,5-tricarboxylic acid (BTC) bridging ligands with copper nodes [100, 200]. The specific bands located at 1645, 1563, 1448 and 1377 cm<sup>-1</sup> correspond to the asymmetric and symmetric stretching vibrations of the carboxylate groups of HKUST-1, respectively. The band at 490 cm<sup>-1</sup> is related to the Cu-O stretching mode of the framework structure, further consistent with the successful isolation of a HKUST-1 MOF. The broad bands at 3400-3000 cm<sup>-1</sup> corroborate the presence of humidity in the powders. The FTIR spectrum shows the typical bands of HKUST-1 MOF (Cu<sub>3</sub>(BTC)<sub>2</sub>) and is consistent with spectra reported elsewhere [49, 50].

[200] A. Roy, A. K. Srivastava, B. Singh, D. Shah, T. H. Mahato, A. Srivastava, Kinetics of degradation of sulfur mustard and sarin simulants on HKUST-1 metal organic framework, *Dalton. Trans.* 41 (2012) 12346-12348.

212 Similar conclusions were drawn from the XRD measurements; the XRD pattern (Fig. 1  
 213 (b)) confirms that the PEG-templated corresponds well to the typical structure of HKUST-  
 214 1 ( $\text{Cu}_3(\text{BTC})_2$ ) with a cubic structure ( $Fm\bar{3}m$ ) [16]. The crystallites size was estimated  
 215 based on the Debye-Scherrer equation (see Equation S1) and found to be about 107.69 nm.  
 216 The particle size was also estimated using Scherrer's technique, and also the Williamson-  
 217 Hall (W-H) method from a plot with  $\sin(\theta)$  along the x-axis and  $\beta_{hkl} \cos(\theta)$  along the y-  
 218 axis (Fig. 1 (c)). The slope and y-intersect of the fitted line relate to the particle size and  
 219 the strain, respectively. The calculated crystallite size is 254.9 nm based on the W-H  
 220 method and 107.7 nm based on Scherrer's technique. The larger estimated crystallite size  
 221 for the W-H method is likely related to the impact of strain effects which also contribute to  
 222 peak broadening.

223  
 224 **Fig. 1.** (a) FTIR spectrum of the benzene-1,3,5-tricarboxylic acid ( $\text{H}_3\text{BTC}$ ) ligand (black  
 225 line) and the PEG-templated HKUST-1 MOF formed from Cu and  $\text{H}_3\text{BTC}$  (blue line); (b)  
 226 **X-ray powder diffraction (XRD)** patterns of our **experimental** sample (blue line) and

227 simulated HKUST-1 (from CIF: with reference CCDC 112954) (black line); (c) Plot of  $\beta$   
228  $\cos\theta$  vs.  $4 \sin\theta$ ; (d) SEM micrograph of PEG-templated HKUST-1 at 1000 $\times$  magnification.  
229

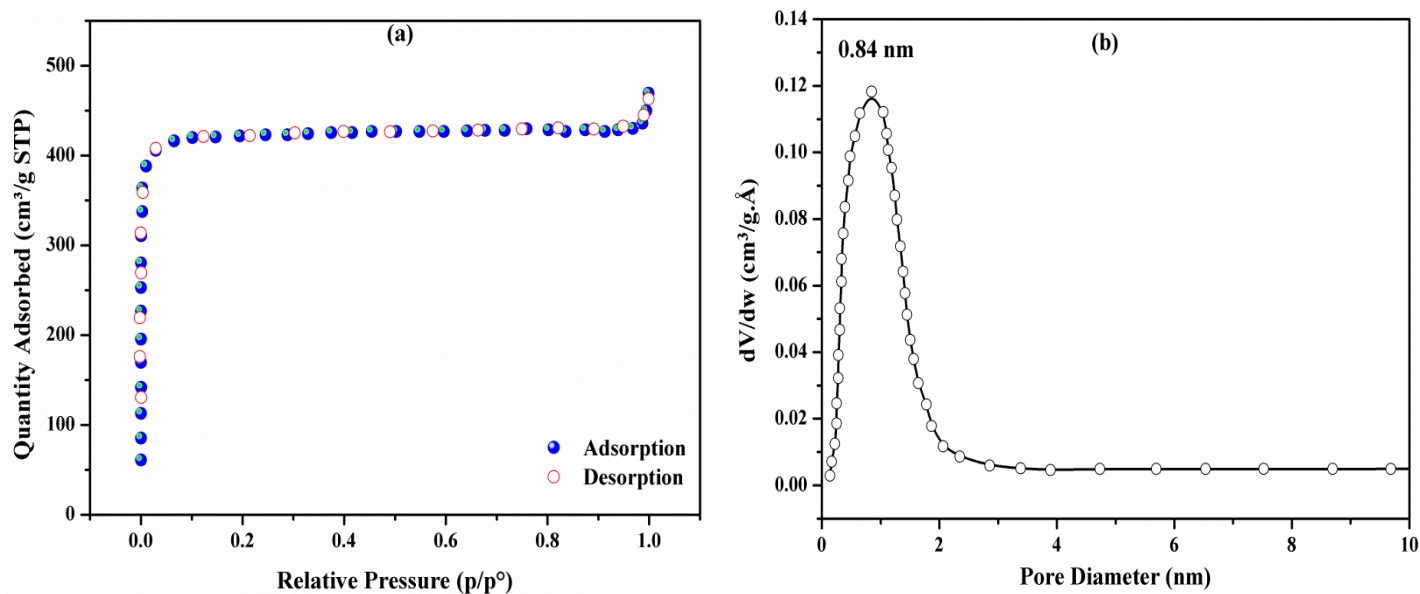

230 The morphology of the HKUST-1 material was examined by SEM (Fig. 1 (d)). The  
231 micrographs displays a large distribution of nano- and micro-particles with crystal surface  
232 features such as a regular smooth surface and faceted structure <sup>[49]</sup> with sizes ranging from  
233 100 nm to 120  $\mu\text{m}$ . HKUST-1 ( $\text{Cu}_3(\text{BTC})_2$ ) is conventionally obtained by solvothermal  
234 synthesis and typically gives microparticles of around 60  $\mu\text{m}$  [51]. Thi et al. reported  
235 MOF-199 ( $\text{Cu}_3(\text{BTC})_2$ ) microparticles with crystal sizes ranging between 30 and 130  $\mu\text{m}$   
236 [47]. The PEG-templated synthesis therefore gives rise to the ‘classical’ microparticles but  
237 also provides easy access to a large nanoparticle size distribution; the latter of which are of  
238 high interest for gas adsorption and separation. The size of the nanoparticles corresponds  
239 well with the crystallite sizes obtained via the Scherrer and W-H techniques, importantly,  
240 highlighting the dominant presence of the nanoparticles.

241 The thermal stability and degradation of the HKUST-1 MOF was subsequently studied by  
242 TGA and DSC analysis (Fig. 2). The TGA curve for the HKUST-1 particles exhibits two  
243 stages of weights loss: the first weight loss of 23.15 % of the initial sample occurred  
244 between 303 to 433 K and corresponds to the removal of terminally-coordinated water  
245 molecules. This is supported by an exothermic signal peaking at 313 K. The second weight  
246 loss of 61.28% started at 573 K and continued to 650 723 K, as evidenced by an  
247 exothermic peak maximum at 623 K. This second feature is mainly due to decomposition  
248 of the adsorbent. The PEG-templated HKUST-1 is therefore considered stable at  
249 temperatures up to 594 K. A lower temperature of 423 K was chosen as a suitable  
250 temperature for degassing prior to gas sorption experiments. The TGA and DSC results for  
251 the PEG-templated adsorbent correlate with those reported for the HKUST-1 synthesized  
252 by Thi et al. [47]. Finally, at 723 K only about 10.65 wt% of the starting weight remained.  
253 The thermal decomposition of HKUST-1 beyond this temperature gave rise to a black  
254 precipitate that may be assigned to copper oxides (e.g. CuO phase) in accordance with  
255 reported data in the literature [52].

256  
 257 **Fig. 2.** TGA and DSC analyses of PEG-templated HKUST-1 under air and with a heating  
 258 rate of 10°C/min.

259 Next we turned our attention to evaluating the porous structure of the PEG-templated  
 260 HKUST-1 material. The blue powders were activated at 423 K under vacuum for 24 h  
 261 prior to nitrogen gas sorption measurements. Nitrogen adsorption/desorption isotherms for  
 262 PEG-templated HKUST-1 are shown in Fig. 3 (a). The adsorption equilibrium was reached  
 263 quickly at the low relative pressure region ( $P/P^\circ$  from  $10^{-5}$  to  $10^{-1}$ ) while an adsorption  
 264 plateau and no hysteresis loops were observed at large relative pressure. According to the  
 265 International Union of Pure and Applied Chemistry (IUPAC) classification [53], this  
 266 behaviour is consistent with a typical type I isotherm. Generally, such materials are  
 267 characteristically microporous in nature (pore size  $< 2$  nm) [54]. A maximum BET surface  
 268 of  $1904 \text{ m}^2/\text{g}$  and total pore volume of  $0.87 \text{ cm}^3/\text{g}$  was determined for the microporous  
 269 PEG-templated HKUST-1 based on  $\text{N}_2$  adsorption at relative pressures of 0.04-0.3 and 0.9,  
 270 respectively. A classical 24 hour solvothermal synthesis of MOF-199 (HKUST-1,  
 271  $\text{Cu}_3(\text{BTC})_2$ ) at 358 K from a DMF reaction mixture produced particles with a BET surface  
 272 area of  $1448 \text{ m}^2/\text{g}$ , and  $0.693 \text{ cm}^3/\text{g}$  maximum pore volume [47]. The BET surface area and  
 273 porous volume of PEG-templated HKUST-1 are also much higher than values for  
 274  $\text{Cu}_3(\text{BTC})_2/\text{HKUST-1}$  of  $692 \text{ m}^2/\text{g}$  and  $0.33 \text{ cm}^3/\text{g}$ ,  $1482 \text{ m}^2/\text{g}$  and  $0.753 \text{ cm}^3/\text{g}$ , and  $1296$   
 275  $\text{m}^2/\text{g}$  and  $0.69 \text{ cm}^3/\text{g}$  reported by Chui et al., Li and Yang, and Chowdhury et al. [16, 55,  
 276 56].

**Fig. 3.** (a)  $N_2$  adsorption-desorption isotherms of PEG-templated HKUST-1 and (b) corresponding pore size distribution.

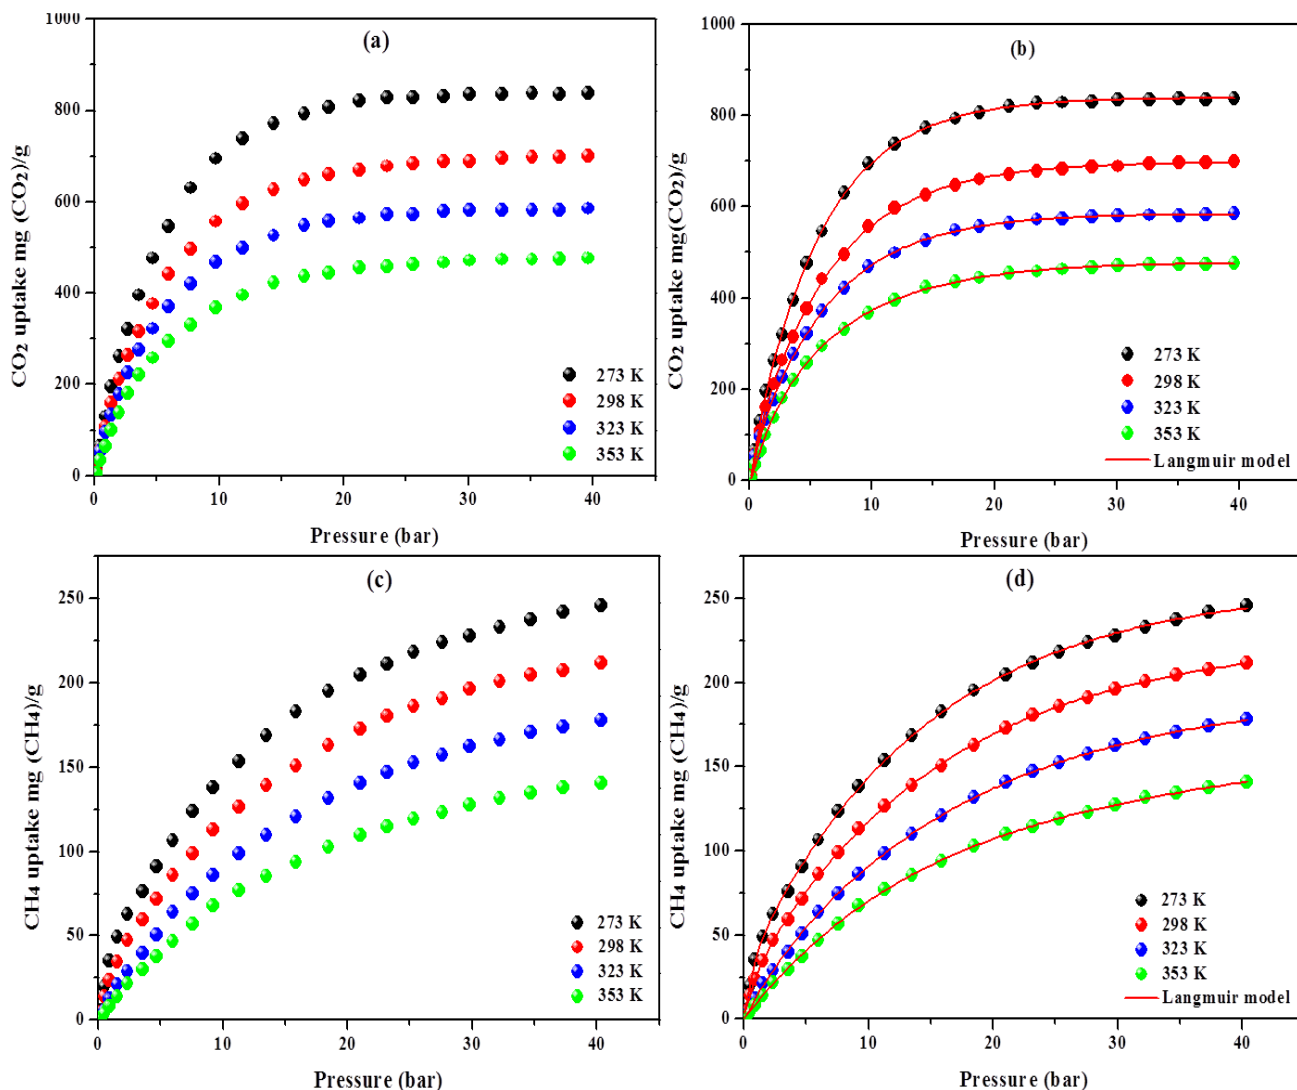

These porosity values are unusually high and certainly attractive when compared with the published results for reported HKUST-1( $Cu_3(BTC)_2$ ) particles and other highly porous MOFs (Table S1). We note that the unusually high surface area is consistent with effective removal of the PEG template but that the possibility that some residual PEG remains is not completely ruled out [57-59].

The pore size distributions (Fig. 3 (b)) shows one peak centered at 0.84 nm, confirming the microporous structure of PEG-templated HKUST-1. In the previous study by Thi et al, the synthesized MOF-199 with mean pore size of 1.18 nm was demonstrated as an effective stable and rigid adsorbent for  $CO_2$ , for example, exhibiting a storage capacity of 9.21 mmol/g at a pressure of 25.76 bar with almost reversible adsorption/desorption isotherms [47]. The comparatively smaller pores of the PEG-templated HKUST-1 combined with the large overall BET surface area are therefore promising.

### 3.2 Gas adsorption studies at PEG-templated HKUST-1: $CO_2$ , $CH_4$ and $N_2$

We subsequently investigated the capacity of the new adsorbent for  $CO_2$ ,  $CH_4$  and  $N_2$  capture and storage at different temperatures from a low to high pressure range of 0 to 40 bar. First, we considered the adsorption of  $CO_2$  and  $CH_4$ . Fig. 4 (a) reveals that the adsorption of  $CO_2$  increases with increasing pressure, reaching equilibrium (adsorption plateau) at higher temperatures and at all pressures. This behaviour is consistent with a strong adsorption capacity for  $CO_2$ . In contrast, the adsorption of  $CH_4$ , while also non-linear, increases more linearly with increasing pressure but no equilibrium is reached

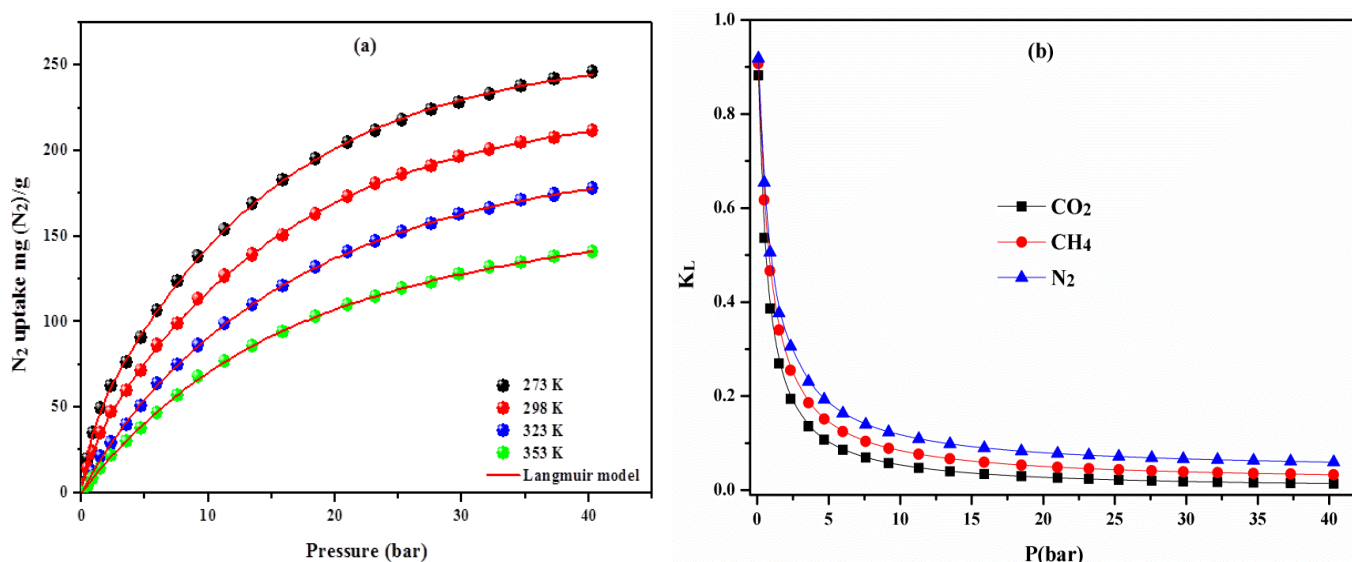

302 regardless of the pressure and temperatures. This phenomenon is consistent with a weak  
303 interaction between  $\text{CH}_4$  and the PEG-templated HKUST-1 MOF (Fig. 4 (c)). The  
304 adsorption isotherms for  $\text{CO}_2$  and  $\text{CH}_4$  that do not exhibit hysteresis are consistent with  
305 type I isotherms according to the IUPAC classification [53].

306 **Fig. 4.** (a)  $\text{CO}_2$  adsorption isotherms at HKUST-1 MOF at high pressure (1-40 bar) and at  
307 273, 298, 323 and 353 K; (b) the  $\text{CO}_2$  adsorption isotherm fitted to the kinetic Langmuir  
308 model, (c)  $\text{CH}_4$  adsorption isotherms recorded at PEG-templated HKUST-1 MOF at high  
309 pressure (1-40 bar) and at 273, 298, 323 and 353 K; (d) the  $\text{CH}_4$  adsorption isotherm fitted  
310 to the kinetic Langmuir model.  
311

312 For both  $\text{CO}_2$  and  $\text{CH}_4$ , the adsorption capacity decreased with increasing temperature,  
313 revealing exothermic adsorption reactions [60]. The maximum adsorbed quantity of  $\text{CO}_2$  is  
314 708 mg ( $\text{CO}_2$ )/g (16.09 mmol/g) at 298 K and 40 bar, which is significantly higher than the  
315 adsorption capacity of many state-of-the-art MOF adsorbents (Table S1). Furthermore, we

316 emphasize that PEG-templated HKUST-1 shows a higher CO<sub>2</sub> adsorption capacity  
 317 compared to our previous MOFs prepared using PEG as a soft template; namely, ZIF-8  
 318 [28] and ZIF-67 [29]. The superior results reported here for HKUST-1 can be linked, at  
 319 least in part, to the unsaturated open Cu metal sites combined with the attractive pore  
 320 characteristics including the very high specific surface area [61]. The maximum adsorbed  
 321 quantity of CH<sub>4</sub> is much lower compared to CO<sub>2</sub> (214 mg(CH<sub>4</sub>)/g at 298 K and 40 bar).  
 322  
 323 Adsorption isotherms for N<sub>2</sub> gas at HKUST-1 were also recorded and show increased  
 324 adsorption with increasing pressure in the considered pressure range (Fig. 5 (a)). The  
 325 maximum N<sub>2</sub> adsorption uptake was determined as 177.22 mg (N<sub>2</sub>)/g (6.32 mmol/g) at 298  
 326 K and 40 bar. Lower levels of N<sub>2</sub> were adsorbed at higher temperatures (122.35 mg(N<sub>2</sub>)/g  
 327 at 353 K, for example). The increase in the equilibrium adsorption temperature that leads  
 328 to a reduction in the amount of adsorbed N<sub>2</sub> is in agreement with an exothermic adsorption  
 329 reaction, as was the case for CO<sub>2</sub> adsorption.

330 **Fig. 5.** (a) N<sub>2</sub> adsorption isotherms on PEG-templated HKUST-1 MOF with Langmuir  
 331 model fitting and (b) Separation factor, R<sub>L</sub>, plot vs. pressure for the adsorption of CO<sub>2</sub>,  
 332 CH<sub>4</sub> and N<sub>2</sub>.

333 The PEG-templated HKUST-1 adsorbent exhibits a much higher CO<sub>2</sub> adsorption capacity  
 334 compared to CH<sub>4</sub> and N<sub>2</sub>. CO<sub>2</sub> has a greater quadrupole moment ( $13.4 \times 10^{-40}$  C.m<sup>2</sup>)  
 335 compared to N<sub>2</sub> ( $4.7 \times 10^{-40}$  C.m<sup>2</sup>) that typically leads to a stronger interaction at the surface  
 336 of adsorbents through physisorption processes, for example, involving polar adsorbent sites  
 337 [62-64]. CH<sub>4</sub> has no dipole (nonpolar molecule) or quadrupole moment hence adsorption is  
 338 not simply based on moment-surface interactions [65]. The higher CO<sub>2</sub> adsorption capacity  
 339 can be partially supported by favorable electrostatic interactions between unsaturated Cu<sup>2+</sup>

340 and axially aligned CO<sub>2</sub> quadrupole moments with negatively-charged oxygen [61, 66, 67].  
 341 Other factors to consider include the similar sizes of the molecules as well as their different  
 342 polarizabilities where CO<sub>2</sub> and CH<sub>4</sub> are more polarizable than N<sub>2</sub> ( $26.3 \times 10^{-25}$  vs.  
 343  $17.6 \times 10^{-25}$  vs.  $26.0 \times 10^{-25}$  cm<sup>3</sup> for CO<sub>2</sub>, N<sub>2</sub>, and CH<sub>4</sub>, respectively) [68].

344 **Fig. 6.** Evolution of (a) ln(*K<sub>L</sub>*) as a function of 1/*T* and (b) ln(*P*) as a function of 1/*T* for  
 345 CO<sub>2</sub>, CH<sub>4</sub>, and N<sub>2</sub>.

346 We performed further analysis on the gas adsorption isotherm data to shed new light on the  
 347 PEG-templated HKUST-1 adsorbent properties. Fig. 4 and Fig. 5 show the CO<sub>2</sub>, CH<sub>4</sub>, and  
 348 N<sub>2</sub> adsorption isotherms fitted according to the Langmuir model (*R*<sup>2</sup> of ca. 0.99). The  
 349 Langmuir kinetic model gave the best fitting with the experimental data for CO<sub>2</sub> and CH<sub>4</sub>.  
 350 The estimated physical parameters and correlation coefficients are summarized in Table  
 351 S2. With reference to the Langmuir model, the equilibrium adsorption capacity, *q<sub>m</sub>*, and the  
 352 adsorption equilibrium constant, *K<sub>L</sub>*, of PEG-templated HKUST-1 were determined for the  
 353 three gases (Table S2). In all cases, the equilibrium values were found to decrease with  
 354 increasing temperature, consistent with physical rather than chemical gas adsorption at the  
 355 adsorbent surface [28, 29, 69].

### 356 3.3 Thermodynamic investigations of PEG-templated HKUST-1

357 To gain further understanding of CO<sub>2</sub>, CH<sub>4</sub> and N<sub>2</sub> adsorption at PEG-templated HKUST-  
 358 1, we investigated several thermodynamic parameters (see **ESI Supporting Information** for  
 359 equations and calculation details). The Gibbs free energy (Δ*G*<sup>°</sup>), standard enthalpy (Δ*H*<sup>°</sup>)  
 360 and standard entropy (Δ*S*<sup>°</sup>) were calculated and are summarized below in Table 2. For all  
 361 three gases, the negative values of Δ*G*<sup>°</sup> highlight the spontaneity and feasibility of the gas  
 362 adsorption process at all temperatures studied. The values of Δ*G*<sup>°</sup> decreased with

363 increasing temperature, revealing that the adsorption processes are more feasible at lower  
 364 temperatures and especially for CO<sub>2</sub>. The ΔG° values were in all cases between -2.77 and -  
 365 0.53 kJ/mol, indicating physical adsorption (0 to -20 kJ/mol) rather than chemisorption (-  
 366 80 to -400 kJ/mol) for the three gases at the PEG-templated HKUST-1 surface [70].

367 **Table 2** Thermodynamic properties for CO<sub>2</sub>, CH<sub>4</sub> and N<sub>2</sub> adsorption at PEG-templated  
 368 HKUST-1.

	ΔH°(kJ/mol)	ΔS°(J/K)	ΔG° (kJ/mol)			
			273 K	298 K	323 K	353 K
CO <sub>2</sub>	-6.52±	-13.72±	-2.77±	-2.43±	-2.08±	-1.67±
CH <sub>4</sub>	-4.93±	-11.38±	-1.82±	-1.53±	-1.25±	-0.91±
N <sub>2</sub>	-3.76±	-9.13±	-1.26±	-1.03±	-0.81±	-0.53±

369 The linear Van't Hoff plot of ln (K<sub>L</sub>) vs 1/T that relates the change in temperature to the  
 370 change in equilibrium constant was used to obtain the standard enthalpy and entropy  
 371 change from the slope and the intercept, as presented in Fig. 6 (a). The negative values for  
 372 ΔH° are between -3.76 and -6.52 kJ/mol, that is, in the 0 to -20 kJ/mol ranges, further  
 373 highlighting the exothermic nature of the physical adsorption process for each of the three  
 374 gases [70]. The slightly larger negative enthalpy for CO<sub>2</sub> adsorption is consistent with a  
 375 stronger adsorption interaction albeit through apparently weak bonding interactions. The  
 376 negative standard entropy changes suggest that the magnitude of the randomness of the  
 377 gases became more ordered (decreased) during the physical adsorption processes,  
 378 consistent with the transition of the molecules in the random gaseous state to an organized  
 379 solid-like phase at PEG-templated HKUST-1.

380 An important parameter to provide a deeper insight into the adsorption process of gases at  
 381 MOFs and other porous materials is the heat (or enthalpy) of adsorption. The isosteric heat  
 382 of adsorption (Q<sub>st</sub>) measures the change of enthalpy when gas adsorbate molecules are  
 383 adsorbed from the bulk phase to the adsorbed phase, providing insight into the binding  
 384 affinity of adsorbed molecules for surface sites on the absorbent. Here we calculated the  
 385 pure component isosteric heat of adsorption via the Clausius-Clapeyron equation and pure  
 386 adsorption isotherm data recorded in the range 273-353 K for CO<sub>2</sub>, CH<sub>4</sub>, and N<sub>2</sub>. The Q<sub>st</sub>  
 387 values were obtained after plotting the logarithm of the pressure as a function of the  
 388 reverse of the temperature (Fig. 6 (b)). The slope of the plots is negative due to the  
 389 exothermic nature of the adsorption processes.

390 The isosteric heats for CO<sub>2</sub>, CH<sub>4</sub> and N<sub>2</sub> adsorption ( $Q_{st}$ ) were calculated from the  
 391 Langmuir-fitted experimental isotherm data recorded at the range 273-353 K at PEG-  
 392 templated HKUST-1, and are presented in Fig. 7 (a). First, we observe that the isosteric  
 393 heat of adsorption decreases slightly with increasing loading of adsorbed gas molecules,  
 394 attributed to heterogeneity in the adsorbent, especially during the initial loading phase, and  
 395 especially for CO<sub>2</sub> adsorption. The  $Q_{st}$  values for CO<sub>2</sub> of 27.5 to 30.5 kJ/mol at 273-353 K  
 396 were the highest observed and more than double the values observed for N<sub>2</sub> adsorption.  
 397 The values of  $Q_{st} > 10$  kJ/mol highlight a practical affinity for the gases and especially for  
 398 CO<sub>2</sub> adsorption at PEG-templated HKUST-1. The  $Q_{st}$  that reflects the bond strength of the  
 399 adsorbent-adsorbate interaction is the highest at lower coverages, reflecting the presence of  
 400 a limited number of initial sites with higher affinity for the initial gas molecules [71, 72].  
 401 The affinity nevertheless remains high for CO<sub>2</sub> even after 5-15 mg/g adsorption. The  
 402 higher thermodynamic affinity of CO<sub>2</sub> for PEG-templated HKUST-1 can be at least  
 403 partially explained by the presence of strong quadrupolar interactions of CO<sub>2</sub> with the  
 404 micropores of the adsorbent including specific interactions with coordinatively unsaturated  
 405 copper sites (Cu<sup>2+</sup>) [61, 66, 67]. The heat of CO<sub>2</sub> adsorption at PEG-templated HKUST-1  
 406 is higher than many values reported in the literature for synthesized HKUST-1 (Cu-BTC,  
 407 Cu<sub>3</sub>(BTC)<sub>2</sub>) particles [73-75]. Pepe et al. measured 25.9 kJ/mol at Cu-BTC [72], while  
 408 Wang et al. and Moellmer et al. measured 25 kJ/mol [74] and 29.2 kJ/mol [75],  
 409 respectively. The values are lower than the heat of adsorption reported for CO<sub>2</sub> with the  
 410 commercially-available CO<sub>2</sub> adsorbent, zeolite 13X (49 kJ/mol) [76]. A lower isosteric  
 411 heat of adsorption has the upside that there is a reduced energy requirement for the  
 412 desorption and therefore regeneration of the adsorbent.

413 **Fig. 7.** (a) Isothermic heats of adsorption,  $Q_{st}$ , for  $\text{CO}_2$ ,  $\text{CH}_4$ , and  $\text{N}_2$  at PEG-templated  
414 HKUST-1 at 273-353 K (b)  $\text{CO}_2/\text{N}_2$  and  $\text{CO}_2/\text{CH}_4$  selectivities of PEG-templated HKUST-  
415 1 at 298 K.

416 A noteworthy high affinity of PEG-templated HKUST-1 for  $\text{CH}_4$  was observed. A value of  
417 ca. 19 kJ/mol indicates strong binding between polarizable  $\text{CH}_4$  molecules and the surface  
418 sites of the adsorbent. Both  $\text{CO}_2$  and  $\text{CH}_4$  adsorption energies are higher than those  
419 reported for commercially-available activated carbon e.g. 16-25 kJ/mol for  $\text{CO}_2$  and 16-20  
420 kJ/mol for  $\text{CH}_4$ , respectively [77]. Fig. 7 (a) shows that the isothermic heat of adsorption  
421 values for  $\text{N}_2$  are notably smaller than for  $\text{CH}_4$  and  $\text{CO}_2$ , and that the change in the heat of  
422 adsorption with gas surface coverage is very low. In other words, the  $\text{N}_2$ -adsorbent  
423 interaction remains heterogeneous but is much more homogeneous in nature compared to  
424 the  $\text{CO}_2$ -adsorbent adsorption. The isothermic heat of adsorption for  $\text{N}_2$  uptake was equal to  
425 14.90 kJ/mol, which is higher than values reported elsewhere [78, 79]. The lower  
426 thermodynamic affinities for  $\text{CH}_4$  and  $\text{N}_2$  bode well for the favorable potential selectivity  
427 of the PEG-templated HKUST-1 material for  $\text{CO}_2/\text{CH}_4$  and  $\text{CO}_2/\text{N}_2$  separations,  
428 respectively.

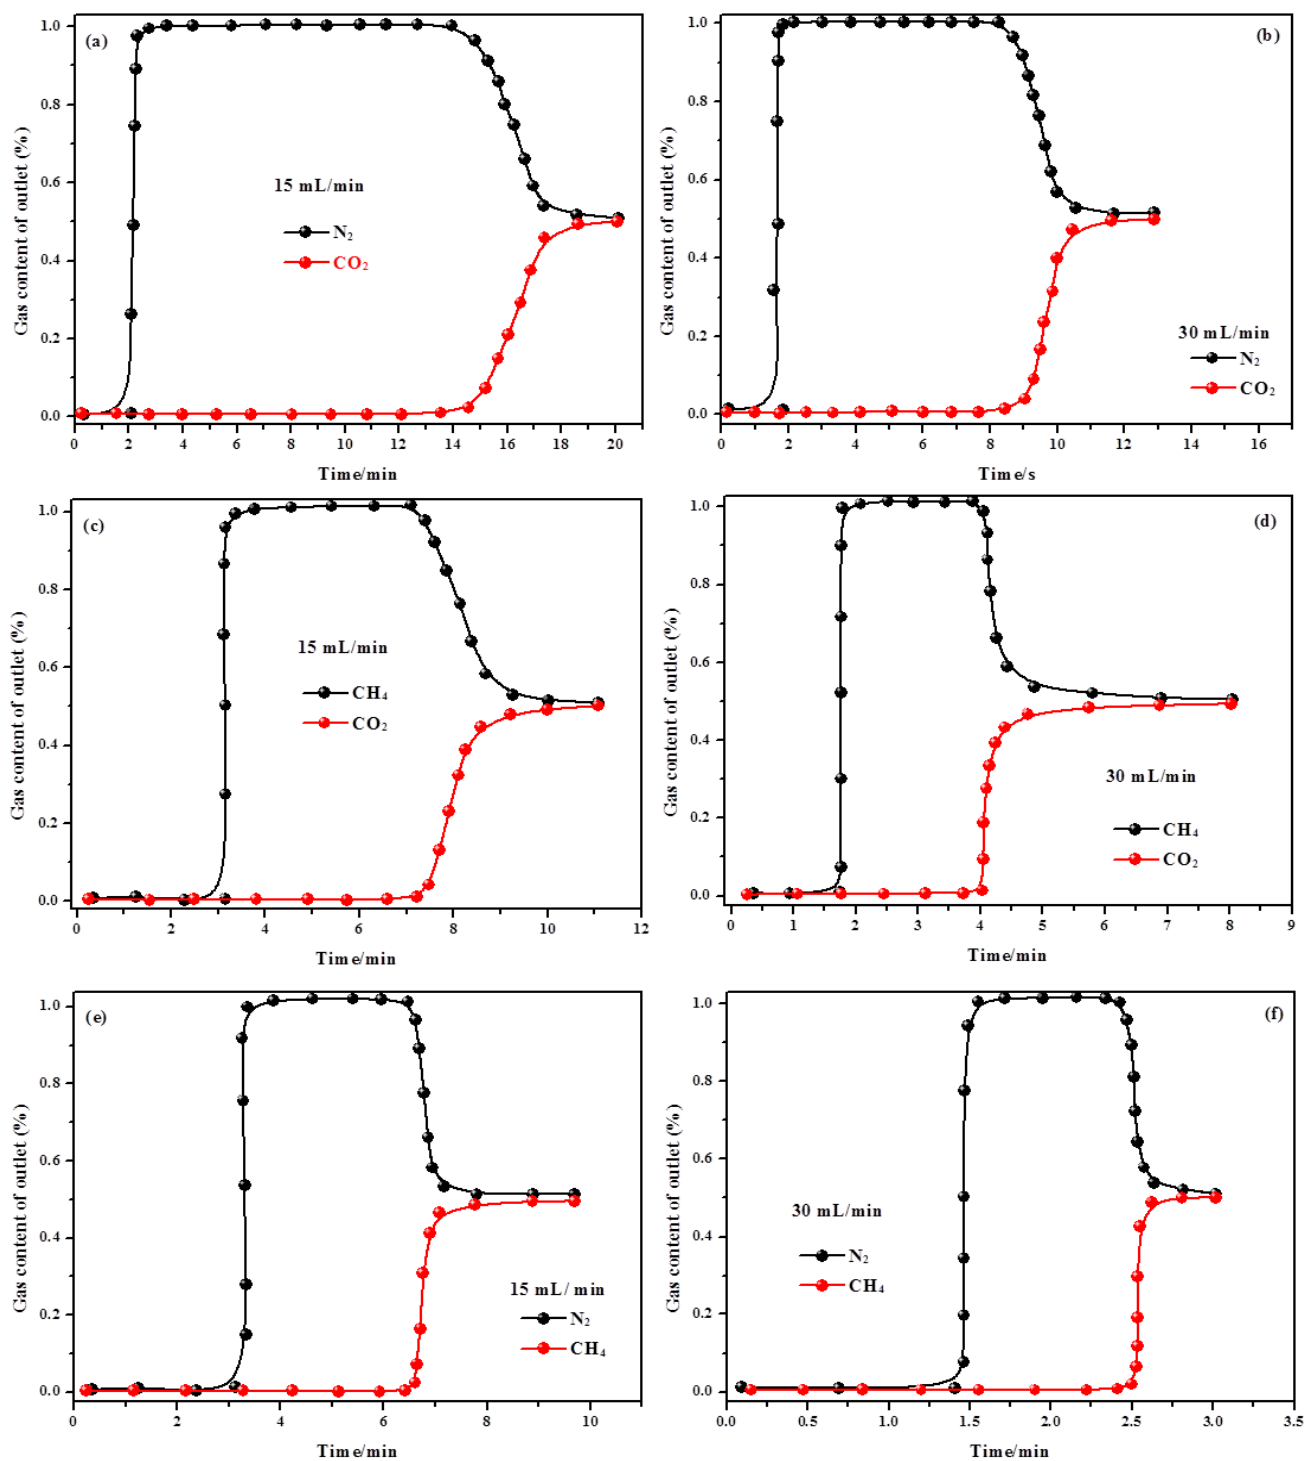

### 429 3.4 Adsorption selectivity for binary gas mixtures: $\text{CO}_2/\text{N}_2$ , $\text{CO}_2/\text{CH}_4$ and $\text{CH}_4/\text{N}_2$ :

430 Building on the preferential heats of adsorption for  $\text{CO}_2$  compared to  $\text{CH}_4$  and  $\text{N}_2$  at the  
431 PEG-templated HKUST-1, we evaluated the gas selectivity of the adsorbent. The  
432 selectivity was estimated from single gas isotherms after dividing the adsorption capacity  
433 for  $\text{CO}_2$  (or  $\text{CH}_4$ ) by that of  $\text{N}_2$  or  $\text{CH}_4$  at each pressure point at 298 K [80]. The gas  
434 selectivity values at different pressures are shown by the plots in Fig. 7 (b) for  $\text{CO}_2/\text{N}_2$ ,  
435  $\text{CO}_2/\text{CH}_4$  and  $\text{CH}_4/\text{N}_2$ . For all mixtures, the selectivity decreased with increasing pressure  
436 while the best selectivity was observed in the 0.01 to 5 bar range. The PEG-templated  
437 HKUST-1 shows superior selectivity for  $\text{CO}_2$  separation from a  $\text{CO}_2/\text{N}_2$  mixture,  
438 particularly at low pressure. The selectivity values of 52, 30, and 27 at 0.01, 20 and 40 bar  
439 are notably higher than those of previously reported HKUST-1 ( $\text{Cu}_3(\text{BTC})_2$ ) [80]. The  
440  $\text{CO}_2/\text{N}_2$  selectivity of PEG-templated HKUST-1 is higher than that of our previously-  
441 reported ZIF-67 (28.02) [29] and ZIF-8 (23.36) prepared via PEG templating methods [28].  
442 At low pressure and at 298 K, the selectivity of HKUST-1 for  $\text{CO}_2/\text{CH}_4$  is between 16 and  
443 24 while the selectivity for  $\text{CH}_4/\text{N}_2$  is between 3 and 13. These values are almost as high as  
444 the separations previously reported at Cu-BTC (HKUST-1) [80]. Eventually, at high  
445 pressure and at 298 K, the PEG-templated HKUST-1 becomes largely ineffective for

446 CH<sub>4</sub>/N<sub>2</sub> separation with a separation selectivity of close to 1. The PEG-templated HKUST-  
447 1 MOF that can be synthesized rapidly therefore shows good promise for separating binary  
448 CO<sub>2</sub> gas mixtures.

### 449 **3.5 Dynamic breakthrough experiments and cyclic stability for gas mixtures:** 450 **CO<sub>2</sub>/N<sub>2</sub>, CO<sub>2</sub>/CH<sub>4</sub> and N<sub>2</sub>/CH<sub>4</sub>**

451 To further confirm the separation performance of PEG-templated HKUST-1 for CO<sub>2</sub>/N<sub>2</sub>,  
452 CO<sub>2</sub>/CH<sub>4</sub> and N<sub>2</sub>/CH<sub>4</sub> mixtures, real-time dynamic breakthrough experiments were carried  
453 out at 298 K and 1 bar. CO<sub>2</sub>/CH<sub>4</sub> (50/50, v/v), CO<sub>2</sub>/N<sub>2</sub> (50/50, v/v) and N<sub>2</sub>/CH<sub>4</sub> (50/50, v/v)  
454 mixtures were flowed into a defined bed comprising the HKUST-1 adsorbent, as described  
455 in the Experimental Section. The breakthrough profiles at 15 and 30 mL/min are shown in  
456 Fig. 8. The data clearly reveals that the N<sub>2</sub> and CH<sub>4</sub> gases were initially eluted  
457 (breakthrough) and reached saturation in the first few min, while the CO<sub>2</sub> was selectively  
458 adsorbed until 8-13 min, depending on the flow rate. For the CO<sub>2</sub>/N<sub>2</sub> mixture at 15  
459 mL/min, the CO<sub>2</sub> breakthrough time was 14.70 min while the N<sub>2</sub> breakthrough time was  
460 just 1.87 min. The data clearly shows the preferential adsorption of CO<sub>2</sub> over N<sub>2</sub> or CH<sub>4</sub>  
461 and that the PEG-templated HKUST-1 is capable of completely separating CO<sub>2</sub>/N<sub>2</sub> (50/50,  
462 v/v) and CO<sub>2</sub>/CH<sub>4</sub> (50/50, v/v) mixtures with only a small amount of N<sub>2</sub> or CH<sub>4</sub> adsorption.  
463 The difference in breakthrough time is higher between CO<sub>2</sub>/N<sub>2</sub> and both CO<sub>2</sub>/CH<sub>4</sub> and  
464 CH<sub>4</sub>/N<sub>2</sub> at both flow rates. The breakthrough times shortened and the separation capacity  
465 decreased in all cases as the feed gas rate increased. The breakthrough experiments are in  
466 accordance with the results reported in Fig. 8 (b). For the N<sub>2</sub>/CH<sub>4</sub> separation, N<sub>2</sub> broke  
467 through the adsorption column first, supporting the notion that N<sub>2</sub> was adsorbed the least  
468 linked to its lighter nature and weaker interactions with the adsorbent. The weaker  
469 interaction is consistent with the weaker quadrupole moment compared to CO<sub>2</sub>, and weaker  
470 polarizability compared to both CO<sub>2</sub> and CH<sub>4</sub>. For N<sub>2</sub>/CH<sub>4</sub> separation at 15 mL/min, the  
471 breakthrough time of CH<sub>4</sub> was 6.72 min while that of N<sub>2</sub> was 3.12 min. The differences in  
472 breakthrough times are consistent with distinctively strong interactions between CO<sub>2</sub>  
473 molecules linked to both the pores and the unsaturated open Cu sites of PEG-templated  
474 HKUST-1 [66, 67, 78].

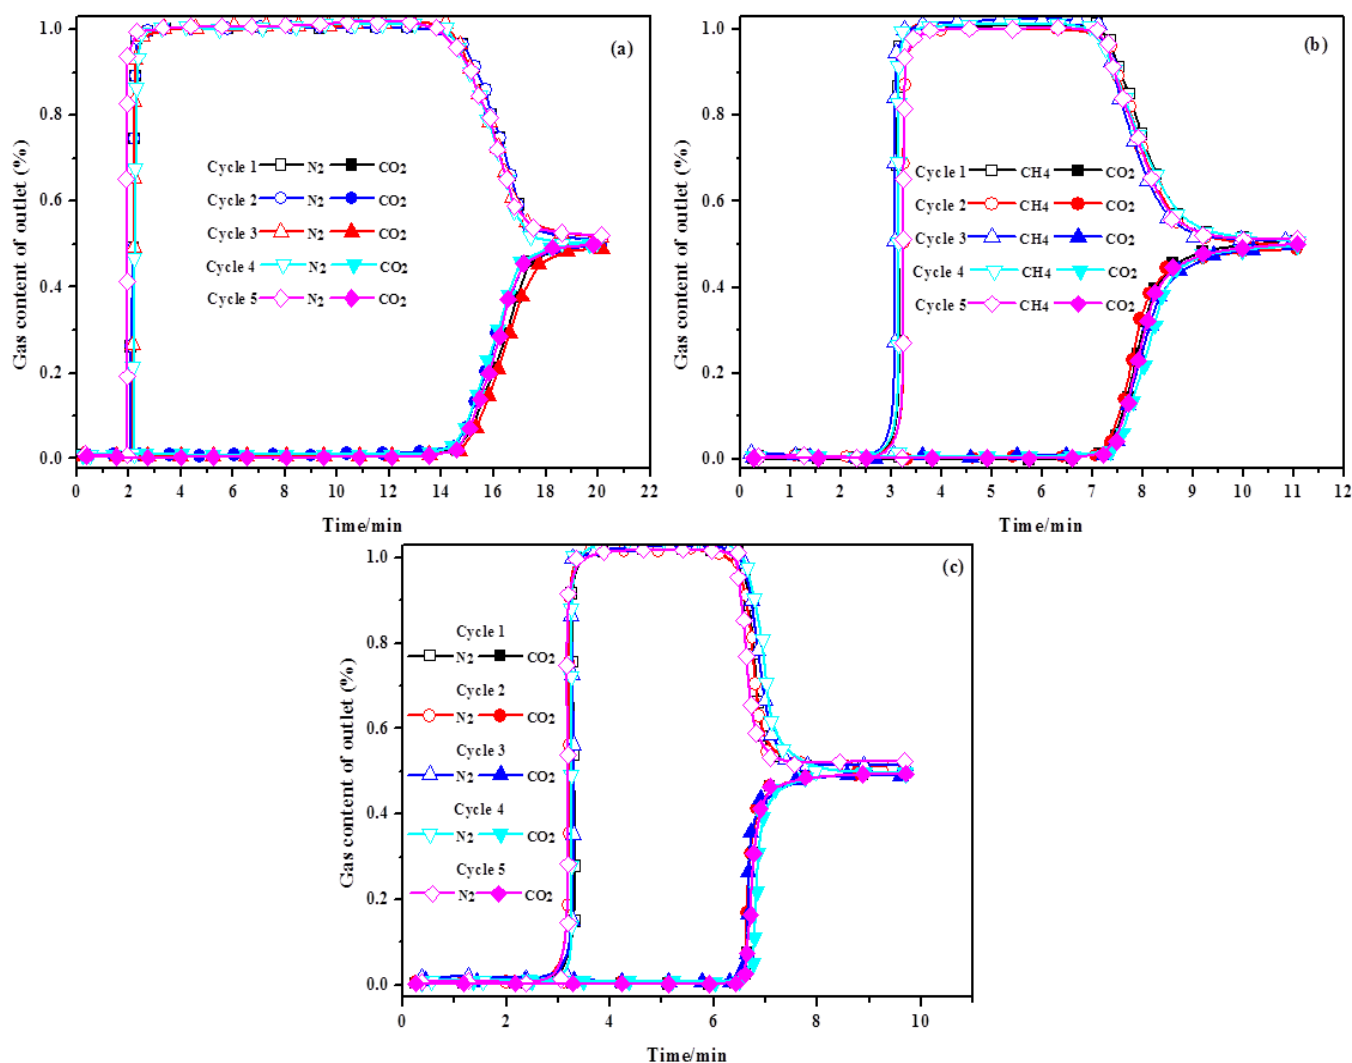

475

476 **Fig. 8.** Experimental breakthrough separation curves for equimolar mixtures of (a, b)  
 477  $\text{CO}_2/\text{N}_2$ , (c, d)  $\text{CO}_2/\text{CH}_4$ , and (e, f)  $\text{CH}_4/\text{N}_2$  at 1 bar and 298 K at different flow rates at  
 478 PEG-templated HKUST-1.

479 The reusability of adsorbents is crucial since it is linked to various ecological and  
 480 economical benefits, for example, including the mitigation of adverse environmental  
 481 impact [81]. We tested the reusability of the PEG-templated HKUST-1 by recording

482 multiple cycles of breakthrough experiments at 15 mL/min at 298 K. The breakthrough  
 483 curves for the three gas mixtures showing 5-cycle reusability are shown in Fig. 9. There is  
 484 no discernable change for the three gases, indicating outstanding cycle stability for the  
 485 PEG-templated HKUST-1 adsorbent linked to the intrinsic stability of the MOF as well as  
 486 the favorable and relatively low isosteric heat of adsorption. The desorption curve at 298 K  
 487 shows that CO<sub>2</sub> completely desorbed after 14.70 minutes of helium purging.

488  
 489 **Fig. 9.** Five breakthrough curve cycles for binary mixtures of (a) CO<sub>2</sub>/N<sub>2</sub> (50/50, v/v), (b)  
 490 CO<sub>2</sub>/CH<sub>4</sub> (50/50, v/v), and (c) N<sub>2</sub>/CH<sub>4</sub> (50/50, v/v), with helium gas purging, for PEG-  
 491 templated HKUST-1 at 298 K.  
 492

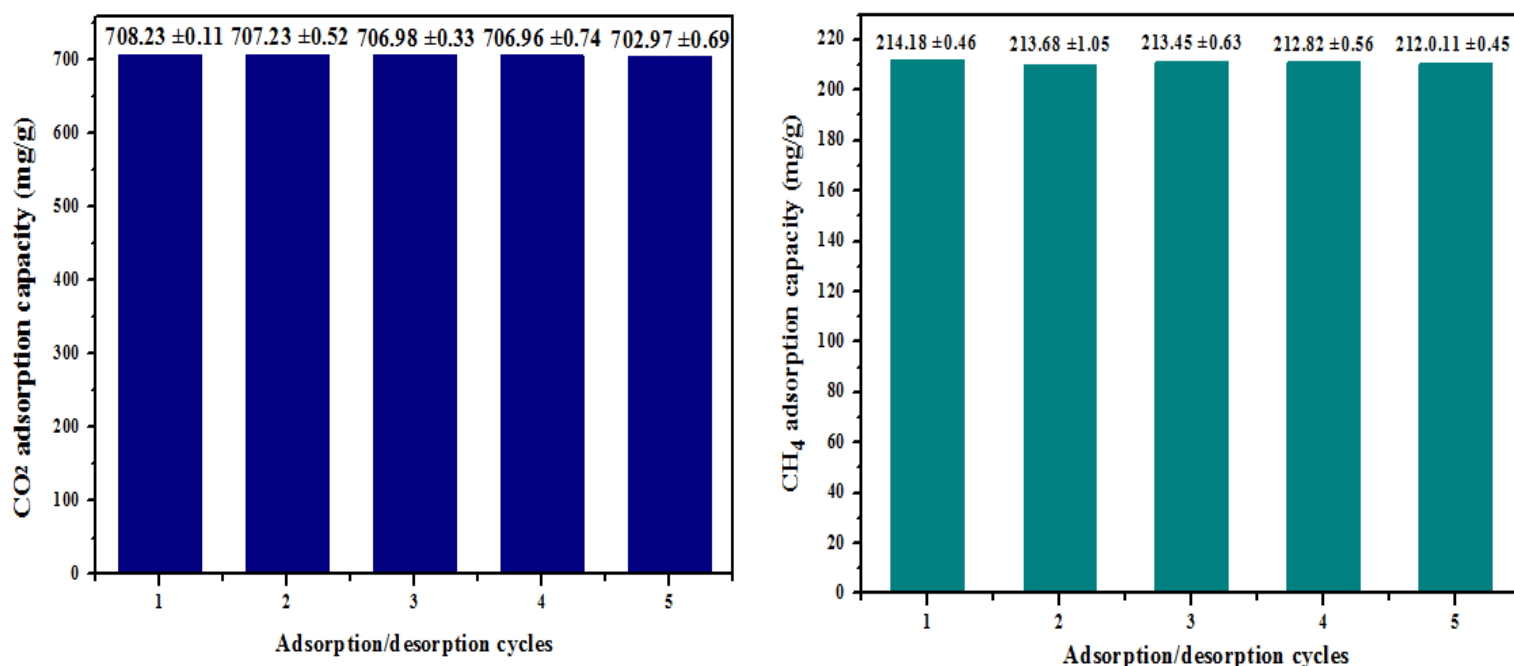

### 493 3.6 Thermal adsorption/desorption stability evaluation

494 We finally made a more rigorous evaluation of the adsorption-desorption stability by  
 495 performing prolonged CO<sub>2</sub> and CH<sub>4</sub> adsorption-regeneration cycles (5 cycles) using the  
 496 pure gases (not mixtures). Following each adsorption cycle at 40 bar, the adsorbent was

497 heated to 393 K (10°C/min) under N<sub>2</sub> gas at 40 mL/min to desorb any adsorbed gases that  
 498 remained on the surface of the adsorbent. The adsorbent was subsequently cooled to 298 K  
 499 under N<sub>2</sub> and then weighed to complete a cycle. The percentage ratio of the adsorption  
 500 capacity of the regenerated adsorbent to the initial adsorbent is defined as the adsorption  
 501 index (AI) and is determined by the equation as follows:

$$502 \quad AI = \frac{q_n}{q_1} \times 100 \quad \text{Eq. (1)}$$

503  
 504 Where, q<sub>1</sub> and q<sub>n</sub> indicate the CO<sub>2</sub> and CH<sub>4</sub> adsorption capacity for the first cycle and the  
 505 n<sup>th</sup> (n = 1-5) cycle, respectively. The adsorption-desorption stability can also be considered  
 506 as a test of recyclability. The stability data for CO<sub>2</sub> and CH<sub>4</sub> adsorption at PEG-templated  
 507 HKUST-1 at 298 K and 40 bar for 5 cycles each is shown in Fig. 10. The adsorbed  
 508 amounts after 5 cycles of 708 mg(CO<sub>2</sub>)/g and 214 mg(CH<sub>4</sub>)/mg represent a loss of about  
 509 0.71 % and 0.97 %, respectively, compared to the initial adsorption capacity. The data  
 510 confirms the robust and reversible or reusable nature of the adsorbent.

511 **Fig. 10.** Evolution of the CO<sub>2</sub> and CH<sub>4</sub> adsorption capacity of PEG-templated HKUST-1  
 512 over five adsorption/desorption cycles at 298 K and 40 bar.

#### 513 **4. Conclusion**

514 We present a straightforward and rapid synthesis method for creating a highly microporous  
 515 PEG-templated HKUST-1 MOF adsorbent with outstanding properties. The synthesized  
 516 adsorbent exhibits a high N<sub>2</sub> BET surface area of 1904 m<sup>2</sup>/g and a mean pore volume of  
 517 0.87 cm<sup>3</sup>/g, with attractive nanoparticle sizes (ca. 0.1–0.5 μm) alongside large microscale  
 518 crystals (up to 120 μm). Gas adsorption studies demonstrate exceptional adsorption

519 capacities for CO<sub>2</sub> and CH<sub>4</sub> (708 mg (CO<sub>2</sub>)/g and 214 mg (CH<sub>4</sub>)/g, respectively, at 298 K  
520 and 40 bar), the highest reported for HKUST-1 (Cu-BTC) samples. The adsorption as well  
521 as separation performance is attributed to the high surface area and attractive microporosity  
522 as well as favorable surface interactions with physical rather than chemical interactions  
523 observed for all gases. Notably, CO<sub>2</sub> adsorption interactions are linked to polar adsorbent  
524 sites, such as electrostatic interactions between unsaturated Cu<sup>2+</sup> and aligned CO<sub>2</sub>  
525 quadrupole moments with negatively charged oxygen. The adsorbent demonstrates  
526 practical and effective separation capacity for binary mixtures of CO<sub>2</sub>/N<sub>2</sub> and CO<sub>2</sub>/CH<sub>4</sub> in  
527 the 0.01 to 5 bar range, validated through breakthrough experiments. Excellent 5-cycle  
528 reusability data, with <1% performance loss, highlights the adsorbent's robustness and  
529 potential for economical production. Future research directions should focus on enhancing  
530 separation performance from ternary and more complex mixtures and gaining further  
531 insights into the polymer templating mechanism to develop new adsorbents with attractive  
532 porous architectures.
