## Introduction

- Identifying **niche overlap** between **congeneric co-occurring species** helps identifying the **taxonomic resolution** meaningful for evaluating the **contribution** of these species to **ecosystem functioning**
- Mangroves are **heterogeneous habitats** → endofauna to tree epiphytes
- Evaluating **habitat partitioning** between species contributes to better characterising the degree of **habitat heterogeneity**
- Identifying **patterns of species' distributions** of **morphologically similar congeneric** species → first step towards evaluating **species' ecological preferences** → important for conservation (Brown et al 1995)
- WIO mangroves host four *Littoraria* species with varying abundances and zonation patterns (Ried 1986 ; Torres et al 2008); **habitat partitioning** between tree leaves or bark has been **reported** previously but **never tested** (Cook 1990)
- Evaluate whether the ***Littoraria* species** found in the **mangroves of Mayotte** shared **identical habitat niches** with respect to **mangrove fringe** (seaward / landward) and **tree substrate** (leaves / bark)

## Results

Significant at  
1 site only

- Significant results of total abundances:

- Significant results of relative & species abundances:

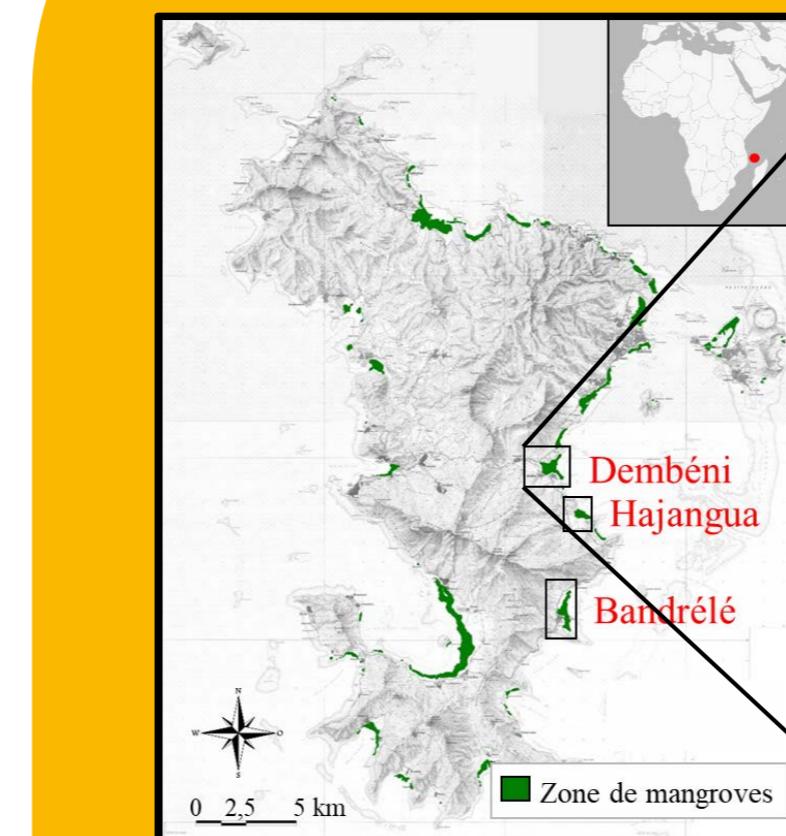

***L. scabra*** = co-dominant on seaward fringe & on bark ; significantly more abundant on bark of seaward fringe at single site

***L. subvittata*** = always dominant

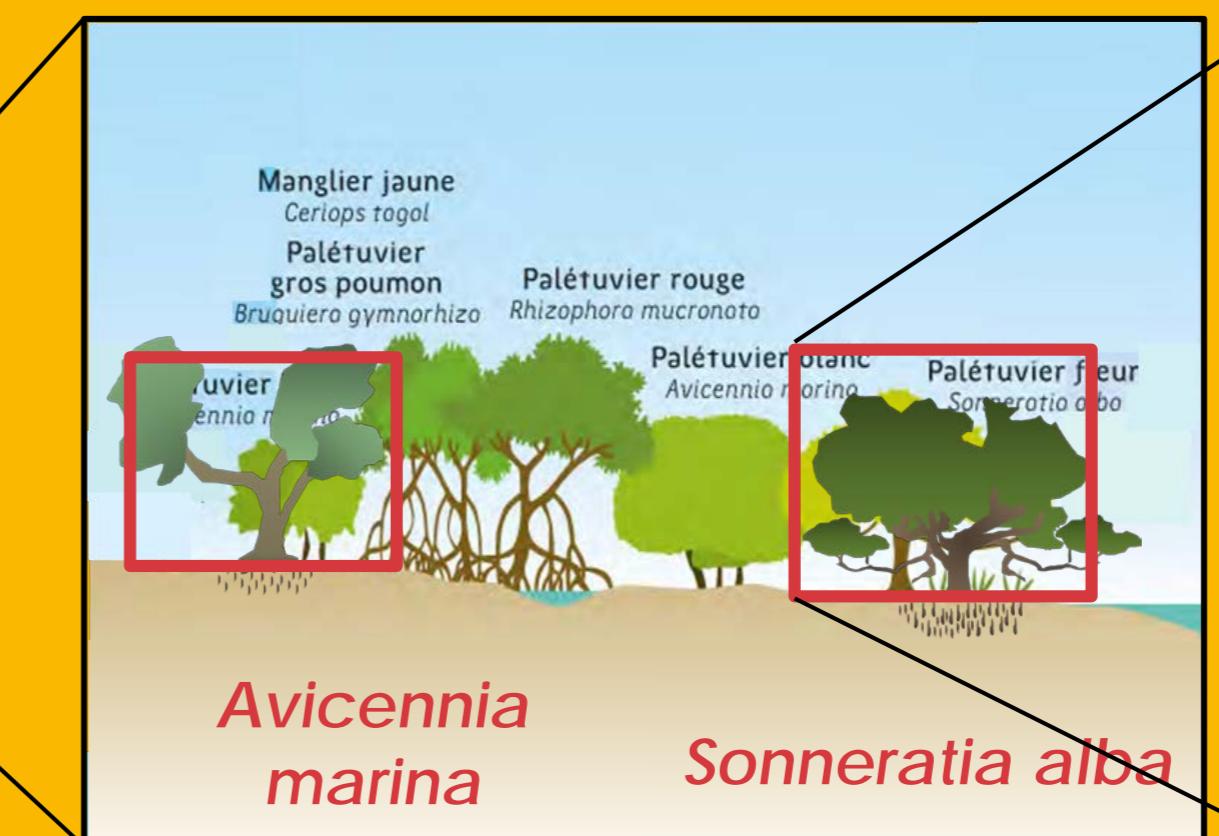

***L. intermedia*** = rare, mostly on bark of seaward fringe

***L. pallescens*** = co-dominant on leaves; on leaves, significantly more abundant on seaward fringe

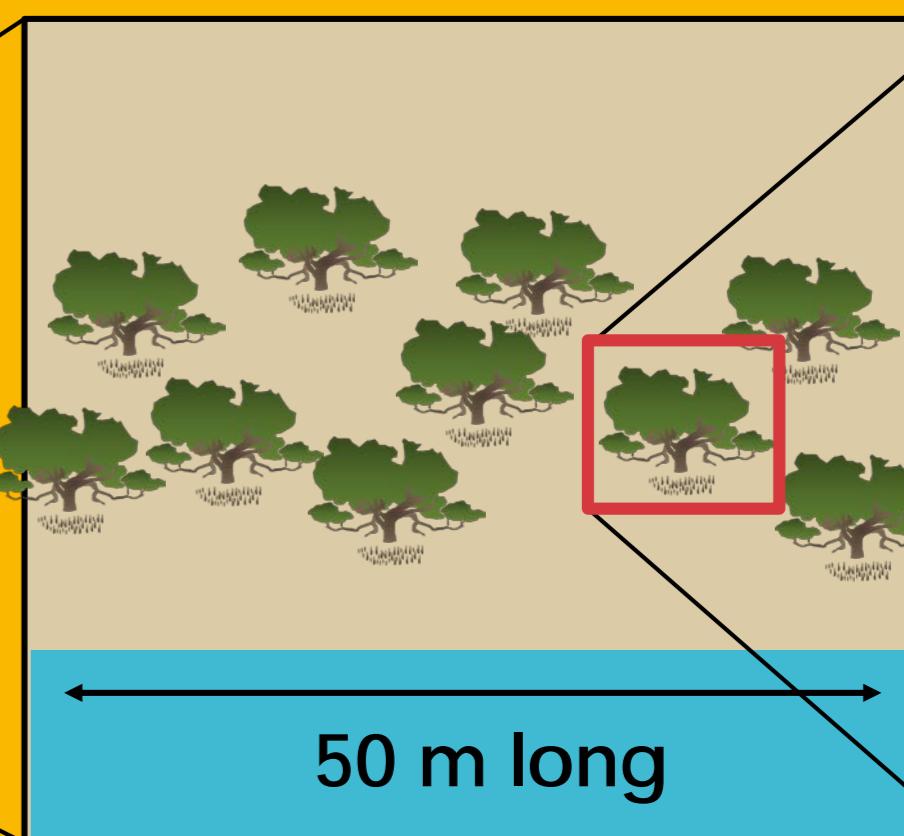

## Methodology

3 sites

2 fringes : landward & seaward

10 trees

2 substrates

- 3-way nested ANOVA :
  - Total abundance
  - Species abundance
- Chi-square test :
  - Relative species abundance

## Conclusion

- Different species strategies:
  - L. subvittata*: **generalist** species, responsible for total abundance pattern
  - L. scabra* & *L. pallescens*: **specialists** of seaward fringe, **habitat partitioning** over substrate
  - L. intermedia*: **Rare** species, confined to leaves of seaward fringe
- Species distributions show ecological preferences otherwise invisible at genus level
- Species level** should be considered to evaluate **ecosystem functioning** & for **conservation purposes**
