HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

The atmospheres surrounding metal parts in many industrial processes rarely comprise a single oxidant. Whether in fossil energy conversion plants, nuclear power plants, jet engines, chemical or petrochemical production routes, several molecules, sometimes present as main components, sometimes at the impurity level, play a role in corrosion mechanisms. Current research into the development of low-emission technologies also clearly demonstrates the importance of considering, in addition to O₂, the effects of H₂, H₂O, NH₃, etc. in the development and selection of alloys.

This collection of papers considers many situations where oxidation competes with, for example, carburizing, nitriding, and sulfidizing reactions and where water vapor can have a significant impact in cases where, at first glance, it would not even be considered. The papers include studies on the effect of H_2 and/or H_2O on pure titanium, on chromia scale, but also the benefits of alumina-forming alloys for many complex environments, as well as the subtle effect of Mn and Fe on the metal dusting resistance of NiCu alloys, highlighting the relevant assistance of thermodynamic and ab initio calculation to address these complex corrosion issues.

The following papers are contributions from the “Oxidation in Complex Atmospheres” session of the 11th International Conference on High-Temperature Corrosion and Protection of Materials (HTCPM 2024), held at Les Embiez Island, France, on 9–14 June 2024.
