ABSTRACT

This research studies the influence of sales configurator capabilities on psychological empowerment and purchase intention in the context of online mass customization. After having customized video game controllers, 263 individuals answered the survey about dimensions of configurator capabilities and psychological empowerment. The results show that, in general, the perceived usefulness of these tools increases the consumer's perception of power. However, the dimension "focused navigation capability" does not seem to influence psychological empowerment. Acquisition of power and mastery seems to go hand in hand. In order to have a perception of power, individuals do not wish to be very brand-oriented in their process of selecting a customizable product. Furthermore, psychological empowerment does not influence purchase intention there is indeed an indirect effect through the mediation of psychological ownership. Our research contributes to the literature on psychological empowerment by highlighting the dimensions of the e-configurator most likely to increase the perception of power, the psychological ownership and finally the purchase intention.

Keywords: Online sales configurator capabilities (OSCCs); Mass customization (MC); Psychological empowerment; Psychological ownership

INTRODUCTION

Although online mass customization (MC) is increasing consumer's perceived value, the complexity of the purchase and the co-creation between the customer and the company remains important for the consumer. According to Kaplan and Haenlein (2006, p. 177) MC is defined as "a strategy that creates value by some form of company–customer interaction at the design stage of the operations level to create customized products, following a hybrid strategy combining cost leadership and differentiation".

Dhar (1997) and Huffman and Kahn (1998) note that too many options infuriate consumers. These authors affirm the fact that to increase the consumer's satisfaction in a mass customization experience, a firm must control the way the information is presented, and the input provided by consumers in data gathering. Al Shibly et al. (2015) add that information and communication flows affect the way consumers perceive power in the mass customization process. That's why managers must optimize online sales configurator capabilities (OSCCs) which accompany consumers throughout the MC process by providing sufficient information to reduce complexity. These toolkits (OSCC) are defined by Von Hippel (2001, p.2) as a technology « giving users real freedom to innovate, allowing them to develop their custom product via iterative trial-and-error».

¹ An earlier version of this paper was published in the EMAC proceedings 2022 (Proceedings of the European Marketing Academy, Annual 2022 : <https://proceedings.emac-online.org>).

In MC process, toolkits are presented as steps, tabs or options on the brand's website allowing client to customize a product according to his/her preferences and in good conditions.

Generally speaking, we cannot talk about mass customization if there is no online sales configurator capabilities. The difference between one program and another is the number and the quality of the OSCC. Nowadays, there are few brands who are offering a physical mass customization program without toolkits. For example, the firm Obag has at the same time a physical and an online mass customisation program of bags.

In addition, there are other kinds of mass customisation who don't require toolkits. We distinguish therefore (1) transparent customization who is feasible when the needs of the customers are easily predictable so the company can offer a personalised product; (2) cosmetic customization which means that the packaging of the product will be different from one customer to another; (3) adaptive customization which occurs when the firm offers a personalized product to its customer and (4) collaborative customization where customers and businesses collaborate together to co create the product. In this paper we take into consideration this fourth type of mass customisation; collaborative MC.

In the collaborative customization, the computer aided design (CAD) leads to increase the consumer's feeling of power and increase perceived value, purchase intention and interest in MC. To our knowledge, the few studies that have focused on the place of OSCC in a MC program, have not considered this concept as an aggregated variable. However, several researchers highlight the importance of being aware of these toolkits. For example, Turner et al. (2020) bring forward the importance of OSCC to have a successful MC program. In addition, Fettermann et al., (2017) appeal to determine the added value for consumer thanks to these toolkits.

Furthermore, MC is considered as a strategy allowing firms to delegate power to the consumer. This delegation of power is addressed in marketing by the term « empowerment » as a process. Most studies have focused on empowerment as a strategy initiated by firms or consumers. Only a few studies considered the concept as a state of mind and approached it by a term “psychological empowerment”. This concept is defined by Ambroise et al. (2015, p.25) as “motivational feelings of “power” and “mastery” that individuals feel towards things which involved them”. It is therefore a consumer's perception of power to act, to choose and to purchase. We suppose in our research that OSCCs increase the perception of power in a MC experience. Some researchers noted the importance of guiding consumers and helping them in a co-creation process in order to provide them with a feeling of power and autonomy. For example, in the pioneer article on empowerment in marketing, Wathieu et al. (2002) highlight the importance of giving consumers « check points » to help them in the selection process in order to make them feel empowered. Given that a relationship between OSCC and psychological empowerment exists, it is important to empirically assess this link. Therefore, we outline below the question of our present research:

What is the influence of online sales configurator capabilities on purchase intention through psychological empowerment and psychological ownership in a mass customization experience?

THEORETICAL BACKGROUND

Online MC sales configurator capabilities are presented as « knowledge-based software » “that support customers, or salespeople interacting with customers, in completely and correctly specifying a product solution within a company’s product offer” (Trentin et al., 2014). These authors and Sandrin et al. (2017) showed that OSCCs increase product value and experiential value of co-design (Merle et al., 2008). “Trial and error” process via MC toolkits increase consumer’s perception of power and autonomy (Novak and Hoffman, 1997; Kamis et al., 2008).

Furthermore, Füller et al. (2009) showed that “Before consumers can make competent contributions, they need a sound understanding of the innovation”. Thus, such toolkits increase perceived competence and the feeling of having an active participation. These authors showed that “the stronger consumers’ perception of support offered by the provided tool to master a new product development task, the more the tool will contribute to the consumers’ perceived empowerment”. We suppose that this observation is valid in a MC context. Businesses contribute to consumers increased freedom by providing them necessary toolkits to acquire knowledge, integrate and develop resources in order to perceive autonomy and power (Banoun et al., 2017).

According to Portes (2018), the fact that people better appropriate web toolkits results from a learning process towards digital experience. Learning is presented here as a process allowing procurement of knowledge and know-how which generates new competences. The experiential learning theory of David Kolb (1984) which is taken from educational sciences stipulates that the experience is the source of learning. This experience is characterized by an increase of knowledge. Kolb defines learning as "the process whereby knowledge is created through the transformation of experience. Knowledge results from the combination of grasping and transforming experience"(Kolb 1984, p. 41). This author distinguishes two modes of transforming experience: reflective and active. According to Trentin et al. (2013), OSCCs enhance the capacity of the consumer to reflect on and observe its previous configuration experiences from many perspectives. The reflective capability (Kolb, 1984, p. 30) play a huge role in transforming experience into deeper understanding and in enabling an effective learning process (Kolb, 1984).

During a mass customization experience, OSCCs improve the learning process (Sandrin et al., 2017; Kolb, 1984). These tools must be presented as a user-friendly interface allowing people to harness their knowledge in order to obtain a desired product quickly and easily by doing several trial-and-error processes. Therefore, based on the experiential learning theory, we hypothesize the link between OSCC and psychological empowerment. During a MC experience and through optimal use of MC toolkits, consumers spend a learning process allowing them to acquire knowledge and *in fine* to have power. Therefore, we hypothesize:

H1: online sales configurator capabilities have a positive effect on psychological empowerment.

Furthermore, researchers showed in certain context that the perception of power leads to a higher purchase intention by consumers. For example, Fuchs et al. (2010) reported that empowered participants in the new product selection process are willing to show stronger demand for the final products than nonempowered customers. These researchers showed also that this relationship could be mediated by psychological ownership. These findings are specific to

« empowerment to select » context. So, how about a mass customization context? We hypothesize therefore:

H2: psychological empowerment has a direct positive effect on purchase intention.

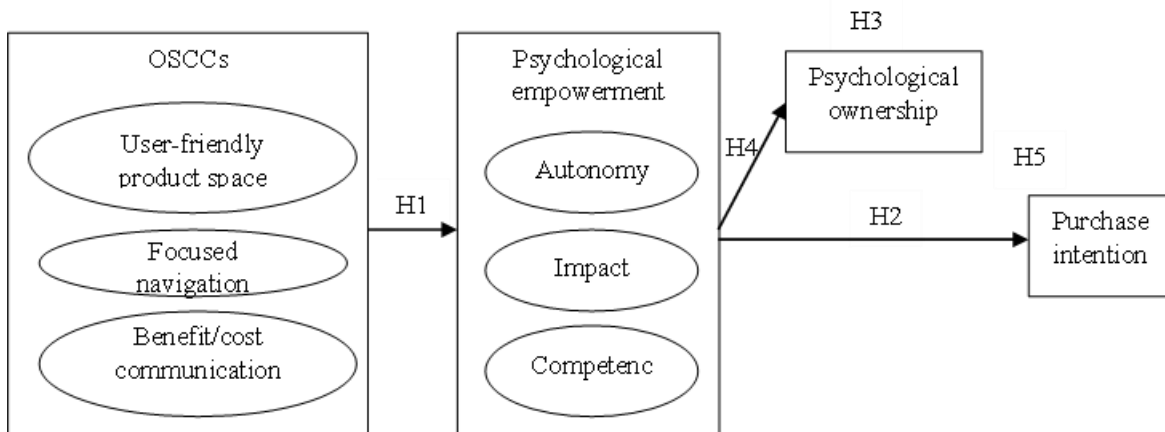

Franke et al. (2010) showed that co-creating a product leads to a perceived ownership value by consumers. Those who have created a product show appropriation of the product more than those who simply purchase it. Psychological ownership is defined by Van Dyne and Pierce (2004) as “the state in which an individual feels that an object is experienced possessively”. Pruche (2015) got interested on decision’s psychological ownership and showed that this variable mediates the relationship between psychological empowerment and satisfaction towards the purchase decision. In a MC context, we suppose that psychological ownership is related to the product and not to the decision. To assess the mediation effect of psychological ownership, we have to test first the direct effect of psychological empowerment on psychological ownership and then the effect of psychological ownership on purchase intention. According to Fuchs et al. (2010), empowered customers experience higher levels of psychological ownership of the final products than un-empowered customers. They added that the relationship between empowerment and product demand is mediated by psychological ownership.

H3: psychological ownership mediates the relationship between psychological empowerment and purchase intention.

H4: psychological empowerment has a positive effect on psychological ownership.

H5: psychological ownership has a positive effect on purchase intention.

Fig. 1 Research Model.

METHODOLOGY

Studies in marketing have been interested in public consumer products emphasizing only individual characteristics. These public products belong generally to the apparel industry (eg. t-shirt, scarf, sneakers). To date, no studies have focused on valuing mass customization for

private consumer product. Therefore, we have chosen a mass customization program of video game controllers as a fieldwork. In fact, contrary to sneakers or clothes, video game controller's users rarely show their product to their circle of friends or acquaintances. In general, Geeks and video game players use to manipulating the game console at home in front of their screen. Interaction with others is virtual most of the time. Consequently, we consider that the video game's controller is a product category which belongs to the family of private consumer products.

Two data collections have been conducted in two steps. The first one consisted of 104 individuals concerns the construction and the validation of measurement scales. The second one consisted of 263 respondents concerns the assessment of the conceptual model. The participants were asked to customize a video game controller from Xbox designLab. Then, they were solicited to fill out a survey. In the Consortium Euroshoe 2002 authors describe the core market for customizable products as computer competent young people looking for exclusivity, co-creation. All studies in mass customization have been conducted with people having these characteristics. That's why we asked people aged 20 to 30. Data gathering was conducted in April 2020 by emailing students. All items were rated on a six-point likert scale which have been confirmed many times in literature (Chang, 1994). To assess measurement quality, we conducted exploratory factor analysis (EFA) on SPSS and confirmatory factor analysis (CFA) on PLS. To assess the research hypotheses, smart PLS 3 was used.

RESULTS

Measurement quality

We tested the four dimensions of psychological empowerment identified by Spreitzer (1995) in the management context and confirmed by Pruche (2015) and Thion (2018) in the marketing field in a French context. The dimensions are competence, autonomy, impact and meaning. EFA showed that "meaning" is not significant. Results showed a satisfactory fit of the model after deleting this dimension (RMSEA = 0,033; GFI = 0,97; AGFI = 0,93).

The measurement scale of OSCC is based on the scales developed by Trentin et al. (2013) and Füller et al. (2009). We consider here three of the five dimensions identified by Trentin et al. (2013): (1) Focused-navigation capability; The ability of an OSC to quickly focus a potential customer's search on those solutions of a company's product space that are most relevant to the customer himself/herself, (2) Benefit-cost communication capability; The ability of an OSC to effectively communicate the consequences of the configuration choices made by a potential customer both in terms of what he/she would get and in terms of what he/she would give And (3) User-friendly product-space description capability; The ability of an OSC to adapt the description of a company's product space to the individual characteristics of a potential customer as well as to the situational characteristics of his/her using of the SC (Sandrin et al., 2017). The two other dimensions which are Flexible-navigation capability and easy comparison are not considered in our study. The first one has been replaced by realistic understanding illustrating the fact that tool kits must enable consumers to actively experience and modify innovative products long before they exist. On the other hand, the dimension "easy comparison" has not been

considered in this study regarding the fact that this option is not available in the MC program chosen for the survey.

Some items were purified because they presented intercorrelations with other items from the same dimension. The cues of the measurement scale model were acceptable after deleting these items (RMSEA = 0,033; GFI = 0,97; AGFI = 0,95). Final measurement scales are presented in the appendix (OSCCs: $R\hat{\rho} = 0,933$; Empowerment: $R\hat{\rho} = 0,94$).

These two variables (psychological empowerment and OSCC) are considered here as an aggregated variable (a second order factor). In fact, the CFA shows cues of T, AIC, BCC and BIC with very satisfactory values respectively: 0.99 (>0.8), 59.75, 61.11 and 127.63 (>10) for OSCC and 0.90, 61.12, 62.18 and 121.83 for psychological empowerment. A second order model is better than a first order model.

The measurement scale of psychological ownership is adapted from Fuchs et al. (2010). “Although I do not legally own this joystick yet, I have the feeling that it is ‘my’ joystick”; “The selected joystick incorporate a part of myself”; “I feel that this product belong to me”; “I feel connected to this joystick”; “I feel a strong sense of closeness with this product”; and “It is difficult for me to think of this joystick as mine” (reversed); $\alpha = .95$ and $R\hat{\rho} = 0,916$.after purification of the reversed item. The measurement scale of purchase intention is adapted from Sweeney and Soutar (1991). “The likelihood of purchasing this product is very high”, “If I were going to buy this product, I would consider buying this model at the price shown” and “My willingness to buy this product is very high”; $\alpha = .84$ and $R\hat{\rho} = 0,873$.

Research model validation

Results show that H1, H3, H4 and H5 are supported and H2 is rejected.

Online sales configurator capabilities have a positive direct effect on psychological empowerment as predicted by hypotheses 1 ($p < 0.001$). Psychological empowerment does not influence purchase intention, therefore this rejects hypotheses 2 ($p = 0.552$). The influence is maybe indirect, as we will see in the next hypotheses.

Mediation effect was evaluated by performing the Hayes (2015) test. Psychological empowerment has a direct significant and positive impact on psychological ownership (coeff = 0,5122; s.e = 0,0532; $p = 0,000$) showing that individuals perceiving a stronger power appropriate the customized product easily. This result supports hypothesis 3. However psychological empowerment does not influence directly purchase intention (coeff = -0,0370; s.e. = 0,634; $p = 0,5605$). There is however an indirect effect through the mediation of psychological ownership (coeff = 0,2952) [0,2132; 0,3778].

GENERAL DISCUSSION

Results allow us to answer the question of our research by confirming that OSCCs increase psychological empowerment. The relationship between these two variables is significant and positive showing that people perceiving a higher capability of sales configurator perceive more power than other people do. The support offered by the provided tool increases the perception of

power. This result is coherent with the research of Conger and Kanungo (1988), in the management context (original context of empowerment). These authors showed that the lack of support provided by an employer reduces the perceived power by employees. Our results substantiate the Füller et al. (2009) findings. They showed that experienced tool support in a new product development increases psychological empowerment. Furthermore, we did some additional analysis to better understand the relationship between OSSC and psychological empowerment. We have observed then that the dimension of OSSCs which is “focused navigation” do not have an influence on any dimension of psychological empowerment (NAV—>AUT $p=0.79$; NAV—>COMP $p=0.89$; NAV—>IMP $p=0.38$)

This result does not substantiate the Lemoine (2008) findings. This researcher has shown that website’s atmosphere may lead to different perceptions of power. Consequently, firms must give sufficient liberty to its customers to make them feel empowered, but not a lot to not make them feel “mass confused” as noted by Joseph Pine (1993).

Finally, even if consumers perceive power thanks to optimum configurator capabilities, they do not immediately purchase the customized product. However, Fuchs et al. (2010) showed that perceived power increases purchase intention of t-shirts. Pruche (2015) has shown the same finding. This controversy with our result could be explained by the fact that the category of product considered in our study is different from the other studies. For example, contrary to joystick, purchasing a t-shirt does not require buyer’s involvement and individuals use to take decisions more quickly. Familiarity, customer loyalty or purchasing frequency are other variables which can explain our result. For example, in the research of Fuchs (2015), respondents were loyal customer and familiar with the travel agency considered in the study (Promo vacances). They will indeed have a higher purchase intention than other customers. We showed through our study that people need to appropriate the product before purchasing it (the mediation effect of psychological ownership on the relationship between psychological empowerment and purchase intention). Managers must focus on psychological ownership to encourage customers buying co-created product.
